These dominant curriculum models have influences on different school subjects and school phases across systems, mostly in blended forms. Different content claims about what should be taught and learned reflect particular paradigmatic positions on the curriculum. But each of these models offers different approaches to the taxonomic grids and descriptive categories for describing what should be taught and learned. Therefore, elements of major curriculum models are evident in the curriculum development and syllabus design of most school systems. However, the technical form of the syllabus has moved toward a technocratic/accountability model through the focus on measurable and observable outcomes within many Western systems of schooling. Within this technical form, different subject areas and phases have been shaped according to different curriculum models, contents, and theoretical assumptions – for instance, preschool and early-childhood curricula in many systems have taken a developmentalist philosophy – but these approaches currently often sit within the technical form of the outcomes-based structure, and in the context of system consensus around the technocratic/accountability model.

These approaches are responses to particular policy contexts, particular national histories and system contexts, and particular economic and social conditions. Further, they are adopted in relation to particular pedagogic patterns, school and classroom structures, and intellectual and cultural traditions. The curriculum settlements of the last

decade are in transition. The demands of the new economy, the multicultural, multilingual, and multimodal nature of new student populations, and changes in educational philosophy, funding, and governance have led to this transition period. There is an extensive published literature on curriculum theory, curriculum contents, curriculum development, curriculum management and implementation, systemic accountability and reporting, and teachers' and students' uses of the enacted curriculum in schools. However, there is very little written about the shape and structure – the technical form – of syllabus documents used to document or map the compulsory school syllabus.

The Technical Form of the Syllabus in High-Equity/High-Quality Systems

The technical form of the syllabus is a neglected area of current curriculum debates and of the field more generally. These debates have largely been preoccupied with questions of curriculum content – variously construed as cultural values, ideologies, specific skills sets, competences, and disciplinary knowledge. We have defined the syllabus as a map and descriptive overview of the curriculum, as a structured summary and outline of what should be taught and learned. The syllabus is not the curriculum – but what occurs in teaching and learning is shaped by a range of factors, with the official syllabus being one key factor. Other factors include, but are not limited to the background knowledge, cognitive and cultural resources that students bring to classrooms; teacher expertise gained through pre- and in-service teacher education and practical experience; textbook selection and content; availability of further training and professional resources; school leadership; system governance and accountability structures; high-stakes testing and examination; classroom assessment; available financial resources; and the physical site of the classroom. The syllabus may enable and constrain, but does not necessarily reflect or index what is taught and learned in classrooms. The principal way that national debates in many Western nations have dealt with this problem of control is to debate the political, cultural, and scientific values and truth claims of different stances on content in syllabus – and to augment this with criticism of teacher workforce capability and professionalism. This approach leads to a dual-policy approach: fix and mandate new (or old) content (change the prescription); and enforce this through increased accountability pressure, incentives, and disincentives for teachers (change the professionalism).

Schleicher (2007) refers to this as uninformed prescription that is linked to uninformed professionalism. Uninformed prescription, he argues, may entail strong centralized accountability without the resources or the opportunities for building strong knowledge-based and evidence-based teacher professionalism. He stresses the

need for an approach to documenting curriculum in syllabus documents that lays out informed prescription centrally (through the syllabus setting core learnings and specification of standards) but that also sets the conditions for local teacher professionalism, school and classroom-based developmental diagnostic use of evidence, and the exercise of local curriculum interpretation and translation, development, and implementation. This is part of a process of lifting expectations that all students will achieve, while encouraging a range of relevant pedagogical approaches. He refers to this as informed prescription.

In high-quality/high-equity systems, teachers use professional knowledge and evidence to make informed and relevant decisions about teaching and learning. In other words, informed prescription depends on teachers' professional capacity to locally interpret, adapt, and adjust curriculum content, pacing, presentation, interaction, and structure to particular institutional, community settings and student cohort characteristics. It includes a capacity to use evidence on student background, prior achievement, developmental and diagnostic progress, and school and classroom-based assessment to make curricular and instructional decisions.

An emphasis on centralized standards and curriculum mandates must be balanced against high levels of workforce curriculum professional decision making. Informed prescription requires well-resourced teacher professional capacity. The approach of high-quality/high-equity systems entails a balance of systemic standard setting and accountability with well-resourced, local school leadership with a strong focus on building teacher capacity at curriculum, pedagogy, and assessment (Schleicher, 2007).

Once the educational goals of a system are established, the syllabi – its contents and technical form – can be part of the solution toward realizing a high-quality and high-equity system, but syllabus documents cannot, in and of themselves, generate change. The syllabus has the important function of setting conditions for enhancing a knowledge-rich professionalism – but other policy settings also need to be in place. These include a clear and simplified message system about aims and priorities regarding quality and equity, professional infrastructure, workforce capacity, school governance, and management structures that likewise are geared to enable instructional quality.

Conclusion

We began this article with the claim that the syllabus is not the curriculum. The confusion of syllabus and curriculum as terms has created a number of issues for school systems. However, in relation to the field of curriculum and syllabus design generally it has resulted in the technical form of the syllabus being neglected in current curriculum debates and

literature of the field. For the past five decades, Western democratic education systems have attempted to strike a balance between the goals of economic development and competitiveness, on the one hand, and social and cultural development and cohesion, on the other. The purpose of democratic education is for all students to reach a democratic threshold (Guttman, 1987) of knowledge, skills, and dispositions for gainful and productive participation in democratic social institutions and economies. The syllabus cannot control the curriculum, but it can set enabling conditions for high-quality/high-equity outcomes. It cannot cause change and progress in any direct or simple way, but can be one of the key elements of an overall system strategy for enhancing teaching and learning.

How the syllabus is shaped, how it is used in the context of system accountability around standards, and how teacher's use of the syllabus is resourced and supported set the conditions for a balance of prescription and professionalism. Establishing that balance in ways that are conducive to high-quality with high-equity teaching and learning is the task facing policymakers and teachers currently. The syllabus is a map, and as such it should aim at low-definition, parsimonious, and economical statements. The syllabus can guide and enhance professional expertise – but it cannot act as a substitute for well-resourced and informed teacher pre- and in-service development and practice.

Glossary

Disciplinary technology – For Foucault (1979), the rise of capitalism involved a new form of “discipline” in which internalized surveillance rather than overt force works to create “docile bodies” necessary for institutions such as schools and the military. Discipline is a type of power and the modality, instruments, and techniques (technologies) through which power is exercised.

Hegemony – In educational studies, most associated with Antonio Gramsci (1971), hegemony is the domination of subordinated groups through ideological and cultural coercion and consent, such that the values and beliefs of the dominant group come to be taken as common sense, thus justifying status quo relations of power.

Literacy – A set of multi-modal, and rapidly changing social practices in which people use talk, texts, images, and other signs and symbols to accomplish specific purposes.

No Child Left Behind (NCLB) – The No Child Left Behind Act of 2001 is the reauthorization of the Elementary and Secondary Education act of 1965 by the United States Congress signed into law by George W. Bush in 2002. NCLB emphasizes accountability and scientifically based instruction, and requires public schools to administer state-wide standardized tests annually to all students in grades 3–8. NCLB mandates that 100% of students are proficient in grade level standards by 2014. Under NCLB, test scores for schools that receive Title I funding must demonstrate Adequate Yearly Progress toward proficiency.

Official knowledge – The title phrase of Apple’s (1993) text, official knowledge captures the inherently political struggle over what counts as the knowledge, history, and truth worthy of teaching and learning in schools.

Packaged Literacy Programs – Books, workbooks, teacher manuals, and related materials produced by a commercial publisher intended as a principal source of literacy instruction for a group of students. Rather than viewing literacy as a set of social practices, packaged literacy programs conceptualize literacy as a set of sequential skills to be explicitly taught and learned.

Textbooks – Books, workbooks, teacher manuals, and related materials produced by a commercial publisher, often intended as a principal source of study material for a given class or group of students. For parents and politicians, textbooks often represent the totality of school curriculum, and therefore often come to serve as de facto or surrogate curriculum. Given their synoptic nature, textbooks are inherently political materials that represent specific ways of thinking, knowing and viewing reality.

Educational textbooks are one of the most important components shaping educational practice in schools. As the primary tool of instruction internationally, textbooks represent the official knowledge considered worth teaching and learning, and often serve as the most significant resource – and the most significant constraint – for teachers. Because of the power of textbooks, publishers of educational materials have a tremendous influence on what counts as knowledge, and how particular constructions of knowledge and pedagogy dominate in schools. The question of who decides what counts as knowledge, and what knowledge students should learn in schools, has been contested since the beginning of public education. The production of textbooks for use in state-sponsored schools has historically been, and remains, a key site of struggle over whose knowledge, ideologies, histories, and values should be represented in curricula, and what kind of national identities should be promoted through education (Nozaki *et al.*, 2005). In different national contexts, textbooks are produced by different entities, including government agencies, multinational firms, and other private industry. While processes vary by national context, the production of school textbooks is an inherently cultural, economic, and political enterprise, with consequences for what and how teachers teach, and students learn. Textbooks are often deemed successful when guarantees are asserted that children will learn, no matter the quality of the teacher (e.g., teacher proofing). What students learn and the meaning and purpose of that content tends not to be examined.

While school textbooks are commonly identified with Western postwar educational theory and practice, the use of a common core text has a long history in many religious and educational traditions, including Confucian educational practices, and hermeneutic training for youth in

Muslim and Hebraic societies (Luke *et al.*, 2003). The contemporary context for textbook production, distribution, and use is complicated by tensions between international publishing concerns and national efforts to develop and use indigenous knowledge and publishing processes (Limage, 2005). This article examines the role of textbook publishers in the construction of curriculum, knowledge, and pedagogy. Then the article discusses the consequences of publisher-controlled knowledge production on teaching and learning using literacy curriculum in the US as a case example. The article concludes with the discussion of the problems associated with static definitions of knowledge and pedagogy that are assumed in textbooks and points to some possible rethinking of knowledge as commodity.

Deskilling, Control, and Discipline

Any discussion of the role of publishing industries in education has to take account of the now ubiquitous collaborations between corporations and governments in the production of knowledge, and the influence that profit-making has on the selection, organization and distribution of curricular knowledge. Due to a market-driven production system in the US and other nations (Larson, 2007), the publishing industry plays a disproportionately large role in determining what counts as knowledge in schools. Ostensibly, the goals of standardizing curricular texts are to promote consistency across schools, districts, and states; to establish a common knowledge base (national history, identity, language, and culture); and to ensure quality control. More often than not, however, corporate standardization and government regulation of textbook publishing impedes innovation and flexibility on the part of teachers and local schools. This results in the deskilling of teachers as professionals, and the production of texts that are characterized by superficial and biased treatment of topics, and include irrelevant materials and unchallenging tasks. Given the focus on competing in a global marketplace, collaborations between governments and corporate publishers usually result in textbooks aimed at covering as much material as possible (i.e., breadth over depth), and usually in ways that represent and reinforce the perspectives of dominant groups.

The power that textbooks have in shaping educational practice comes, in large part, from the dominant models of knowledge, teaching, and learning that so often accompany the use of textbooks. The heavy reliance on textbooks represents a traditional concept of knowledge as static and objective; a model that comes out of Enlightenment views of knowledge and rationality that form the basis of traditional common core and efficiency models of curriculum. This hegemonic view of knowledge is often paired with a static notion of teaching and learning as the transmission of objective knowledge. The model can be

summarized as follows: Knowledge resides in the textbook and learning is just a matter of getting it out of the textbook and into the heads of students. Studies of educators' beliefs about and uses of textbooks often confirm this view. For example, Shannon's (1992) work has shown that teachers and administrators often believe that the textbooks themselves can teach reading, irrespective of the role of skilled teachers. Thus, textbooks deliver the curriculum and shape the daily routines of classrooms. Powerful collaborations between governments and private publishing corporations determine what counts as quality in textbooks by focusing on standardized outcomes measured by tests produced by the same government/publisher collaboration. Specifically, the textbook has been transformed in a powerful "multinational phenomenon that can be adapted, translated, and niche marketed in a range of national and regional markets; a comprehensive suite of educational commodities with a pedagogic reach that extends far beyond children's narrative reading text; a scientifically 'tested' and 'proven' product" (Luke *et al.*, 2003: 251).

In what follows, the article moves to discuss further issues around control of textbook content and publishing in a global marketplace and some of the consequences of disciplinary practices associated with maintaining control over knowledge production (Foucault, 1977).

An Overview of Curriculum Publishing in a Global Context

A basic tension can be seen between national contexts in which decisions about texts are made locally, and contexts in which text production and/or adoption decisions are determined by state or national governments, in collaboration with publishing companies. Since colonial times, the production of textbooks has been imbalanced, with Western European countries, and then later the US and Japan, having the material and political capital to produce texts for dissemination to colonized states or developing nations. Altbach (1995) argues that textbooks are increasingly international commodities, given that multinational firms are increasingly the dominant producers of textbooks. However, the tension between global corporations and national publishing remains. During the opening up of textbook production in postwar Taiwan, for example, hegemonic struggles over school knowledge and textbook production focused on nationalizing Chinese culture, and the decentralization of curricular decision making forced the state to guide production of official knowledge from a distance (Chen, 2005).

Major text-publishing companies' domination of the international market and perpetuation of cultural domination remains a fact of life. Apple (2000) argues that this is partly because of the economic control of communication

by multinational firms and partly because of ideological control over official knowledge by new elites in former colonial states. Knowledge production is linked to new social and economic formations, cultural globalization, and geopolitical instabilities in the construction of what counts as official knowledge, text, discourse, and discipline (Nozaki *et al.*, 2005). Moreover, textbooks serve as a tool of bodily and ideological regulation that enforce a sense of duty, morality, nationalism, and cultural continuity in whatever society they are used and are vital in the construction of national identities (Chen, 2005).

In many developing countries, the state maintains controls over textbook form, content, production, and distribution; in the north and west, multinational publishing companies are the link between policy, assessment, and accountability systems in textbook production and consumption (Luke *et al.*, 2003). The reliance on multinational firms in the Third World is due to a variety of factors, including the shortage of paper in these contexts, as well as limited infrastructure for printing. Also at stake are disagreements over whether textbooks should be publicly or state produced.

In spite of a general agreement that multinational firms should not produce textbooks for Third World countries (Altbach, 1995), international corporations maintain a near monopoly on expertise, publishing infrastructure, and access to paper and capital (Limage, 2005). With the exception of some larger countries who can afford to maintain publishing industries, developing countries are dependent on centralized production and distribution controlled by others. One serious consequence of this inequity is international homogenization as profit-oriented companies standardize a curriculum that can be repeated year after year in order to maximize profit (Limage, 2005; Starnes, 2004). Limiting divergence of content is also applied in colonized African nations. Newly independent nations expanding their educational systems were prime markets for publishing companies who could use existing infrastructure to produce Africanized textbooks that adapted language and national curricular guidelines but were published by multinational corporations in Europe (Limage, 2005). Given their dominance in these markets, multinational corporations have little incentive for supporting the development of indigenous publishing infrastructures.

National curricula have been developed in countries such as England, France, and Cuba. In British schools, textbooks are the most widely used resource for teaching and learning, yet there remains a high level of negativism toward them (Marsden, 2001). The dominant view is that “textbooks undermine professionalism, typify an undesirable transmission model of teaching and learning, and are generally incompatible with progressive educational practice” (Marsden, 2001: 1).

In Asia, publishing has often not followed a Western model; however, textbooks quickly became a political tool

after World War II, when some countries insisted on government control of educational materials (Taylor, 1995). As in other contexts, textbook production has been bound up with the assertion of and resistance to certain representations of national interest. As mentioned earlier, Chen (2005) shows how textbook deregulation in postwar Taiwan contributed to a more democratic educational system and more diverse curricula in response to struggles over school knowledge and textbook production focused on nationalizing Chinese culture.

This article contextualizes the issues associated with knowledge production, curriculum, and the politics of curriculum publishing at the national level in the following discussion of literacy curriculum in the US.

The Political Economy of Literacy Curriculum in the Contemporary US: A Case Example

In the US, which has never officially produced national curricula, recent corporate consolidations have limited the number of publishing houses to four companies that now dominate the market: Pearson, McGraw-Hill, Reed Elsevier, and Houghton Mifflin (Sewall, 2005). This small circle of corporate publishers connects policy power with publishing in Western contexts, although the same corporations have expanded to Asian markets either within their current corporate structure or by taking over local publishing companies. Public and private zeal for reform has stimulated sales of textbooks, and the effect of fluctuating markets, corporate consolidation, and restrictive government policies about the content of curricula – and what counts as scientifically-based evidence of effectiveness – has led to a situation in which these four publishing houses produce 80% of the textbooks used in US schools (Sewall, 2005).

Further complicating matters in the US market is the dominance of the state adoption system in which state governments give an approved list of books for school districts to purchase. Given the relative lack of profitability in the textbook sector, publishers focus content on the largest markets (California, Texas, and Florida). Other states and local districts, even if they are not in a state with a mandated adoption policy, often purchase these same textbooks. In other words, publishers normalize content in order to make the largest profit. This normalization results in a “dumbing down” of the content as publishers vie to capture the largest market share (Sewall, 2005). US education policies, notably, the No Child Left Behind Act (NCLB), have made this much worse (Larson, 2007).

In the following section, we show how NCLB’s list of approved texts/companies amount to the restriction of the sources and kinds of educational materials used in

schools through a detailed description of one such corporate educational package, America's Choice. The rise in accountability and standardization associated with NCLB in the US has brought with it deeper, more reductionist calls for fixes to the problem of student performance indexed by annual yearly progress (AYP) on standardized tests. This pressure for rising scores has resulted in a plethora of curricular fixes that include Reading First, Success for All, and America's Choice. The lower performing schools in the US are overwhelmingly located in high-poverty areas in which non-dominant families struggle. The targets of these fixes, then, are pathologized as deficit and in need of repair (Larson, 2007). Under NCLB, schools are forced to adopt these packages to demonstrate AYP in particular ways or lose their funding. These packages include textbooks tightly coordinated to tests, and encourage highly scripted pedagogy.

Recent public hearings on the development and mandated use of Reading First in the US are more examples of the conflict inherent in private/state relationships that is coming to light (Manzo, 2007). The recent release of the Inspector General's audit of Reading First that reveals some of the inappropriate contracts and serious flaws in the research base for the program shows how deep the roots of corporate profit motive may lie. Furthermore, by limiting what counts as valid curricular materials to that which is deemed scientifically based, NCLB narrows local choices while improving corporate profit (Starnes, 2004). The case of America's Choice is a telling example of how a government provides regulations and financial resources while the private sector provides the materials.

America's forced choice

Paired with the high-stakes accountability system of rewards and punishments found in the NCLB and restrictive requirements for Reading First grants, America's Choice represents a forced choice in literacy instruction for many urban schools (Osborn, 2007). Furthermore, by focusing on low-performing and disadvantaged schools and students, America's Choice serves to perpetuate a parallel tracking system in which students from urban schools receive instruction that focuses on low-level skills in isolation of actual practice, while students in many suburban schools have opportunities for more authentic curricular and instructional practices.

America's Choice emphasizes systematic instruction and well-aligned instructional materials for higher rates of implementation and stronger effects (National Center on Education and the Economy, 2002: 1). The origins of America's Choice, a for-profit subsidiary of the National Center on Education and the Economy (NCEE), can be found in the scientific management and social efficiency movements of the early 1900s and extends to NCLB and

current federal mandates and initiatives, drawing on the discourse of business and industry with the influence of "A Nation at Risk" (1983) (National Commission on Excellence in Education, 2001), the National Business Council, and NCEE (Osborn, 2007). Like similar packaged literacy programs, America's Choice incorporates the language of federal standards and accountability mandates for scientifically based programs to facilitate adoption and ensure government funding.

America's Choice includes evaluations, curriculum that provides explicit and systematic instruction, a classroom organization system, routines and rituals for students that promote on-task behavior, and a data analysis tool. As such, America's Choice delivers what Luke *et al.* (2002) refer to as "a whole suite of 'teacher-proofed' curricular commodities" as well as materials to "assess teacher and system efficiency at delivering the whole package" (p. 251). This range of materials represents a trend toward total learning systems that include guides and workbooks, CDs, films, and technology-based tools. In addition, America's Choice provides professional development and on-site technical assistance, thereby exemplifying a recent development in the publishing industry to increase profits by providing support for a fee. In this way, money that otherwise would have been spent for professional development to deepen teachers' pedagogical knowledge, understanding of child development, and awareness of innovative practices is used to assure consistent and efficient delivery of the package. Adoption of America's Choice School Design costs between \$70 000 and \$105 000 per school.

America's Choice boasts that it "is built on the premise that teaching to explicit standards is the best strategy for helping disadvantaged and low-performing students — the same strategy adopted by the authors of NCLB" (National Center on Education and the Economy, 2006).

When urban schools choose America's Choice because it will facilitate Reading First grant money, or because they are deemed low performing, it presents these schools with a forced choice that dictates a certain kind of instruction that is supposed to be good for disadvantaged students and low-performing schools. From the perspective of America's Choice and similar packaged programs, improving literacy is just a matter of breaking skills down to more discrete units, and making instruction more systematic and explicit. Adoption of programs like America's Choice diverts attention from issues of race and poverty, and discussion of culturally relevant curriculum. At a time when literacy curriculum and instruction should encourage students to learn a range of discourses and modes of communication (Johnson and Kress, 2003), America's Choice focuses instruction on narrow, limiting conceptualization of literacy that is a mandate rather than a choice for many urban schools and contributes to the development of narrow and limiting identities for students.

The role of America's Choice in US school reform is illustrative of the deep and often hidden collaborations between educational policymakers and for-profit publishing companies. The strategic alignment of policies, curriculum, standardized tests, and school reform by government officials and corporate publishers is, in the current US context, generating profits for publishers, and dramatically inhibiting educators' decision-making about texts, teaching, and learning at the local level.

This coordination among educational policy, curriculum, and publishers constitutes a kind of disciplinary technology (Foucault, 1977) that has major consequences for what counts as knowledge in schools. At stake in these complex political and economic processes is not just the content that is produced for use in schools, but fundamentally, conflicting definitions of the common good and the purpose of schooling.

Conclusion

Recent years have been marked by a sharply increased alliance between textbook publishers and various levels of government through implementation of educational mandates and increasing reliance on high-stakes standardized tests, as well as the establishment of national curricula in some countries. A focus on accountability has resulted in narrow, selective, and minimalist goals that facilitate control over educational content and processes. An emphasis on efficiency and economic competitiveness characterized by standards and accountability movements, and reified through textbooks, has silenced discussion about other possible goals for education.

Textbooks promise discipline, standardization, and accountability in the mass delivery of instruction (Luke *et al.*, 2002). The seemingly unquestioned authority and privilege granted to the knowledge and pedagogy embodied in textbooks has become an invisible and pervasive part of the professional socialization of teachers, as well as the overall socialization of students and society at large. As a result of this domination, particular viewpoints about curriculum, instruction, and the very organization of schools are validated and maintained.

In part, textbooks have been accorded privilege because of presumed objectivity and neutrality in their content. Textbooks, however, are far from neutral. What counts as knowledge and pedagogy in textbooks is selected from a much larger universe. Certain principles, practices, and meanings are chosen for inclusion and emphasis while others are excluded, reinterpreted, or diluted. The exclusion of knowledge and alternative voices from textbooks represents a technique of disciplining power that pathologizes that which is outside of the norm (Foucault, 1977). In this way, students' identities are deformed by what is excluded from textbooks – absences, denials, and incompleteness.

If the examination embodied in high-stakes standardized tests provides “a normalizing gaze, a surveillance that makes it possible to qualify, to classify and to punish” (Foucault, 1977: 197), then traditional school curriculum provides the normalizing voice that accompanies and directs this gaze. Publishing companies codify this normalizing voice in the form of curriculum and programs like America's Choice. The new frontier in educational publishing – the production of full-service packages of educational materials, including textbooks, computer programs, test preparation supplies, and instructional materials (Osborn, 2007) – strengthens the power of these programs to mold teaching and learning in school, while at the same time remaining largely invisible. Like the normalizing gaze of the examination, the disciplinary power of curriculum is exercised through its invisibility; invisibility achieved through a focus on sameness, and supposed neutrality, which legitimates and may even disguise the exercise of power.

Current trends in curriculum publishing increasingly treat knowledge as a commodity that can be developed, produced, and marketed by private industry to a variety of national and local markets. While government and corporate publishers of curricula often assert their commitment to high-quality materials, a static notion of knowledge and learning undergirds the production of these educational commodities. Packages of coordinated educational products are often meant to inject standards into schools, and teacher proof the content to which students are introduced. A key question in this current context is what do teachers do with these powerful mediating forces. It seems that some follow textbooks closely, believing they can teach (Shannon, 1992) and, more recently, many follow them for the scope and sequence connected to mandated testing.

In summary, publishers of curricula have an enormous influence on the kinds of knowledge and texts that teachers and students have access to in schools. This influence is mediated by government policies; the extent to which decisions about textbook adoption are made at local, state, or national levels; and whether nations produce their own texts or, increasingly, contract with multinational firms who produce and adapt already-existing texts to particular national markets. Given that textbook production and distribution is an increasingly global enterprise, dominated by multinational firms with profit as their main motive, the relationship between curriculum and the publishing industry deserves serious scrutiny. The cases of NCLB and America's Choice in the US point to the key role that government policies and agendas play in endorsing particular curricula and publishers. Attention should be given to who makes consequential decisions about the production and codification of knowledge in the form of curricular materials, and who is benefiting – economically, politically, and culturally – from these globalized and unequal processes of production and consumption.

Curriculum and Teacher Change

J G Ladwig, University of Newcastle, Newcastle, NSW, Australia

©© 2010 Elsevier Ltd. All rights reserved.

At least since its formation in the early twentieth century, curriculum has become almost synonymous with questions of educational reform and change. The very notion of curriculum development is fundamentally embedded in a modernist commitment to progress and reform: development implies change, and in modern times, education implies development (see, e.g., Popkewitz, 1991, 2004). When the focus of curriculum development is within schools, where teachers are the people who ultimately deliver curriculum, the commitment to curriculum reform has long implied a commitment to teacher change. Thus, for at least the past century, teacher change has been a major focus of attention in educational research and practice. Literally hundreds of thousands of references to teacher change are found in the archives of the twentieth- and the twenty-first-century educational literature in English-language databases alone. The commonality of calls for ways and means to change teachers is so prevalent that it has become part of the taken-for-granted hegemonic background of education globally.

One of the reasons a focus on teacher change has become so prominent comes from within the curriculum field itself. The connection between curriculum development and teacher change has been recognized throughout the twentieth and into the twenty-first centuries and is part of the mainstream canon of curriculum development. From Bobbitt's seminal push for efficiency and his adaptation of Taylorist principles of labor management in 1918, through Tyler's *Basic Rationale* in 1949, to Taba's expansion of Tyler in 1962, or from Smith, Stanley, and Shore's broader outline of curriculum development in 1950, up to the contemporary traditionalists of curriculum such as Tanner and Tanner, virtually all of the major mainstream addresses of curriculum development come to the question of teacher change in one form or another. The reason for this connection is clear once it is recognized that whatever the official curriculum may be, what students experience as curriculum fundamentally depends on what teaching they experience.

While several explanations can be, and have been, forwarded to understand this reality, there are two basic observations which help understand why the focus on teacher change has become so embedded in curriculum development. On the one hand, prior to some recent post-modern critiques of curriculum which decry development *per se*, all major paradigms of curriculum development shared a common commitment to teacher change no matter how fundamental the paradigmatic differences debated were. On the other hand, no matter how much

attention and overt research and action have been dedicated to teacher change, changing teaching and teachers in some consciously planned manner remains an unsolved dilemma for educational reformers (cf. Richardson and Placier, 2001). Add to this background one of the emerging understandings from research into instructional improvement – that substantial improvement in teaching requires significant changes in teachers. Taken together, it is clear that whoever wants improvements in the quality and nature of school curriculum simultaneously commits to both curriculum development and teacher change. Let us consider each of these points in turn.

The question of how curriculum development links to teacher change, no matter what the theoretical view is, can be demonstrated whether one draws together a very broad view of the curriculum field, or if more specific differentiations of curriculum perspective are developed. From a broad view, recent studies in curriculum that analyze the curriculum field as formed by multiple discourses include a wide range of curriculum perspectives. For example, Pinar and his colleagues address curriculum as different forms of texts: political, racial, gendered, phenomenological, post-modern, autobiographical/biographical, esthetic, theoretical, and institutionalized (Pinar *et al.*, 2002). In this view, curriculum development is identified specifically with the institutionalization of curriculum. However, even in this broad view, it is clear that no matter what the discursive perspective taken, the link between any notion of curriculum change and teacher change is pragmatically implicit. It is possible to analyze, theorize, and comment on curriculum without concerning oneself with teacher change, but it is not possible to change curriculum without also considering the people who will deliver it. From a more specific view of curriculum, Snyder *et al.* (1992) outline three perspectives in their review of curriculum implementation: the fidelity, mutual adaptation, and enactment perspectives. Each of these perspectives includes a role for the teacher as an agent of curriculum development, from the most proactive (the enactment perspective) to the least (the fidelity perspective).

From the perspective of curriculum development, the reason it is so important to recognize the link with teacher change is to confront a basic reality, that is, despite more than a century of attempts to change the educational experiences of students through curriculum reform, the realities of the classroom have not shifted all that much. This common finding in American research can also be noted globally. In Australia, for example, where there has

been a significant shift in the official, centralized, curricula of State authorities, there is little reason to believe that classrooms have changed considerably. In the words of one of Australia's most widely acclaimed curricularists, in his lament on the lack of pedagogical change in Australia after decades of dramatic curriculum changes, the late Garth Boomer noted, "It could well be that the last thirty years has been a matter of change on paper, rather than change in essential practice" (Boomer, 1999: 127). So, working simply from the question of curriculum development, the need to understand and find ways to enact teacher change is clear.

Another reason teacher change has become central in educational research and reform over the past decade or so has come from studies of educational reform and school effects. When focusing on what schools can do to improve student outcomes (typically, but not always, meaning student academic outcomes), research into what contributes the most to student outcomes has long pointed out the importance of differences between teachers and pedagogy. That is, when considering what levers of change a school can reasonably impact directly, the main focus has to be on the quality of teaching and teachers. (There are, of course, many other factors that schools cannot directly leverage.)

Sociologists of education have long spoken of variance within schools as a major contributor to the differential educational outcomes, at least since the 1966 Coleman Report (Coleman *et al.*, 1966). Picking up on this line of reasoning, sociological studies of streaming and tracking have also pinpointed differences in the nature of curriculum and instruction as key factors in understanding within-school effects. Any attempt to change the effects of streaming and tracking therefore implies changing curriculum and teaching. Many of the factors that contribute to differential effects of streaming and tracking are directly related to aspects of curriculum and teaching that vary significantly among teachers. In this way, even from the less-direct path of analyzing the social implications of schooling, the focus of school improvement eventually turns to the question of teacher change.

Levers and Dimensions of Teacher Change

With the focus on teacher change, research on curriculum development has identified several dimensions of teachers and teaching which need to be changed if pedagogical change is the desired result. Additionally, and consequently, to get these dimensions of teaching to change, research has attempted to identify levers which might lead to such changes. Around many of these levers and dimensions of teacher change, there is something of an uncontested consensus. Seven of these are discussed below.

Instructional Techniques

The historical legacy of curriculum development is built on what is now seen as a traditional split between curriculum and instruction. While it is now common to speak against this split as a simplistic dichotomy, it is equally true that many current reform efforts to improve teaching leverage a sharp distinction between the development of curriculum and the specific teaching techniques intended to deliver the goods of that curriculum. Perhaps the most obvious example of these can be found in the Success for All reform initiative in the United States (Slavin and Madden, 2001). Within this tradition, the question of teacher change is largely framed in terms of the implementation of pre-specified teaching techniques which can occur with varying degrees of implementation fidelity. This understanding of curriculum development and teacher change is consistent with and at least as old as Bobbit's Taylorist understanding of schooling.

Teacher Beliefs

Where studies in implementation fidelity have done a fine job of documenting failed or incomplete reform initiatives, they have often pointed out that the application of teaching techniques is likely to have a limited scope and range of success, without necessarily changing the beliefs teachers bring to their work. The focus for changing teacher beliefs can be a question of their beliefs about learning, teaching, students, subject areas, knowledge, and epistemology (Calderhead, 1996). While the specific focus of belief differs in each line of reasoning, the basic logic remains similar. If teacher behaviors are to change more than temporarily, across multiple contexts, then something more durable than a set of techniques is required to carry on along with the teacher herself. The idea of focusing curriculum development on the implementation of specific teaching techniques almost by definition precludes lasting change, to the extent that applications of technique are almost always context and time specific.

Content Knowledge

Since before the turn of the past century, one of the central questions of teacher change, whether from the point of view of specific pedagogical practices or larger curricular reform, has been a persistent questioning of teachers' content knowledge and expertise. At least from the publication of the first issue of *The School Review* in 1893 in the USA, in those heady days of secondary school curriculum reform advocated by The Committee of Ten, the question of the content expertise needed by teachers was central in the minds of those who sought to professionalize teaching (Hart, 1893). For example, later in the

same year, Aven Nelson (1893) decried the need for teachers to keep up with the growing knowledge demands of an ever increasing crowded science curriculum in high schools. Given the relatively stable nature of school practice and the continually growing nature of knowledge, it is perhaps not surprising to find similar calls for advancement of teachers' content knowledge in contemporary school reform literature. Current research has been decisive in measuring the ultimate effect of teachers' content knowledge on student achievement (Hill *et al.*, 2005). From this, it is not a far stretch to find policy implications drawn for any attempt to improve curriculum development that point out the need to improve teachers' content knowledge as a lever of change. Whereas early calls for teachers to improve content knowledge may have been fairly blunt and simple, contemporary focus on this area of teacher change sees the need to link teachers' content knowledge with the materials intended to be used in the reformed curriculum.

Pedagogical Content Knowledge

Since Shulman's 1980s call for a renewed reform focuses on teachers and teaching, knowledge about this link between specific content knowledge and instructional practices designed to maximize students' learning has been dubbed pedagogical content knowledge, and is seen to be the special province of teachers and teacher educators (Shulman, 1987). As perhaps the one form of knowledge unique to the profession, as noted by Hart (1893) above, the need to center curriculum development and teacher change on pedagogical content knowledge follows clearly from his position, and has been touchstone in the literature since Shulman's articulation of the idea. Around the time of Shulman's appeal, the question of changing teachers' pedagogical content knowledge figured in several areas of curriculum reform, notably in mathematics education (Peterson *et al.*, 1989). Since then, it has been a reference point for commentary on teacher education and professional development around the globe. The concern for developing teachers' pedagogical content knowledge in specific subjects continues in most, if not all, subject areas. For example, 124 years after Hart's 1893 lament about the needs of science teachers, similar calls can be found in contemporary educational research literature (e.g., Nahum *et al.*, 2007).

Dispositions to Their Own and Others' Learning

While the question of changing teachers' techniques, beliefs, and knowledge leaves much work for would-be curriculum developers, studies on the work of teachers sheds another light on the observation that teacher change is not altogether common. From a sociological view,

Lortie's (1975) seminal study of teachers and teaching has made it clear that any attempt to understand change in teaching must also recognize the durable dispositions that are developed while working as a teacher. Richardson and Placier (2001) pick up on this insight in their review of teacher change, pointing out that intentional attempts to change teachers are but some of the factors that lead teachers and teaching to be as they are and change as they do. In a sense, the literature on teachers' dispositions is linked to questions of beliefs, as is noted by some authors, but dispositions are seen to be less consciously accessible, being the individual equivalent of culture. And it is this link to the culture of schooling and teaching which drives several analyses of the lack of successful reform in curriculum development and teacher change (e.g., Sarason, 1993). The question of situating teachers into a broader social context that builds from and carries its own culture is the linchpin in the now-ubiquitous calls to see teachers as part of learning communities.

Professional Communities of Teacher Learning

In the wake of a two-decade push for teachers to adopt Vygotskian insights into the socially situated nature of learning, and pedagogical reforms that appeal to constructivist ideas, there is a consistency to the concurrent push to understand and develop teacher learning communities more broadly as well as in schools. From a focus on the collective nature of teachers' beliefs and sense of efficacy, to foci on school restructuring, to more skeptical theoretical examinations of the idea of teachers working in communities, it would be difficult to read any contemporary research on teacher change that does not in some way include the idea of a teacher professional community, or professional learning community. As Grossman *et al.* (2001) point out, the idea of community is now so overused that it has virtually become meaningless. Nevertheless, be it from a specific focus on teacher change (Richardson and Placier, 2001), or from a concern for teachers' professional development (Borko, 2004), the question of teacher change is clearly now recognized as not getting far without also taking their professional and social context into account. The logic behind this view carries the weight of common sense: however much teachers are effective individually, they are not likely to change their teaching on their own, since they do not work alone. This view, and the continued lack of successful intended teacher change, has led some researchers to focus on understanding how schools might support teacher change organizationally.

Organizational Change

The school restructuring research that was contemporaneous with Shulman's call to understand teachers' pedagogical content knowledge yielded a focus on schools'

organizational capacity long before the current interest in understanding organizational strategies to support teachers' learning. Newmann *et al.* (1996) began focusing on organizational supports for restructuring schools in the early 1990s. Following on from the work directed by Newmann, which focused on understanding how school restructuring could promote authentic pedagogy, researchers in this lineage have maintained a keen interest in understanding how the organizational efforts of schools and school systems might ultimately change teaching. This line of research has addressed questions of accountability, the relationship between professional development and school organizational capacity, teacher learning, school-wide inquiry, and collaborative teacher development, as part of a larger model of school organizational capacity building. Examining the role of leaders at school and system levels in attempts to steer curriculum development and teacher change follows the same analytical trajectory of this line of research.

Conclusion: Teacher Change as an Unintended Consequence of Policy Initiatives

The focus on teacher change in literature that links it with curriculum and pedagogical development has historically been ever hopeful, but the current literature related to the issue is frustrated by globally ubiquitous contemporary policies. While significant investments have been made in gaining implementation fidelity, there is little reason to believe that dominant policy initiatives akin to those deployed in the US are likely to leave any lasting improvement in teaching or learning. Elsewhere, the messages of developing professional communities of teachers, with foci on beliefs, knowledge, pedagogical content knowledge, and the like are pushing along. In the meantime, even as some US research has documented how policy in that country might best facilitate teacher change and curriculum development (Cohen and Hill, 2001), it seems the continued capacity to generate unintended consequences from policy initiatives will keep US researchers' attention, at least for a while longer. For example, while resource allocations to schools and school districts become ever more starkly distributed in the US, it appears that one unintended side effect of this has been in further institutionalizing the inequitable distribution of teachers. A growing production of international comparisons makes it increasingly clear that there are significant differences in how teacher change occurs within systems as part of an internally natural progression, but at the same time, within any one of those systems, attempts to purposively shift history's tides and consciously direct teacher change remain merely wishful aspirations.

Here, the critical call for understanding curriculum as part of the hegemonic apparatus of the school might perhaps be the most realistic call for teacher change. Where Apple's (1979) foundational analysis of curriculum in its larger social and political context leads him to call for all parties involved in curriculum development to become organic intellectuals, it is perhaps not all that idealistic to suggest that teacher change and curriculum development ultimately lie in the capacity of teachers to take up the challenge of being public intellectuals.

Curriculum Governance and Planning

B Levin, University of Toronto, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The development of curriculum by governments or other sanctioned authorities for standard use in schools across a state, province, or country inevitably involves elements of both policy and politics, because it involves questions of public values (Manzer, 1994). The term politics here includes a wide range of informal influences and larger social processes in addition to the standard processes of elections and party politics.

Most frameworks for understanding politics and policy formation address similar topics, such as the institutional setting and structure around decisions (e.g., Crowson *et al.*, 1996), how issues come to be on the political agenda (e.g., Kingdon, 1994), and the processes through which decisions are made in the face of different interests and points of view (e.g., Ball, 1990).

The discussion in this article uses a heuristic framework drawn from Young *et al.* (2007), who propose analyzing political decisions in terms of five overlapping categories: issues, actors, processes, influences, and results.

In making decisions about curriculum governments are subject to the usual pressures and constraints that form the political process (e.g., Edelman, 1988). Citizen preferences are critical, since getting elected is a fundamental concern of every government. Citizens are not necessarily interested in or knowledgeable about every public issue, which is why there is pressure on politicians to communicate in very simple messages. At the same time, citizens can care deeply and feel strongly about issues about which they know very little. Where beliefs are very strongly held, political leaders challenge them at their peril. Issues that seem minor can take on great salience if they engage people's emotions, or are used by political opponents, or take on public salience through the media (Levin, 2005). The time available for any issue is very limited due to many simultaneous competing pressures and events, while unexpected events can have very large consequences; consider the impact on school curricula of the collapse of the Soviet Union and its satellite regimes.

Educators may believe that education policy should be based on their knowledge and experience, but from a political perspective evidence and experience are not enough to drive decisions, and they may be among the less important factors. Even when policy decisions in education are not of public concern, they may be controversial and highly political within the education sector,

engendering the same political dynamics as above within the system. A subfield of education politics, micropolitics, examines these small-scale political interactions.

Issues: Scope of the Politics of Curriculum

At one time curriculum was almost universally seen as central to education, in that it was assumed that students would learn what was in the course of study. Decades of experience with educational change have made it evident that the situation is much more complex. There is a substantial debate as to how important formal education as a whole is in shaping student outcomes, with some arguing that socioeconomic status and other nonschool factors are by far the most important influences on outcomes while others believe that what happens in schools – which in any case involves much more than the official curriculum – can play an important role (European Commission, 2006; Organisation for Economic Co-operation and Development, 2007). Ideas about the importance of curriculum have also been changing over time as a result of growing knowledge – for example, increasing awareness of the importance of teachers' assessment practices (Black and William, 1998).

As governments have attempted to make large-scale changes in schooling, curriculum has become less an activity in its own right and more one element in a comprehensive approach to education change. In many jurisdictions with centralized curriculum, review and renewal processes have been altered to be more consistent with wider education programs. In other settings curriculum has been a prime vehicle for realizing wider change (e.g., Luke, 2004). The United States is an interesting case in that there is a national education reform strategy – No Child Left Behind – that is based largely on demanding curriculum standards, yet curriculum is controlled mainly at the district or even school level, creating some substantial disjointedness.

The politics of curriculum can be thought of as involving two kinds of discussions. The first concerns the overall shape of school curricula: what subjects will be included (or excluded), how much of each, and at what stage of students' education. Examples would include debates over whether literacy or mathematics are getting a sufficient share of the school day and school year, whether sex

education or religion should be part of the curriculum, or when students should first study a foreign language.

The second area of debate is over the content of particular subjects: what should be included in each subject and at each age or stage of education. These debates take place not only in the most obvious areas, such as what is taught in history or studied in literature, but also in areas that might be thought to be more objective, such as science or mathematics.

In addition to the content of specific subjects, schools are seen as the place where children will be inoculated against all social ills or taught all the virtues. Schools are expected to prevent bullying, obesity, and drug abuse while also eliminating racism and promoting equity in all its forms. In many cases these topics cut across the formal school curriculum, so who provides what instruction and when can be an important curriculum issue.

Some of these discussions are a matter of pragmatics. There simply are not enough hours and days in 12 years of schooling to accommodate all the areas people want children to develop. So debates take place about the relative importance of various areas of study in the competition for scarce school time. These discussions can be intense in part because they are often led by people with a strong personal interest in the decision.

A second set of arguments, often much more vitriolic, occur when curriculum debates occur due to disagreements on important value questions. Because schooling is seen as so fundamental to the development of our children, it can turn into a battleground for wider social disputes. Significant philosophical or value disagreements are expressed in many areas of curriculum, such as the content of history and literature curricula or the role of first languages for immigrant students. Any issue that is politically contentious can also turn into a curriculum dispute. These debates are sharp because they embody deeply held views not only about the nature of education but about essential values. Edelman's (1988) concept of condensation symbols, in which even relatively small instances become highly symbolic as they seem to embody, or condense, a range of beliefs and values in a particular case, applies often to curriculum politics.

Because everyone has gone to school, just about everyone feels knowledgeable about and has a personal response to educational issues. The same would not be true of other policy fields such as environment or energy. One important result of the universal experience of schooling is that adults, like children, tend to see curriculum as a collection of subjects and topics without necessarily requiring coherence or integration across the curriculum.

Another significant feature of curriculum politics is that in many cases questions of content cannot be separated from teaching practice. Many of the most heated issues in curriculum – for example, whole language or constructivist mathematics – are as much about teaching

methods as they are about curriculum content. These debates often spill over into decisions on curriculum structure and content.

Actors: Who Is Involved?

Curriculum politics involve a wide range of participants. Education governance typically involves some combination of national, regional, and local input. The division of powers and responsibilities across these levels is quite variable from one country to another. In most jurisdictions final authority over curriculum rests with national or regional governments or with agencies they create for this purpose. In many federal systems it is provinces or states that control curriculum. In a few situations curriculum authority is largely located within local districts or even individual schools.

The central role of governments brings into play a range of both political and bureaucratic elements. An individual in a key position, such as a powerful minister or political advisor, can either shape or hold up decisions, including details of curriculum content, if determined enough.

An important element of governance structure is the role of elected lay persons as against civil servants or experts. Countries vary significantly in how much authority lay people have in shaping education policy, ranging from ministers to local school authorities to school councils, or governing bodies involving parents and others. Each of these forms will bring different dynamics to curriculum politics. Depending on national governance arrangements, local schools, or districts have varying degrees of control – from almost none to quite substantial – over the formal curriculum.

Whatever the formal control system is, in almost all settings, schools have some influence if only through the choice they are able to make as to which courses and programs are actually provided and the amount of attention that is given in the day-to-day life of the schools to particular subjects or topics. High schools, for example, may be able to choose which optional courses to offer. Elementary teachers and schools typically make important decisions about curriculum emphasis, especially where – as is often the case – the formal curriculum has more elements to it than can be taken up in most classrooms. Schools or districts also often decide on the areas of the curriculum will be the subject of professional development.

The main education stakeholder groups – teachers, principals, senior administrators, and elected local authorities where they exist – are almost always involved in curriculum reviews and decisions. Students, however, typically have a very small role, if any, in curriculum governance. Subject matter experts from schools and universities usually play a central role in the curriculum formation and review process and may also be very involved in public debates. Indeed, a

central dilemma in curriculum formation is the balance between subject matter expertise and larger perspectives on the role of a given topic in the overall school program. Not surprisingly, those associated with each subject or topic will advance its importance – which, it must be pointed out, is often linked with their own employment prospects and importance.

Tertiary institutions may have a powerful influence on school curriculum, especially in secondary schools, through the setting of entrance requirements to their institutions. Since secondary schools often see themselves – and are widely seen by students and parents – as preparing students for further study, schools may find themselves quite constrained by requirements set by tertiary institutions. Views about school curriculum expressed by the tertiary sector may not be particularly well grounded in evidence but may rest on the beliefs of individuals holding key roles. As elsewhere, tertiary experts tend to believe that all students need more of their subject and at a higher level.

Because schools are widely seen as playing a central role in the socialization of children and young people, a wide range of interest groups may be involved in curriculum politics depending on the issue. For example, business groups may have strong views about aspects of curriculum. Various industries may try to promote subjects and programs that support their labor market needs. In the wider society, many groups want the curriculum to reflect particular issues and perspectives – for example, the desire to include the language, history, and literature of various minorities and indigenous peoples. As discussed in the next section, curriculum processes do not necessarily provide very much direct opportunity for input from various interests. As usual in political processes, those bodies that are better organized and financed or whose concerns are more deeply felt will tend to be much more active and may have disproportionate influence (Lindblom, 1980).

Curriculum can also be influenced significantly by other policies. Student assessment policies may shape curriculum decisions, and are often important drivers of what is actually taught (Mehrens, 1998). The effect of assessment will be positive if schools and teachers understand the standards and if the tests are aligned to appropriate curricula and teaching methods, which is not necessarily easy to achieve (European Commission, 2006). Where assessment is disconnected from curriculum, the consequences may be problematic.

Processes: How Are Curriculum Policy Decisions Made

Jurisdictions normally have well-developed formal processes for creating and revising curricula. Typically, these processes involve bringing together groups of experts and sector representatives to draft the elements of a new or revised curriculum. Teachers of the subject will often be

in the majority, with representation from tertiary subject experts as well. The processes are often organized and to some degree directed by government officials from ministries of education. Typically, a curriculum review or renewal process would involve examining the existing curriculum, gathering data as to the strengths and weaknesses of current arrangements, considering various ideas for changes, and trying to arrive at consensus on recommendations for the new curriculum. Altogether curriculum processes can be quite extensive depending on the level of detail in the work, sometimes taking several years to be completed. However, if substantial authority is vested at the level of the local school, curriculum development or renewal is likely to be much more informal and ad hoc, as no school will have the resources or capacity to undertake these larger processes.

Expertise in a subject or in teaching that subject does not necessarily equate to expertise in constructing a curriculum. By definition, experts know more and care more about their subject than will most teachers. An expert-dominated curriculum development process may result in a product that can be used effectively only by people with high levels of expertise, while the reality of schools everywhere is that many teachers, especially in elementary schools, will have only a limited background in a given subject. One danger in curriculum development then is the production of curricula that are not readily usable by ordinary teachers. Interest groups can and do promote ever-higher standards for their subject and then use those standards to argue for more time in the school schedule as well as for more teachers, higher qualifications, and more resources.

A further consequence of expert input is the clash between experts with competing views – for example, those who favor new pedagogic approaches versus advocates of traditional content organization and teaching. Educators themselves are often divided over such questions, while the clash of expertise may be a subject of media interest as well.

The expert-dominated approach to curriculum development is changing as experts no longer have the political legitimacy they once did. An increasingly better-educated public is demanding greater input in all areas of public policy. Governments are therefore moving away in many areas from reliance on experts to greater involvement of average citizens through various forms of consultation and opinion gathering as part of policy formation. In curriculum decisions review groups are now more likely to include parents or students or noneducators such as business representatives. As discussed in the next section, these changes in composition can have significant implications for the ways in which curriculum processes unfold because they will bring different and more diverse interests to the table.

Curriculum review groups do not do their work in a vacuum. Sometimes these processes proceed relatively smoothly, but they can also be highly contentious.

Where important disagreements exist about curriculum there may be intense lobbying by various interests as to who should be named to a working group. Although these processes are not often documented, some interesting accounts exist of the politics of curriculum review. More such accounts would be valuable in understanding these processes more fully.

Curriculum formation may also be linked to more public political processes. Public debates around curriculum issues can occur simultaneously with official processes – as, for example, when public interest groups are aware of and try to influence the outcomes of the official process by lobbying for particular changes. Or public debate and concern can be the springboard for an official process as the system tries to respond to public concerns, as is evident in debates about issues such as global warming. Or public debate can erupt following a formal curriculum change proposal as various interests mobilize to change a draft curriculum they do not support.

Influences: What Shapes Decisions?

One essential tension in curriculum decisions, as already noted, is between expert opinion and concern of key interests or of the general public. Political leadership will take account of expert opinion, but will inevitably take much more interest in public opinion and particularly the views of opinion leaders in key sectors or constituencies.

Even where the curriculum process is dominated by experts there may be substantial disagreement on what to do. Teachers may see curriculum issues quite differently from tertiary experts. The latter may focus on the need for high-level skills in their own area, whereas teachers may be more concerned with a curriculum that will work for students with widely varying skills and interests. Advocates may want more topics at higher levels, whereas classroom teachers may push for exactly the opposite. In some fields, teachers of the subject are themselves deeply divided on key curriculum and teaching questions. They also have varying opinions on issues such as the relevance of interdisciplinary studies as opposed to more traditional disciplinary boundaries, or on the value of project work.

Research has increasing importance in influencing education policy generally as a more educated population is more inclined to want evidence about public policy issues. In school practice too there is growing interest in the use of evidence to guide decisions about teaching and learning practices (e.g., Marzano, 2003). The interest in research does not, however, mean that there will be a direct link between research results and policy choices; the latter will always remain the result of political processes. The commitment to evidence is shown in that all sides in the political debate do attempt to bring evidence to bear whenever possible and do use it to legitimate and support their own positions, which may increase public

confusion. Yet empirical evidence can also shape and change public and professional views on important questions, as it has around tracking in secondary schools, or the impact of socioeconomic status on school outcomes. Despite significant advances in education research evidence, it remains the case that in many – probably most – areas of curriculum there is not enough knowledge to guide policy or practice sufficiently; and quite often, existing knowledge is not available in a form that speaks effectively to the real problems and issues of policy and practice.

Still, curriculum review will generally take account of emerging knowledge in the field under discussion precisely because the process has so much expert participation. More recently, in keeping with a general trend in education toward using student assessment data, curriculum review may include data on student outcomes, both for the curriculum overall and for particular groups of schools or students. However, regular use of student outcome data to guide education policy is still not standard practice everywhere. Nor do curriculum working groups necessarily pay careful attention to research as part of the work. Even expert processes are susceptible to a preference for interest bargaining instead of evidence.

Results

It has been at least 20 years since it became evident that there is a large gap between producing a curriculum and the experience of students in the classroom. A substantial body of research (e.g., Cohen *et al.*, 2003; Hubbard *et al.*, 2006) shows how far classroom practice can be from new curricula and how little impact a change in curriculum can have on teaching practice. The more significant the proposed change, the more likely it is to have limited adoption.

Various efforts have been made to produce curriculum that would have a greater impact on students' real experiences. These efforts range from so-called teacher-proof curricula, in which teaching practice is built into the curriculum at a high level of specificity, to attempts to connect new curricula with extensive professional development so as to change teachers' practices. However given the nature of schooling and teaching, with very large numbers of teachers of quite varied backgrounds in highly varied contexts and with considerable autonomy in their daily practice, central attempts to circumvent these limitations are unlikely to be successful. Working practices of teachers are shaped primarily by day-to-day realities of their workplace, their habits, and their views about what is practical (Organisation for Economic Co-operation and Development, 2005). Insofar as curriculum changes do not pay attention to these realities, they further limit their chances of having an effect.

Research has helped develop understanding of the factors that do shape implementation. Fullan's (2007) work has been particularly influential. However, these

considerations may still not be well integrated into formal curriculum processes, as it is still common to find accounts of some new program that was carefully developed only to fall far short in the implementation stage for entirely predictable reasons, such as violating teachers' norms around their practice. Issues of implementation and results are often marginal to the curriculum development process.

Conclusion

Although curriculum is a fundamental part of the framework of schooling, curriculum decisions and choices are shaped in large measure by other considerations – ideology, personal values, issues in the public domain, and interests. Curriculum decisions are often part of a much larger public debate that often extends beyond education to larger questions of public goods. These dynamics tend to be poorly understood by most educators, who tend to believe that education policy choices can and should be made on the basis of educational expertise. When processes are put in place without adequate regard for the real drivers of decisions, the likelihood of poor decisions – that is, decisions that fail to produce the intended results – increases.

Curriculum Planning and Systems Change

Z Deng, Nanyang Technological University, Singapore

Systems theory, as conceptualized by theorists after the 1950s, views the world in terms of a unified whole and self-organizing systems, with an emphasis on the interdependent nature of the relationships that exist among all components of the unified whole (Boguslaw, 2000). From this perspective, significant change requires systems change that entails impacting changes across all constituent systems. Such a theory is useful in analyzing the nature, character, and complexity of curriculum planning for significant change.

This article first describes three basic domains of curriculum planning which can be viewed as three constituent systems. It then discusses their interrelationships and the implications for curriculum planning for significant change. This is followed by an examination of three common models of curriculum planning which are intended to bring about significant curricular change. The article concludes with addressing what is entailed in curriculum planning for significant change.

Three Levels of Curriculum Planning

Curriculum planning refers to the decision-making process concerning the substance of schooling, that is, the knowledge, skills, and dispositions that constitute the experience and outcome of schooling. Broadly construed, it operates across three basic domains of curriculum; institutional, programmatic, and classroom (Doyle, 1992a, 1992b). Each of these curriculum domains constitutes a system or subsystem that, in varying degrees, has an impact on what is taught and learned in school.

Institutional Curriculum Planning

The institutional curriculum embodies a conception or paradigm of what public schooling should be with respect to a society. Curriculum planning at this level is characterized by discourse on curriculum policy at the intersection between schooling, culture, and society. It invokes images, metaphors, or narratives to “typify” what could happen in a school or school system (Westbury, 2000). For instance, thinking School is used by the Ministry of Education in Singapore to convey a vision of schooling for the twenty-first century – a vision that defines the development of critical thinking and creativity as a central purpose of schooling. Institutional curriculum planning

frames what should go on in a school or school system in terms of broad goals and general approaches to education. It serves as a means of drawing attention to educational ideals and expectations shared within a society and putting forward the forms and procedures of schooling as responses to those ideals and expectations (Doyle, 1992b: 70). Such curriculum links what is taught in schools to the social and cultural systems beyond schooling, and is always under pressure for change. Since social and cultural contexts often change rapidly, school systems always use the institutional curriculum as a convenient instrument to communicate responsiveness to the outside communities (Doyle, 1992a: 487).

Institutional curriculum planning is always a national or regional political undertaking. In countries with centralized education systems like France, Singapore, Malaysia, and China, the legal responsibility for institutional curriculum planning is the province of the central government. National educational bodies (ministries, departments) play a substantial role in the planning process. In countries with decentralized systems such as Canada, UK, and Australia, state or provincial governments are constitutionally responsible for making institutional curriculum decisions. Regional educational agencies are instrumental in the planning process. Regardless of it being in centralized or in decentralized systems, curriculum planning at the institutional level, more often than not, involves soliciting the opinions and suggestions from various representative groups – including policy advisory bodies, employment agencies, educational specialists, heads of schools, and various civic and special interest groups.

Programmatic Curriculum Planning

Programmatic curriculum planning is at the intermediate levels between institutional curriculum and classroom curriculum planning, with a focus on curriculum writing in the form of curriculum documents and materials (Doyle, 1992a). It translates the expectations and ideals embedded in the institutional curriculum into operational frameworks for schools, thereby bridging the gap between the abstract institutional curriculum and the (enacted) classroom curriculum (Westbury, 2000). In Singapore the notion of thinking schools becomes the introduction of thinking programs to be implemented in primary and secondary schools. The programmatic curriculum is characterized by an array of school subjects, programs, and courses of study provided to a school or a system of schools.

For those school subjects, programs, and courses of study, the programmatic curriculum also spells out instructional guidance in terms of content standards, instructional frameworks, criteria for textbook approval and adoption, and assessment criteria.

Programmatic curriculum planning refers to the formal process of constructing the curriculum which involves “framing a set of arguments that rationalize the selection and arrangement of content [knowledge, skills, and dispositions] and the transformation of that content into school subjects” (Doyle, 1992b: 71). The planning process, Tyler (1949) believes, entails addressing the questions concerning purposes, content, organization, and evaluation in a sequential fashion:

1. What educational purposes should the school seek to attain?
2. What educational experiences can be provided that are likely to attain these purposes?
3. How can these educational experiences be effectively organized?
4. How can we determine whether these purposes are being attained?

Tyler’s model prescribes what steps one needs to follow in planning a curriculum. However, it does not describe what curriculum developers actually do when they are engaged in curriculum planning (Westbury, 2008). In practice, programmatic curriculum planning is a highly sophisticated undertaking. It is a collaborative and cooperative endeavor that always involves committees made up of representatives from governments, educational agencies, schools, universities, business, industry, and the community at large. It occurs within “webs of societal and cultural ideologies and symbols, politics and organized interest groups, organizational and administrative structures and processes, and local understandings, beliefs and practices” (Westbury, 2008). As in institutional curriculum planning, national and regional educational agencies play a key role in programmatic curriculum planning.

Classroom Curriculum Planning

The classroom curriculum, also called curriculum as event or the enacted curriculum, is characterized by a cluster of events jointly developed by a teacher and a group of students within a particular classroom (Doyle, 1992a, 1992b). It is an evolving construction resulting from the interaction of the teacher and students. Curriculum planning at this level involves transforming the institutional and programmatic curriculum embodied in curriculum documents and materials into educative experiences for students. It requires further elaboration of the programmatic curriculum, making it connect with the experience, interests, and the capacities of students in a particular classroom (Westbury, 2000). Curriculum

planning can be the effort of an individual teacher or a team of teachers responsible for identifiable students, deciding alone or with students what shall occur in a specific educational setting. Such curriculum is shaped in a powerful way by a range of local factors, including teachers’ own classroom perspectives, students’ interests and experiences, school principals’ requirements, and parents’ expectations (Doyle, 1992b).

The three levels of curriculum planning together imply a hierarchy of decision-making activities from the institutional to the classroom arena. This, however, does not mean that curriculum planning must begin with a national ministry or state department of education in formulating curriculum policy, proceed to writing curriculum documents and related materials, and eventually end up with school teachers in implementing the documents and materials in classroom. In practice, curriculum planning could begin anywhere. It could, for example, start with an individual teacher or a group of teachers and a class of students. Teachers can participate in what is called school-based curriculum development (SBCD) in which they articulate their own visions and goals of teaching, develop their own curriculum materials in the light of their visions and goals, and put the materials into practice with students. However, this does not mean that teachers could completely ignore the existence of curriculum goals and instructional guidelines developed at the national or state level – a point that will be further addressed in sections that follow.

The Interdependence of Three Levels of Curriculum Planning

The three levels of curriculum planning are interrelated and interdependent; each does not function in isolation of others. Curriculum planning at the institutional level provides a departure point and a frame of reference for curriculum planning at the programmatic level. It serves to clarify the normative, ideological bases for curriculum decision makings, drawing attention to the public character of curriculum that goes beyond the private interests and concerns of individuals. By articulating the aims, purposes, ideals, and expectations for public schooling, institutional curriculum planning points to a desirable direction for programmatic curriculum planning. Without attending to those aims, purposes, ideals, and expectations, programmatic curriculum planning could lose sight of the responsibilities that schooling as an institution needs to bear in contributing to the common good of a society.

Classroom curriculum planning, although remote from institutional curriculum planning, has an indirect yet significant link with the institutional curriculum. The construction of the classroom curriculum often involves a teacher’s use of curriculum materials (e.g., textbooks

and teacher guides) adopted by a school or school system – materials that are normally developed with reference to what is desired and valued in the institutional curriculum. In planning instructional activities, a teacher interprets and transforms the materials in the light of his or her knowledge and beliefs about the purposes of schooling, about his or her students, about pedagogy, and about the school and classroom contexts (Wilson *et al.*, 1987). To a certain extent, the classroom curriculum thus reflects the teacher's interpretation of "what is desired by unseen, remote decision makers" (Goodlad *et al.*, 1979: 21). Furthermore, when the classroom curriculum becomes visible in various ways (such as public examinations, classroom surveys, and parent meetings) to administrators, parents, and others interested in education, questions concerning the interplay between schooling and society could be inevitable: for example, what are the purposes of schooling? How well does the curriculum prepare students to meet the current and future challenges of the social and political order? Social and political forces are brought to bear at the school or classroom level. The classroom curriculum thus is connected indirectly back to the institutional curriculum which, in one way or another, "serves as a normative framework for defining and managing the work of teachers" (Doyle, 1992a: 487).

Apparently, institutional curriculum planning seeks to affect classroom curriculum planning through the programmatic curriculum – curriculum that provides the medium in and through which the institutional curriculum operates. By translating the institutional curriculum into an array of school subjects, programs, and courses of study, programmatic curriculum planning creates the organizational and operational structure for classroom curriculum planning. School subjects, programs, or courses of study constitute the locus of classroom teaching; they frame the character of the classroom curriculum and the ways in which the curriculum might be seen within the school community (Grossman and Stodolsky, 1995). The ways of teaching a traditional school subject (e.g., history) and an integrated subject (e.g., social studies) in a classroom could be substantially different, so are the criteria of judging these two subjects. Furthermore, by developing content standards, instructional frameworks, syllabi, assessment criteria, and the like, for those school subjects, programs, and courses of study, programmatic curriculum planning furnishes the instruments that serve to regulate and control classroom curriculum planning, guiding what is to be taught and learned in the classroom (Doyle, 1992a). These instruments could "steer" classroom curriculum planning in the direction set out in the institutional curriculum (Cohen and Spillane, 1992). They could also be resources for teachers to learn the ideals and reform visions embedded in the institutional curriculum (Cohen and Hill, 2001).

The effect of programmatic curriculum planning on classroom curriculum planning, however, is complex and

in no sense straightforward. It has to do with the governance structure of curriculum planning. As already mentioned, in centralized education systems programmatic curriculum planning is carried out mostly by government educational agencies (e.g., national ministries of education). The programmatic curriculum, which more often than not is linked with high-stakes public examinations, tends to have high power and authority over the classroom curriculum. Classroom teachers are supposed to follow closely the standards, frameworks, and guidelines laid out in the programmatic curriculum; they have relatively less latitude in deciding what to teach and how to teach it (Cohen and Spillane, 1992). Programmatic curriculum planning thus could significantly influence classroom curriculum planning. However, in a decentralized education system where high-stakes public examinations do not exist and local or regional authorities make most programmatic curriculum decisions, classroom teachers have considerably high latitude in shaping the content and process of their curriculum. Programmatic curriculum planning tends to have much less impact on the classroom curriculum. The education system in the United States typifies this governance structure of curriculum planning in which state developed or mandated curriculum frameworks and materials do not have formal authority over classroom practice (Cohen and Spillane, 1992).

Furthermore, programmatic curriculum planning, whether in a centralized or a decentralized system, depends, for its effect, on those implementing the programmatic curriculum in school and classroom. While school leaders could make decisions concerning the adoption of a particular curriculum framework and related materials as the programmatic curriculum for the school, classroom teachers are the ones ultimately responsible for carrying out the programmatic curriculum in their classrooms. Programmatic curriculum planning affects classroom curriculum planning only if teachers understand and employ the adopted framework and materials (Synder *et al.*, 1992). Teachers are not "conduits" for the use of a curriculum framework and related materials; as mentioned earlier, they interpret and transform the framework and materials in the light of their experience, beliefs, and practice. This could further compound the impact of programmatic curriculum planning on the classroom curriculum. Teachers' entrenched beliefs, experience, and practice could override the educational ideals and innovations embedded in the programmatic curriculum.

Curriculum Planning for Systems Change

As highlighted in the above discussion, the three basic domains of curriculum are interrelated and interdependent, together constituting an organic whole. Significant curricular change thus cannot be achieved by just

tweaking one or two domains in isolation; it entails systems change that requires impacting change across all three domains of curriculum. To achieve this, all three levels of curriculum planning are necessary and need to work together in a way that ensures sustainable curricular change at the classroom level. A defensible model of curriculum planning for systems change, therefore, needs to take account of all three levels of planning and their relationships. None of the levels can be undermined without undermining a vital factor in curriculum planning and development. With this in mind, three common models of curriculum planning – namely top-down, bottom-up, and combination – that intend to bring about significant curricular change, or by implication, systems change – will be considered.

Top-Down Model

The top-down model has been widely used in countries with a centralized education system. For many centralized countries, curriculum reform has been for a long time part of national plans and development strategies. Usually, the central government initiates curricular change by putting forward new curricular visions and goals. These visions and goals are then translated into programmatic or curricular frameworks that specify course structure, content standards, pedagogy, and assessment. Using these frameworks as a point of reference, the national education body would implement a series of initiatives such as textbook revision, assessment modification, teacher preparation, and professional development restructuring. These initiatives are expected to steer teaching and learning in classroom toward the reform visions and goals, resulting in significant change in the classroom curriculum. Also termed the framework approach (see Skilbeck, 1994), the top-down model was adopted by many traditional decentralized systems over the last two decades. For example, in the 1990s following the lead of the federal government, virtually all American states developed their statewide curriculum frameworks. In Australia, Canada, and other federated countries, there was a growing collaboration between state and federal authorities concerning the construction of an overall framework for the school curriculum based upon new curricular visions and goals (Skilbeck, 1994). These curriculum frameworks were believed to play a crucial role in steering the classroom curriculum in the reform direction.

Such a top-down, centrally driven, and command-oriented model places an extremely high emphasis on institutional and programmatic curriculum planning for change. Curriculum planning virtually becomes a national or state enterprise under the authority of the central educational agency. This model, however, rarely works well at the school or classroom level. New curricular visions and frameworks often do not get implemented,

or are not implemented in the way they were intended due to various reasons. There could be problems in communication between the central agency and schools. Teachers might resist a new vision and a framework in the belief that they know better than those working at the central agencies (Chapman and Mählck, 1997). Furthermore, a reform vision and a curriculum framework can be read and understood by teachers in very different ways according to their varying beliefs, values, commitments, and experiences, thereby leading to different ways of implementing that vision and framework (Cohen and Ball, 1990). The importance of curriculum planning at the classroom level, and particularly the complex relationship between programmatic and classroom curriculum planning, is largely overlooked or ignored in the top-down model. In addition, the means and support for implementing curricular change at the classroom level is always inadequate in top-down approaches to curriculum planning for systems change.

Top-down, centralized planning for curricular change can be seen as an effective instrument for steering curriculum discourse at the institutional and programmatic levels; the discourse, however, often gets lost in school and classroom (Westbury, 2008). When coupled with high-stakes tests and accountability measures, this model could have a detrimental impact on the classroom curriculum. The current implementation of the No Child Left Behind (NCLB) Act in the United States, Apple (2008) argues, leads to an impoverished curriculum that is defined and driven by the measure of student ability and competency which is extremely narrowly defined, and that creates greater inequalities between minority and majority children in educational attainment.

Bottom-Up Model

In contrast to the top-down model, the bottom-up model holds that significant curricular change comes from inside out rather than the outside in or from the top down. Central educational agencies (e.g., ministries of education) can really do little to influence what happens in school and classroom. To bring about change at the classroom level, curriculum planning must be grounded in the deliberative knowing and practical action of school practitioners. By participating in bottom-up approaches to curriculum planning like SBCD and action research, teachers can become the central players in the curriculum reform endeavor (MacDonald, 2003). Furthermore, a school could become a learning organization by creating conditions for school leaders and teachers to continually develop new ideas and improve their quality of thinking and capacity for reflection. They can work with students and parents to form new curricular visions, translate their visions into operational frameworks, and decide how best to bring about change in the classroom curriculum

(Fullan, 1993). The assumption is that successful curricular change could be relatively easy to achieve in a local school or a cluster of local schools, and a significant number of such local changes can, over time, in an innovation diffusion process build from the bottom up into a major change in the overall education system (Farrell, 1997).

This bottom-up, decentralized model, while appearing promising, is fraught with problems and pitfalls. When the entire enterprise of curriculum planning is reduced to nothing but school and local business, the public character of the school curriculum would be seriously undermined, together with the public governance of curriculum planning. Personal and local interests and powers would prevail over those broader concerns for the society and the welfare of mankind. Furthermore, when the full task of curriculum planning is lobbed onto schools, at all three levels, with all its complexity, it creates tremendous demands on classroom teachers. Most teachers are neither prepared for, nor do they have the experience and expertise necessary to undertake, such a task. With respect to the implementation of SBCD, MacDonald (2003) observes that “what occurred in many Australian states and in the USA were less demanding, poorly resourced and loosely assessed curricula” (p. 141). The above innovation diffusion assumption is indeed questionable. When planning for curricular change is entirely left to the school, the possible consequences include: (1) not much change at school or classroom level; (2) changes in a problematic direction; and (3) changes that do not spread out or endure (Fullan, 2003). The basic problem of the bottom-up model lies in the failure of recognizing the need for institutional and programmatic curriculum planning that necessarily go beyond the realm of school localities.

Combination

There has been an increasing interest in strengthening the relationship between curriculum planning at the national or state level and at the school and classroom level. This is based on the realization that top-down guidance and bottom-up initiatives need each other. While central educational agencies are incapable of dictating or mandating change at the school and classroom level (Fullan, 1993), they still have a fundamental role to play in designing reform and translating reform into curricular frameworks, documents, and materials that could support and enable curricular change at the school or classroom level. While classroom teachers need to have sufficient freedom and autonomy in planning and carrying out curricular change, they need guidance and support provided by schools and external agencies as well.

A successful combination model needs to strike a balance between top-down and bottom-up approaches. It needs to acknowledge, on the one hand, the key role of classroom teachers as curricular change agents and, on the

other hand, the need for institutional and programmatic curriculum planning in guiding, supporting, and enabling curricular change at the classroom level. Three conditions are critical with respect to institutional and programmatic curriculum planning by external agencies. First, there needs to be coherence among new curricular visions, curriculum frameworks, assessments, and teacher professional development. Inconsistency would lead to different and divergent interpretations of curricular change. Second, curriculum frameworks and materials need to be developed in a way that supports teachers’ planning for significant change (Cohen and Hill, 2001). Curriculum frameworks and materials can be an effective agent that enables classroom teachers to plan for significant change in a particular classroom context, if they were designed to “place teachers in the center of curriculum construction and make teachers’ learning central to efforts to improved instruction” (Ball and Cohen, 1996: 7). Third, teachers need to have substantial opportunities for professional learning that are grounded in practice and in specific curricular changes (Cohen and Hill, 2001). In other words, substantial professional learning is a key element in curriculum planning for systems change.

Conclusion

Significant curricular change requires systems change that entails impacting change across the institutional, programmatic, and classroom curriculum. Curriculum planning for systems change is a highly complex and challenging endeavor. It entails a coordination of institutional, programmatic, and classroom curriculum planning, the absence of any of which would not result in significant change. It requires a collaboration of a multitude of participants and representatives from the government, educational agencies, universities, business, schools, and communities at large. It needs to provide teachers with sufficient support and resources. Furthermore, it is important to bear in mind that curriculum reform is part of a larger effort to reform the school system. Curriculum planning thus needs to be related to larger issues of school change and improvement, significantly influenced by other policies and factors.

Curriculum, Digital Resources and Delivery

Y Zhao, G Zhang and C Lai, Michigan State University, East Lansing, MI, USA

© 2010 Elsevier Ltd. All rights reserved.

Over the past decade, digital technology has made significant inroads into education, largely due to the rapid spread of the Internet and its associated applications. Not only has digital technology become more accessible to students and teachers, but it also has expanded the scope of what teachers and students can do with digital technology. This article presents an overview of the interactions between digital technology and curriculum, with a focus on how digital technology affects the delivery of curriculum.

Recent Developments in Digital Technology

Expanded Access

Digital technology has become much more accessible in schools. In 2005, almost all public schools in the United States were connected to the Internet, among which 97% had broadband connections. On average, in 2005, every 3.8 students had access to a computer connected to the Internet in public schools, which was an increase from the 12 students per computer in 1998. In addition, 45% of schools nationwide enabled video streaming, 28 US states had digital whiteboards in over 35% of their public schools, 15% of all public school instructional rooms had wireless Internet connections, 19% of public schools provided hand-held computers to students or teachers for instructional purposes, and 10% of public schools lent laptop computers to students.

While the US may be ahead of many nations in equipping its schools with digital technology, it is certainly not the only one. Many developed countries, for example, Singapore, South Korea, and the United Kingdom, have all generously put technology into schools. Other nations, including many developing countries, have also been investing in digital technology. China, for instance, has been implementing a scheme to equip its rural schools with computers and connect them to the Internet. The MIT's One Laptop per Child initiative is developing laptops that would cost 100 dollars and has plans to distribute them to developing countries. It is expected that 40 million units will be shipped to some 14 countries in the next few years.

Expanded Capacity

Along with expanded availability of digital technology came expanded capacity. In the 1950s, the computer was still what its name suggested, a machine that did mathematical

calculations. But today, the computer is a television, a telephone, a telegram machine, a piano, a typewriter, a music box, a library, a community center, and much more. Thanks to digitization, the computer has integrated many media into one – enabling the mixing of contents that were once not mixable. Rapid development in storage technology has significantly lowered the cost of information distribution. High-speed computer networks, low-cost storage, increasingly sophisticated search engines, and digital format together enable the accumulation and sharing of unprecedented amounts of information among institutions and individuals. Today, virtually all organizations and many individuals in the world maintain a website in order to share and broadcast information. Google's attempt to digitize and make available millions of books to worldwide users is just one example of global information gathering and sharing.

Personalized Publishing

Perhaps the most fundamental change in information and communication technology is the capability it affords individuals to publish and broadcast their ideas to a broader audience. Low-cost digital tools and wider access to the Internet have made it possible for anyone with a connection to publicize his or her ideas, images, or any other personal information to a worldwide audience. Publishing and broadcasting are no longer controlled by corporations or organizations. They are now within the reach of the individual. Podcasting, Weblogs, and YouTube.com are just a few examples of personalized publishing and broadcasting.

Characteristics of Digital Technology and Impact on Curriculum

The expanded access provides the infrastructure and incentives to deliver curriculum and other educational resources to schools, while the expanded capacity of digital technology brings new possibilities for reshaping the format and nature of curriculum. Digital technology is different from traditional media in many ways, but three – multimedia, interactivity, and socialization – are among the most relevant to curriculum development and planning.

Multimedia

The defining quality of digital technology is that all information is in digital format. In other words, all forms

of information, be it video, audio, text, photographs, graphics, or mathematical symbols, can be encoded in zeros and ones, making it possible to mix different forms of information. While it is possible to combine these formats with traditional media technology, the effort and associated cost are considerably higher, if not prohibitive for most people, than with digital technology. Hence, one of most fundamental characteristics of curriculum delivered through digital technology is multimedia.

Multimedia presentation of curriculum affects how the content of curriculum is delivered. For example, CD-ROM books include multiple multimedia features, such as animation, illustrations, music with text, and online assistance features. Such CD-ROMs, digital library collections, and other computer-based digital sources are providing students and teachers with access to the world's knowledge in a form that can be readily searched and downloaded.

Multimedia presentation of curriculum not only has great influence on how the curriculum is delivered, but also redefines the content of curriculum itself. For example, the definition of literacy is expanded from traditional print-based text to computer-communication-based reading and writing. Text in the era of multiliteracies is intrinsically multimodal as nonverbal language (such as the visual, the audio, and the gesture) becomes more and more significant in the media. Being able to search for online information and publish writing online are considered the new skills required in this digital age (Leu, 2000; Reinking, 1998). As a result, the adoption of computer-based technology in literacy redefines literacy and transforms the literacy curriculum.

Multimedia curriculum resources are recognized to hold great potential for improving learning. Well-designed multimedia instruction materials have been shown to hold the potential to enable students to learn more deeply than from traditional single-mode communication with written words only (Baddeley, 1998; Mayer, 2001). Curriculum delivered in multimedia format can foster deeper learning in students than traditional print-only curriculum (Cognition and Technology Group at Vanderbilt, 1990).

Interactivity

Digital technology also affords increased interactivity. It is necessary to differentiate interactivity from two closely related concepts: interaction and transaction. While both interaction and interactivity include learner involvement, interaction is more often interpersonal and occurs within a social context and interactivity is often between a human and a computer. Compared with interactivity, transaction does not include any learner-initiated engagements. For example, simply reading the text would be considered learner-content transaction, while learner-content interaction would be something like creating new materials, seeking out additional Web materials and

posting content, or reorganizing the materials into a new presentation.

There are numerous instances of interactivity in digital-delivered curriculum, which is significantly less in traditional print-based curriculum. Hypertext or hypermedia reading, for example, involves learners to interact with the content. Learners are given the choices to access the embedded links in the text for more information or learning support. By clicking or not clicking these links, learners are making choices of how much to read, what to read, and in which sequence to read. Another example is e-textbooks, which enable students to learn at their own pace. Interacting with an animation-based simulation has become an increasingly popular practice for teaching complex scientific or mathematical concepts. Educational games require even more intense interaction between the learner and the content. Online tools, such as databases and search engines, also enable learners to seek information through user-generated interaction.

Learner-content interactivity is considered to be an integral component of digital-delivered curriculum. Students examine, consider, and process the learning material during the educational experience. It is through interacting with content that learners actively reconstruct knowledge and deepen their understanding. A highly interactive learning environment would be one in which learners have frequent opportunities to make a wide variety of significant choices. By doing so, learners feel a higher degree of involvement and engagement and as a result, become highly motivated.

Such learner-content interactivity reflects the trend of student-centered learning enabled by digital-delivered curriculum. Traditional curriculum is prescribed, teacher-centered, pre-packaged, and pre-sequenced. Interactivity of digital technology makes it possible for students to personalize their own learning and redesign their curriculum. The immediate access to online information makes it possible for students to seek knowledge of the areas of their interest instead of being fed with prescribed content. Technologies make curricula no longer a fixed learning plan to be implemented by the teacher and followed by the students. Instead, learners become the designers or co-designers of their own curriculum. In addition, it provides more opportunities for students to initiate their learning and bring their knowledge into learning. Students using digital-delivered curriculum are found to have the same or higher degrees of engagement compared to those in traditional instruction.

Socialization

While multimedia and interactivity affect how the learners approach and process content, technology, especially the vast computer networks and other communication devices, also expands the possibility for students to socialize. Thus, it

adds another dimension to digital-delivered curriculum. Researchers suggested that computer-mediated communication (CMC) would develop a potentially new type of learning community that would provide space for collective thinking and access to peers for socializing and communication. The Internet – with the choice of synchronous or asynchronous communication, communication connection at any time and anywhere, and embedded video and audio streaming – offers a wide range of possibilities for actively engaging students. Many different CMC applications have been successfully used to promote collaborative and cooperative learning.

CMC technology supports online social interaction on two levels. First, it supports instructor–learner(s) and learner–learner interaction. For example, course-management systems (CMS), such as Blackboard and Angel, enable instructors and students to easily communicate with each other. Second, it offers a variety of opportunities for learners to seek resources and interact with people outside the classroom. For example, communicating with native speakers from a distance has become an increasingly common practice in foreign-language teaching.

The socialization capacity of digital communication technologies has significant impact on curriculum because it has significant potential for student collaboration, cooperation, and co-construction of knowledge. Theories highlight the socially distributed nature of learning (Lave and Wenger, 1991; Pea, 1993; Vygotsky, 1978). It is now generally accepted that learners develop understanding through interacting with others. Research has confirmed the positive effects of collaborative learning on student achievement. Digital-delivered curriculum taps the power of distributed cognition by integrating a wide variety of tools to support online collaborative learning.

It is apparent that digital technology, as a new medium for curriculum delivery, has the potential to reshape curriculum in a number of significant ways:

- to enrich forms and sources of curriculum materials by mixing different media and bringing in content from different sources;
- to increase learners' control (thus decrease the developers' and teachers' control) of the curriculum;
- to make available an unprecedented amount of content to use; and
- to demand curriculum to be more fluid and flexible.

Uses of Digital Technology in Curriculum Planning, Implementation, and Delivery

The expanded access to and capacity of digital technology have resulted in an explosive growth in digital curriculum content, but not all digital content has fully taken

advantage of the capacities of the new medium, actually nor need they. Consequently, the nature of digital curriculum content varies on a continuum of complexity and comprehensiveness, ranging from simple electronic books (print books simply digitized without taking advantage of the new medium) to fully interactive comprehensive curriculum such as online courses. Correspondingly, the uses of digital technology in the delivery, implementation, and planning of curriculum vary.

Digital Curriculum Resources for Teachers

Online curriculum standards

Curriculum standards are one of the core components of curriculum planning and development since they define goals and expectations of curriculum. Making curriculum standards accessible to teachers and curriculum developers so that they can better incorporate these standards in their teaching has become popular. Today, virtually all curricular frameworks and content standards in the US and many other countries are available online. A search using Google or other search engines can point teachers and curriculum developers to these documents.

Curriculum planning tools

Digital tools have been developed to assist teachers plan their lessons. Teachers can find numerous lesson templates that help them create a new lesson plan or learning activity. These templates usually generate a step-by-step process and include major components in lesson planning, such as description of the activities, goals, and assessments. These tools can also be adjusted to better meet each individual teacher's need. For example, Florida Department of Education maintains a website for curriculum planning, which claims to provide a step-by-step instruction on lesson plan and learning activity design.

Lesson plans

One of the earliest efforts in the use of digital technology in curriculum planning and delivery is to make collections of exemplary lesson plans online so that teachers can use them as references. This is particularly useful for promoting new ways of teaching. There are numerous websites devoted to publishing lesson plans. For example, Scholastic offers K-12 lesson plans in reading, language arts, social studies, math, and science. From the Scholastic site, teachers can also find helpful information on thematic lessons to help them make lesson plans for more than one class session. Some other sites focus more on specific subjects. Teachers are also invited to share their own teaching experience and publish their lesson plans on the Scholastic site.

Curriculum resources

A variety of resources have been made available to teachers so that they can incorporate it in their delivery of

the curriculum. Such resources include audio and visual material, pictures, interactive material, global subjects, as well as local events. These resources have been provided by many different organizations and are often aligned with certain school curriculum. Some of them were created by education authorities and libraries, for example, the InforOhio website provides curriculum resources for all K-12 subjects. Some others were created by professional organizations or universities, for example, the MathForum at Drexel University has been providing curriculum resources for math teachers since 1992. And then there are those that were created by organizations and institutions outside the sphere of education, for example, the British Museum presents a great site of learning world culture.

Assessment tools

Assessment has been greatly affected by the introduction of digital technology into curriculum. The changes may be as simple as teachers using online spreadsheet to document students' attendances or as complicated as data-driven decision making (DDDM). DDDM's primary goal is to use students' assessment data and relevant background information to inform decisions related to planning and implementing curriculum at the district, school, classroom, and individual student levels. Systematically collected data are analyzed and used to measure student progress, measure program effectiveness, guide curriculum development, allocate resources, and promote accountability. By doing so, assessment becomes an integrated component of curriculum planning and development. Assessment is not the end of instruction, but a significant analytical tool for designing/redesigning curriculum. While DDDM is still a relatively new concept in education, there are some successful stories in adopting such performance systems into schools.

Online discussion forums

Online forums can help create learning communities that provide professional development for teachers to interact with both pre- and in-service teachers. Online discussion forums have been recognized as a potentially powerful tool for creating an online learning community for teachers. Online discussion can be synchronous or asynchronous. Teacher forums in Dave's ESL Café are examples of asynchronous online discussion forums for teachers. This forum is open to English as second language (ESL) and English as foreign language (EFL) teachers around the world. There are a total of 14 258 registered users of this forum and a total of 31 030 posted articles. The forum consists of about 20 relevant themes of ESL/EFL teaching. Upon entering the forum, users can choose the theme(s) that they are interested in and find more sub-topics under each theme. The live-chat room at Teachers.net is an

example of synchronous discussion. Meetings are usually scheduled in advance and teachers interact with others at the assigned meeting time.

Digital Curriculum Resources for Students

There is a continuum of digital curriculum resources for students with increasing complexity and comprehensiveness. The simple form of digital content is electronic books that are converted directly from printed materials. There are also digital contents in the form of supplementary CDs that come with print-based books. Following that, a series of digital materials – drill and practice programs, tutorials, multimedia learning materials, simulations, and educational games, can be integrated to support the curriculum or serve as stand-alone learning materials. Moreover, there are databases and encyclopedias such as Wikipedia, communication, and cooperative environments. Furthermore, there are comprehensive digital contents such as online courses and virtual learning environments that stand alone as digital curriculum.

E-textbooks

E-textbooks are some of the common digital curriculum resources for students. They vary in terms of degrees of interactivity. Some e-textbooks are simply electronic copies of the printed texts, some add advanced organizers and search functions into the text to ease the navigation of the texts, and others add multimedia components. e-textbooks enhance the accessibility and the mobility of as well as the ease of navigation through the textbooks and present multiple views of content, which are projected to make important contributions to a text's effectiveness and enhance motivation. Currently, there are at least 115 000 commercial English-speaking e-book editions offered in the US market. The production of e-texts has been increasing at an annual rate of 20% for the last 20 years. Despite the push for e-textbooks, researchers have noted limited use of e-textbooks in classrooms and suggested that the effectiveness of e-textbooks rests on the design of the e-textbooks and reading-technique training for students.

Educational software

Educational software is another form of curriculum delivered with digital technology. There are several categories of educational software: (1) productivity and presentation software (application software) that enables students to produce and present documents, spreadsheets, databases, and other products, such as Powerpoint, Hypercard, and The Writing Center; (2) drill and practice software that helps students practice on content they have already learned and provides immediate feedback, such as Number Munchers and Learn to Speak Spanish; (3) tutorial software that teaches a specific task, skill, or application, such as Success with Typing on keyboarding instruction

by Scholastic; (4) simulation software that gives students life-like experience to explore concepts in individual subject matters or integrated thematic units such as SimCity and Sky Lab; and, (5) educational games that embed problem-solving activities and enable experiential learning, such as the Carmen Sandiego series, the Oregon Trail series, and the JumpStart series.

Due to the large variation in the forms and types of educational software, research on the effectiveness of educational software is controversial. The most recent and perhaps the most comprehensive study on the effectiveness of educational software in the US found that educational software has no effect on student achievement. There is an abundance of literature lending support to the educational value of simulations and games in various fields such as medicine, language, and business. However, researchers also noted that their effectiveness depends a lot on the designs of the software and the characteristics of the users.

Online learning systems

Online learning systems have two basic forms: Online CMS and three-dimensional (3D) immersive online learning environments. A CMS typically mimics the traditional course organization and structure. It typically consists of user and content management components. Common online learning management systems include open source systems like Moodle and Sakai, and commercial systems like Angel and Blackboard. 3D virtual-learning systems provide interactive environments that attempt to provide a more immersive and social learning experience. For example, the River City Project is an interactive computer simulation that embeds standards-based content and learning activities into a 3D virtual world to teach middle-school students disease transmission and scientific inquiry. Slooodle combines Second Life, a 3D social game environment and Moodle, an open-source CMS, to provide well-managed immersive learning experiences to students. Online learning systems have been used to deliver completely online curriculum and used as a supplementary component to face-to-face instructions.

Although the research on 3D virtual worlds is still at initial stages, researchers have found these online learning systems extremely helpful in facilitating collaborative learning, peer mentoring and learning community building, and supporting situated learning in immersive, psychosocial contexts (Dieterle and Clarke, in press).

Online courses

Online courses have been gaining more and more popularity in all sectors of education. According to an NCES report in 2003, 56% of degree-granting postsecondary institutions offered distance education courses with around

three-million enrollments in the 2000–2001 academic year, and another 12% planned to start online education courses in the next three years. During the 2002–2003 school year, about one-third of public school districts with an estimated 8200 public schools had students enrolled in online courses – an estimate of 328 000 K–12 students enrolled in distance courses. Some online courses are offered in a blended manner with the majority of the learning contents and activities online, supplemented by some face-to-face meetings. Other online courses are offered completely online through either asynchronous or synchronous interaction or a combination of both. There is a great variation of online courses in terms of interactivity both among the students and with the instructors.

A series of meta-analyses on distance learning and online learning have concluded that they are at least as effective as face-to-face instruction (Bernard *et al.*, 2004; Zhao *et al.*, 2005). At the same time, research has also identified a variety of contextual and learner factors that affect the effectiveness of distance courses (Bernard *et al.*, 2004, 2007; Zhao *et al.*, 2005).

Issues and Concerns

Digital technology has been transforming both the content and format of curriculum. This transformation brings along a series of issues and concerns.

Ability to Use Digital Delivered Curriculum

Fast adoption of digital delivered curriculum does not necessarily guarantee real use (Cuban, 2001). Abundant evidence suggests that the best way to integrate technology into curriculum is to establish strong links between digital contents and curricula, that is, to align digital content with specific curriculum requirements. Thus educators need to develop the ability to make use of the available digital resources, which includes both the ability to conceptualize curriculum in a new way and the technical ability to use the necessary hardware and software (Mishra and Koehler, 2006; Zhao, 2003). Ability to use digital delivered curriculum also includes the ability to discern the authenticity and credibility of the digital resources. With the large amount of digital contents available, teachers must have the ability to evaluate their reliability and usefulness.

Power Relationship in Developing and Using Digital Delivered Curriculum

There are several layers of relationship that need to be dealt with in digital delivered curriculum: between technology and human, instructor and designer, and instructor

and student. First, technology and humans have their respective advantages in teaching and learning. Technologies' strengths lie in providing personalized learning, rich media content and representations, learning tools for basics, real-life simulation, and tremendous storage and computing power. However there are also activities and practices for which humans have a decided advantage: high-level communication practices, relevant feedback, social interaction, and instructions about learning strategies. Thus when developing and using digital delivered curriculum, educators need to capitalize on the respective strengths of technologies and human factors. In digital delivered curricula, teachers should play a facilitative and monitoring role, leaving technologies to the mechanical aspects of teaching and learning.

The relationship between designers and the instructors is also crucial. In the K-12 context, designers of the curriculum are often not the instructors. For any curriculum reform to be successful and sustainable, the involvement of the instructors is indispensable. The instructors' authoritative voice lies in their intimate knowledge of the content, their students, their colleagues, their school structures, and the resources available to them.

Technology can potentially change the power equation within the curriculum as well. Technologies that enable students to publish their work make students partners in generating knowledge and contributors to the curriculum. In a way, a digital delivered curriculum allows students to negotiate their individual learning. As such, the instructor or designer has less control over the curriculum. Teachers need to adjust their mindset to face the changed power equation within their terrain, and balance student involvement and teacher autonomy.

Attitudes toward the Effectiveness of Digital-Delivered Curriculum

There are two unproductive attitudes toward digital technology in curriculum planning and delivery. The first is the naive belief that multimedia technology automatically improves student learning. While digital technology indeed holds tremendous capacity for improving learning when used properly, poorly designed digital curriculum can be as ineffective as curriculum delivered using traditional media. Multimedia instruction must be designed in ways that are consistent with how people learn in order to promote learning (Bransford *et al.*, 1999; Bruner, 1993; Mayer, 2001). The second unproductive attitude is the belief that if you build it, they will come. While it is true that digital technology can potentially reach a broad audience, it does not guarantee eventual uses. Many digital curriculum resources have been underutilized and wasted. Thus it requires the developers to seriously consider how to ensure that their materials are adopted.

There is little doubt that both the capacity of and access to digital technology will continue to grow in the foreseeable future. It is likely to replace traditional print technology as the primary medium for curriculum delivery. However, how soon that can happen and to what degree the educational potentials of digital technology can be realized depends on a host of factors: institutional (how schools and educational systems respond to technological changes), pedagogical (how pedagogical theories and practices interact with technological capacities), and technological (how technology changes and how it reacts to school needs).

Textbook Development and Selection

P Shannon, Pennsylvania State University, University Park, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Textbooks are fixtures in schools, nearly as ubiquitous as teachers and tests. Traditionally, textbooks have been considered enduring repositories of knowledge that enable students to move past their daily experiences in order to grasp the possibilities encoded in the textbooks' articulation of history, the sciences, mathematics, language, the arts, and other topics deemed to be important. Educators have assumed that the relative extent to which students could understand those possibilities predicted their life paths throughout their further schooling and into the workplace. Attending to textbooks, then, is fundamental to understanding schooling and its role in society. As Michael Apple notes,

textbooks are simultaneously economic goods (they are often sold to students, parents, and schools), political objects (they are subject to state control and regulation and hence are the result of political and ideological tensions and compromises), and cultural representations (what is included and not included, and how such knowledge is organized, is a form of cultural politics). (Apple, 2003)

Although school textbooks have limited markets, publishers generate over 10-billion US dollars income annually through textbook sales worldwide. Textbooks are commodities – subject to market forces, even within countries with tight regulations or central controls. Following trends in other industries within a global economy, the number of independent school textbook publishers has decreased through mergers and purchases. For example in the United States, four corporations control over 85% of the school textbook market – two of these corporations are international firms and another was recently purchased by a consortium of private equity groups (Sewell, 2005). Consolidation within any market raises concerns for prices, product quality, and distribution (Baker, 2005).

School curricula are selected from all possible knowledge and ways of knowing. Who makes these curricular choices, how they are made, and by what criteria create politics that extends well beyond textbook pages. Groups vie to participate in these decisions in order to influence the knowledge that will be authorized as most important by the governments. As a primary means to translate the curriculum into instruction, textbook content and design must match the curricular choices in order to be considered viable – regardless of whether they are state or privately produced. In this way, textbooks encode the

power relationships among social groups within nations and states.

Despite the economic and political conditions of textbook production, the consequences of textbooks within school classrooms cannot be assumed. Allan Luke (1988) puts it simply, “For texts do not always mean or communicate what they say.” Rather, teachers and students construct meanings from textbooks employing values, beliefs, and ideas from the multiple groups of which they are members. This does not prevent their construction of meanings closely aligned with those that curricular designers and textbook publishers intend, but it is to suggest that those intended meanings are mediated rather than simply translated. Textbooks are a site and a result of economic, political, and cultural struggles and compromises.

A Global Focus

In its *Comprehensive Strategy for Textbooks and Learning Materials* (UNESCO, 2005), the United Nations Educational, Scientific, and Cultural Organization (UNESCO) affirms the central role of textbooks in schooling. Building on its 1995 textbook report, the comprehensive strategy articulates new challenges for textbooks in a world becoming increasingly connected economically, politically, and socially. Acknowledging that digital media and the Internet enable some populations to supplement textbook forms and information, UNESCO seeks policy, quality assurance, and greater access concerning printed textbooks that will promote equity in school outcomes internationally. Although cognizant of the potential of textbooks to help preserve local languages and cultures, the *Comprehensive Strategy* seeks international standards, and it poses and addresses six general questions for all concerned with schooling as a basic human right:

1. What is the purpose of textbooks?
2. How should the content of textbooks be decided?
3. What means of textbook production are possible?
4. How should textbooks be selected?
5. By what means should textbooks be distributed?
6. How should textbooks be used?

The *Comprehensive Strategy* treats the question of the purpose as a given: “The primary purpose of textbooks – to transmit knowledge, values, attitudes, skills and behaviors – is a constant”. Textbooks are expected to convey the accepted truths within academic disciplines,

enabling students to approximate the habits of mind and body of acknowledged experts in those fields. By sequencing the content of textbooks appropriately, schools can enable students to develop expertise in one or more academic disciplines according to their abilities and capacities. All other elements of students' lives being equal, the purpose of the textbook is to equalize access to that information.

The content of textbooks, then, becomes paramount. UNESCO has enough experience with textbook revisions since World War II to recognize the controversial nature of how textbook content is decided and by whom. "The question of which knowledge, which values, and which skills [textbooks] teach is of concern to localities, nations, and to the international community." Although the authors of the report entertain the possibility of conflicts among the local, national, and international levels of participation, they invoke the principle of rights-based education in order to suggest that human understanding and peace should guide all parties during their considerations of content in geography, history, literature, and even biology textbooks.

Textbook production includes issues of participation, design, publishing, and expense. Traditionally, countries with national school systems and the economic means have developed centralized systems to choose content, design, and publish textbooks. Although centralized practices afforded economies of scale and tight control of textbook content, the *Comprehensive Strategy* presents a market perspective for the production of textbooks, in which private publishers supplant the centralized organizations in order to enable more flexibility, innovation, and participation. Private companies, they argue, will build a sustainable context in which periodic review and modifications of textbooks can occur without taxing public funds. Moreover, the authors contend that privatization of textbook production will improve national and local economies, providing jobs and taxes.

A market economy means competition among publishers because publishers' customers must provide consumers with choices to produce sales. In the report, UNESCO considers the selection of textbooks within countries with the capacity to support multiple publishers of textbooks and for countries and regions that cannot support any textbook industry at all. At both ends of this spectrum, the authors of the report contend that decisions concerning textbook selection should be made as close as possible to the students who will use them. Toward this end, they offer policies intended to ensure that teachers and parents are able to participate in the selection among alternatives. Invoking a rights-based philosophy again, the authors reiterate their concern that minority populations are considered and involved in the selection process because their exclusion will diminish minority students learning from the selected texts.

The *Comprehensive Strategy* commits UNESCO to assist national and local school systems in order to ensure that each student has access to at least one textbook. The authors offer two barriers to equitable textbook distribution: cost of textbooks and a lack of appropriate infrastructure. In regions with few libraries or bookstores, the textbook may be the sole text available for students to read. Without mentioning the generosity of more affluent countries and publishers that send used and old textbooks to such regions, the UNESCO report states that the organization favors quality and up-to-date textbooks in the hands of students worldwide.

Making sure that every student has a textbook will have little effect unless the textbooks are part of what UNESCO labels quality education. Here the issue comes full circle, as the authors state that quality of use can only be measured against the purposes of textbooks. The *Comprehensive Strategy* advocates that teachers use textbooks to prompt, challenge, guide, and illustrate in ways that will accommodate the learning styles of all the students in their classes. The authors assume that the privatization of textbook production will bring innovations from publishers as they work to capture more of the market share. Such innovations would include charts, photographs, and illustrations that have proved too expensive for some national publishing operations. Kress (2003) argues that the printed page of textbooks have taken on the visual grammar of the computer screen affording readers more points of entry and nonlinear modes of addressing the text. More innovative textbooks provide teachers with more opportunities to use the texts creatively. UNESCO advocates that schools engage in research in order to determine the effectiveness of the textbooks, the innovations, and the new pedagogies, leading to new innovations and greater learning.

Research on School Textbooks

Despite their obvious importance in educational programs, Jason Nicholls (2005) laments the current state of research on school textbooks. He considers the extant research to be under-theorized and weak methodologically, and critiques three recent attempts to develop guidelines for further research: Falk Pingel's (1999) *UNESCO Guidebook on Textbook Research and Revision*, Robert Stradling's (2001) *Teaching 20th Century European History*, and Jaan Mikk's (2000) *Textbook: Research and Writing*. Nicholls organizes his critique loosely around Habermas' (1972) framework for understanding how human interests lead to different types of knowledge and research. Grounded in different aspects of social existence – work, interaction, and power – these interests produce different types of knowledge and different ways of determining whether knowledge claims are warranted.

Work refers to the way one controls and manipulates one's environment. Work interests about textbooks would include determining how textbooks are produced, selected, and distributed effectively and efficiently; how teachers use textbooks; and how effective the textbooks are in reaching intended goals. Work interests are concerned with getting things done well and seek knowledge about causes and effects of actions and consequences. Such knowledge is established through objective empirical investigations and is governed by technical rules.

Interaction interests consider the social aspects and meaning of human life. Social knowledge is directed by consensual norms, which define reciprocal expectations among and between individuals within specific contexts. Although social norms relate to empirical and analytical propositions, their validity is grounded only in the intersubjectivity of mutual understanding of intentions, and can never be completely determined. Rather than the empirical analytic methods to determine causality for work interests, the knowledge of norms, expectations, and intentions requires interpretive methods investigating negotiations and their meaning among participants in social events. Interactions with interest, knowledge, and research would consider the negotiation surrounding the purpose, content, production, selection, distribution and use of textbooks, and the ways that participants understand their actions and the entire process.

These negotiations, however, do not take place among equals. During each event, groups of participants exert different levels of force to accomplish their objectives. For example, government officials, often, influence textbook content more than classroom teachers; publishing companies typically, effect textbook design more than parents; and educational psychologists, usually, direct studies of textbook use more than school administrators because past social relations have framed institutional practices in ways that afforded them greater power. This power is not only coercive, but also discursive, leaving the participants with few ways to conceptualize alternative ways of acting during these events. Interests in this power would produce knowledge concerning the ways in which textbooks enable and/or limit the continuous development of members of differing groups within a social context. Production and validation of knowledge of power involves studies of the intersections of history, biography, and social structures with a goal of facilitating human agency to address unjust conditions.

Work Knowledge about Textbooks

Researchers and educators who pursue work knowledge about textbooks accept the purpose of textbooks without question. They seek to understand how that purpose can be realized most effectively within specific environments.

Toward that end, they establish empirical investigations of the relationships among the six questions reiterated by UNESCO's Comprehensive Strategy. For example, Erik Knain (2001) analyzed Norwegian middle grade science textbooks and found an overemphasis on science as an individual activity of discovering truth, projecting science as indisputable and directly from nature. Acknowledgment that science is conducted within a community with norms, values, interests, funding, priorities, and institutional organizations was largely omitted from the books. None conveys the ways in which the scientific community within those constraints transforms scientific findings into established facts that are to be trusted as presenting the world as it really is. He concludes that this imbalance poorly prepares students to understand and engage in science.

In a report on textbook adoption, the Thomas B. Fordham Institute presents a case for how reform in the K-12 textbook selection process in the United States would improve textbook content and effectiveness of textbooks on student learning (Finn and Ravitch, 2004). The report describes the process by which 21 states use centralized systems to broker the content and production quality of textbooks in all subjects, and then, make them available to school districts without charge. "This form of textbook adoption distorts the market, entices extremist groups to hijack the curriculum, enriches the textbook cartel, and papers the land with mediocre instructional materials that cannot fulfill their important educational mission." According to the report, the flawed system permits interest groups to insist on preferred content and design that result in "absurd sensitivity guidelines that have dumbed down textbook content in an attempt to render them inoffensive to every possible ethnic, religious, and political constituency." In the end, states with these centralized systems have the lowest achievement test scores in the United States. The report's recommendations echo those of the *Comprehensive Strategies* – encourage small private publishing companies to participate in publishing and make selections as close to the classroom as possible.

In a discussion paper from the Institute for the Study of Labor, Fragfich and Michaelowa (2005) use new statistical techniques in order to determine the effects of textbook distribution on students' learning in Francophone sub-Saharan Africa. Within these regions, textbooks are provided privately either through family purchase or communal ownership. By translating methods of labor research in which more variables can be factored into equations, the researchers make the case that textbook effects have been underestimated because previous studies have only examined the impact on textbook owners within these countries. By recognizing that more students than owners use and benefit from available textbooks, the researchers demonstrate the remarkably efficient power of textbooks to achieve their purpose of transmitting

knowledge, values, attitudes, skills, and behaviors. From these results, they recommend that funds should be allocated to the quality and distribution of textbooks before they are directed toward other innovations (e.g., reduction of class size, raising teachers' salaries, or other forms of instructional tools).

Interaction Knowledge

Researchers and educators interested in interaction knowledge about textbooks seek to describe how participants negotiate and understand the norms, values, and meaning of textbook purpose, content, production, selection, distribution, and use. In order to produce interaction knowledge, researchers and educators observe the interactions among participants and analyze their words and symbols as they work through the different events associated with textbooks and schooling. By making the intentions behind those actions and words more transparent, interaction knowledge promises the possibilities of more inclusive and productive outcomes in future negotiations surrounding textbooks. For example, in *School Science and Mathematics*, William Newman (2004) recounts his role as a parent on an elementary-level mathematics textbook adoption for a US school district. His efforts include analyses of the school district's criteria, the various ways in which teachers, parents, and administrators interpreted those criteria, an inability of the committee chair to elicit discussion among the selection committee members after validating a particular position early in the process, and an ultimate intervention from higher-level administrators and the school board. While Newman appears to describe dysfunction, he argues that each group acted appropriately by representing its intentions for the textbooks selection in explicit and subtle ways.

On a much larger scale, the Ateneo School of Government (2005) in the Philippines presents a report on the development of new procedures for monitoring and facilitating textbook production and distribution based on the coordination of private and public resources. Through surveys and interviews, they assess how the different groups understand their charge with the new system and field concerns for the greater coordination and articulation of efforts. Issues of public service collide with profit motives as the boy and girl scouts wait for, and then unload textbooks from trucks that local Coca Cola bottlers lent to the operation. Some parents objected to the company's participation in the textbook project as they felt it contradicted parents' efforts to improve the nutritional value of school lunches. The report ends with recommendations for how the various constituents might be blended, and blend themselves, into a culture of textbook quality and assessment through more open communication of intentions.

In *Globalization, Society, and Education*, McEneaney and Nieswandt (2006) describe the effects of the fall of the wall on an East German textbook publishing house. Prior

to that, the publishers worked within the highly centralized, tightly controlled, norms of government regulation within a planned economy. After being purchased by a Western publishing company in 1991, the company was plunged into a fiercely competitive textbook market with a broader focus on world cultures. The study examines the ways in which these new norms of publishing and textbook production were negotiated between the existing publishing house and the new owners. Complicating the transformation, the previous consumers of the textbooks remained closely aligned with a more nationalistic focus, despite attempted educational reforms. The study adds remarkable depth to the meaning of the tension between the global and local in textbooks and schools.

Power Knowledge

Power interests consider how the work and interaction of life position social groups and individuals within historical and institutional frameworks that distribute the benefits unequally among groups. The production of power knowledge is meant to inform groups concerning the mechanism through which the frameworks were and are constructed and maintained and to suggest how those poorly served do resist and reform the frameworks and distribution working toward equity. Power knowledge concerning textbooks identifies why and how groups struggle for control of content and flow of school knowledge.

For example, in *Pedagogy, Culture and Society*, Jyh-Jia Chen (2002) presents a power analysis of the textbook deregulation in Taiwan during the 1990s. Following Apple (1993), Chen argues that textbooks are not only commodities vying for a market share; they are also state-regulated products and cultural artifacts that reflect and create values and ideas. The historical forces of the 1970s and 1980s in Taiwan led both popular and government groups to call for a liberalization of the economic, social, and political norms and a repositioning of Taiwanese identity. Attempts to reform society provided opportunities to question the traditional Taiwanese curriculum and its conservative impact on popular cultural values and actions. Over time, the liberalization project, then, afforded the government and dominant social groups control in the creation of the new official knowledge to be encoded in school textbooks. As Chen concludes, "textbook deregulation was a hegemonic project through which the state and oppositional forces contended for control over textbook production, educational decision-making, and legitimate knowledge."

In *Argentine Educational Reform: Tensions between Democratic and Neoliberal Discourses*, Gabriela Mendez (2006) employs critical discourse analysis of the print and illustrations within social science textbooks in order to identify the government's official definition of democratic values and citizenship. Mendez demonstrates how the possibilities of democracy after the fall of the military

dictatorship in 1993 were/are narrowed further at each seceding level from law to policy to textbooks. In the passages and illustrations, she finds repeated appeals to neoliberal values in which the entrepreneurial self is created, seeking happiness, self-esteem, actualization, and fulfillment through individual projects and markets. By selecting certain topics and images and contrasting the limits of the past with the promise of the future, the textbooks normalize the neoliberal subjectivities and make it difficult for teachers and students to imagine other definitions of democracy and ways of being a citizen. Mendez considers the textbook renderings to be betrayals of the democratic promises of 1993 and offers teachers oppositional ways to use the textbooks in order to revitalize those promises.

Shannon (2007) reports on the role of commercial reading textbooks in the search for the one best method of teaching reading throughout the US during the twentieth century. From educational psychologists' first call for a real rationalization of reading instruction through to the scripted reading lessons promoted in the current federal education law, No Child Left Behind, educational publishers have offered textbooks and teachers' guides as the technological solutions to variability among teachers and students in order to reach universal literacy. Claiming scientific authority and backed by the state, the teachers' guidebooks direct the reading instruction in over 95% of the classroom, supplying the goals, planning, content, instruction, and tests for daily teaching; deskilling the classroom teacher; and limiting students' reading development to tested skills. Despite rhetoric concerning a free market of reading textbooks, only four companies control 90% of the reading instruction sales. Recently, the Department of Education Inspector General concluded that educational scientists while acting as federal officials violated conflict-of-interest laws when they forced states and school districts to purchase textbooks in which they had financial interests.

The State of Textbooks

The researchers and educators pursue different interests concerning textbooks, and thereby demonstrate that there are multiple ways of addressing the six questions raised in UNESCO's comprehensive strategy. Even the purpose of textbooks, which the report assumed to be fixed, is negotiated among participants who produce, select, and use them. While those pursuing work interests define the purpose of textbooks as furthering students' understanding in a straightforward manner, those working to produce power knowledge demonstrate how textbooks and textbook content are used to limit students' development in fundamental ways. Issues of content, production, selection, distribution, and use are equally complex and contested worldwide. Market-forces pressure centralized the production in Asia, Africa, and the United States, but did

not necessarily bring innovation; interest groups negotiate for recognition within textbook content in South America and Europe, yet treatments remain unequal; distribution problems, while more acute in some regions, are still apparent in wealthy nations; and use of textbooks varies greatly within and among schools at all levels, across all disciplines, and in all areas, and is not always an improvement on teaching without textbooks. Much of the research on textbooks makes the recommendations of the *Comprehensive Strategy* problematic. Local and particular knowledge and tactics challenge the universal and the strategic concerning all aspects of textbooks.

By definition, textbooks represent the sanctioned knowledge of the world to students. Throughout their history, schools have afforded textbooks sufficient authority to spawn social aphorisms of correctness – doing something by the book or an example is a textbook case. Such important artifacts warrant interest from all who are concerned with schooling and education.

Curriculum and Globalization: Higher Education

K H Mok, The Hong Kong Institute of Education, Hong Kong, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

No matter how we assess the impact of globalization on contemporary societies, no one can deny that globalization and the evolution of the knowledge-based economy have caused dramatic changes in the character and functions of education in most countries around the world. Recent research has demonstrated in a number of ways how the idea of the knowledge economy represents a qualitative shift from the assumptions and policy prescriptions of the 1980s and 1990s (Peters, 2001). A close scrutiny of agenda-setting documents published by the World Bank and the Organization for Economic Co-Operation and Development (OECD), as well as analyzing how nation-states in East Asia and in the West have responded to the challenges generating from the rise of the knowledge economy, has clearly indicated strong needs required by the knowledge economy to transform education systems and fundamental shifts from teaching-oriented to learning-emphasis reforms (Delanty, 2001). Comparative education analysts even believe that radical education reforms would be insufficient to bring about the shift from education in institutions to learning anywhere, any time and just for me (Dale, 2005). This article sets out in the context briefly outlined above to examine what major values underlying the design of new curricula in coping with the globalization challenges and what are the major curriculum changes. The article concludes with a critical reflection on globalization and curriculum changes.

Globalization: The Rise of the Knowledge Economy and University Education

Whether we agree or disagree to what extent the globalization discourse has affected curriculum design and educational governance, we cannot deny the fact that the rise of the knowledge-based economy has significantly affected the way knowledge is defined. Alvin Toffler, writing in 1990, before the knowledge economy was only a concept instead of being quantified and developed as a form of economy, argues, "The most important economic development of our lifetime has been the rise of a new system for creating wealth, based no longer on muscle but on mind" (Toffler, 1990: 9).

With the growing impact of the globalizing economy, Toffler was prescient in noting the now well-recognized changing patterns in employment internationally, moving from blue-collar, low-skilled jobs to white-collar, highly skilled employment. According to the definition adopted by the OECD, a country with a knowledge-based economy is one where "the production, diffusion and use of technology and information are key to economic activity and sustainable growth" (OECD, 1999: 7). In order to enhance the national capacity to compete in the globalizing world, a growing number of countries have begun to invest more in research and development (R&D) to generate new ideas and new knowledge. According to the recent report published by the World Bank, not only the

developed economies in the West but also the developing economies in Southeast Asia have increased their investments in new knowledge, its creation, dissemination, and adaptation to production (see Table 1).

In addition to the impact of the rise of the knowledge-based economy on educational transformations, another major drive for curriculum changes in higher education is the new definition of education as a tradable service. The Uruguay Round of the General Agreement on Tariffs and Trade (GATT) and the General Agreement on Trade in Services (GATS) classified education as a service and sought to ensure the gradual reduction of restrictions on educational services such as technology transfer, consultancy, and distance education. The eventual aim with the newly defined notion of education as a tradable service is to create an international marketplace in education (Kelsey, 1998; Knight, 2006). Abby Riddell has succinctly summarized the impacts of the rise of the knowledge-based economy and the new definition of education as a service to education:

Changing trade patterns influence the productive possibilities of the economy and thereby the demand for education, the uses put to education, and the demands made on education for tailoring the workforce to those demands. (Riddell, 1996: 1363)

In response to the shift from factory-based production to hi-tech and knowledge-intensive industries, the Fordist style of industry which was characterized by “narrowly specialized tasks on the factory floor and the fragmentation of skills and knowledge” is rendered inappropriate (George, 2006: 592). With industries of the future relying more on individuals who are able to adapt to rapidly changing environments, a number of countries have begun to reform their university curricula in order to nurture students with the flexibility to adapt to changing situations and emphasis has been placed upon work-based education. Having critical reflections on the role

of education in the knowledge-based economy, some scholars even argue for a shift from traditional economic models that regard education/training/knowledge formation/technology as exogenous factors in economic growth to newer human capital models developed by economists. Moving beyond the Fordist model of education in preparing students skills for the manufacturing sector, the post-industrial age needs students to be innovative, creative, flexible, and adaptive to their changing situations. In short, the knowledge-based economy has created a new set of expectations and demands for skills in education. Recognizing the changing dynamics of the global marketplace, it is believed that higher education institutions have to reform their curricula in general and teaching/learning strategies in particular in order to enhance students to become more creative, innovative, and adaptive to rapid social and economic changes.

Globalization and Curriculum Design: Some Major Underlying Values

There are many ideas/values underlying the debates on globalization and curriculum reforms. Some core values are related to the proposed shift from a teacher-oriented to a learner-oriented approach in learning, advocating the importance of lifelong learning, work-based learning, and whole-person development. Extending the market model, the World Bank has advocated lifelong learning for the global knowledge economy in recent years. In its 2003 report titled, *Lifelong Learning for the Global Knowledge Economy*, the World Bank states clearly that:

A knowledge-based economy relies primarily on the use of ideas rather than physical abilities and on the application of technology rather than the transformation of raw materials or the exploitation of cheap labour ... The global knowledge economy is transforming the demands of the labour market throughout the world. It is also placing new demands on citizens who need new skills and knowledge to be able to function in their day-to-day lives ... Equipping people to deal with these demands requires a new model of education and training, a model of lifelong learning. (World Bank, 2003: 1)

Believing that the knowledge-based economy is dependent upon a regime that is able to promote entrepreneurship, a skilled and educated population with a capacity to be creative and innovative is essential for the success of further social and economic development (Lloyd and Payne, 2003). What kind of education system that could nurture such a population? The answer given by the World Bank is straightforward: this education system must transform itself by “replacing the information based, teacher directed rote learning provided within a formal education system governed by directives with a new type of learning that

emphasizes creating, applying, analyzing and synthesizing knowledge and engaging in collaborative learning throughout the lifespan" (World Bank, 2003: xviii). **Table 2** compares and contrasts the characteristics between traditional and lifelong learning models.

The lifelong learning model set out by the World Bank moves beyond the traditional model which emphasizes "the weightiness of the past in the hands of teachers who prohibit progress through gate-keep learning and imposing a one-size-fit-all curriculum and pedagogy on the pupils" (Robertson, 2005: 161) to a new model that attaches weight to individualized learning plans. Unlike the traditional model, the lifelong learning model emphasizes the importance of developing individual learners' decision making and problem-solving skills as well as teaching them how to learn on their own and with others (World Bank, 2003: 3). In response to this fundamental shift, the UK government has started promoting a new learning approach which attaches weight to personalized learning, developing new strategies to help students learning to learn (DfES, 2004). In order to nurture students with a broader base of knowledge, some academics urge the development of an integrated and interdisciplinary curriculum for university education.

In addition, the globalization forces have not only resulted in developing a learner-oriented paradigm but also provoked debates and discussions about the importance of multiculturalism and internationalization in university education. In order to prepare students to take up the challenges of globalization, it is important to create a

conducive learning environment that could enhance students to appreciate the growing diversity of cultures and social differences, understanding and accepting divergences in social, economic, political, and religious systems across the globe. Recognizing that the globalizing world has become increasingly socially complex, culturally diverse, and politically contested, an ideal curriculum in global/multicultural world should provide equal learning opportunities to all students from different national, ethnic, cultural, and social backgrounds to promote the values of social inclusion, cultural pluralism, and world citizenship (Haigh, 2002). According to McFadden *et al.* (in Morey, 2000: 26), a curriculum addressing the complicated issues generated by globalization challenges should include: (1) the promotion of equity and of social justice; (2) the improvement of intergroup relations and the promotion of intercultural competencies; (3) the reduction of prejudice, stereotyping, and discrimination; (4) the acquisition and the imparting of knowledge of human diversity and commonality; (5) the acquisition of knowledge for cultural consciousness regarding one's own and other cultures; and (6) the development of skill in the critical understanding of the processes of knowledge construction.

Similarly, Leask (1999) points out the importance of the awareness of otherness, suggesting a new curriculum should be able to enhance students' (1) willingness to think globally and inclusively, (2) awareness of local implications for international communities, (3) self-awareness, (4) awareness of professionalism in both global and local perspectives, and (5) values of cultural diversity ability and other cultures, which is the indicator of graduate quality in a global environment. Moreover, Haigh (2002) points out that the progress of designing a curriculum for responding to understand multiculturalism/internationalism is to meet the needs of an international student body, by which no individual student from any particular social group or tradition would be granted an innate competitive advantage. In a deeper sense, internationalization and cultural inclusion are about universal suffrage (Haigh, 2002: 51).

Apart from helping students become more aware of the differences and diversity in cultural, social, economic, political, and religious aspects in the globalizing world, another globalization drive is to prepare students to be more competitive in the global marketplace. Therefore, universities and schools, in the age of globalization, are under pressure to enable their students to compete in an increasingly global world of work. Along with the multiculturalism, students should also be able to handle and cope with a multicultural working environment and to cooperate with people from different backgrounds. In this regard, education or higher education institutions are therefore expected to provide training for their students with transnational skills or competences such

Table 2 Characteristics of traditional and lifelong learning models

<i>Traditional learning</i>	<i>Lifelong learning</i>
<ul style="list-style-type: none"> • The teacher is the source of knowledge • Learner receives knowledge from the teacher • Learners work by themselves • All learners do the same thing • Tests are given to prevent progress until students have completely mastered a set of skills and to retain further learning • Teachers receive initial training plus <i>ad hoc</i> in service training • Good learners are identified as permitted to continue their education 	<ul style="list-style-type: none"> • Educators are guides to sources of knowledge • People learn by doing • People learn in groups and from one another • Assessment is used to guide learning and identify pathways for further learning • Educators develop individualized learning plans • Educators are lifelong learners; initial training and ongoing professional development are linked • People have access to learning opportunities over a lifetime

as the mastery of an international language (i.e., English), the mastery of information and communications technology, and the abilities of problem solving, creative and critical thinking, which are considered as major components in a new curriculum which would fit the global world (UNESCO, 2000). It is against such a wider context that a number of scholars have pointed out the importance to strengthen the work-based learning, enhancing students to integrate their academic learning with the real workplace. Work-based learning curriculum and work-integrated learning are becoming more popular, with attempts to promote the tri-production of specific and non-disciplinary knowledge (Boud and Symes, 2000). Having briefly discussed some major values underlying the paradigm shift in education toward a more learner-oriented, work-based, and problem-solving approach, let us now examine major curriculum changes.

Globalization and Major Curriculum Changes

Institutional Change in Promoting Curriculum Reforms

In order to promote the international and global outlook of the students, there has been significant structural change in the curriculum by making students better appreciate multiculturalism. Morey's framework for systemic change regarding multiculturalism at college level is considered as a relevant framework to shape the academic environment in the context of globalization. In the last few years, Morey has implemented her framework to assist nearly 100 American universities to make their students more aware of the cultural diversity and prepare them for a socially complex society. Central to Morey's framework, multiculturalism and internationalism are emphasized by:

1. increasing faculty expertise in multicultural and international education;
2. increasing the knowledge base on multiculturalism and internationalism through faculty research and other forms of scholarship;
3. infusing the curriculum with content and instructional strategies appropriate to the improvement of teaching and learning in multicultural/international contexts;
4. forming linkages and consortia with higher education institutions and other appropriate organizations to draw upon their expertise and resources; and
5. increasing the ethnic and international diversity of students (adapted from Morey, 2000: 27, 28).

With a significant weight attached to the multicultural and international elements in college education, Morey believes that the structural change at the college level is necessary because such changes would support changes in

the curriculum. With a strong conviction to connect the school and the outside world, Morey sees the importance of forming linkages and consortia, by which teachers can learn how to respond quickly to changing external environment. Moreover, the structural change can also be taken inside the school/university in order to break down the rigid hierarchies of the organizations, thereby empowering teachers and students to make educational choices and promoting curriculum changes. According to another study conducted by Vidovich (2004), the schools in Singapore have adopted the concept of consortia to create schools within a school in order to motivate teachers to take a more active role in curriculum reform. Similar to Morey, Vidovich (2004) found one of the schools in Australia has restructured its 22 departments into eight learning areas of curriculum framework. On the one hand, this restructuring exercise has flattened hierarchies in each school for empowering the frontline teaching staff. On the other hand, it also helps the school to develop a curriculum-oriented structure, which departs from the traditional curriculum dominated by mathematics and science to a more integrated and interdisciplinary curriculum (Vidovich, 2004).

Contents

In the context of globalization, education is expected to promote not only multiculturalism but also cultural inclusion. In accordance with Kitano's (1997) change model, the content of a cultural inclusive course should provide alternative perspectives through materials, readings, speakers, and the analysis of a diversity of sources. This multicultural component can be further transformed into a nondominant perspective by reconceptualizing the content through a shift in paradigm or standard (Kitano, 1997). To develop such a content of curriculum, educational institutions and educators may need to change their teaching and learning strategies. As for institutional changes, some institutions were founded to serve a particular social group, by which these institutions self-consciously conceive their role in national, religious, and/or gender-specific terms (Haigh, 2002). Embracing with internationalization, these institutions need not only to abandon their partisan link with those smaller geographical, cultural, or social units but also to reinvent their geographical and cultural identity with a broader view. For educators, they need to transform their styles of teaching from one based on the thought that defining student's role as learning to copy their way to a new way of allowing students to meet their own personally tailored learning needs (Haigh, 2002: 53). According to Haigh, the traditional British curriculum has been widely perceived as predominantly Eurocentric and most British universities have actually built upon an assumed knowledge base of English traditions, history, geography, art, music,

popular culture, and literature. To cope with the growing number of overseas students with diverse backgrounds, the British universities are needed to transform their curricula and teaching/learning strategies. For example, university faculty shall no longer assume that students are native British-English speakers with a thorough understanding of local accents and colloquialisms. Indeed, beyond the language used in its delivery, the pursuit of internationalism and multiculturalism in curriculum should also involve rethinking the presumption of course design and the character of course contents.

Nevertheless, alongside the tension between homogeneity and heterogeneity, globalization can mean the cultural imperialism and colonization that results in a transplantation of Western knowledge production system to other cultural sites and consequently causes the suppression or erosion of the local knowledge traditions (Gough, 2002). Language, for example, is a subject reflecting the tension between the demand for internationalization of curriculum and the resistance of universalizing imperialist discourse and practices. In Asia, many countries, such as Taiwan and Japan, treat adopting English as a medium of instruction on campus as a sign of internationalization of education. Indeed, these countries often have well-established local knowledge systems, which use local language for teaching. However, there is another story in Africa, especially in those former colonies, where the use of English is labeled as a sort of re-colonization or an instrument in effecting social stratification (Gough, 2002). Seen in this light, we must be culturally sensitive and politically aware of the potential tensions between the quest for the global trends and the local resistance.

Instructional Strategies and Activities

As discussed earlier, the change of power relation between teacher and student is another impact of globalization on curriculum. The core value of such a transformation is to involve students in constructing knowledge, thereby encouraging peer learning and critical analysis (Kitano, 1997). Some scholars also believe that even for launching transnational higher education programs, students enrolling in these programs should be given the opportunities to express their interests and expectations, while the offering institutions should take their views into serious consideration in order to meet the educational needs of the students. As Sadiki (1998) suggested, an internationally accessed course should also provide “a democratically responsive learning environment founded on conjunctive and consultative processes” (p. 5). Such a learning environment would leave greater scope for pluralism than conventional didactic instruction. The course should also be taught in a language that all students could understand. Instructor should not use dialects and local accent. The language requirement set by, and the language used in, the institution must be equivalents (Haigh, 2002).

Moreover, the inclusive form of instructional strategies and activities should adopt a method-centered and issue-oriented approach (Kitano, 1997). It is argued that beyond multicultural perspective, the inclusive instruction should also involve multidisciplinary approaches, which generalize different knowledge together based on an issue-oriented theme. Language in the globalization era is redefined as a sort of communication skill, which tends to integrate literacy with information and communication technologies. This simultaneously involves cross-cultural communication, of which students are expected to communicate with alien traditions by making use of various instruments of medium. Hence, many universities have heavily invested in developing multimedia courses. Cameron (2002) suggests that the evolution from language to communication skills is a result of the new work order, in which employer focuses on employees’ ability of interacting with others no matter in verbal and nonverbal (e.g., visual and oral) forms. It is against this context that there is an emergence of a new type of computer literacy, which usually consists of a large amount of visual materials but has very little literacy contents. The rise of nontext type of literacy has resulted in the language–literature divide, which requires a curriculum of language courses to handle different a set of concepts around linguistic features and linguistic analysis.

Assessment Methods

The changes discussed above in the curriculum have inevitably affected the assessment strategies. An inclusive course should be assessed upon multiple methods and alternatives to standard examinations and paper. It should also encourage self-assessment and focus on student growth. More practically, the assessment in an inclusive course should focus on its transferability and connectivity. The newly emerged computer literacy is an example of the new standard in globalized learning environment. As mentioned above, non-text-type materials are commonly used in current language education by highlighting language as a communication skill instead of knowledge. Then, the focus of assessment is no longer the strength of students in linguistic content but their ability to establish interpersonal relationship and being aware of others’ psychological and emotional needs (Cameron, 2002). In those courses set for linking language and cultural studies and technologies, good presentation, for instance, is to use less linguistic content to express more information. The decline of linguistic content in the language courses represents a transformation toward issue-oriented approach of curriculum in the age of globalization. In short, the learning objectives, the curriculum, and the teaching and learning strategies must be aligned with the assessment; hence, suggesting changes proposed in

the curricula should have resulted in changes in terms of assessment measures.

Although some scholars have advocated a diversification of assessment in response to multicultural context, centralization or universalization of assessment has been spread through the trend of globalization in parallel. Cambridge University O-level examination in English is widely adopted as a benchmarking system in many former British colonies (Gough, 2002). Another example is the worldwide adoption of the International Baccalaureate in school education. We can argue that there are different curricula and assessment frameworks, which are internationally adopted and are competing with each other. Therefore, this may not be a rigid homogenization of curriculum and assessment. The key issue here is that these internationally mandated curriculum and assessment frameworks, which usually originate from the West, have been replacing the conventional national framework in some countries. This brings us to reconsider the relationship between state and supranational forces and the extent to which globalization represents homogeneity and heterogeneity.

Classroom Dynamics

According to Morey (2000), classroom dynamics refer to “the human interactions that take place in the classroom between instructor and students, and among students” (p. 33). Sadker and Sadker (1992) argue that race, ethnicity, or sex can be factors affecting the interactions and relations between instructors and students in the classroom. In a globalized and inclusive learning environment, instructors are obligated to prevent any biased behaviors, as they may generate a hidden curriculum, which presents enforced rules about knowledge and behavior valued in the classroom (Morey, 2000). It is worth noting that the advance in technology has transformed the forms of instruction. Web-based conferencing has been used for tutorial and learning. This newly emerging form of teaching allows the private and interruption-free conversation between the instructor and students. The synchronous technology even allows the face-to-face and real-time interaction, which provides greater flexibility and enables collaborative learning through distance education and would eventually improve the quality of teaching as the traditional forms of distance learning tend to focus on content delivery but the synchronous interactions can facilitate problem solving and critical thinking. Nevertheless, there are queries raised about the extent to which a web-based conferencing can formulate a multicultural and international learning environment, which is regarded as an essential element for nurturing personnel who are able to work and learn in international and multicultural settings in the age of globalization. Our above discussions have briefly reviewed some major areas for curriculum changes,

the following will reflect on how far the globalization discourse has really offered more alternatives and diversity for or create potential constraints on nation-states in curriculum design.

Globalization and the Curriculum Reforms: Critical Reflections

Despite the fact that one of the principal values underlying the globalization discourse is to enhance students to appreciate the ideas and practices of multiculturalism and internationalism, it has been a dilemma between homogeneity and heterogeneity in the globalization discourse. Under the influences of globalization, it is believed that education should well prepare students to cope with “a world characterized by cultural diversity, inequity, interconnected-ness, co-operation, and conflict” by developing their cross-cultural skills and competencies (McFadden *et al.*, 1997: 10). Nonetheless, such an interpretation of globalization has simply adopted a practical approach which equates multiculturalism with globalization. In the real world, we are confronted with the tensions between homogeneity and heterogeneity, generating difficulties for formulating new curricula. Since universities/schools in general, and, teachers/academics in particular, have different interpretations of multiculturalism and internationalism, the different approaches that they adopt should have shaped the curriculum differently. In addition, the positioning of the institutions (as local or regional/international one) and the mission/vision in teaching (as locally oriented or cross-cultural oriented) should also affect the way curriculum is designed (Haigh, 2002). In this regard, to what extent would schools/colleges/universities adapt themselves to the changing world depends very much on staff’s and institutions’ willingness and readiness. However, one key question, which we are presently confronting is to what extent the curriculum design should be guided/driven by the globalization agendas/tides? From this point of departure, we must be aware of the tensions between developing a curriculum that can protect/promote local cultures and scholarship or going for the global one. More fundamentally, we should be aware of the potential costs of going along with the global trends: limiting choices instead of promoting diversity in curriculum design.

In addition, we should not simply understand that the process of curriculum formulation as an entirely autonomous enterprise beyond the control of the state or exempted from the constraints coming from the economic, social, cultural, and historical sources. Similar to other social services/public goods, education is affected by globalization with the same characteristics of the new state steering power and capacity. As Dale (2000) rightly points out, globalization does not represent a “new and distinct shift

in the relationship between state and supranational forces” (p. 90); conversely, there is the need for nation-states to respond to global force. Therefore, in the process of formation and implementation of curriculum policy, nation-states act as an agency to merge local traditions and influences with global trends through a process of glocalization (Green, 1999), by which local distinctive features are able to exist side by side in order to provide opportunities for heterogeneity of cultural tradition (Henry *et al.*, 1999: 86). Our above discussion regarding the structural change at the college level is seen to promote more diversity; the change of framework at the national level is developing toward a reversed direction. It is recognized that there are recent curricular trends of leading states to a central control over the curriculum and assessment.

According to Priestley (2002), the governments in the United Kingdom, the United States, Australia, and New Zealand have made attempts to introduce national curriculum since the late 1980s. These initiatives of national curriculum are characterized by a unitary competency-based system for all academic and work-based qualifications. From a national perspective, the centralization of curriculum and assessment is a response to economic globalization, by which a nation-state can enhance its competitiveness through the adoption of the technical-rational curriculum. Such a view is sponsored by the notion of developmental state, in which education is seen as an instrument for nation building. Then, a centralized national curriculum can effectively serve the national needs to respond to the challenges brought by the globalization of economic life and the advance in communication, information, and technology. Nevertheless, this form of centralized governance in education has indeed run contrary to the ethos of the globalization discourse that values diversity but the development of which has clearly demonstrated the tensions between the global forces and local drives and the dialectical push-and-pull nature of globalization.

Conclusion

In this article, we have discussed the wider policy context for driving changes in the university curricula across different parts of the globe. We have also examined the underlying values/guiding principles that have shaped the most recent curriculum reforms and also critically examined what major aspects of curriculum have changed. Before concluding the article, we have had deeper reflections on the role of the state in curriculum reforms, also examining whether the global trends of curriculum changes have promoted more diversity or limited choices in curriculum design. More importantly, we must be sensitive about the cultural and social differences embedded in different education systems and proper contextualization is needed during the processes of policy learning.

Curriculum Development as Subject Matter: Social Studies

J Brophy[†]

J Alleman, Michigan State University, East Lansing, MI, USA

The Social Studies Curriculum Strand

In addition to basic skills, schooling typically includes two broad content areas, addressing the physical world (science) and the social world. In some countries, the latter strand is organized as social studies; in others, it consists of separate courses in history, geography, the social sciences, cultural studies, religion, or philosophy. In the United States, the National Council for the Social Studies (NCSS) and most leaders in the field think of social studies (singular) as a coherent K-12 subject organized to prepare young people for citizenship. However, some discipline-based organizations and leaders view social studies (plural) as an umbrella term for courses in history, geography, and the social sciences.

The emergence of social studies in the United States is credited to a committee report issued by the National Education Association (1916), calling for incorporating content from history, geography, and civics within a social education strand to be called social studies. Its content would be selected based on its meaning and relevance to students and its value in preparing them for citizenship. This vision is still emphasized by social studies educators. For example, the NCSS defined social studies as “the integrated study of the social sciences and humanities to promote civic competence,” adding that its primary purpose is “to help young people develop the ability to make informed and reasoned decisions for the public good as citizens of a culturally diverse, democratic society in an interdependent world” (National Council for Social Studies, 1994: 3).

Elementary social studies (grades K-6) developed along the lines envisioned in the 1916 report. The curriculum drew from history, geography, civics, and economics, and later from sociology, anthropology, and psychology. The content was taught as integrated social studies, rather than as courses in the academic disciplines. Gradually, the expanding communities sequence became the dominant structuring framework. Also known as the expanding horizons or the expanding environments sequence, it begins with the self in kindergarten and then expands the purview to the family and school in first grade, the neighborhood in second grade, the community in third grade, the state and region in fourth grade, the nation in fifth grade, and the hemisphere or world in sixth grade.

Secondary courses (grades 7–12) are also taught within a social studies strand that includes responsibility for preparing students for citizenship. However, most secondary

courses are school-subject versions of history, geography, or one of the social sciences, in which content is addressed primarily within the single discipline rather than through integrated treatment of topics. The pattern for these grades is shown in Table 1.

There have been exceptions to this general trend: courses in law-related education, global education, peace and environmental studies, and conflict resolution; mini-courses on a variety of topics; and a 12th-grade problems of democracy course intended as a capstone for citizenship preparation. However, most secondary courses feature titles such as US history, economics, or American government.

Social studies educators hold contrasting definitions of citizen education and assumptions about how to accomplish it. Some differences are linked to curricular tensions observable in all subjects; some reflect issues especially salient to social studies; and some reflect competition for curriculum space among disciplinary and special-interest groups within social studies.

Curricular Tensions That Cut Across Subjects

Curriculum debates in all subjects reflect continuing struggles among supporters of four competing ideas about what should be the primary basis for K-12 education (Kliebard, 2004). The first group believes that schools should equip students with knowledge that is lasting and important. It looks to the academic disciplines as storehouses of knowledge and sources of authority on how to organize and teach it. The second group believes that the natural course of child/adolescent development should be the basis for curriculum planning. It would key content to the interests and learning needs associated with each grade level's ages and stages. The third group works backward from society's needs, designing schooling to prepare children and adolescents to fulfill adult roles in the society. The fourth group seeks to use the schools to combat injustice and promote social change, by focusing curriculum around social policy issues. Many curricular debates in social studies reflect ongoing competition among these four generic approaches to curriculum development.

Competing Approaches to Social Studies

Contrasting perspectives on citizen education lead to disagreements about how to prepare students for responsible

[†] Deceased

Table 1 Social studies courses commonly taught in grades 7–12

Grade	Courses
7	World or state history and geography
8	US history and government
9	Civics, world geography, or state history
10	World history or modern history
11	US history
12	Elective courses in sociology, government, economics, or psychology.

Table 2 Five approaches to social studies

<i>Social studies should be taught as</i>	<i>Citizenship education should consist of</i>
1. Transmission of the cultural heritage	Transmitting traditional knowledge and values as a framework for making decisions
2. Social science	Mastering social science concepts, generalizations, and processes to build a knowledge base for decision making
3. Reflective inquiry	Developing reflective thinking and inquiry dispositions through applications to social and civic problem solving and decision making
4. Informed social criticism	Providing opportunities for examination, critique, and revision of past traditions, existing social practices, and modes of problem solving
5. Personal development	Developing a positive self-concept and a strong sense of personal efficacy

citizenship. Five alternatives are discussed in **Table 2** (Martorella *et al.*, 2005; Vinson, 1998).

Transmission of the cultural heritage, the mainstream approach, emphasizes didactic teaching of content that features support for the *status quo*, focus on Western civilization, and uncritical celebration of and inculcation in American political values and traditions. Periodically, it is challenged by historians and social scientists who want preservation of the integrity of their disciplines in the form of separate courses, or by social reformers who want more inquiry into and discussion of social issues with emphasis on critical thinking, values analysis, and decision making.

Some social studies educators have called for additional emphases. Berman and LeFarge (1993) encouraged lessons in cooperation, conflict resolution, and respect for diversity. Hess (2001) suggested discussions that focus on divisive issues that students face. Wade (2001) suggested that citizenship is developed most powerfully through service learning.

To plan good social studies programs, teachers need to clarify their priorities concerning social education goals and their implications for curriculum. Most curricular models share commitment to citizen education goals, making it possible to construct a richer, yet still coherent, curriculum by incorporating multiple perspectives. A unit on government, for example, might incorporate all five: core democratic values (citizenship transmission), the three branches of government (political science), what it means to be an informed voter (reflective inquiry), rights and responsibilities of citizens in a democracy (social criticism component focused on whether there is justice for all in America), and the idea that government cannot do everything, so citizens should consider volunteering to contribute to society (personal efficacy).

Competition for Curriculum Space among Interest Groups within Social Studies

Organizations representing history, geography, and the (separate) social sciences have begun to issue policy statements concerning how their respective disciplines should be taught in K–12. These statements contain helpful summaries of powerful content and suggestions about learning activities. However, they also imply that each discipline ought to be taught much more extensively, usually without specifying what might be reduced to create the required curriculum space. Some advocates of history have gone to the extent of calling for a return to a social studies curriculum focused primarily on history. They argue that history is “the grand integrator” that allows for comprehensive coverage of each topic – not only its historical aspects but also its geographical, civic, cultural, economic, and social aspects (Bradley Commission on History in Schools, 1988; California State Department of Education, 1997). However, arguments for the other disciplines are just as compelling as those for history; the limited geographical and social science content that would be integrated within a history curriculum is only a small proportion of the content that is worth teaching; embedding it within history courses would not allow for systematic teaching of the other disciplines’ basic principles and processes; such integration efforts usually either advance the agenda of one subject at the expense of the other or result in content and activities that trivialize both subjects (Alleman and Brophy, 1993); knowledge about the past has limited application to the contemporary world (Engle and Ochoa, 1988; Evans, 2004); and replacing the pandisciplinary social studies curriculum with all history courses makes no more sense than replacing the science curriculum with all biology courses.

In addition, the history-centered proposals are associated with a politically conservative philosophy of schooling that emphasizes inculcation in a highly traditional

selection of knowledge and values (Cornbleth and Waugh, 1999; Nash *et al.*, 1997; Symcox, 2002). Most social educators prefer curricula that are more global and multicultural in purview, more critical of traditions, and more focused on current and future issues than on the past. Spillover from the culture wars that developed in the United States in recent decades has heightened the controversies surrounding these curricular issues in social studies.

NCSS Standards

The National Council for the Social Studies (1994) published standards for K-12 schools, after gathering input from social studies educators, scholars in the academic disciplines, and the general public. They provide a framework that includes ten thematic strands; performance expectations regarding essential knowledge, processes, and attitudes; and examples of classroom practice. The ten themes are:

1. culture;
2. time, continuity, and change;
3. people, places, and environments;
4. individual development and identity;
5. individuals, groups, and institutions;
6. power, authority, and governance;
7. production, distribution, and consumption;
8. science, technology, and society;
9. global connections; and
10. civic ideals and practices.

Basal Textbook Series

The curriculum enacted in most classrooms is influenced primarily by the basal textbook series produced by the major publishers. Some teachers use textbooks rarely if at all and others use them mostly as reference sources (Haas and Laughlin, 2001), but most use them extensively (Goodlad, 1984; Shaver *et al.*, 1979; Zhao and Hoge, 2005). The textbook publishers are highly responsive to state adoption guidelines and other market pressures. Consequently, their textbook series mainly reinforce the *status quo* by providing materials for teaching the traditional curriculum (Mehlinger, 1992). There are few alternatives available for educators who wish to experiment with different curricula or even vary the grade levels at which certain subjects are studied (Sewall, 2005).

Critiques of the textbook series commonly conclude that they feature bland, boring content that avoids controversy and seldom alerts students to multiple perspectives; try to cover too much, so the treatment of most topics is sketchy (the mile-wide, inch-deep problem); include a lot of trivia that occupies space that could

have been used to develop big ideas; isolate skills content from knowledge content instead of integrating them; are difficult for students to use as learning resources because of poor content coherence and lack of connections to prior knowledge; and offer suggested questions, activities, and test items that are mostly trite or superficial (Beck and McKeown, 1988; Beck *et al.*, 1989; Brophy, 1992; Brophy and Alleman, 1992/1993; Elliott and Woodward, 1990; Larkins *et al.*, 1987; Tyson-Bernstein, 1988).

Such textbooks lead to instruction that emphasizes memorizing of miscellaneous facts. As a result, students traditionally have rated social studies as their least favorite subject (Shaughnessy and Haladyna, 1985). However, it has become more popular lately (Chiodo and Byford, 2004; Pahl, 1995), especially with minority students, as it has become more multicultural and otherwise relevant. Overreliance on textbooks now is less necessary than ever, given a proliferation of good children's literature and Internet websites on social education themes (Berson, *et al.*, 2004; Shiveley and VanFossen, 2001).

Conclusion

Good curriculum development in social studies requires clarity about purposes and goals and systematic follow-up in constructing the program accordingly. To facilitate teaching for understanding, appreciation, and life application, the curriculum needs to be represented as networks of connected content structured around powerful ideas and taught with emphasis on their connections and applications. This implies reducing breadth of coverage to develop powerful ideas in depth, which is difficult to do using contemporary textbooks, especially given the recent imposition of high-stakes testing programs.

Curriculum Development in the Area of Reading

C L Madda and T E Raphael, University of Illinois, Chicago, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Success in reading is accepted as a major determinant for students' achievement in school across disciplinary areas, and out-of-school in terms of personal, social, and economic success. Conventional descriptions of the reading curriculum content generally focus on basic skills and strategies readers need to make sense of words on a page (e.g., decoding skills, word knowledge, and comprehension strategies). In the United States, the reading curriculum, when defined in this way, is often equated to a commercially prepared program consisting of a teachers' guide that accompanies the students' texts, activity books, and assessments (such as a basal reading program). These programs prescribe what to teach, the order in which to teach it, texts for instruction and practice, contexts for applying what is taught, and assessments to measure students' progress. Often, both curricular content and instructional delivery are linked to national and state standards that establish generic end-of-year outcomes for students in each grade level and for related standardized tests.

It is important to expand conceptions of the reading curriculum beyond those of prepackaged program materials to understanding reading curriculum to be a developmental process that relies on the professional expertise of multiple stakeholders and is designed to address the diversity of students' needs. This article first describes traditional content central to a reading curriculum and typical performance standards. Second, it identifies issues that complicate traditional curriculum content in light of globalization, increased diversity across students and schools, and preparing students for the technological advances that affect living and working in the twenty-first century. Third, it describes principles underlying the process of reading curriculum construction designed to support today's linguistically, economically, and ethnically diverse learners.

Defining the Reading Curriculum: Traditional Content

Scholars have identified well-established reading curricular components with compelling research bases in key areas of comprehension, word knowledge, decoding, and genre study. Strategies and skills within these traditional components provide readers with the foundation to engage in higher-level thinking and meaning making, the long-standing goal of a quality reading curriculum.

To begin with, decades of research in comprehension and comprehension instruction detail both the processes good readers use and the ways in which teachers facilitate students' learning of these processes, through a model of instruction that moves from explicit teaching through guiding, coaching, and students' independent application (Pearson, 1985). Scholars have documented that good readers draw on prior reading and experiences to form hypotheses about upcoming text content, revise their ideas as they read, monitor their understanding, and use strategies as needed for meaning making (Pressley and Afflerbach, 1995).

Strategies taught within the reading curriculum support readers' predicting, identifying important information, summarizing, making inferences, questioning, and monitoring (Snow, 2003). Predicting is the readers' ability to draw from their background knowledge, text features, and structures to form hypotheses about upcoming information. Identifying important information requires locating the central idea in a text section and distinguishing it from supporting details. Summarizing is the ability to synthesize and condense the important information into new text. Making inferences involves reading beyond the words on the page – noticing authors' clues that require adding information not explicitly stated. Questioning requires that readers use their own knowledge in combination with information from the text to guide their reading. Monitoring refers to the reader's ability to evaluate their understanding of the text and apply strategies when comprehension breaks down. Each category is comprised of a variety of potentially useful strategies, depicted in **Table 1** (Raphael *et al.*, 2006).

Skilled readers apply these reading comprehension strategies in combination before, during, and after reading. Students' mastery of strategy use is then evidenced by a capacity to use them flexibly and, therefore, effectively based on different purposes for reading. Frameworks for instruction can promote students' fluid and efficient application of multiple strategies. Such frameworks serve as a vehicle for teaching this part of the reading curriculum, however, not as the curriculum itself.

Word knowledge, with its strong relationship to comprehension, is sometimes called the cornerstone of literacy (Beck and McKeown, 1985: 12) and is the second fundamental component of the reading curriculum. While scholars have attempted to identify a best method for vocabulary instruction, it has proved to be elusive. In many cases, studies that claim the superior effectiveness

Table 1 Comprehension and sample strategies

<i>Comprehension category</i>	<i>Selected sample strategies</i>
Predicting: creating a hypothesis based on background knowledge, text features, and text structure about upcoming information in a text.	<p>Hypothesizing about what the author might discuss next in the text</p> <p>Using relevant sources of information for predicting, such as</p> <ul style="list-style-type: none"> • Background knowledge the reader already possesses • Text features such as titles, headings, and embedded questions • Text structures – how the text is organized <p>Setting a purpose for reading: confirming content or disproving hypotheses (connects to monitoring if prediction is not confirmed – does it indicate comprehension block or is the author successfully surprising the reader?)</p> <p>Engaging in appropriate routines such as taking a picture walk or a book walk or using knowledge of parts of the text – index, title, table of contents, and illustrations – to predict</p>
Identifying important information: Identifying the superordinate, driving idea in a section of text; distinguishing this superordinate idea from the details that elaborate on it.	<ul style="list-style-type: none"> • Recognizing that some ideas are more important than others in a passage • Distinguishing between main ideas and supporting details • Identifying key story elements • Underlining or highlighting the sentence or phrase that captures the important information presented in a paragraph • Understanding the gist or overall topic • Identifying key words or phrases • Making use of text structure to identify key ideas • Distinguishing between author-determined versus reader-determined importance
Summarizing: creating a new, succinct text that encompasses the important information in the section of text being summarized	<ul style="list-style-type: none"> • Making use of story structure to highlight key points in a narrative • Composing a brief, new text based on important ideas already identified • Synthesizing text ideas in a succinct and coherent fashion • Integrating material into a coherent, accurate representation (such as a graphic organizer) • Distinguishing between writer-based and reader-based summaries • Selecting key information and deleting unnecessary or redundant material • Condensing some material • Substituting superordinate concepts (e.g., wild animals for lions, tigers, and bears) • Composing a topic sentence • Composing a thesis statement • Distinguishing between summarizing and retelling
Making Inferences: reading between the lines to add information not explicitly stated by the author but needed to make sense of the text.	<ul style="list-style-type: none"> • Reading more than the words, or between the lines • Accessing prior knowledge triggered by information or words provided by the author • Seeing connections among text ideas, when those connections have not been explicitly stated by the author • Making text-to-self, text-to-text, and text-to-world connections • Visualizing or creating mental images based on the text • Thinking of contexts in which the information learned might be useful • Imagining how a character might feel • Identifying with a character • Interpreting the author's message • Creating a theme or thesis for the text • Distinguishing between literal and figurative meanings
Questioning: using knowledge for answering and asking questions, including creating relevant questions to guide reading for explicit and implicit text information, drawing on both the reader's knowledge base and information presented by the text.	<ul style="list-style-type: none"> • Setting purposes or goals for reading • Clarifying confusions or confusing information • Determining the author's position or intention in writing the piece (this begins to get at critical thinking and evaluation) • Distinguishing among types of questions and knowing when to ask what kind (e.g., eliciting factual and explicit information; inferences that can be made with text information; critical and evaluative text interpretation; author's craft and style; and relationships among texts) • Understanding sources of information for creating questions and, thus, better understanding where appropriate information is found for answering questions
Monitoring: evaluating text understanding and using fix-up strategies appropriately in the face of comprehension difficulties.	<ul style="list-style-type: none"> • Evaluating understanding and appropriateness of the strategies used to learn from text • Establishing goals and consciously evaluating the degree to which the goals are being met • Modifying strategies when necessary to read goals (i.e., having a repertoire of strategies to draw on in appropriate circumstances) • Determining whether or not the text read makes sense based on expectations (can get at this by paraphrasing, checking predictions against current understanding of text information, and clarifying)

Continued

Table 1 Continued

<i>Comprehension category</i>	<i>Selected sample strategies</i>
	<ul style="list-style-type: none"> • Knowing reasons why text might not have made sense (e.g., unfamiliar vocabulary, awkward structure, unclear referent words, and idiomatic expressions) • Key strategies for teaching monitoring include asking questions before, during, and after reading; working collaboratively to answer questions because students must clarify their understandings when explaining to another student

of a particular approach are often contradicted by other studies with conflicting findings. It is likely that situation-dependent contexts exist for vocabulary instruction, varying in best method depending upon students' backgrounds, targeted words, goals for instruction, and both school and curricular contexts.

Supporting the components of higher-level thinking are lower-level processes. The third component of the reading curriculum contributes to students' ability to master language conventions. Several decades of research have established students' understanding of the linguistic base or symbol-sound relationships as necessary for early reading achievement in particular (e.g., National Reading Panel, 2000). These initial steps toward decoding and word recognition are part of the foundation for student's understanding of how language systems work. Phonological awareness (such as phonemic awareness, blending, and segmentation) serves as a building block for beginning readers working within an alphabetic system (Goswami, 2000; National Reading Panel, 2000). However, research findings indicate that the value of phonics instruction in the reading curriculum diminishes when applied in the intermediate and upper grades.

Research has demonstrated a range of effective methods for instruction in teaching this knowledge base of the language code. Ehri (1995) describes four approaches to helping young students learn to read words: sequential decoding, analogy, contextual analysis, and sight-word recognition. Sequential decoding consists of sounding words out letter by letter. Analogy teaches children to look for spelling patterns (known as phonograms or rimes) in words that are often used to characterize word families – or groups of words that look and sound similar. Contextual analysis applies to words not readily solved by methods of sequential decoding or analogy. In cases such as these, one must consider the morphology of the word in addition to its surrounding context. Sight-word recognition requires students' immediate retrieval of words from memory.

While overwhelming evidence from research has established the value of phonics or word-solving strategies in early reading achievement, lower-level emphases must not overshadow the more meaning-based emphases on word study and comprehension. This need to achieve balance often presents the greatest challenge to the reading curriculum. Just as reading must be balanced

with other school subjects in the curriculum, so must the wide body of knowledge be balanced within reading instruction.

The fourth component of the reading curriculum includes knowledge of various text forms or genre knowledge. Historically, the reading curriculum has emphasized learning to read through traditional literary genres such as narrative, contemporary realistic fiction, poetry, and so forth. As a consequence, there has been a dearth of informational text in the reading curriculum overall and, particularly, for young children (Duke, 2000). This stands to disadvantage readers given that the vast majority of mature reading involves informational text.

It is useful, though, to move beyond conventional genres for different underlying reasons. At a pragmatic level, in contexts such as the United States, with the stress on high-stakes testing, students benefit from being knowledgeable about the testing genre – knowing how to read and respond to test formats and various question types. However, beyond the pragmatic, issues of equity and access to a successful future require due consideration to genres of the twenty-first century where reading transcends traditional forms. A twenty-first-century reading curriculum must engage students with multimedia formats that may not only build on traditional curricular content, but also require a distinct set of literacy skills. In the following section, the article (re)considers reading as a part of the literate practices that shape our lives as twenty-first-century citizens, and explores implications for constructing curriculum.

Reading Curriculum in the Twenty-First Century

Life today represents a time of unprecedented diversity, complexity, and dynamic change that requires an ecological approach to literacy education (Luke and Elkins, 2000), and a redefining and broadening of the reading curriculum. Readers are not passive receivers of the printed word. Rather, skilled readers actively construct meaning, using many of the same processes that writers do as they create text. Further, readers today – even those reading conventional texts – must be facile at reading various images in addition to print. Reading today

involves meaning making from print and electronic media, through words as well as visual images. Schools must therefore prepare students to become literate citizens of the twenty-first century, using all the tools, texts, and systems that these citizens will encounter. School reading curricula must account for “the context of our culturally and linguistically diverse and increasingly globalized societies, the multifarious cultures that interrelate, and the plurality of texts that circulate” (New London Group, 1996: 61), that is the social, political, and economic contexts, texts, and readers of this century.

Changing Contexts

The implications of changing social, political, and economic contexts for the teaching and learning of students impact classrooms, pedagogy, and curriculum alike. For example, the workplace has been redefined by globalization and the increasing presence of new technologies. In many of today’s industrialized economies and institutions, individuals are “faced with the challenges of navigating community and academic discourses and of balancing forms of identity, new work practices, and the demands of new technologies and popular cultures” (Luke and Elkins, 2000: 396). In this “global, hypercompetitive, science-and-technology-driven capitalism, products and services are created, perfected, and changed at ever faster rates” (Gee, 2000: 414). What was once a stable, labor-driven economy has morphed into one that is fluid, market driven, knowledge based, and geographically dispersed (Bean and Readence, 2002). This new order of today’s workplace demands a labor force that is proficient in multiple and overlapping forms of literacies.

Changing Texts and Literacies

“In the emerging digital economic era, spurred by the recent proliferation of technology tools and resources in the form of affordable desktop computers, an accessible Internet, and user-friendly multitask and multimedia software, traditional concepts of what it means to be and to become literate are being challenged” (Labbo *et al.*, 1998: 273–274). Lankshear and Knobel (2003) describe new literacies as those “mediated by new information and communications technologies, as well as literacies that employ more conventional tools and forms of text” (p. 18). New literacies include weblogs, console games, instant messaging, and chatting online, to name a few. The presence of new literacies as well as shifting ideologies, economies, and demographics points toward a need to reconceptualize learners, the reading behaviors they engage in now and in the future, and the texts with which they interact.

Successful reading for the twenty-first-century global citizen requires two important added considerations to traditional reading curricula. First, the curriculum should

promote the reader’s ability to effectively navigate and construct meaning across a variety of text modes. For example, digital or multimedia text types often require navigating visual, spatial, audio, and printed forms. Such multimodal texts have implications for the reading strategies and skills our students need to be proficient in, and raise questions about the range of texts (or genres) students need to be able to control to achieve different purposes (Pearson *et al.*, 2007). Second, the curriculum must address the need for critical analyses of all texts, regardless of modality. The proliferation of texts and new text forms that characterizes today’s Information Age calls for the ability to navigate an abundance of resources and to identify those most credible or reliable. Critical literacy skills should also be promoted so that students can come to recognize the cultural and ideological assumptions embedded in texts that aim to position them in the world.

Changing Readers

The experiences of the twenty-first-century student are unique in that they have grown up in a world of unmatched technological growth, exposure to multimedia, and globalization. As a result of our changing global context and the range of text forms that now occupy our literate lives, it is necessary to reconceptualize the readers themselves that fill our classrooms. Diversity among today’s students includes the ethnic and racial background, family economic status, and linguistic resources that students bring to the task of reading. The curriculum must then account for this diversity in experience. A one-size-fits-all approach to curriculum is not only impractical, but would also be unjust. Curricular decisions must draw on the strengths and resources that students bring to the classroom in order to best support their specific needs. In addition, globalization and shifting world demographics bring new and increased access to education and corresponding issues of equity. In light of changing contexts, it is critical that curricula foreshadow the texts and tasks that students will be expected to engage in throughout their adult lives. To prepare students for anything less would be inequitable. Schooling and curriculum, in particular, need to do a better job of meeting the real needs of today’s students. This requires a process of curriculum development that involves multiple stakeholders and is rooted in the real needs of students. Prepackaged programs not only limit opportunities for constructing a curriculum that reflects the complex nature of reading today, but also lack the flexibility necessary to accommodate a range of student needs. In the following section, the article outlines the underlying principles of curriculum construction that stand to best serve students today.

(Re)Constructing the Reading Curriculum Today

Many general principles for curriculum development established over a half century ago (Tyler, 1949) continue to be relevant today and relevant to a myriad of contexts. At their core, high-quality curricula consist of clearly defined and appropriate outcomes, relevant learning experiences organized in a way that maximizes the impact of the instruction, and a system for evaluating the effectiveness of the curriculum and teaching. A curriculum is not simply a program, though programs can make useful contributions. Ultimately, the stakeholders closest to the clients being served – the teachers who serve the students in their school – must construct the curriculum, and do so in a way that insures they will meet high standards of achievement.

Since the mid-1990s, several successful school–university partnerships have attempted to raise school reading achievement levels through a combination of improving the reading curriculum and providing the related professional development (Taylor, Raphael, and Au, in press). Constructing and implementing the curriculum through the work of the school's professional learning community – a culture of collaboration focused on student learning and effecting change for school improvement (DuFour, 2004) – have shown to be key (e.g., Au, 2005). These approaches are consistent with both Tyler's (1949) long-standing and accepted guidelines for curriculum

construction and more recent research detailing factors that support successful school reform. These studies of school improvement and the theoretical base underlying them suggest that curriculum construction leading to increased student achievement privileges both the top-down voices, represented by high national and state standards, and bottom-up voices, the teachers and other school personnel with the closest knowledge of the students they serve. In what follows, the standards-based change (SBC) process (Au, 2005; Au and Raphael, 2007; Au *et al.*, 2008) is presented as illustrative of current models for principled construction of a customized reading curriculum.

Rather than implementing a solution or program designed by outsiders, the SBC process is adapted by insiders to meet the needs of their own school setting. Through professional development, the SBC process guides educators to customize curriculum designed to raise students' achievement. The SBC process is organized within four concepts illustrated in **Figure 1** that are consistent with Tyler's principles: (1) establishing curricular goals at the school level, (2) establishing grade-level end-of-year goals that contribute to the school graduation goals and making these goals visible to students, (3) determining where students are in relation to end-of-year goals, and (4) planning curriculum and instruction that helps students reach the target performance levels.

These components form an ongoing, iterative cycle of work in the professional learning community that leads to

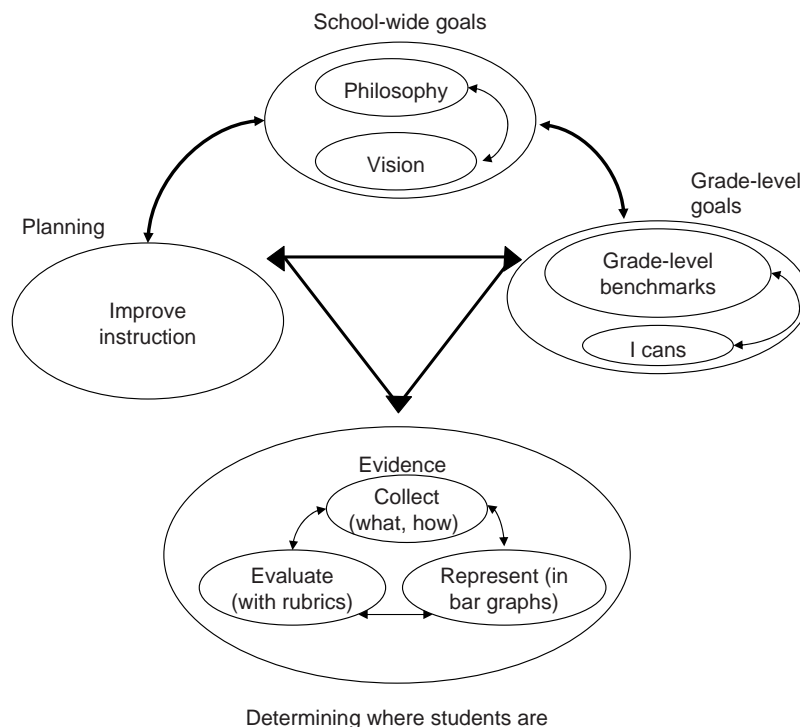

Figure 1 Four concepts of the SBC process. Reproduced from Au, K. H., Raphael, T. E., and Mooney, K. (2008). Improving reading achievement in elementary schools: Guiding change in a time of standards. In Wepner, S. B. and Strickland, D. S. (eds.) *Supervision of reading programs*, 4th ed., pp 71–89. New York: Teachers College Press.

Figure 2 Staircase curriculum versus fragmented curriculum.

the construction of a staircase curriculum, represented in **Figure 2**.

The staircase curriculum (Au, 2005), illustrated on the left side of **Figure 2**, stands in contrast with what is often the case in schools struggling to achieve targeted levels of student performance.

First, while all schools have desired reading outcomes for their students, schools engaged in the SBC process have clearly articulated and defined outcomes that the staircase curriculum helps their students to attain. Second, the curriculum is defined by its coherence (Newmann *et al.*, 2001). In other words, grade-level teams consciously build upon specific instruction of the prior grade level, and work to insure students are prepared adequately for the subsequent one. The staircase curriculum contrasts with a fragmented curriculum, shown in the right side of **Figure 2**, in which teachers' work at different grade levels is not closely coordinated. The quality of the work in each grade level may be individually fine, but there is no schoolwide vision of their graduates' literacy knowledge and skills, thus reducing the possibilities of cumulative learning. The staircase metaphor underscores the importance of constructing curriculum so students receive strong, well-coordinated instruction as they progress through the grades – ultimately leading to rising expectations each year as students enter grade levels at higher levels of progress.

Some educators hope that a staircase curriculum can be achieved by adopting a packaged reading program, such as a basal reading program or a comprehensive reform model. Research suggests, however, that simply adopting a reading program does not lead to schoolwide curriculum coherence (Au, 2005; Newmann *et al.*, 2001) because teachers can choose not to follow the adopted program closely or they can interpret the program in different ways. Constructing a customized reading curriculum using an approach such as

the SBC process, however, involves the schools' professional learning community in four increasingly complex areas of focus: (1) learning the SBC process, (2) institutionalizing schoolwide reports, (3) constructing the school literacy curriculum, and (4) student and family ownership.

Learning the SBC Process

First, the professional learning community members work on learning to implement a series of steps to insure that the four concepts represented in **Figure 1** are in place at their school. To establish a common vision of the reading accomplishments of their graduates, teachers work across grade-level teams to articulate their philosophy of teaching, learning, and literacy, and then construct a vision statement that describes their graduate. A Chicago, Illinois, public school's vision states: the graduating students of South Loop Elementary School (name used with permission) will be lifelong readers who read for both information and enjoyment. They use reading effectively in their everyday lives (Au *et al.*, 2008).

With the school's vision of their reading graduate in place, each grade level determines their contribution to students' achieving the outcome drawing on state and national standards documents, school curriculum scope and sequence documents, and their own professional knowledge and experience. Benchmarks are constructed for each grade level and translated into "I can" statements for accessibility of students and their families, making curriculum goals at each grade level transparent to all stakeholders. The "I can" statements also make the progress on constructing the staircase curriculum easily visible to all professionals in the school and open for analysis and revision as needed. The "I can" statements of grades 1 through 3 constructed by South Loop Elementary School's grade-level teams reflect the increasing expectations as students move through the primary grades:

Grade 1 – I can understand a story I have read and retell it in order using my own words.

Grade 2 – I can understand, make connections to, and summarize stories I read.

Grade 3 – I can tell the difference between fiction and nonfiction books, what is important in a text, make inferences, and summarize what I have read.

With grade-level goals established, teachers then construct an evidence system that can be used at the beginning, middle, and end of the school year to determine where students are, the progress they have made, and success in achieving year-end outcomes, respectively. Performance levels at the beginning and middle of the year are central to the instructional decisions teachers make – the curriculum materials and the instructional approaches (including how to teach, grouping arrangements, and level of instructional materials) that will be used to insure

that students are engaged in appropriate learning experiences. Within the professional learning community, each grade-level team prepares a presentation following the beginning, middle, and end-of-year evidence gathering. The presentation is given at a schoolwide event in which each team describes their goals, how they evaluated students' progress toward their goals (the evidence gathered, the scoring rubric, and illustrative samples of students' work at each level), their analysis of their instructional response to the students' performance levels, and what they plan to do in the near future to address students' needs as indicated by the evidence.

Institutionalizing Schoolwide Reports

Second, once the process of the to-do list is learned, the professional learning community works to institutionalize 3-times-per-year reporting, using the schoolwide event as an opportunity to revisit and revise their staircase curriculum, evaluate the effectiveness of curriculum materials in place and instructional strategies used, and assure that the evidence system is capable of providing the information needed to insure high-quality teaching for high levels of thinking.

Constructing the School Literacy Curriculum

Third, with the institutionalization of the 3-times-a-year schoolwide reporting, the next focus for the professional learning community is to construct their school's reading curriculum more formally. Each grade-level team creates the grade-level curriculum guide to the content of their reading program that lays out the goals, evidence system, instructional materials, and instructional strategies. These guides provide the basis for the curriculum's sustainability over time and in the face of changes in school personnel.

Student and Family Ownership

The fourth focus of the professional learning community builds student ownership and engagement in their own learning processes, as student portfolios are developed to align with the constructed reading curriculum.

As a school engages in this reform process, learning within the professional community deepens and the reading curriculum is kept current as well as continues to be targeted to meet the needs of the students within the school. If maintained, this process can contribute to the upward progression of the school's overall performance levels (Au, 2005). Moreover, while illustrated here with relatively conventional reading goals and content, the process can be applied to any school subject area as well as to teaching twenty-first-century curricula.

Summary

Students' success in life is, in many ways, contingent upon their ability to construct meaning from a variety of texts. Research provides evidence to support the inclusion of several well-established curricular components in key areas of reading such as comprehension, word knowledge, decoding, and genre study. However, in addition, school reading curricula need to be responsive to changes in today's students, texts, and contexts. Twenty-first-century citizenry requires a broadened notion of the types of literate behaviors students will be expected to engage in, and the types of text forms they will be required to navigate with a critical eye. Furthermore, globalization and shifting world demographics contribute to diverse student populations where children often vary in the cultural and linguistic resources that they bring to the task of reading. Prepackaged commercial programs have limited flexibility and adaptability to differentiate the curriculum to meet the needs of the diverse range of students that fill our classrooms. What is more realistic is understanding curriculum construction as a process of development rooted in the professional collaboration of school colleagues and customized to the real literacy needs of real students.

Curriculum in the Arts

Curriculum Development–Subject Matter: Curriculum in the Arts

Arts education in public schools has assumed radically different forms at different historical moments and in different contexts. It has served to cultivate the mind and the spirit, address utilitarian goals in the interests of industrial production, and provide children with emotional outlets and means of self-expression. The cognitive value of the arts has been recognized in the past 50 years, while the role of the arts in cultural experience dominates contemporary thought. Arts curricula are shaped by attitudes toward the arts, children, and education. They are influenced by developments in the informing arts disciplines, including the blurring of boundaries within and between art forms. Contemporary developments remind us of how dramatically arts curricula are shaped by external theoretical influences, political developments, and social conditions. The goals and functions generated in response to shifting sociohistorical circumstances, attitudes, and understandings suggest different rationales and practices for arts curricula. For example, as trends in the art world and conceptions of childhood shift, the values embedded in arts curricula respond in subtle but decisive ways (Wilson, 1997). Preservation of the lush energetic strokes of preschool painting motivated visual art curriculum practice in an era dominated by the philosophies of Lowenfeld (1957), the esthetic of abstract expressionism, and a postwar vision of idyllic childhood fed by Dr. Spock, Dick-and-Jane readers, and the televised utopia of *Leave it to Beaver*. In the sadder, but wiser, era of the 1970s, adolescent marginalia was recognized, valued, and cultivated as an artistic practice similarly in tune with its times.

Given these multiple, layered aspects of the arts, the fundamental nature of arts education in the school is perennially contested. Theories of esthetic education, as well as related theories and changing practices in individual arts disciplines, generate aspirations and justifications that scaffold practice. Excellent teaching in any curricular area is contextual, specific to individuals and situations. School arts invariably reflect an array of contexts, crucial to the design and implementation of curriculum. At the individual school level, these include practitioners' beliefs, goals, and perceptions; financial constraints and allocations; teachers' expertise; and the school's mission as part of the community in which it operates.

Educational institutions also operate within broader cultural contexts, introducing issues that shape education in general and arts education in particular. For example, new communication technologies alter our interactions with the arts in fundamental ways. Today's recording technologies eliminate barriers of time and geographical distance: The traditional listening and viewing spaces – churches, museums, and concert halls – give way to homes, hotel rooms, and cars. These changes make it difficult for school arts programs to compete with the pace and energy of the commercial art world. However, arts education provides complementary opportunities for direct immersion in creative interactions and performances, enhancing a sense of community in the school.

Technology plays an important role in bringing art to large and dispersed audiences, to the point where artwork is increasingly known by its reproductions. In educational settings, technology shapes contents and pedagogies, transforming experiences of creation and art appreciation. In music education, technology functions as a tool for the development of various skills and a novel medium for performance, and creates innovative possibilities for musical composition. In visual art, technology is used for studio/creative work, and provides access to images of many kinds. In dance and drama, videotapes are used to show masterful performances, provide material for pencil-and-paper assessment, and serve as a reliable and cost-effective means of recording student responses. Much of the impact of technology on drama and theater education is based on the increased communicative potential that interacting in a virtual space affords.

Similarly, globalization has meant the westernization of the world, generating increasing homogeneity between cultures and blurring distinctions between national, regional, and local communities. A closer look reveals that globalization produces diversity and heterogeneity through increased hybridization, highlighting historical, social, and cultural contexts. Arts education can play a central role in a globalized society as a frame through which various cultures are understood and appreciated and the students' concept of art is expanded.

Curricular areas are typically distinguished by their subject matter: visual art, music, dance, or drama and, in some countries, also poetry, literature, film, and media. They are also defined in other ways, by genre and types of instruction. Among the genres of arts used in the school

are: (1) child art, (2) child craft, (3) fine art, and (4) art for children (Bresler, 1998). Each genre is associated with different contents, pedagogies, and evaluation practices, as each is based on a separate set of ideologies and goals, related to different underlying assumptions about the nature of arts and arts learning.

Child art refers to original compositions created by children in dance, drama, visual art, and music. Child craft refers to products with prespecified outcomes, expected to be uniform. Fine art refers to classical works in the different genres created by established artists. Art for children refers to art created by adults specifically for children, often for didactic purposes.

Child art emerged with the child study movement more than a century ago. It is child produced and encourages self-expression. Fine art highlights the acquisition of cultural knowledge, typically through cognitive, factual, and critical approaches grounded in disciplines of arts history, arts criticism, and, less frequently, esthetics. Child craft and arts claim no scholarly framework, but serve practical needs in engaging children with materials meant to be developmentally appropriate, accessible, and relevant to children's lives. Though these types exist in all four arts disciplines, the emphasis on each differs depending on the discipline. Child art is prevalent in visual arts and, when taught, in dance and drama, but almost nonexistent in music instruction. Art for children is most prevalent in music in the form of songs or easy instrumental/choral works composed for young people.

An issue pertinent to all disciplines of arts education is the extent to which the curriculum is organized around masterpieces or exemplars of the fine arts, or focuses on children's processes of exploration, discovery, and self-expression. Similarly, the range and variety of images, objects, and performances that might be addressed in arts curricula vary widely, encompassing everyday phenomena such as advertising, music videos, toys, and other forms of commercial and vernacular culture, as well as images recognized as esthetically noteworthy. A related but different distinction arises between the arts as performance oriented, emphasizing the replication or interpretation of plays and established musical repertoire, and the arts as process oriented, focusing on the creation of original works of dance, drama, visual art, and music by children and youth. Schools across the world embrace curricula that display both orientations.

Two major orientations toward curriculum have shaped theory and practice in arts education. The first orientation highlights construction of knowledge through creation and engagement with artistic media, while the second highlights knowledge about the arts gleaned from the study of art history, criticism, and appreciation. These orientations are exemplified in the theories of John Dewey (1859–1952) and Harry Broudy (1905–1998), whose influence was decisive in the past 50 years of scholarship and practice in arts education.

Dewey (1934) recognized the essence of art in lived experiences rather than in the art works themselves. Art is a process, a conceptual and perceptual activity, sharing features of the methods of inquiry more commonly associated with science. Dewey's focus on art as experience supported the forms of exploratory, student-centered learning, and the focus on personal meaning that characterized art education in the United States for much of the twentieth century (Bresler, 2005; Lowenfeld, 1957).

The second, discipline-based orientation emerged in the late 1950s and 1960s, when increased attention to disciplinary learning was triggered by the launch of Sputnik and the American anxiety about being left behind in the technological race. As a result, individual disciplines were required to justify their inclusion in the curriculum in terms of their contribution to the total enterprise of education. Harry Broudy became a key voice in discussions about how the intellectual disciplines could be transformed into a program of general education in a democratic society. His rationale for the arts as part of general education was based on esthetic literacy, cultivated through esthetic experiences, involving the analysis of formal, sensory, and expressive qualities of artworks.

Broudy's ideas, along with those of Manuel Barkan, Laura Chapman, Elliot Eisner, Bennett Reimer, and others, provided a foundation for arts curricula that countered the exclusive focus on making art that prevailed in the first decades of the twentieth century. Esthetic perception entails reading images in much the same way as texts are read. Broudy (1980) emphasized the body of knowledge about the arts, specifically the history of the arts and their philosophical bases, and knowledge of the principles of criticism. He recommended a curriculum revolving around exemplary works, oriented toward students' acquisition of the knowledge of arts disciplines.

These ideas flourished in the next two decades through the Getty Center for Education in the Arts, established in 1982 and operating until the late 1990s as a strong advocate of discipline-based arts education (DBAE) (Dobbs, 2004). The Getty Institute played a major role in arts education, publishing papers by leading scholars of arts education, developing materials, and disseminating these ideas widely across the country. The promotion of academic respectability for the arts, based on a sophisticated body of knowledge and exemplary artworks, sat well with the Getty's commitment to fine arts and museums. The impact of these ideas at the level of policy was manifested in national and state goals and curricular guidelines developed during the 1990s in the US and elsewhere. DBAE represented a widespread reconceptualization of the aims of arts education at the level of theory and policy.

Critics of DBAE expressed concern that discussion and knowledge about art would replace more direct and intimate work in art. Searching for a balance between making and reflecting on the arts, North American

schools never tipped precipitously toward systematic reflection. The tradition of arts production in school arts programs remains strong. Current interest in more inclusive approaches to visual culture, multimodal, and vernacular practices in arts education emerged from the interest in the critical reading of images, objects, and events introduced by DBAE. This broadening of perspective emerged as a critique of DBAE's tendency to focus on the Western canon. This interest in criticality is motivated by social reconstructionist ideals and the desire to empower students to resist oppressive economic and political practices. Current approaches to visual culture in art education emphasize the pluralism of contemporary esthetics, focusing on artistic concept over technical mastery or craft, with art-making projects utilizing appropriation, collage, and digital technologies. The focus on artistic expression is less than it is on social critique. Social reconstructionist ideals are also evident in applied drama, which is significantly influenced by Augusto Boal's *Theatre of the Oppressed*.

Each discipline in arts education has its distinct historical context, and these are elaborated in excellent resources (see, e.g., Efland, 1990). The 1960s were times of intense activity in arts education. The esthetic education movement of the 1970s and the 1980s promoted an inclusive concept of arts education, uniting the individual disciplines of dance, drama, music, and visual art with their respective, well-established traditions. This movement to gather the four arts disciplines under one umbrella gained political power in the 1990s. As a result, dance and drama education found a place in national standards and many state goals. Still, of all school subjects, dance and drama receive the least attention in schooling, a fact reflected in the 1997 National Assessment of Educational Progress (NAEP) testing. In contrast to the widely assessed music and visual arts, the assessment in theater was confined to students who had completed at least 30 h of instruction in theater, and no assessment was conducted in dance. A survey in the Chicago public schools during 2000–01 exemplifies the same trends: The average student received 58 min per week of arts education from in-school arts specialists in the four arts disciplines: music was taught an average of 28 min per week, visual art for 27 min per week, theater for 2 min per week, and dance for 1 min per week. The relative proportion of minutes per week in each of the disciplines in the six regions in the city remained consistent (Costantino, 2003).

Even when the arts are consistently taught, arts instruction may be provided by arts specialists or by general classroom teachers. When taught by arts specialists, contents typically are conceptual, centering on elements of art such as color, shape, orchestration, melody, level, and plot. When taught by classroom teachers, contents typically are thematic, revolving around holidays, seasons, and academic content.

The Arts Education Partnership (AEP) database for 2003–04 indicates that 48 states have content standards in the arts, but only 20 states clearly mandate arts instruction (Chapman, 2005). In 1999–2000, 87% of public elementary schools offered some form of instruction in the visual arts (NCES, 2002). Reports suggest that there is strong support for arts education among administrators (67%), with less support from classroom teachers (47%; Chapman, 2005; NCES, 2002). In schools that offer arts instruction, 55% have at least one full-time teacher certified in the visual arts. About 15% of schools where arts instruction is offered schedule these classes less than once a week; this percentage increases to 36% in low socioeconomic status (SES) schools and to 42% in schools with a high proportion of students in minority groups.

The No Child Left Behind (NCLB) Act, introduced in 2001, carries complex implications for arts education. Arts educators long ago realized that standards-based reforms raise awareness of the arts as worthy domains for study. These hopes form the subtext of the national standards in the arts formulated by the Consortium of National Arts Education Associations in their 1994 document *National Standards for Arts Education*. Although NCLB includes the arts in a list of core academic subjects, the law does little to support education in the arts, foreign languages, or the humanities (Chapman, 2005). These subjects have been called the lost curriculum by the Council of Chief State School Officers (CCSSO, 2002) and cited in a discussion of the atrophied curriculum by the Council on Basic Education (2004).

Clearly, much has been achieved in arts education in the past 30 years, in terms of the range and complexity of arts curriculum, its visions, and contents. A central curricular challenge is how to cultivate qualities – depth, creativity, and originality – that are essential to the arts. These qualities have not been central values in schools. Creativity and originality in the arts always exist within a tradition, requiring mastery of skills and concepts. At the same time, they highlight the individual child's voice and interpretation. The need for mastery to create art raises the issue of depth versus breadth, within and across the arts. Mastery drives home the interconnectedness of skills, cognition, and affect, which support and enhance one other. A tension between the preservation of traditions and the push toward innovation, familiar to artists in all fields, pervades arts education.

A related challenge concerns the issue of accountability. Accountability is not a problem for arts educators (e.g., Donmoyer, 1999; Eisner, 2004): The results of arts instruction are often on public display, and arts programs receive more scrutiny from the public than programs in most other curricular areas, concerts, exhibitions, dance, and theatrical productions (Donmoyer, 1999). However, accountability in the lexicon of schooling entails standardized assessments rather than the informal and local assessments familiar to

arts programs. The impact of what is tested on what is taught is well established. Since it is easier in large-scale testing to assess the technical and factual, rather than the significant, addressing lower cognitive skills rather than those requiring synthesis and evaluation, narrow accountability (of the sort that is feasible economically) can trivialize arts instruction. Moreover, the arts are about breaking new ground and finding innovative solutions, aspects that are difficult to capture in standardized testing. When adopting tests in the arts, it is crucial to reflect on whether we are measuring what is important or what is easily measured.

An additional challenge concerns the role of the arts in schools dedicated to comprehensive education. Hope (1999) refers, tongue in cheek, to the wealth of approaches available – arts education, arts in education, arts as education, arts sprinkled on top of education, arts undermining education, arts transcending education, or arts saving education. One wonders, writes Hope, whether any other subject has the same problematic richness. For the most part, it seems that in other K-12 disciplines, the basics of each subject are more clearly defined. As the arts function so dexterously as processes, traditions of practice, methods of inquiry, and symbolic languages, they can be understood as intentional in nature: that is, a work of art is always about something, whether that something is a political position, a mood, a place, or an event.

The roots of arts integration can be traced to the ideals of progressive education and its child-centered curriculum at the beginning of the twentieth century. John Dewey, prominent in the formation of the ideals of progressive education, regarded experience and, in particular, esthetic experience as the basis around which education should revolve (Dewey, 1934). Integration penetrated from the scholarly world to the more practice-oriented circles of music and arts associations. Its earliest voices can be traced to the progressive era, for example, in the *Music Educators National Conference Yearbook* of 1933 and of 1935, which listed titles such as ‘Projects in the interrelation of music and other high school subjects’ and ‘Fusion of music with academic subjects’.

The notion of integration was revived in the 1960s and 1970s, a period of social upheaval when concern about students’ achievement yielded to concern for students’ experiences. Instead of regarding curriculum as a rigidly defined, given entity, educators focused attention on its meanings to students. This environment of innovation and experimentation with new educational goals, contents, and pedagogies promoted a fusion between the arts and academic subjects.

In the past decade, we seem to be witnessing a renewed interest in integration. Advocates for integrating the arts with academic disciplines reflect a variety of perspectives, interests, and goals. Since integration, similar to all concepts, is a construction, it can mean different things to

different people; yet, this multiplicity of meanings is not always explicit in the ways the term is used. Each constituency – principals, teachers of academic subjects, and arts specialists – has unique perspectives on contents and pedagogies in the arts, and, often, a different model in mind of what integration implies in terms of resources, planning, structures, and outcomes (Bresler, 2005). Eisner’s (1982) rationale for arts integration relates to the power of what he sees as forms of representation. Auditory, visual, and kinesthetic forms of representation develop our ability to interact with and comprehend the world around us and draw multiple meanings from it. By expanding forms of representation beyond the verbal and the numerical, our perception of the world is enriched immensely. This philosophy is embodied in the use of graphic languages and other means of symbolic representation in the early childhood schools of Reggio Emilia, where projects emerging from children’s conversations with teachers employ multiple symbolic languages as forms of exploration.

The cognitive merit of the arts and their ability to connect to other areas of human endeavors have made integration particularly appealing. Indeed, integration has been a hot issue all over the world. How is integration manifested in American curricula? Research studies suggest four ways in which the arts have been integrated into the school (Bresler, 1995). The most prevalent style in American public schools is the subservient style, in which the arts serve the basic academic curriculum in contents, pedagogies, and structures. A second, co-equal style, brings in the arts as equal partners, integrating the general curriculum with arts-specific contents, skills, and expressions. This expands perception and interpretation and typically addresses larger themes and issues. A third, affective style is typically manifested in the implicit or informal curriculum. An example is in exposure to music – as background or stimulus for movement, to soothe, calm, or to encourage free expression. It can also be manifested in exposure to the arts through concerts and museum visits that are not connected to the curriculum. The fourth, social style, rarely a part of the formal curriculum, but present in many American schools, revolves around the social function of the school and its role as a community. It is typified in school performances by children.

The subservience of arts education to other disciplines is common across cultures. In the past, writes Flolu (2000), drawing, weaving, sculpting, and the other art disciplines were taught in Ghana as creative training activities. Now, they are used as a means of enhancing understanding of other subjects. For example, after a lesson on ‘Building a healthy individual’, pupils may be asked to draw pictures of children at work (CRDD, 1998: 1) and use clay or paper to model the school building. In the US, the arts serve academic disciplines when classroom teachers ask music teachers to teach songs and dances to accompany their curriculum (e.g., to teach songs about the planets to

support study in science, or the Virginia reel for American history).

Similar to all curricular areas, arts education faces the persistent challenge of determining “What’s worth knowing, who decides, and in whose interests are decisions being made?” (Stinson, 2007: 144). These are exciting, if potentially perilous, times for arts education: times of rapid expansion of educational programming in museums, community-based settings, and other cultural institutions, balanced against the threat of constriction and dilution in schools dependent upon test scores in reading and math for their survival. These are times in which innovative curricular materials and proposals proliferate, and new media and technologies expand the possibilities for making and responding to works of art and popular culture, in which theoretical ideas from the informing disciplines of the arts and education stimulate innovation, and dialog across disciplines, within and beyond the arts, is possible. The influence of DBAE persists in recognition of the intellectual dimension of art experience and the importance of acknowledging multiple ways of creating, performing, and responding to works of art and to an expanded range of objects, images, and events, beyond the traditional Western canon of the fine arts. New materials, tools, and processes introduce new possibilities for art making, and new formats for viewing and responding to art forms. This is a time of rich multiplicity, in which the curricular orientations of the past coexist as possibilities and inclusive visions of arts education prevail.

Curriculum: Foreign Language Learning

Angel M Y Lin, City University of Hong Kong, Hong Kong SAR, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

This article presents an overview of various issues related to curriculum in foreign language learning, and in particular focuses on learning English as a foreign language (EFL). Foreign language learning is taken to mean the learning of a language other than the learner's first language (L1), and this language is not ordinarily used in the learner's everyday life. Thus, foreign language learning contexts are very different from second language learning contexts, for in second language learning contexts, the language being learned is often used in the learner's larger social context (even though it might not be always used in the learner's immediate home or community). This distinction should not be seen as categorical, as some contexts lie in between the prototypical foreign language learning contexts and the prototypical second language learning contexts. However, as is discussed in this review, the importance of understanding the sociocultural, sociopolitical, and socio-economic situatedness of second and foreign language learning in diverse contexts of the world has, until recently, been underrepresented in the literature.

The Production and Circulation of Received Knowledge about Foreign Language Curricula

In the English language world, the key sites of production of knowledge about foreign language education lie in the English-speaking worlds (e.g., US, Britain) and Europe, where many applied linguists and educators work on developing (English as a) foreign language curricula and teacher education programs, and publish their findings and views in the English language academic world. Their publications have constituted the classic literature on foreign language curriculum (e.g., Wilkins, 1976). In the field of EFL education in particular, there is a lot of spilling over of knowledge from English as a second language (ESL) education, with knowledge derived from ESL research in English-speaking contexts often taken as largely pertinent to EFL education in diverse contexts of the world. Foreign language (and EFL) education knowledge paradigm shifts thus largely mirror second language (and ESL) education knowledge paradigm shifts. These paradigm shifts are discussed in the next section.

Paradigm Shifts in Second and Foreign Language Education

The major disciplines informing second and foreign language education have traditionally been linguistics and psychological theories of language acquisition. It follows that knowledge paradigm shifts in these disciplines also lead to corresponding shifts in knowledge and views on second and foreign language curricula and pedagogy. In designing any language curriculum (or curriculum in general), two central questions naturally arise: What should be included in the curriculum and how should the curriculum content be taught (e.g., in what sequence and with what kinds of teaching methods)?

Structural linguistics has long been the chief framework underlying the development of language curricula. Richards (2001) reviewed the historical background of vocabulary and grammar gradation/selection in developing language curriculums from the 1920s to the 1970s. The assumptions underlying early structuralist approaches to language syllabus design can be summarized as follows:

- the basic units of a language curriculum are vocabulary and grammar;
- learners everywhere have the same needs;
- learners' needs are identified exclusively in terms of language needs;
- the process of learning a language is largely determined by the textbook;
- the classroom and the textbook provide the primary input to the language learning process; and,
- the goal of the syllabus designer is to simplify and rationalize this input through selection and gradation (Richards, 2001: 15–16).

It can be seen that the basic assumptions of structural linguistics permeate the early approaches to language syllabus design. Mastering human language communication is seen as equivalent to mastering the structural units of the language system. The systematic, logical, sequencing and presentation of linguistic structural units become the central task for language syllabus designers. These assumptions had influenced the design of language syllabus and pedagogy until the 1970s, when functional linguistics became the strongest rival of traditional, structural linguistics.

From Structural/Grammatical to Notional/Functional Syllabuses

With the rise of functional linguistics in the 1970s and 1980s, there has been a movement toward the notional, semantic, and functional syllabi (Johnson, 1982; Wilkins, 1976). Instead of treating the structural linguistic elements as the units, the units are now functions and notions. Topics, settings, functions, and notions become the units to be rationally sequenced and organized in a language syllabus. So, whereas the traditional structural syllabus is basically an inventory of linguistic items, graded and sequenced in terms of their structural complexity, the new syllabus consists of an inventory of communicative functions (e.g., requesting services, seeking information, changing topics, expressing disagreement), notions (i.e., concepts such as distance, duration, quantity, quality, location, size), organized around different settings/situations or topics. However, unlike the task of the structural syllabus designer, the functional/notional syllabus designer has a much more difficult task. Whereas traditional structural linguistics provides a straightforward approach to describing, grading, sequencing, and organizing the different linguistic elements according to structural complexity (e.g., from simple to complex structures), the functions are much more diverse and messy to organize into a finite inventory. Thus, needs analysis was proposed as the main procedure informing the design of a functional/notional syllabus for a specific group of learners, addressing their communicative needs (e.g., ESL university students studying English to learn specific academic subjects). Needs analysis was thus introduced into language teaching mainly through the English for specific purposes (ESP) movement. Functional linguistics, especially register analysis, was also drawn upon to identify the linguistic features of disciplines such as medicine, engineering, or science. It can be seen that the ESP movement and the functional/notional syllabus movement have developed together and the student body served is usually adult learners of a second or foreign language, often for immediate, identifiable, specific purposes. The procedure of needs analysis, however, may not be easily applicable to general school foreign language learning contexts, where immediate needs for learning the foreign language might not be easily identifiable.

From Traditional Approaches to Communicative Language Teaching

While the what-question (i.e., what to include in a language curriculum) has been answered by notional/functional syllabus designers with the dual procedures of

needs analysis and register analysis, the how-question (i.e., how to teach the syllabus content) is answered by scholars working on the development of the communicative language teaching (CLT) approach. Richards (2001: 3) summarized the different teaching methods which characterized different periods in the past century:

1. grammar translation method (1800–1900);
2. direct method (1890–1930);
3. structural method (1930–60);
4. reading method (1920–50);
5. audio-lingual method (1950–70);
6. situational method (1950–70); and
7. communicative approach (1970–present).

Approaches before the 1970s are largely structure-drill-based. Behaviorist theories of language learning had emphasized the formation of accurate language behavior through habit formation based on practice and drills of structures. The rise of Krashen's (1981) SLA model and interactionist models leading to input studies of language acquisition have led to the pedagogical principles of providing comprehensive input in the classroom for students to develop their own L2 interlanguage, encouraging students' active negotiation of meaning, lowering learner anxiety by encouraging learners to speak up and take risks, and developing students' own monitoring ability to self-correct. These theories of language acquisition have converged with the rise of functional linguistics to focus on the learners' use of the foreign language for authentic, meaningful interaction and self-expression. CLT educators have since developed repertoires of techniques to promote communicative use of the target language in the classroom, for example, information-gap activities to promote authentic exchange of meaning. Task-based and project-based approaches (Nunan, 1989) to language learning have been proposed with the principle of promoting students' authentic use of the target language for meaningful communication. All these represent a departure from past approaches based on repetition and drills. However, some CLT educators also recognized the need for pre-communication activities or a pre-production phase, where practice/drill-based methods are used to help the learner acquire the necessary linguistic structures to be used later in the communicative production phase of the language lesson.

Tension between Local Approaches and CLT in Diverse Contexts of the World

By the late 1980s, CLT was widely accepted as the latest innovative teaching methodology in the second and foreign language education literature in the Anglo-speaking

world although there were still some unsolved questions, such as those summarized by Richards and Rodgers (1986: 83) in their review of CLT:

1. Can CLT be applied at all levels of a language program?
2. Is it equally suited to ESL and EFL situations?
3. Does it require existing grammar-based syllabuses to be abandoned or merely revised?
4. How can it be adopted in situations where students must continue to take grammar-based tests?

CLT has since been implemented and received with mixed responses by teachers and students in diverse contexts of foreign language learning, especially in contexts where English is taught as a foreign language. This has led to some language educators reflecting on the importance of considering the social context in determining what counts as appropriate methodology and the need to value indigenous knowledge, perspectives, and pedagogies. The 2000s further witnessed a new body of research literature, chiefly authored by language education scholars researching on the sociocultural and sociopolitical incompatibility between local approaches and CLT in diverse sociocultural and sociopolitical contexts of the world (e.g., India, China, and South Korea). These new scholarly voices (e.g., Ramanathan, Ouyang, Shin) show the inadequacies of the classic literature on second/foreign language education, especially those canons established in the English-speaking academic world. Below is summarized the major contribution of these new scholars in pointing to the need to pay attention to the sociocultural, socioeconomic, and sociopolitical situatedness of language learning and language curriculum (Ouyang, 2000), and the need for indigenous, nonuniversalist perspectives (Ramanathan, 2006; Shin, 2006) regarding how to develop appropriate foreign language curriculum and pedagogy in diverse contexts of the world. The major problematic aspects have been summarized by several scholars around a few recurring points:

1. CLT and ELT methodologies have been treated as a neutral, objective discipline or technology that can be exported from one country to another. However, this implementation of a West-based methodology has ignored many local constraints, communal needs, and values (Ouyang, 2000; Ramanathan, 2006; Shin, 2006).
2. In CLT, the role of the teacher is constructed in such a way as to mainly facilitate the acquisition of competence in performing communicative functions in the target language. However, the teacher in many cultures and societies is also expected to play other important roles; e.g., as an authoritative, moral leader to students (Ouyang, 2000).
3. CLT has been constructed in the West-based literature mainly as a value-free technology to teach a second or foreign language effectively. However, CLT actually

carries implicit values and ideologies such as utilitarianism, egalitarianism, and individualism. The kind of social relations encouraged in the CLT classroom might not be seen as acceptable in certain traditional societies and cultural milieus (Ouyang, 2000).

4. Certain local pedagogical practices disfavored by CLT might have their own rationality and usefulness in the local contexts of the students (e.g., use of L1, use of choral responses and translation techniques, drawing on students' familiar L1 lifeworld experiences to stimulate student interest and response, systematic and authoritative transmission of grammatical knowledge, etc.) (Ouyang, 2000; Ramanathan, 2006).
5. CLT and West-based TESOL implicitly assumes that the language teacher and learner naturally want to become like the native speaker. However, this might not be the case; for example, many Korean English language teachers and students might want to keep their Koreaness while they are teaching, learning, and speaking English. For instance, the teachers might want to keep their local identities as Korean teachers, or Chinese teachers, even when they are teaching English and do not want to adopt the teaching styles of foreign teachers (Ouyang, 2000; Shin, 2006).

To the above list is added Ramanathan's (2006) point about the need to pay attention to the socioeconomic and sociopolitical embeddedness of ELT in a society, especially the position of English when compared to other languages in society and how differential access to English and different pedagogies of English contribute to social stratification and inequalities (see also Lin, 1999). It is to a consideration of this point that we shall turn to in the next section.

Crisscrossing of Statist and Capitalist Desires in English Language Teaching

The list of critiques of CLT and West-based methodology in the above section can be summarized in the key observation that there is a fundamental problem with the traditional literature's key assumption and mission. This key assumption and mission can be summarized as follows: the language curriculum researcher's task is mainly that of the search for the most effective language curriculum and pedagogy as neutral technologies and procedures that are universally applicable and effective, without due attention to the sociocultural, sociopolitical, and socioeconomic embeddedness of language learning and language teaching in different societies.

Much of the critique of CLT and West-based ELT curriculum theories and pedagogies can thus be understood by situating the institution of EFL teaching in its

larger sociopolitical and global capitalist context, and by understanding the hidden but nonetheless inherent nature of (language) teaching and schooling as a socio-political and sociocultural process of (re)production of subjectivities and identities. With the processes of globalization and global capitalism growing fast at the turn of the century, the question of the global hegemony of English cannot be evaded and its impact on language-in-education policy and practice in diverse contexts of the world must be examined. Several major sources of tensions and dilemmas have arisen as scholars have examined the experience of teachers, students, parents, and language curriculum planners and policymakers in diverse contexts of the world.

Conflicts and Social Division

Under forces of globalization, many Asian states have begun to adopt a strong ELT policy in their schooling curriculum with the aim to produce a workforce communicative in English to feed the desire of global capitalism for English-conversant human resources. Shin (2006) described the South Korean government's lopsided emphasis on promoting the status of English in schools and parents' strong desire for English as related to the neocolonial role of the US in Korean history and not just to the status of English as a global language. And good English is often defined as the variety of English spoken by Anglophones from Western countries while Korean teachers of English are denigrated for their Korean accent (Shin, 2006). In Iran, middle-class parents who can afford it are sending their children to private English tutorial centers to learn to be communicative in English, in reaction to the drills-based, structure-oriented English curriculum taught in public schools. In China, a CLT-trained teacher moved to a private language school to teach English and make more money after being frustrated by the traditional curriculum culture and practice of her old school which resisted her CLT-oriented efforts in curriculum and pedagogical reform, although the Chinese government has spent the past decade reforming its national English assessment format to make it more communicative to produce a workforce more amenable to the English demands of the new market economy (Ouyang, 2000). In India, Ramanathan (2006) wrote about the social division created by two different sets of institutional curriculum goals and practices for the haves and the have-nots in the economy of English. In Hong Kong, the government's initiative to reform the O-level public exam in oral English into a school-based speaking test, with the aim to introduce more communicative, formative assessment formats to induce progressive pedagogies in the English curriculum, has created more workload to school

teachers and worries about how to ensure fairness of such a high-stake public exam.

The above examples of tension and conflicts revolving around English are illustrative of what is happening in many diverse contexts of the world. The sources of conflict and social division can be summarized as follows:

1. Under the global capitalist desire for an English-conversant workforce, the modern states, often under internal pressure of the business sector and the state's own desire to globalize, have, in the twenty-first century, begun to initiate reforms in their traditional structure-based English curriculum toward a more communicative curriculum.
2. However, conflicts arise due to other institutional and social demands: for example, the traditional societal and cultural emphasis on national, standardized tests for screening and credentialing purposes in many Asian states (e.g., communicative functions are difficult to assess in a national, standardized exam); and the traditional cultural milieu of de-emphasizing egalitarianism and individualist self-expressiveness in classroom interactions/teacher-student relationships, which have served good social control functions in maintaining the social order of many traditional societies.
3. The desire for English as a global commodity, the marketization of languages (Block and Cameron, 2002), and the global spread of the ELT/TESOL industry, combined, in some contexts, with the legacy of political colonialism of Western countries (Shin, 2006), have elevated the status of the foreign expert (Ouyang, 2000), that is, the native-English-speaker teacher, way above the local teachers of English, whose contribution in developing an indigenous, culturally compatible curriculum (Lin, 1999) is often under-estimated or unrecognized in the West-based CLT curriculum literature.
4. Progressive pedagogies such as the CLT curriculum and methodology often require ample linguistic and cultural capital in the schools to make them work (Lin, 1999). CLT English curriculum reforms have often created difficulties for the poorer sectors of the school communities; for instance: large class-size (e.g., 40 students); heavy teaching load; limited-English-proficiency students with little familial and community support to learn English; teachers lacking the training to teach and assess communicative functions, etc.

Thus, ELT curriculum development cannot be assumed to be a neutral technology but is embedded in, and constitutive of, sources of social division, stratification, and inequalities. ELT practitioners need to be aware of how their profession falls along socially stratifying lines and explore what they can do as teachers to sidestep these policies both inside and outside classrooms. The traditional ELT curriculum and research literature is,

thus, in dire need of a critical turn, after its functional/communicative paradigm shift in the 1970s and 1980s resulting in the CLT curriculum. In foreign language teacher education, especially EFL teacher preparation, a standard course in CLT curriculum might often leave EFL teachers ill-prepared for student resistance and classroom realities, because of a lack of attention paid to students' desires and identities.

Whose Desire Counts? Students' Resistance in EFL Classrooms

Unlike ESP curriculums tailor made for adult learners who have specific immediate needs for learning English, the general school English curriculum, especially in EFL contexts where English is not used in the students' everyday life, is often designed with the state's and the employers' desire to produce an English-conversant workforce in the future. Students themselves often have no immediate communicative needs to learn English except the extrinsic need to pass English examinations. In recent years, however, many postcolonial states (e.g., Malaysia) have re-installed their former colonizer's language (which is usually English) as the medium of instruction in schools and universities under the desire to produce an English-conversant workforce to participate in the global economy. Using immersion as an ambitious form of foreign language instruction has its origins in the often-cited French immersion programs started in Canada in the 1960s and 1970s. The rationale lies in creating in students an authentic communicative need for the second or foreign language by using it as the medium for teaching and learning other content subjects. However, this ambitious form of foreign language instruction has created difficulties in contexts where both students and teachers struggle to use an unfamiliar language to learn content subjects. In Kenya, the policy of installing English as the medium of instruction from Primary Four onward typifies enormous challenges to the majority of children and teachers, particularly those living in rural

and poor urban communities, where there is little access to English outside school.

The marketization of language teaching and the commodification of English have promoted approaches that lose sight of the desires of young learners themselves, who cannot be assumed to be ready and willing consumers of CLT curriculums infused with statist and global capitalist desires. What does learning English mean to young school learners, especially in contexts where English occupies a superior socioeconomic position in relation to the first language of students under increasing globalization forces? The converging desires of the state, the employers, and the larger society (including parents and principals) for students to acquire English for socioeconomic reasons has often led to the students' own resistance in the English classroom: students engage in creative verbal play by drawing on their indigenous language and youth pop cultural resources to subvert the English lesson agenda, to mock the English teacher, the English curriculum, or the language learning task being imposed on them, in a way to assert their own indigenous identities and youthful desires to engage in fun, transgressive verbal play of their own choice.

The Critical Desire in Foreign Language Curriculum

Desire is the motivating force behind a person's investment in the arduous task of language learning. The school foreign language curriculum is usually infused with the desire of the state, the employers, the parents, and increasingly the global capitalists. The 2000s have, however, witnessed the beginning of the critical and sociocultural turn in foreign language curriculum research. **Figure 1** from Osborn (2000) succinctly outlines what can be conceptualized as a desire and linguistic matrix that a critical foreign language curriculum researcher can present to teachers, students, and policymakers to help them critically reflect on and decide upon their own stance toward foreign language learning in their respective contexts.

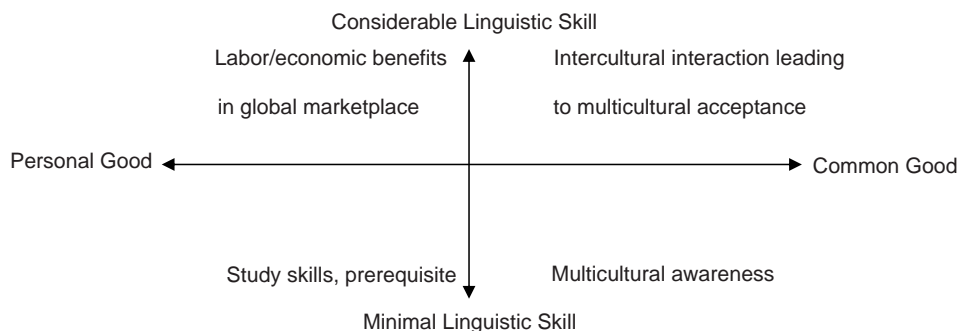

Figure 1 Proposed curricular advantages in terms of linguistic skill requirement. From Osborn, T. A. (2000). *Critical Reflection and the Foreign Language Classroom*. Westport, CN: Bergin and Garvey. With kind permission from osborn.

While CLT curriculum researchers and developers can still apply their needs analysis procedure and negotiate with their target student groups to chart out what might possibly count as their short-, mid- and long-term valuable learning goals (e.g., specific structures, functions, communicative, academic language, or examination needs) as perceived by the students, critical curriculum researchers can simultaneously work out and negotiate with their students the humanistic goals of intercultural understanding, multiculturalism, and social justice through learning foreign and world languages, including English as a lingua franca. However, for English to serve the critical desire as a language for common good (e.g., intercultural understanding and acceptance, respect for ethnic, linguistic, and cultural diversity) rather than global capitalism and social stratification, the kind of English to be taught and learnt has to take on different world accents and has to be multiculturalized and hybridized by speakers of other languages in the world, that is, to be interpenetrated and interilluminated by other voices, accents, meanings, and languages (Bakhtin, 1981).

Critical foreign language curriculums/educators can be as imposing and alienating as traditional or CLT curriculums/educators, depending on the context and the actual classroom interactions that transpire. However, if “education is ultimately the process of non-coercive rearrangement of desires,” as pointed out by the postcolonial scholar, Gayatri Spivak (personal communication, July 2002), critical foreign language educators need to work on exploring ways of noncoercively re-arranging and re-engaging students’ desires in the linguistic and critical project of learning world languages for social justice and intercultural understanding. Osborn (2006) has laid out some useful principles and practical resources that teachers can draw on in such a project. However, there will not, and should not, be any recipe books for delivering critical language curriculums, apart from some general principles and perspectives serving as guidance for the critical educator to adopt and develop their own indigenous, situated pedagogies for their students.

Conclusion: Toward Internally Persuasive Discourses in Foreign Language Curricula

The analyses of students’ resistance and verbal play in their attempts to subvert the imposed English lesson agenda underscore the resilience of human agency and creativity, the human need to go beyond monoglossia, that is, the types of social languages imposed on them in school and society, the drive to turn them into future worker commodities, disciplining them in the foreign languages expected of them in the adult worker world, forcing them to parrot service-worker languages, and constituting their

voices for them. Even in such a situation, some students did not fail to accentuate the parroted utterances with their own voice and accent, attaching to the prescribed utterances their own implicit social and political commentary and meanings.

Bakhtin differentiates between two kinds of discourses: authoritative discourse and internally persuasive discourse. Authoritative discourse is language or discourse imposed on one, but for one to really accept, acquire, and own a language or discourse, it has to become an internally persuasive discourse, hybridized and populated with one’s own voices, styles, meanings, and intentions:

... Both the authority of discourse and its internal persuasiveness may be united in a single word—one that is simultaneously authoritative and internally persuasive—despite the profound differences between these two categories of alien discourse. But such unity is rarely a given—it happens more frequently that an individual’s becoming, an ideological process, is characterized precisely by a sharp gap between these two categories: in one, the authoritative word (religious, political, moral; the word of a father, of adults and of teachers, etc.) that does not know internal persuasiveness, in the other internally persuasive word that is denied all privilege, backed up by no authority at all, and is frequently not even acknowledged in society (not by public opinion, not by scholarly norms, nor by criticism), not even in the legal code (Bakhtin, 1981: 342).

Bakhtin’s insights on the need for heteroglossia and local creativity even in the face of monoglossia suggest a way to resolve these tensions by co-creating heteroglossic, internally persuasive dialogs of interest to students so that English (or a foreign language) can become a language populated with students’ own voices and serve as a tool that students can draw on to construct their own preferred worlds, preferred identities, and preferred voices.

Future directions of research might further draw on cultural studies, postcolonial studies, critical pedagogy, and critical sociolinguistics to develop both theoretical and pedagogical projects. These projects can explore how teachers and students can cross and destabilize the socially constructed boundaries of codified languages, cultures, races, and so on, in exploring how different languages (e.g., the first language and the foreign language) and cultures can be brought together to interilluminate, interpenetrate, and mutually enrich and hybridize each other (Bakhtin, 1981), to create a heteroglossic, multicultural language classroom where both the teacher and students’ desires can be brought to critical consciousness, to be examined, negotiated, re-arranged, and re-engaged to work toward both personal good and common good. Research also needs to focus on how foreign language curricula can draw on new digital media, youth informal literacies, youth popular culture, and Internet practices

(Gee, 2007), areas all infused with young people's intense fantasies and desires, which might, perhaps, await a non-coercive process of re-arranging.

Glossary

Critical literacy – Defining literacy as carrying power.

Diaspora – The movement of peoples.

Diglossic – Speaking two closely related languages.

Meta-cognitive strategies – The conscious control and awareness of one's own learning strategies.

Meta-language – The language about how written and spoken texts carry meaning.

Mother tongue – The first language spoken.

Multiliteracies – Literacy as consisting of multiple languages and modalities.

Phoneme – The smallest unit of speech that carries meaning.

Validity in interpretation – The meaning of a literary work that is ascertainable and related to authorial intent.

This article presents an overview of various issues related to curriculum in first language learning, including what is commonly referred to as language and literacy instruction from kindergarten through secondary school. It is important to point out that first language learning often takes place in students' second or third language, or in a language distinct from their mother tongue. Therefore, the term first language learning in this article refers to the language of schooling or the official language of education in any given country. The particular focus of this article is on language and literacy education in English.

When considering first language learning in English, it is important to recognize that in many contexts, although English is the official language of schooling, it may or may not be related to the mother tongue of many or, in some cases, most school-aged children or adolescents in a country or region. When English is used as an official language or as a language of schooling, it is generally the result of complex colonial, diasporic, and political histories. In some contexts, such as India and some countries in Africa, few students may actually speak English at home and yet, English is used as an official language in governments, businesses, and schools. In other countries, such as Singapore, English may be the official language of particular schools. However, students in those schools may be diglossic speakers using English as one of a number of languages with their friends

and family. In addition, there are contexts (e.g., Canada) where English is neither the only official language, nor the only language of schooling.

Factors Influencing Language and Literacy Curricula

Many factors influence the way teachers approach language and literacy teaching in their classrooms, ranging from the diversity of their students, the official and the tacit or hidden (Freire, 1972/2000) school curricula, current research and professional development, government policy and related means of accountability, publishing corporations, and the media. Language educators are also responsive to the interests of parents and communities, fellow educators (including teacher unions), researchers, and policymakers – both close and more distant. In other words, language curricula in all contexts are simultaneously influenced by local and global discourses of language, literacy, and learning in society. In examining current curricula and practices related to first language and literacy teaching, it is useful to remember that these instructional practices, similar to other cultural practices, travel across contexts and are often accompanied by ideological struggles (Brandt and Clinton, 2002).

In some contexts, language and literacy education is framed as part of larger political issues – such as the attempt to increase literacy among historically disenfranchised groups as a means of addressing their marginalization. In other contexts, language and literacy teaching is framed by more local, but nonetheless polarizing, debates, such as the focus on the best methods for teaching reading to young children. The myriad factors that affect first language curricula make an examination of first language learning in English a complex task. Therefore, this overview describes the central components of first language curricula in English, focusing on areas of tension and debate.

Curriculum: First Language Teaching across Primary, Intermediate, and Secondary Schooling

In the past 100 years or so, first language teaching has been known as the teaching of reading and writing, language arts, communication, English, and literacy or literacies.

Curricula for first language learning typically include instruction in understanding and producing alphabetic print and oral language as well as the integration of arts – such as drama and visual arts – and disciplinary subject matter. Students are generally asked to make sense of and produce a range of materials including informational texts, research reports, personal reflections, and fictional stories. In the past 10 years or more, first language and literacy instruction has also begun to be influenced by digital technologies and information literacies. First language classrooms may include the use of word-processing and digital-editing software, reading and researching using the Internet or other electronic databases, use of popular culture materials, and new media such as film and video consumption and production.

Issues and tensions in first language teaching shift as children move from the primary years of schooling into secondary schooling. This article, therefore, considers these two stages separately, while also recognizing continuities across the school years.

Primary Language Curricula

Early literacy curricula

Early childhood first language instruction in English often includes opportunities to learn the concepts and conventions of print (and, increasingly, of multimodal texts), shared reading and writing experiences, letter-sound instruction, and instruction in other relationships between spoken and written text. Over the past 40 years, work in emergent literacy (Clay, 1967) has influenced early literacy instruction in many schools by focusing attention on how young children construct their own understandings of print. This research asserts that children come to conventional literacy practices through extensive personal experimentation and that early efforts at representation can be seen as part of a literacy development continuum. These perspectives reject a distinct literate/nonliterate divide and, instead, view literacy learning as a process that begins before and continues after children produce or decode conventional print.

Work in primary literacy instruction has also been deeply influenced by studies of the relationships among home, community, and school language and literacy practices. Even when homes are filled with a range of rich language and literacy practices (Taylor and Dorsey-Gaines, 1988), some children experience a disjuncture between home and school language and literacy practices. While some children make a seamless transition, others struggle to appropriate school-based speaking, reading, and writing practices. This research suggests that children's ease or difficulty with school-based language practices depends on the alignment of literacy events and cultural practices in home and school contexts (Heath, 1983). Unfortunately, some educators and researchers

have interpreted this work to mean that homes must conform to school expectations, thus locating risk within families, rather than focusing on the ways that schools might be more sensitive and responsive to differences between home, community, and school language and literacy practices. Recent work in social literacy theories (Barton *et al.*, 2000) have been informative in illustrating the ways that the activities of reading and writing shape, and are shaped by, social contexts and structures.

A second area of contention in early childhood language education has centered on how official languages or the language of school should be positioned in relation to other languages. This is a particularly contentious issue in countries where English is the dominant or official language of schooling and yet, significant numbers of children enter school speaking other languages. In some regions, teachers are given the option of establishing a porous relationship between English/the official language of schooling and children's other languages. In these classrooms, teachers and students code-switch between official and other languages as needed, allowing students to scaffold their language learning. In other regions, policies and legislation dictate that teachers may only use the dominant or official language of instruction in school. In places where English is the language of schooling, these policies are known as English-only policies. However, because there is much evidence that becoming literate in one's mother tongue is a foundational step toward becoming literate in another language, and because of the important relationship between language and cultural identity, interest in preserving these policies are currently being challenged by newer understandings of the importance and value of mother tongue education (Alidou *et al.*, 2006).

Reading in the Primary Schools

One of the most contentious aspects of primary curricula in English has been how best to teach young children to learn to read, or how to teach them to break the code of printed text. How reading is taught has become a highly politicized topic in many countries, perhaps most notably in the United States. Beginning in the 1950s and extending into the present day, this struggle has often been referred to as the reading wars, and is characterized by dichotomies between phonics or code-based approaches and meaning-centered whole word or whole language perspectives on reading acquisition. The former are often associated with behaviorist or systematic learning theories, and support for this approach is generally drawn from traditional experimental studies of reading. These studies use standardized reading assessments or measures of phonological awareness. A measure of a child's ability to decode words is used to make predictions about how children learn to read. In contrast, proponents of whole language approaches to reading acquisition generally draw on constructivist

theories of learning, such as the work of Vygotsky, and on sociolinguistic theories of alphabetic print. Proponents of this approach draw parallels between learning to read and learning to speak, and emphasize the importance of using naturally occurring texts and authentic reasons to make meaning and to communicate over learning decontextualized phonemes.

In the past decade, governments in the United States and England have adopted national strategies to improve literacy that emphasize the teaching of phonics and other word-level skills. These mandates have thus defined what counts as literacy and have imposed code-oriented approaches to early reading instruction on a great number of public schools. In the United States, the authors of the *Report of the National Reading Panel* published in 2000 suggest that they used a particularly narrow definition of evidenced-based research in order to make a stronger case for their assertions concerning the need for direct instruction in phonics. However, recent initiatives based on these directives have come under considerable scrutiny. For instance, the New York Times (Schemo, 2007) publicized evidence that researchers and consultants hired to advise the US government on its Reading First Program had deep financial ties to publishers of specific reading programs, which has cast doubt on the solely scientific bases of their recommendations.

A less-contested area of reading education is the focus on the development of reading comprehension strategies among students in what is often referred to as the intermediate or middle years of schooling. There is a growing consensus that students need to be able to read a variety of text genres with understanding to be academically successful as they proceed through schooling. While the research base for this perspective is not new, there is a renewed focus on teaching reading comprehension strategies in the schools.

Literature Teaching in the Primary Schools

The history of books written for children is bound up with moral and instructional purposes. In the West, children often either read the same works as adults, such as religious texts, or folktales and fables intended to inculcate young readers with societal values (Zipes, 1983). The more recent notion that children might read for pleasure can be traced back to the 1800s with the arrival of books, such as *Alice in Wonderland* by Lewis Carroll and *The Wizard of Oz* by Frank Baum, in England and America. The use of children's literature in schools was often limited to religious texts and instructional readers until the middle of the last century when children's trade book publishing burgeoned, followed by the advent of literature-based approaches to teaching. Many primary classrooms and school libraries are now filled with trade books of many genres from fantasy to realism that are central to the

language arts curriculum; however, the didactic legacy of children's literature is still evident in many literary works for children, and in attempts to limit access to stories deemed inappropriate for young readers by private groups who attempt to block works of literature from being purchased, taught, or read in schools through censorship campaigns.

Writing Instruction in the Primary Years of Schooling

Writing instruction that emphasizes more than the products – penmanship, traditional grammar, and structured essays – is a relatively recent development in language and literacy education. Beginning in the 1970s, researchers and educators began to pay attention to the processes and contexts of composing texts (Graves, 1975). Research on younger children's writing processes gave rise to the recognition of children's use of recursive subprocesses, such as planning, drafting, revising, and editing. These process approaches to writing have been associated with progressive pedagogies that stress the importance of giving voice to students and valuing process over product. However, this approach has also been subject to various critiques. In particular, some educators and researchers have asserted that a process approach lacks attention to issues of power and difference in language use (e.g., Delpit, 1995). These educators and researchers have argued that if a school adopts a process approach and other progressive pedagogies, some students may not gain facility in dominant forms of literacy that they have not been exposed to outside of school.

A notable response to the inadequacy of process writing approaches to support disadvantaged students is the development of a genre-based approach to writing in several Australian states. This approach, developed in the 1980s (Martin and Rothery, 1986), was based on aspects of systemic functional linguistics (Halliday, 1975). The main argument for genre approaches is the importance of explicitly teaching key features of text structure to those students who do not otherwise have access to genres and registers of written language crucial to success in schooling and many workplaces. The genre approach, sometimes referred to as genres of power, is considered to be a form of critical literacy in which relationships between social context, functions, and structures of texts crucial to their functionality are made visible (Bernstein, 1990); a text-level meta-language is provided that allows students to access, deconstruct, and reconstruct texts, and to understand their own positions in relation to such texts. Critics of the genre approach to writing point to the way that this approach could actually reproduce, rather than transform, current social structures. It has been suggested that if an understanding of genres is not part of a larger critique of relationships among discourse, power, and

society (Luke, 1996), then students are not given an opportunity to critique and rework current unequal social relations. Those who support a genre approach argue that education cannot create equality unless all students are given an opportunity to master academic genres and participate in the production of knowledge (Hasan and Williams, 1996).

Secondary Language Curricula

The core components of the language curricula in secondary schools are writing (composition) and literature instruction. Often included in the curricula are courses in communication and media studies. Key debates and tensions related to secondary language and literacy education include what constitutes the literary canon and literature instruction, issues related to the literacy skills or practices that are most important for future citizens, and, more recently, the role of new technologies and media in the secondary curricula.

The content and structure of the language courses students experience in secondary school often depend on the ways and extent to which students are tracked or streamed – placements that are often linked to issues of race, class, and gender, rather than ability (Oakes *et al.*, 1992). Students who are streamed into academic tracks take courses in literature and composition, and are often taught a very different kind of curriculum than are students who are streamed into vocational tracks. Academically tracked students are more likely to be exposed to a range of titles considered to be the core of the Western literary canon that are often taught more traditionally. Students who are streamed into vocational tracks might take courses that are more remedial in nature, such as communications or courses that focus on functional or work-related literacy practices. These students are often taught through less traditional or more popular texts and a range of instructional methods. In fact, much of the current research and practice in new forms of literacy and multimedia with youth take place among marginalized students and in alternative or community settings.

The Literary Canon and Literature Instruction

One significant area of tension that has arisen over the past 40 years is what constitutes the role and content of literature teaching in the secondary language curriculum. Traditionally, literature teaching in the language of schooling curricula includes the reading and analysis of a range of works, including poetry, drama, fiction, and nonfiction. While the selection of works, beyond mandated textbooks, is often quite open in the primary years of schooling, secondary schools often privilege works that constitute the received literary canon (Applebee, 1993). In recognition of the literary canon as socially constructed

and representative of the interests and values of dominant cultures, some educators have worked to diversify the range of texts that students may study in class. Beyond traditional classics such as Shakespeare or the English Romantic poets, some educators have begun to include authors of color and women authors on their reading lists. In this way, moves to interrupt the canon and arguments for the inclusion of literature from a range of cultural groups seen in universities in the 1980s have been mirrored in primary and secondary schools.

The introduction of new works of literature in the secondary language curricula has been accompanied by new critical approaches to reading and analyzing texts. In the mid-twentieth century, the teaching of literature often focused on teaching students to recreate analyses of texts that were considered valid by renowned literary critics (Hirsch, 1967). Meaning was considered to be stable and students were expected to unlock authors' intended meanings through careful deliberation and a familiarity with other critics' ideas of such texts. More recent approaches include the influences of reader-response theory, cultural theory, and psychoanalytic, Marxist, feminist, and post-structural perspectives. These perspectives have opened up new ways of reading and responding to texts. In particular, these theories have made it possible to see literary works as cultural productions that both reflect and (re) produce specific kinds of social relations. While some secondary educators continue to teach as if there have been no changes in literary theory over the past four or five decades, others have begun experimenting with bringing new texts and new literary theories and perspectives into classrooms.

Adolescent Literacies and Social Futures

In addition to questions concerning the boundaries of the literary canon and how students should analyze a text, secondary school curricula have been influenced by work in content area reading, writing across the curriculum and, more recently, content literacies. This work focuses on the variety of comprehension, writing, and meta-cognitive strategies needed for academic success, given the diverse demands of negotiating texts across the disciplines. Reading skills in these paradigms are often defined as the ability of students to construct, expand, and reflect on the meaning of what they have read in a wide range of texts common both within and beyond school – skills that are assessed internationally by organizations such as the Office of Economic Co-operation and Development – and are seen as central to educating tomorrow's workers.

In the past decade, however, there has been increased attention paid to a broader range of literacy practices found in the lives and communities of adolescents in and out of schools. This area of research, often referred to as adolescent literacies, emphasizes the importance of identity,

culture, and multimedia on young adults' literacy practices (Moje *et al.*, 2000). This research has suggested that the new demands and new roles for youth coming of age in the twenty-first century may not be well served by curricula that focus on print literacy, or an emphasis on individual cognition with individual texts in literacy practices. The hybrid, multiple, and social texts associated with new technologies and media require new ways of reading, writing, viewing, and communicating, thus potentially transforming the epistemological foundations of language and literacy education (Luke, 2003).

While these new conceptions of literacy are exciting, there remain some tensions related to students' access to new media and new technologies, or what some have termed the digital divide. In some contexts, there is a significant gap between those who have access to informational and digital technologies and those who do not. This gap is often rooted in socioeconomic class and gender relations. Secondary school educators are often faced with the task of bridging this gap with few resources and little training. In many regions, students learn far more about using technology at home than they do in school. When educators choose to bring new technologies into schools, they are faced with further issues concerning commodity consumption associated with popular culture and media and how to take up such technologies in a way that allows new practices to emerge rather than just reproducing what students and teachers already know and do. Future educators and researchers are faced with the task of attempting to keep up with current changes in communication practices, integrating new and old language and literacy practices, and reflecting on the implications of their choices for the future lives of their students.

Conclusion

Approaches to teaching language and literacy have been affected by changing cultural and political perspectives and emphases (Lankshear, 1997). These approaches variously include skills emphases (e.g., phonics and basic skills), progressive pedagogies (e.g., whole language and look-say), sociocultural perspectives (e.g., New Literacy Studies and sociolinguistics), and postprogressive or critical approaches (e.g., genre based, critical literacy, and multiliteracies). The defining features of each of these emphases, respectively, represent shifts from a focus on language itself and its codes, to the construction of meaning, to social and cultural contexts of language and literacy learning, to the use of language and literacy to critique a range of texts, and to transform society. In turn, these approaches are often theorized by competing conceptualizations of literacy, learning, and schooling as cultural practices.

However, perhaps the most pressing consideration for first language researchers and educators in the twenty-first century stems from recent assertions that language and literacy policies and practices have a long history of perpetuating social inequality (Blackledge, 2001). While first language and literacy learning is often depicted as indispensable to social and economic participation, and as a means toward contributing to human development and poverty reduction by organizations such as UNESCO, others have argued that such constructions of language or literacy education need to be seen as part of what is referred to as a literacy myth (Graff, 1979). Recent research has begun to question how current discourses of language and literacy learning may obscure the role of economic, political, and social contexts in children's and adolescents' first language learning. As first language educators, we need to be attentive to the way debates about language curricula are discursively framed, the ideologies they carry, and their material consequences for children and youth, if we are to maintain a role for formal education in the creation of a just society.

Learning a Second Language in First Language Environments

E Bernhardt, Stanford University, Stanford, CA, USA

D J Tedick, University of Minnesota, Minneapolis, MN, USA

© 2010 Elsevier Ltd. All rights reserved.

This article uses the 1970s as an embarkation point from which to describe and discuss curriculum selection, development, and implementation in contexts in which second languages are learned in first-language environments. In the US and some European contexts this is referred to as foreign-language education, in other parts of Europe as language education, and in Australia as instruction in languages other than English (LOTE). The decade 1970s denotes a time of massive global movement in immigration and expatriation. Indeed, politics as well as natural and man-made disasters provided the impetus for much of this movement. Yet, at the same time, advances in technology enabled more and more individuals to consider living and working abroad. The broad-based need to prepare learners in traditional schooling contexts for using languages across the globe had a profound impact on language education: the forced march through a grammatical syllabus rooted in the virtue of understanding grammatical structures as grammatical structures had to be jettisoned – it was too costly, too time consuming, and too impractical. The concept of being able to do something with a foreign language took hold and has remained the mantra of language programs since that time.

The time frame also coincides with an awakening of research in sociolinguistics, discourse analysis, and second-language acquisition. Not only was doing a curricular philosophy, but also research indicated that learners did not learn and use language forms in the order in which they were presented in traditional textbooks; that is, they did not learn the present tense and then move on to learn the past. In like manner, learners did not absorb all of the prepositions, then move on to the adverbs, and so forth. In fact, research indicated that learners learn to use multiple grammatical functors and syntactic patterns over time, distributed across the learning of previous forms and often contingent on native-language background, sociolinguistic context, and communicative intention (Doughty and Long, 2003). These kinds of research findings and directions coupled with the need, desire, and ease to move about the globe mandated radically different curricular set-ups, dramatically diverse and varied materials, and profound modifications in teacher-preparation programs that conflate to characterize language teaching in the present day.

Key Concepts in Foreign-Language Teaching and Learning

The Notion of Doing

The intellectual shift from having learners know facts about language structure (such as: How is the periphrastic future formed in Spanish? Or, how is tense marked in Chinese?) to actively being able to use those structures in oral speech was profound. The driving intellectual force behind the shift is exemplified by Hymes' (1972) coinage communicative competence and codified in language teaching theory by Widdowson (1978) and in language teaching curricular models such as notional-functional (Wilkins, 1976). Subsequent to these important contributions, significant project work was conducted across the globe that attempted to describe how learners developed in their abilities to use oral speech. Importantly, it was critical to develop the descriptions apart from textbook, set of objectives, quality of teacher, or length of seat time devoted to language learning. In other words, the objective was to develop descriptors external to particular curricula that would enable a sense of what learners could or could not do with the language that they had learned at any given point in time not what they did or did not know about that language. In the United States this was referred to as the common yardstick and in Europe as common reference levels.

Proficiency Orientation in the US

Foreign-language teaching in the US was fundamentally altered by 'Strength through wisdom', the report of the President's Commission on Foreign Languages and International Studies (1979). This report, which called for a common yardstick, spurred US policy into the direction of developing descriptors for language proficiency. The American Council on the Teaching of Foreign Languages (ACTFL) took leadership in developing the descriptors across multiple languages and across the four skill areas of speaking, listening, reading, and writing. The original set of descriptors, known as the ACTFL Provisional Proficiency Guidelines (1983), were unveiled in 1982 and were adapted from the Foreign Service Institute scale. This scale made provision for 11 major ranges of proficiency, beginning with 0 (no functional ability in the language) to 5 (proficiency equivalent to an educated native speaker), using + designations between levels. The nominals on the

scale are novice (N), intermediate (I), advanced (A), and superior (S), and capture word-level (N), sentence-level (I), and paragraph-level (A) speech, through the upper reaches of highly educated native speech (S). In order to generate data for the scale, a structured interview – an oral proficiency interview (OPI) – that probes through questions and role plays, the function (what one can accomplish with language), content (themes and topics), and accuracy (grammar and discourse) of a speaker – is administered.

The proficiency orientation in the US enabled a national dialog among educators about, for example, how far a secondary school language program could bring learners (through the early intermediate level perhaps) and where post-secondary programs could pick up (at the intermediate level and into the advanced) with study abroad necessary for the development of the upper reaches of language on the scale. With the focus on doing, the concept of grammatical accuracy became only one dimension of language ability rather than the dimension of language ability. Over the years, the descriptors have been modified and refined (with most recent versions of the speaking and writing guidelines available at the ACTFL website), but the basic framework of a scale with ranges of language performances remains intact.

Common European Framework

The concepts embodied in the Common European Framework (CEF) are rooted in urgencies parallel to those identified by the proficiency movement in the US: a need to understand language development independent of particular curricula and teaching methods and a desire to have a common yardstick. The urgency of developing a common yardstick in Europe is/was, of course, much more complicated than that found in the US because development and consensus had to take place across speakers of multiple languages, speech communities, and national boundaries.

Similar to proficiency-based language teaching philosophies, the CEF examines language abilities in multidimensional spaces (Council of Europe, 2001). These spaces entail function, topic, purpose, and modality as well as micro-level grammatical precision. In these basic beliefs, proficiency and the CEF are absolutely identical. In like manner, the basic nominal scale is similar. CEF contains six levels from basic to proficient: basic (A1 and A2); independent (B1 and B2); and proficient (C1 and C2). Basic can be referenced as waystage; independent as threshold; and proficient as mastery. CEF descriptors contrast, however, with proficiency descriptors in that they are much more precise regarding the social contexts in which language is used and much less precise regarding

particular grammatical forms. CEF at A2, for example, notes: “Can communicate in simple and routine tasks requiring a simple and direct exchange of information.” US proficiency descriptors would note the use of the present tense. Importantly, proficiency descriptions often use the command of particular tenses as benchmarks. Ability to narrate in the past, as an example, is often noted as the main marker of crossing a major border, namely from intermediate to advanced. Such a definition is not found in the CEF descriptors. Rather, major boundaries such as moving from waystage to threshold are crossed by abilities to use greater quantities of language and greater social skill such as the ability to gain and hold the floor. A second significant feature that distinguishes the CEF from the American proficiency approach is substantial attention to self-assessment. Accompanying CEF are diagnostic statements of the “I can...” type that empower the learner to participate in a personal understanding of his/her language development and control.

Standards

The 1990s brought the advent of US national standards in all school-based subject-matter areas, including foreign language. The content standards define what students should know and be able to do in foreign-language education (National Standards in Foreign Language Education Project, 1996). They are intended to inform curriculum but do not in and of themselves serve as curriculum. Language-specific standards were unveiled in 1999 for eight modern languages and the classical languages.

The influence of the proficiency orientation in the US is clear in the standards, as the emphasis on doing remains. This influence is particularly prominent in the area of communication, one of five goal areas under which the 11 standards are organized. Yet, the standards reveal a departure from the separate skill areas of listening, speaking, reading, and writing that characterize the proficiency guidelines, to a framework of communicative modes, which emphasize the context and purpose of communication. This framework includes the interpersonal mode (direct oral or written language that reflects spontaneous, two-way communication between individuals in personal contact and involves negotiation of meaning), interpretive mode (interpretation of oral and written text when negotiation of meaning is not possible), and presentational mode (production of written or oral language for an audience without the opportunity for negotiation of meaning). In addition to the communication goal, the standards include goal areas of culture (understanding of the cultural contexts in which language use occurs), connections (links to other disciplines and knowledge that is unavailable to monolingual English speakers), comparisons (overt comparisons both linguistic

and cultural), and communities (culturally appropriate language use with communities outside of the school and the US). Together, these five goal areas are known as the five C's of foreign-language education (National Standards in Foreign Language Education Project, 1999: 31).

The Notion of Meaning

Similar to the shift from knowing to doing, there occurred a shift in language education from a focus on form to a focus on meaning. In a curricular sense, the focus on meaning is perhaps best captured by language-education programs that fall under the umbrella of content-based instruction (CBI; in the US and Canada), or content and language integrated learning (CLIL) (in Europe).

Content-Based Instruction

CBI refers to the integration of language and content in the language curriculum. The notion of what constitutes content in CBI varies, with some indicating that it refers to academic subject matter, while others argue that it need not be academic but can include any topic of interest to learners that is cognitively demanding and engaging for the learner. Met (1999) proposes a continuum of content and language integration with content-driven programs on one end of the continuum and language-driven programs on the other. In content-driven programs, content is given more importance than language, and students and teachers are held accountable for content learning. In language-driven programs, language learning is the priority and content is often used to contextualize the language and is often considered incidental.

CBI program models lie on the continuum depending upon whether they are more content or language driven. Met (1999) argues that immersion is “the most salient example of a content-driven language program” (p. 4). Indeed, in immersion programs the focus is on academic content, which children learn through the medium of the non-native language. More detailed information about immersion programs is discussed below. On the other end of the continuum, Met identifies content-related elementary school foreign-language programs that reinforce subject-matter concepts using the foreign language. For example, learners might review simple addition and subtraction problems as they practice the use of numbers in the foreign language. The emphasis in such programs is undeniably on language learning, and content is merely used as a vehicle for making language use more cognitively engaging.

A range of other CBI programs also lies on the continuum between the two extremes. Sheltered courses are content courses that incorporate a variety of teaching strategies to scaffold instruction and make the content

accessible to the learners, non-native speakers of the foreign language. Such courses might lie closer to the content-driven end of the continuum. The adjunct model lies at the center of the continuum, given its equal emphasis on language and content. In this model, students are enrolled concurrently in two linked courses, one focused on content and taught by a content instructor and the other focused on language and taught by a language instructor. Students are held accountable for content mastery and for the acquisition of academic language proficiency. Content instructors and language instructors share responsibility for student learning; the content instructor evaluates students' content mastery, while the language instructor assesses students' language skills. The adjunct model may combine students who are learning the language used for instruction as well as native speakers of the language. Only non-native speakers of the language are enrolled in the language course, whereas all students, native and non-native speakers alike, take the content course. Both sheltered courses and the adjunct model appear most often in post-secondary settings and are examples of Foreign Language Across the Curriculum (FLAC).

Yet another example of a CBI model is language for special purposes (LSPs) which is also commonly found at the post-secondary level. In this model, learners are introduced to specific linguistic features and discourse attributes related to a particular field, such as business or the health industry. Such courses may be categorized as being more language driven if the emphasis is on language or may lie at the center of the continuum if the course emphasizes both language and content learning.

Immersion

Language immersion education was pioneered in 1965 in Canada as a grassroots, parent-driven response to the perceived ineffectiveness of traditional French instruction. In immersion programs students receive at least 50% of their subject-matter instruction through the medium of a foreign language. The model was introduced in the US in 1971 in Culver City, California and since then has proliferated in the US and around the world.

The design of contemporary immersion programs varies depending upon the extent of instructional time in the immersion language (total vs. partial) and the grade at which the immersion program begins (early, mid, late, or late, late). In total/early immersion programs, the immersion language is used 100% of the time for subject-matter instruction in the early grades, K-1. English is not introduced until grade 2 or later, and is gradually increased so that by grade 6 both the immersion language and English are used approximately 20–50% of the time. In partial immersion programs, the immersion language and English are used for approximately 50% of subject-matter

instruction from the beginning of the program. In mid immersion programs, immersion begins around grade 4 and in late programs from grades 7 to 10, with the assumption that learners have studied the immersion language as a subject in school before the immersion experience begins. Late, late immersion begins at the post-secondary level. Mid, late, and late, late programs are found primarily in Canada, though late immersion programs in English are not uncommon in Hong Kong. Preschool immersion programs are found increasingly around the world and in the US. Irrespective of the model chosen, all immersion programs strive for additive bilingualism, referring to the acquisition of a second language at no expense to the first.

The early theory that drove the establishment of immersion programs argued that second-language acquisition would progress much like first-language acquisition. That is, if students were immersed in the second language, using it to communicate meaningfully about relevant content, they would acquire it. Research has since shown that although immersion students develop high levels of functional proficiency in the immersion language, achieving native-like proficiency in the receptive skills (listening and reading), they do not achieve native-like proficiency in their productive skills (speaking and writing). Immersion learners' language lacks grammatical accuracy, lexical specificity, and becomes increasingly Anglicized over time, particularly as instructional time in the immersion language decreases. Immersion scholars and teacher educators have therefore long advocated for a systematic and overt focus on language (form) in the context of content instruction (meaning). Thus, it is no longer a notion of meaning or form but rather meaning and form. Such seamless integration of language and content in immersion and other content-based instruction teaching environments is the ideal.

Supporting Language Teachers

Teacher Preparation

Teacher-education programs are designed for preservice foreign-language teachers and lead to an initial teaching license or certification. In the US most teacher-education programs exist at the undergraduate level, where prospective teachers pursue a major in the language they wish to teach and, often, a minor in education. They typically require a methods course and student teaching for a term, and these experiences constitute prospective teachers' foreign-language-specific teacher preparation. In this model, language departments are responsible for providing prospective teachers with requisite content knowledge and opportunities to develop proficiency in the target language, while departments of education are responsible for providing foundational coursework in

education and meeting state standards for teacher preparation, and the school-based practitioner is responsible for mentoring the student teacher in the context of the student-teaching experience (Schrier, 1994).

Some language-teacher-education programs in the US are at the postbaccalaureate level and require language proficiency as a prerequisite for admission to the program. Often housed in schools of education, these programs offer teacher candidates intense and extended coursework focused on foreign-language curriculum development and assessment, language pedagogy, culture integration, and general educational foundations along with concurrent, extensive school-based experiences. Such programs were developed in the late 1980s as a result of the Holmes Group report (Holmes Group Executive Board, 1986), which emphasized the need for more professionalism in teacher preparation.

Teacher preparation for immersion education takes a decidedly different direction. In Canada, programs designed specifically to prepare teachers for language immersion programs have long been available. In the US, immersion teachers are required to be licensed in elementary education or specific subject matters for the secondary level. The vast majority of states offers no specific programs to prepare immersion teachers even though it is established that immersion teaching requires a unique set of skills and a knowledge base that is different from that needed for regular classroom teaching or foreign-language teaching (Hartiala, 2000). The only state that offers a program to prepare immersion teachers is Hawaii, where an undergraduate program builds proficiency in the Hawaiian language while leading to an immersion teaching license. A similar program is offered in Australia, where teacher candidates increase their proficiency in Japanese while completing requirements to become teachers of Japanese either in an immersion or regular school setting. This Language and Culture Initial Teacher Education Program (LACITEP) was established in response to Australia's aggressive national policy agenda regarding the teaching of LOTE (Erben, 2005).

Just as there has been a shift in language education to emphasize the notions of doing and meaning, a parallel shift in language teacher education has occurred. There have been calls for moving beyond method to embedding a focus on understanding language teaching as it occurs within social, cultural, historical, and political contexts to developing reflective practitioners, and to striving for a critical pedagogy within both language teacher education as well as language teaching (Tedick and Walker, 1994).

Infrastructure for Language Teaching

Teacher development has become more centralized over the years. In the 1990s, the growth of National Language Centers as well as university language centers has

provided a dynamism and a research-based focus on language learning and teaching that did not exist in prior decades. In the US, a network of foreign language resource centers provides intensive workshop opportunities for teachers as well as for materials development and curriculum development assistance. In Canada, the Modern Language Centre has played an important role in fostering bilingual language policy as well as conducting research into different instructional models for the development of bilingualism. In the European Union, a significant multinational effort runs in parallel. It includes the important dimension of accrediting cross-national language programs. The National Centre for Languages in the United Kingdom is one example as are endeavors by the Federation of Modern Language Teachers Association in Australia. In like manner, individual universities have tended toward centralizing their language programs, making professional development and enrollment play more significant roles in the management of large language programs.

Ongoing Dilemmas in Language Teaching

The very theme of this article, learning a second language in a first-language environment, reveals the two most significant challenges encountered in language teaching: teacher language proficiency and student access to immediate, authentic, and copious native-language samples. Teachers who teach a language in a first-language environment are very often non-native speakers of that language. This demographic by and large makes for excellent, empathic teachers who are sensitive to grammatical and social contrasts between the native language and the second language. The demographic also means that these teachers often have no language example other than themselves, creating a constraining situation linguistically and culturally. The only way to break the constraints is by frequent and sustained interaction with native speakers; such interaction often implies lengthy stays in another country. The costs of such sustained interaction are not inconsiderable. Monetary costs involve living expenses, room and board, and sometimes tuition costs; these are inconsequential when compared with the personal costs of time spent apart from family, community, and work. Yet, without spending significant time in a setting where the language is spoken at fairly frequent intervals, language teachers face issues of credibility with their own students, a potential lack of confidence in their speaking abilities, and feelings of professional inferiority. As language teaching grows on a global scale, these issues will be exacerbated (Llurda, 2005).

The second major dilemma presented by language teaching is access to useful, appropriate, and plentiful language materials in all modalities. In the developed

world, almost all contemporary language-learning materials contain video components and digitized material for drills and exercises; yet, this material ages quickly. In this regard, a call to use the Internet seems to be a quick fix. Problematic is that the research base available from which to understand the impact of these technologies on the development of language proficiency is in its infancy. In addition, of course, confronting the issue of access to copious contemporary language examples in the underdeveloped world is a different dimension to the dilemma. Given that electricity is still not universally available and reliable, to speak of Internet- and other digitally-delivered materials to buttress language instruction borders on the absurd.

Caveats

This article does not presume to characterize every development in language teaching over the past decades. It provides the broad brush strokes of curricular trends and issues in language teaching. In fact, in spite of the important trends and issues in language teaching discussed above, many language programs around the world – whether they be in elementary or secondary and post-secondary institutions – remain decidedly grammar driven. This phenomenon occurs for a variety of reasons: lack of opportunities for professional development across the profession, lack of teaching materials that are not grammar driven, the tendency to teach the way one was taught, and the excessive teaching and student load placed on teachers, to name a few. Urging teachers to move from formal grammar instruction to operating with language contextually is demanding and exhausting. The fundamental belief is, however, that the language abilities of learners taught to use language in content or in context are substantial, sophisticated, and usable.

This article argues that changes in literature curricula have typically reflected major historical and political developments within particular regions of the world. It begins with a brief overview of major shifts in literature curricula in the United States, followed by a comparative discussion of literature curricula internationally.

A Brief History of Literature and Its Teaching in the United States

In the United States, the purpose of reading in schools has shifted from the learning of religious and moral precepts in the seventeenth, eighteenth, and early nineteenth centuries, to the development of personal and social skills during the progressivist and neo-progressivist movements of the twentieth century, and finally, to the development of critical awareness and social transformation inspired by contemporary literary theory in the latter part of the twentieth and early twenty-first century. As the following discussion will reveal, this movement has been neither steady nor stable, but has reflected the ebb and flow of historical, economic, and political events.

From Primers to Anthologies: Literature Textbooks and the Purposes of Teaching

The early primers in colonial America were composed of precepts, prayers, and biblical excerpts designed to teach Christian ethics and ideals. Throughout the seventeenth and much of the eighteenth century, literary texts, as currently defined, were not part of the curriculum. These texts did not make their official entrance into American classrooms until the early nineteenth century, when various readers and textbooks from related fields such as rhetoric began to depart from the typical religious and moral fare to offer excerpts of poetry, prose, and other types of literature designed to improve the reading, memorization, and elocution skills of students. As the study of literature began to break away from its roots in reading, grammar, and rhetoric in the nineteenth century, a number of literature textbooks emerged. Most were historical and biographical discussions of literary periods and authors rather than collections of literary texts. Eventually, a few textbooks began to include excerpts from British, American, and even world literature. Nevertheless, throughout the mid-nineteenth and early twentieth centuries, literature textbooks remained narrowly confined to historical and biographical information with

an occasional smattering of classic British texts. Despite increasing racial and ethnic diversity in the population during that time, definitions of what counted as literature remained narrow and myopic. It was not until the latter part of the twentieth century that the literary canon expanded in the United States to include authors, protagonists, and content from beyond the English-speaking world. As the following sections will demonstrate, the teaching of literature in American schools, colleges, and universities during the twentieth century has undergone several shifts in focus and methodology.

Text-Based Approaches to Literature Teaching

From the 1920s to the 1960s, New Criticism emerged as a reaction to the preoccupation with the historical and biographical study of literature. Wimsatt and Beardsley (1946a, 1946b) popularized the notion that neither the author's intention (the intentional fallacy) nor the reader's emotional response (the affective fallacy) was relevant to the reading of literature. Borrowing from Richards' (1929) classic work, *Practical Criticism*, the New Critics believed that texts should be examined and analyzed apart from published biographical scholarship or contextual factors external to the work itself. As a result of New Criticism's powerful influence, literature curricula focused on the study of literary devices, genre characteristics, and close textual analysis. Even with the popularity of reader-response criticism in the early 1960s, New Criticism still exerts considerable influence on secondary and college/university literature curricula in the United States (Applebee, 1993).

Reader-Centered Approaches

A move from text-centered to reader-centered teaching began around the time of the Dartmouth Conference in the late 1960s, when a group of teachers and scholars from America and Britain were called together through the joint efforts of the Modern Language Association, The National Council of Teachers of English, and The National Association for the Teaching of English, for the purpose of defining English as a content area and discussing how it should be taught. The conference both reflected and promoted a revival of educational progressivism, an interest in cognitive developmental psychology, and what has come to be called constructivist education. A concern for the

cognitive development and esthetic/emotional needs of readers began to supplement, if not displace, the practice of close textual analysis and the study of literary forms in many literature classrooms. In describing the work of the Dartmouth conference, Squire (1968) noted that, as a result of Dartmouth, a new concern for “imaginative and emotional education” (p. 526) and the diminishing importance of British literature courses in college curricula had begun to displace discipline-centered approaches to English in the United States.

Under various umbrella terms, such as response-based, child-centered, learner-centered, or whole language instruction, learner-centered teachers assumed that students learn best when reading authentic unexcerpted literary texts that appeal to their unique learning practices, preferences, and developmental needs. The mass marketing of young adult and children’s literature also began to influence the available literature in schools. On the elementary level, teachers began to replace the skills-based basal readers with tradebooks or anthologies featuring authentic children’s literature. On the secondary level, the reader-response movement promoted the teaching of fiction written specifically for and about adolescents and privileged personal esthetic response over close textual analysis. During this time, the notion of multiculturalism emerged as a way of developing cultural understanding and tolerance among America’s youth. Today, this trend toward cultural inclusivity is reflected in the growing cultural, racial, and ethnic diversity, as well as the inclusion of female authors and protagonists, in the literary offerings of contemporary literature anthologies.

Critical Theory, Politics, and the Teaching of Literature

Toward the end of the 1980s, the proliferation of critical theories such as postmodernism, Marxism, cultural studies, feminism, and gender studies has spurred a redefinition of multiculturalism from a cultural tolerance to a social transformation perspective. Much has been written in the past two decades about literature and literacy as the cornerstone of a social justice, antiracist, antibias, or service learning curriculum. Teaching literature from this more critically and politically motivated perspective means redefining reading beyond a search for meaning to a way of acting upon and changing the world. Proponents of this approach argue for expanding the literary canon to include not only literature from a variety of racial, cultural, and ethnic perspectives, but also texts that challenge typical racist, sexist, homophobic, and ableist stereotypes. As with all curricular innovations, however, this movement has been neither orderly nor far reaching. Despite a growing interest in contemporary critical theory in secondary teacher education, curricular

reforms based on contemporary literary theory have been largely confined to the college and university level, and a great many institutions of higher education remain tied to genre-based or historically organized literature curricula. Similarly, teachers in America’s secondary schools have been slow to embrace contemporary critical perspectives, continuing instead to rely on some combination of reader response and New Criticism – approaches often in direct conflict with each other (Applebee, 1993).

Literature and Its Teaching in International Perspective

Just as the American literary canon has remained relatively ethnocentric throughout its history, prior to the 1970s, few scholarly publications focused on how literature was taught outside the American and British tradition or on cross-national analyses of literature curricula. In 1968, the United States Office of Education established the Institute for International Studies, and grant monies were allocated for studies on international and comparative education “in countries of interest to the United States and concerning which little useful material was readily available in English” (Leestma, 1981: 273). From the National Defense Education Act of 1958 until the early 1980s, much available research on comparative education has focused on foreign languages, particularly those uncommonly taught languages outside Western Europe (Leestma, 1981: 273).

In the early 1970s, as part of this initiative, a comparative analysis of international literature curricula was sponsored by the Institute of International Studies. In *Literature education in ten countries* (Purves, 1973), the report of this 9-year study, Alan Purves and colleagues concluded that schools have minimal effect on students’ interest in literature, but do impart a preferred style of response. The report concluded that American schools seem to do this earlier and with more impact than schools in other countries. In a later publication, Purves (1975) described three deep structures in the literature curricula of the countries in the International Association for the Evaluation of Educational Achievement (IEA) study: the imitative structure, the analytic structure, and the generative structure. Italy and Iran were closest to the imitative; Belgium and Chile, analytic; and England, generative. Purves noted the importance of a country’s curriculum in shaping the cognitive styles of students.

Although ambitious in scope, the IEA study was based on survey data. Since the time of the IEA study, no large-scale comparative analyses of literature education have been conducted. The extant literature tends to include comparisons of one or two countries (typically, those with a similar linguistic base) or, more typically, historical examinations of literature curricula within one country

or region (Applebee, 1993). Thus, it is difficult to discuss national and cultural differences in any comprehensive way. The remaining sections are an attempt to pull together a group of disparate studies and draw cross-national comparisons. The discussion centers on some key issues relevant to the political, social, historical, and economic influences on literature and its teaching.

Literature, Colonialism, and Revolution

In colonial and postcolonial periods, literature serves as a tool of colonizers and revolutionaries alike. In colonial times, literature was often censored when it reflected negative aspects of colonization. For example, D'Arcens (2000) has described attempts to repress or write over England's violent colonization of aboriginal people in Australia's university literature curricula during the nineteenth century. In post-revolutionary societies, literature often serves as a vehicle to promote political ideals. In describing the literature curriculum in Russia prior to the dissolution of the Soviet Union, Hopkins (1974) noted that literature chosen for classroom study was "oriented toward projecting an image – the dark pre-Revolutionary past vs. the glorious present" (p. 49). Under autocratic regimes, literature often serves an overt role in advancing a political or social agenda. Perhaps nowhere is this more apparent than during the African independence movements in the 1960s, many of which were followed by the institution of autocratic governments. For example, under the socialist regime of Sékou Touré in Guinea, writings by African authors in French were criticized for their precolonial associations, and students were expected to memorize Touré's poems and other writings in favor of Francophone literature by African authors.

Often, well past a country's independence, it is difficult for indigenous or national languages and literatures to make their way into the curriculum. Precolonial notions often prevail long after political revolutions have rendered them obsolete. As Bray (1993) notes, the term independence is often slippery, and relationships in post-colonial nations can range from full sovereign independence to sovereignty with strong ties to the former colonial power. For example, it was not until the latter part of the twentieth century that American literature, and later, the literatures of indigenous peoples, made their way into the curriculum of the United States. Although the *Journal of American Literature* was founded in 1929, it was not until mid-century that American literature began to enter high school and college curricula. In the same vein, Robinson (1987) has discussed the slow emergence of Canadian literature from the British tradition in Canada during the 1950s and 1960s.

Bray (1993) distinguishes between colonialism and neocolonialism, which he describes as "the control of

states by external powers despite the formal appearance of constitutional independence" (p. 334). Neocolonial influences have been exerted by countries such as Great Britain and the United States, which have no formal colonial relationships, but maintain economic superiority over smaller or developing nations. English, for example, is still a mandatory subject in many parts of the globe, and literature from the American and British tradition forms a significant core of literature curricula in a great many formerly colonized and noncolonized countries. For example, after Kenya's independence from Great Britain, the literature curriculum remained largely British due to its continued economic dependence and the lingering influence of the Cambridge Local Examinations Syndicate. Similarly, students in post-revolutionary Gabon continued to study a combination of Francophone and African literature due to the country's strong economic and social ties with France. In general, across Africa, few works by African or African diaspora writers have made it into classrooms, despite the achievement of independence in countries across the continent.

Thus, in many postcolonial societies, literature is a vehicle for establishing a national identity or promoting political ideologies. Notions of high culture are often tied to the languages and literatures of colonial or neocolonial powers and persist long after political revolutions should have diminished or negated their influence.

Political Stability and the Literature Curriculum

English-speaking countries such as the United States, Canada, Australia, New Zealand, and the United Kingdom have enjoyed relatively unchallenged political and economic stability. Thus, curricular debates in these countries often center on philosophical and epistemological questions such as enlarging the literary canon to meet the tastes and cultural backgrounds of students or the teaching of skills and strategies versus the development of esthetic sensibilities. In regions marked by political instability, large-scale curricular decisions often have dire consequences for citizens and schools alike. In such contexts, literature is often used as a vehicle for imparting political ideologies or suppressing antigovernment ideas, as, for example, the censorship campaigns in Nazi Germany prior to and during World War II.

In comparing the literature curricula of Greece and Great Britain, Hodolidou (1995) noted that the "political and constitutional stability of England is relatively unknown to Greece which has faced major political and constitutional changes during the last fifty years" (p. 86). The Greek education system is controlled by the Ministry of National Education and Religion, and strongly influenced by the Greek Orthodox Church. During the military dictatorship

prior to 1974, politically progressive ideas were censored and the prescribed literary canon served as a tool for the promotion of a unified Greek identity. By contrast, although the literary canons in Britain and the United States remain relatively narrow, politically progressive ideas have not been overtly censored, and teachers are relatively free to debate issues of inclusivity and exclusivity in the literary canon (Hodolidou, 1995).

Literature and the Economy

It is important to recognize that national identities are created as much by economic exigencies as they are by natural geographic boundaries. Movements toward national unity are often thinly veiled schemes to promote economic and political stability or supremacy. Often during challenging economic periods, the literary canon is restricted or narrowed, and concerns for personal relevance and artistic creativity in the teaching and writing of literature are stifled. In the recent history of the United States, political documents such as ‘A nation at risk’ (National Commission on Excellence in Education, 1983) and reform movements such as The Goals 2000: Educate America Act of 1994 and The No Child Left Behind Act of 2002 have stemmed from a desire to promote global competition, produce capable or compliant workers, and compete internationally on various measures of achievement. A similar move toward accountability and curricular reform occurred in Great Britain under the Education Reform Act of 1988 with the creation of a national curriculum and a mandatory testing program.

In other countries around the globe, large-scale attempts at curricular reform aimed at the production of a capable workforce have coincided with periods of economic insecurity or a perceived lack of global competitiveness. Under autocratic regimes, these reforms have had troubling consequences for schools and citizens alike. During the Chinese Cultural Revolution of the 1950s, for example, Mao Tse-Tung abolished traditional university and school programs, sending students and teachers from the cities to rural areas to be re-educated by peasant farmers. Often this re-education was as a response to perceived crises such as the need for steel production or the building of hydraulic power or irrigation systems. The Cultural Revolution resulted in the abolition of humanities programs in colleges and universities, the shortening of time spent in primary and secondary schools, and the persecution of writers who did not promote an overtly communist agenda. Similarly, inspired by China’s example, African socialist Julius Nyerere in Tanzania required all teachers to teach a curriculum based up socialist notions of practical action, specifically targeted toward the development of agricultural knowledge and farming skills. Cuba’s utilitarian education

movement in the mid-1960s resulted in a similar closing of schools and a migration of young people to rural areas to work and participate in a national literacy campaign. Due to the heavy emphasis on vocational training and applied science, enrollments in the humanities sharply declined in these countries. Similar radical movements were enacted in countries such as Brazil and Nicaragua. As socialist or communist reforms failed to exact their predicted economic effects, academic literature study slowly reentered the curriculum. In countries such as China and Cuba, basic literacy levels were raised among the population as a whole, but the neglect of more formal education exacted a heavy price in terms of intellectual development among all citizens and national economic competitiveness.

Recently, in response to global economic competition, the European Union movement has forced European countries with disparate linguistic, cultural, religious, and political traditions to seek common ground in a process similar to that experienced by American colonists prior to the creation of the United States and the nations of Africa during the pan-African movement of the 1960s. Hodolidou (1995) has suggested that literature curricula might play an important role in “promoting a new European identity” (p. 84).

Literature in Crisis: War and Other National Emergencies

Concerns for literature’s role in the transmission of national heritage as well as in the teaching and testing of literary analytic skills often arise due to fears over wars or terrorist acts, large or unusual immigration patterns, or changing racial and ethnic demographics. Learner-centered progressivist movements associated with the political left in the United States have often fallen out of favor as national insecurities have polarized public opinion toward a more skills-based accountability system in education. For example, in the United States, the launching of the Soviet satellite, *Sputnik* in the 1950s coincided with calls for intellectual rigor in the field of English through national programs such as Project English. The periods surrounding World War I, World War II, and the 2001 bombing of the World Trade Center all coincided with calls for national standards and testing programs, as well as with the need for some version of cultural literacy (Hirsch, 1987) as evidenced by familiarity with texts from an accepted literary canon.

Notably, however, one of the first efforts to broaden the American literary canon occurred in the period surrounding World War II, when literature began to be viewed as a vehicle for “sustaining peace, brotherhood, and democracy” (Leary, 1943: 88). This call for the inclusion of literature from non-English-speaking authors arose

more from a need to understand (and presumably compete with) foreign nations than a desire for peace, cultural tolerance, or social change; thus, it did not result in a significant expansion of the canon. In 1940, for example, the National Council for Teacher Education (NCTE) Committee on International Relations published two narrowly confined lists of foreign books in English, one encompassing Latin-American, and the other Russian literature (Leary, 1943). A glimmer of what has come to be called multiculturalism in the literature curriculum began in the early 1970s with arguments for the inclusion of world literature in the college and high school classroom (Dieterich, 1973). Citing the proliferation of new technologies, developing nations, and other signs of global dependence, Dieterich argued that when children are exposed only to British and American literature, "[T]hey learn that the rest of the world is incapable of writing literature which merits inclusion in their curriculum; that only the British and, to a lesser extent, Americans are capable of producing works of real literary value" (p. 482).

Literature and the Politics of Difference

Perhaps ironically, growing cultural, racial, or ethnic diversity within a nation has often yielded a reification, rather than a transformation of the literary canon. In the United States, the mass immigration of Chinese people in the mid-nineteenth century and the immigration of Italians, Slavs, and Jewish people from southern Europe in the early twentieth century spurred the first English-only legislation in American schools and a federal English-speaking requirement for citizenship. Citizenship and access to education were not granted to African American, Native American, Asian, or Mexican people until the mid-to-latter part of the nineteenth century. During the nineteenth century, the common schools movement was instituted as an attempt to Anglicize Native American and immigrant children. The teaching of literature during this period often focused on the creation of an American identity and culture, resulting from the growing fear that a rising immigrant population would displace American workers and enact a radical shift in political ideology among America's poorer classes.

More recently, the move toward high-stakes testing and basic skills instruction in the United States has been further intensified by the large numbers of children from non-English-speaking households entering American schools. Shortly after 'A nation at risk' was published with its conclusions about a rising tide of mediocrity (National Commission on Excellence in Education, 1983: 5) in American schools, the National Census Bureau reported a steep rise in the numbers of foreign-born residents in the United States. Around this time, bilingual education programs were dismantled in Florida and California.

On the other hand, what has been called the browning of America has resulted in a significant broadening of the literary canon in America's primary and secondary schools to include texts written in languages other than English, as well as a wider cultural and ethnic representation in contemporary literature anthologies. Teachers in Great Britain are caught in a similar struggle to include the literature of immigrant and other minorities into the British curriculum. It is not coincidental that, as the United States and the United Kingdom have become more dependent upon formerly disenfranchised Third World nations for economic success and political security, concerns for inclusion of the underrepresented have increased. Competing concerns for the narrowing or the widening of the literary canon have always existed, and such clashes and controversies will no doubt continue far into the future.

In sum, literature curricula are never politically neutral. Within the United States, the role of literature in schools has shifted from promoting social morality and a unified national identity to enhancing the esthetic, social, and cognitive sensibilities of individual learners. The mid-to-latter twentieth century has witnessed a move from literature as personal identification and a representation (or reification) of culture toward a view of literature as a vehicle for cultural critique and transformation. Within and beyond the English-speaking world, curricular changes are rarely bounded by distinct historical periods, but reflect the changing political, economic, and historic landscapes of particular countries. In periods of colonialism, literature tends to reify colonial values. Revolutions and political instability often result in governmental control of literature curricula for the purpose of advancing social reforms or political agendas. Economic uncertainty and national emergencies often lead to calls for national unity or increasing economic productivity through national literature curricula or standardized assessment programs. Large or unusual patterns of immigration or increasing cultural diversity have two very disparate effects. On the one hand, cultural changes often result in arguments for the creation of a national identity through familiarization with an accepted literary canon; on the other hand, increasing diversity often results in calls for the expansion of the literary canon to reflect a changing cultural, racial, and ethnic landscape.

Several recommendations can be drawn from the foregoing review. First is a pressing need for systematic study of literature teaching outside the American and British tradition and for cross-national studies of literature curricula from a variety of research methodologies. Without such large-scale analyses, it is difficult to understand the exact ways in which historic, geographic, political, and social exigencies shape literature curricula across cultural boundaries. It is also imperative to recognize that the politicization of literature and governmental censorship

of politically unpopular ideals in literary texts cannot be safely relegated to the past. In a time of great instability, evidenced by war, genocide, and international terrorism, nations must be eternally vigilant against repression in all of its forms. Even in the secular educational systems of multiparty states, researchers and scholars are often indirectly pushed to reify a political agenda when particular research perspectives and methodologies are kept outside the cycle of government funding. While scholars may exercise a certain degree of academic freedom within the walls of universities, it is notable that much academic discourse gets ignored by political administrations, school districts, and popular media. For example, no large-scale studies exist on the effects of high-stakes testing on the ways in which literary texts are read, taught, and evaluated in classrooms. Given the politically charged nature of the topic, it is questionable whether government funding would be available for such inquiry. Perhaps now, more than ever in the history of the world, members of the academy must bring the principles of cultural critique to their own work, redefining scholarship from a search for information to a form of political action – a way of transforming the world.

Mathematics

Mathematics is an essential component of the school curriculum. It nurtures both the faculties of logic and reasoning among learners. In addition, its inclusion in the school curriculum as a compulsory subject until a certain level of schooling is justified by its utilitarian value. Hence, the content knowledge that comprises the school mathematics curriculum is shaped by the purposes it serves. The canonical school mathematics curriculum, a result of curriculum developers in one educational system simply copying what is being done in another, was developed in Western Europe in the aftermath of the Industrial Revolution. This curriculum was adopted practically in every country during the twentieth century (Howson and Wilson, 1986). The adoption was either voluntary or via colonization.

Over the span of the last two centuries although the content of the school curriculum has expanded to meet the changing needs of society, in the deeper structure with reform mostly confined to surface structure (Kilpatrick, 1996). The Trends in International Mathematics and Science Study (TIMSS) 2007 Assessment Frameworks (Mullis *et al.*, 2005) is an illustration of how core mathematical knowledge is globalizing. In the 2007 study 50 participant countries exhibited enough concurrence of curriculum that allowed the testing of the same basic mathematical (and science) content knowledge at certain grade levels.

Despite its structural stability, school mathematics curriculum has made two significant shifts in emphasis: one during the 1950s and 1960s known as the era of new mathematics and one from the 1980 onwards known as the era of problem solving. The era of new mathematics brought to many countries greater efforts to attract students to the study of mathematics by emphasizing its abstract structures with the hope and expectation that they would understand and appreciate mathematics more if they could see the simplicity and elegance of its laws (Kilpatrick, 1996). The impetus for the new mathematics era was the successful launching of Soviet Union's first artificial satellite into orbit around the Earth on 4 October 1957. The launch of Sputnik and the apparent Soviet lead in rocket technology disturbed many politicians and academics in the West. Consequently, political decisions translated into school curricula initiatives resulting in the new mathematics era. A major consequence of the political imperative was a desire to see the nurturing of budding scientists and mathematicians in the classroom.

The era of problem solving essentially emphasized the acquisition of mathematical knowledge to solve nonroutine

problems or doing realistic mathematics through applications, modeling, and mathematization (De Lange, 1996). This emphasis stemmed from the need to prepare students to be competent citizens for democratic life as opposed to qualifying for the future workforce (Keitel, 1993). A further development of the problem-solving era has been mathematical literacy as a goal of school mathematics curricula. Through the implementation of a differentiated curriculum for a diverse range of learners, intended so that all students could have access to the basic content knowledge deemed necessary for competent citizenship, attempts have been made to address equality and equity issues. Hence many of the issues related to the content knowledge of mathematics in curriculum development stem from the aims and objectives of teaching the subject rather than the body of content knowledge *per se*. For example, Wagner and Parker (1993) proposed the need to reconstitute the algebra curriculum by changing the emphasis from doing to thinking to meet the needs of knowledge-based economies. Similarly, two central issues that affect the geometry curriculum are; what geometry to teach at the respective year levels of schooling so that students are able to make sense of it, and, the debate about proofs in school mathematics. Advances in technology such as the advent of calculators (performing simple mathematical techniques to complex scientific and now graphic technologies) and the availability of technological tools such as computer graphics in the mathematics classroom have also had an impact on the emphasis of the content.

Curriculum development in mathematics may be addressed at three main levels: the intended, the implemented, and the attained. This article focuses on four aspects of the intended and implemented curriculum. They are curriculum selection – what guides the choice curriculum development and revision – how development may be done and what process of revision is followed, curriculum implementation – a consequence of how it was developed and what the different models of implementation are, and curriculum reform – some examples and their impact on mathematics education. Wherever necessary, relevant examples will be cited.

Curriculum Selection

Curriculum selection: What guides it? This phase usually precedes the initiation one. According to Howson *et al.*

(1981), curriculum development may be initiated for one or several of the following reasons:

- *Societal and political.* Economical and technological development, often result in reconsideration of education for larger or diverse groups and also education for specific desired outcomes which may be related to workforce requirements.
- *Mathematical.* Mathematics content knowledge is constantly evolving and, therefore, its implications are often addressed at the school level.
- *Educational.* The emergence of new theories of learning together with the advent of new technological aids and apparatus may result in reconsideration of some aspects of the curriculum.
- *The rewards of innovation.* A constant need to review and revise curriculum to keep abreast with world trends and also experiment may lead to attempts at innovation, thereby resulting in curriculum development.

The initiation phase would result in establishing guidelines for the need to develop curriculum, be it revision of a present curriculum or creation of a new curriculum. The selection of curriculum inevitably would be guided by a set of clear aims. Aims are expressions of intent, and intentions belong to groups or individuals. Therefore, who contributes to the aims would naturally be responsible for the direction of the intended curriculum.

Two dominant philosophical views influence what curriculum should look like: the traditional and the progressive views (Doll, 1996). The traditionalist view maintains that what has been done in the past has been done well and thus must be kept in the future. The progressivist view pleads to look at curricula more critically to see what can be done differently to enhance learning. These two views are, to a certain extent, manifested in mathematics curriculum development. Curricular reforms generally come slowly because of the resistance of traditionalists who do not wish to shake up old ways to welcome in new ideas or perhaps find the reforms difficult to implement. For example, in the Philippines, it took many years before mathematics curriculum specialists agreed to include probability in the elementary mathematics curriculum despite the numerous recommendations from studies to teach basic and intuitive concepts of probability.

How does one select curriculum? In several countries, such as Singapore, Malaysia, Hong Kong, and the Philippines, school mathematics curricula were adoptions of mathematics curricula of countries that ruled them at some point in their history (Wong *et al.*, 2001). In the case of Singapore, Malaysia, and Hong Kong, the curricula were adopted from Britain and in the Philippines it was adopted from America. Initially, these countries mimicked everything about the curricula; syllabi, textbooks, and assessment practices but gradually revised it in light

of their own needs and their changing positions in the increasingly globalized environments.

Much of the selection also has to do with the educational goals of a country. For many countries, these national goals are articulated in a document that government leaders and concerned educators prepare. The document helps mathematics teachers and educators focus on the educational goals. Culture also plays an important role in the selection of curriculum contents. This explains the different focal points in the mathematics curricula. For example, the Chinese-Confucian-influenced countries value public mathematics examinations and, as a result, examinations are a big part of their curricula.

Curriculum Development and Revision

There is no single way to develop and revise mathematics curricula. Countries follow their own curriculum development processes. In some, this includes a time frame. It may also either be process oriented where teachers take on the role of creators or product oriented where teachers take on the role of consumers. The role of the teacher in official curriculum development projects is shaped by beliefs as to who can and who should determine the curriculum.

Most countries set a period during which they study the current mathematics curriculum and its effectiveness according to the established national goals and standards for school mathematics. Asian countries, such as Japan, China, Singapore, and South Korea, are known to have established periods of curriculum reform. Japan, for example, follows a 10- to 12-year cycle during which their mathematics education curriculum leaders assess the goals of mathematics education and the implementation of the curriculum for that period (Nebres and Vistro-Yu, 1998). Until recently Singapore also followed a 10-years cycle, but in 2000 Singapore's Ministry of Education (MOE) decided that in order to remain relevant in a fast-changing world, the school curriculum should be reviewed every 7 years.

Following are two examples (or case studies), which compare the curriculum development and revision processes in Singapore and the United States. Exhibit A is an example of a curriculum development process which is engineered and carried out by a government body, the MOE, to produce a curriculum which is tightly aligned with the aims and goals of the nation's education system and also its socio-political goals. The curriculum developed is used in all schools and the implementation is also facilitated by the ministry. Exhibit B is an example of a curriculum development process which is undertaken by a professional body with inputs mainly from teachers, researchers, and mathematicians. In theory the curriculum development is only a guide, the adoption is left up to the different state systems to meet their specific needs.

Exhibit A: Curriculum Development and Revision in Singapore

Curriculum development in Singapore adopts the center → periphery model (Howson *et al.*, 1981) where a group of competent mathematics specialists, who are mathematics teachers seconded to the Ministry of Education's Curriculum Planning and Development Division (CPDD), engineer the entire process with inputs from all significant stakeholders. Being part of the school curriculum, the mathematics curriculum is naturally aligned with the aims and objectives of education in Singapore and also the desired goals of education for all students in the system. Mathematics is a compulsory subject at the primary (grades 1–6 corresponds to ages 7–12 years) and secondary (grades 7–10 corresponds to ages 13–16 years) levels. The curriculum is differentiated to meet the needs of students of differing abilities. The MOE issues the syllabus for the primary level and also for the lower secondary level (grades 7 and 8). Students take the Singapore-Cambridge Examinations at the end of their secondary schooling and therefore the syllabus for upper secondary levels (grades 9 and 10) are issued by the examining body in consultation with the MOE. The curriculum development and review process is the same for all the different courses of school mathematics.

The curriculum development process is set in motion by the setting up of a Mathematics Syllabus Review Committee comprising of a chair from the CPDD and members from the CPDD, Singapore Examinations and Assessment Board (SEAB), polytechnics, institutes of technical education, the National Institute of Education, and universities. The terms of reference guide the review and revision. Wong (1991) stated that in 1988 the terms of reference were, “To study the adequacy of the syllabuses

in meeting the needs of the pupils and to revise the syllabuses to reflect appropriate recent trends in mathematics education” (p 155).

Feedback gathered about the curriculum – be it anecdotal, or through research carried out by officers of the CPDD, or the Centre for Research in Pedagogy and Practice (CRPP) at the National Institute of Education – provides areas that require attention and revision. This feedback provides the committee with leads for verification and further exploration. At the start of the process, the committee would decide on the ways and means to gather information in a rigorous manner. Data collected provide the basis for decision making in due course. Some activities the committee may carry out to gather data include designing questionnaires and gathering feedback from heads of departments and teachers, organizing focus group discussions with teachers and pupils, and analyzing pupils' performance in national examinations and international studies such as TIMSS. The committee also studies reviews of mathematics curricula of other countries such as those in Europe, East Asia, the United Kingdom, as well as the United States and Australia. Feedback is also obtained from tertiary institutes such as polytechnics and the universities about the adequacy of the syllabi in preparation for future studies.

During the meetings, the data collected are reviewed and implications discussed. The aims and objectives of the curriculum under review are reexamined and aligned with educational policies and initiatives resulting in changes made to the mathematics content of the syllabus as well as the suggested pedagogy. Since 1990 the framework of Singapore's mathematics curriculum has mathematical problem solving as its primary goal, with five explicit contributory factors as shown in **Figure 1**. The framework

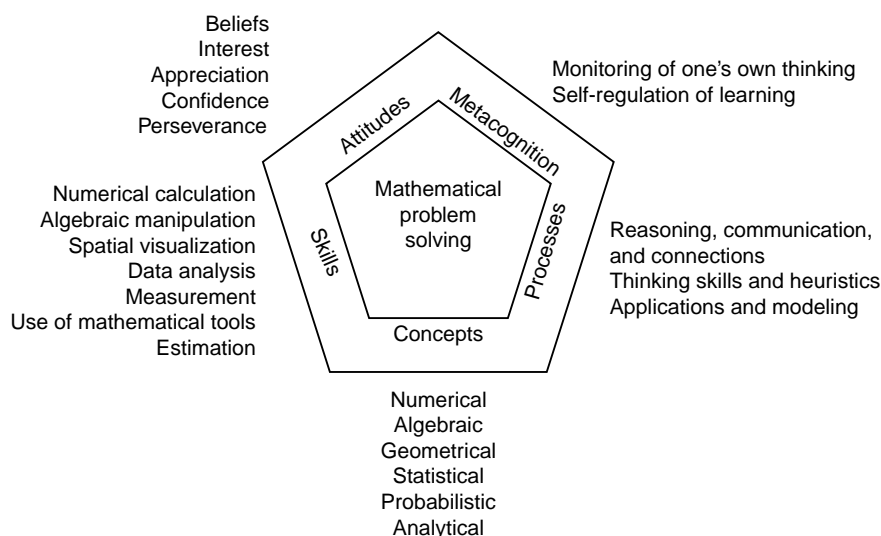

Figure 1 Framework of school mathematics curriculum (MOE, 2006).

Figure 2 Approval seal.

is also updated during the revision. The process of reviewing and revising the curriculum usually takes about a year. Once the revision is completed, the intended curriculum, which mainly is in the form of syllabus documents, is complete.

In Singapore, textbooks are produced commercially. When the revision of the syllabi is complete, the CPDD calls for expressions of interest to produce textbooks from the commercial sector of the economy. After an initial submission of sample chapters, the successful parties are guided very closely by the CPDD officers in the production of the textbooks. Only textbooks with the approval seal as shown in **Figure 2** may be used by schools.

Exhibit B: Curriculum Development and Revision in the United States

In the United States no single government agency controls grades K-12 public education at the national level. Authority for most educational decisions lies with education agencies in the 50 individual states, who in turn share decision making with the 14 883 individual districts contained within the United States. Hence, each district operating under its own authority and various state laws sets standards, designs delivery programs, and provides financial support for its own mathematics-education program. The guidance that states provide to their schools also varies. All states, with the exception of Iowa, provide schools with curricular frameworks for mathematics in required programs of study.

Two bodies, the National Council of Teachers of Mathematics (NCTM) and the United States National Commission on Mathematics Instruction (USNCMI), have significant influence on the school mathematics curriculum across the United States. NCTM is a professional body of teachers of mathematics founded in 1920 dedicated to improving mathematics teaching and learning from kindergarten to high school. It facilitates ongoing dialog and constructive discussion with all stakeholders about what is best for the nation's students. The USNCMI facilitates

the participation of the United States at the international level in mathematics activities and through the National Science Foundation (NSF), NCTM, and the Conference Board of the Mathematical Sciences advance mathematics education at the national level.

NCTM has been active in the curriculum development of school mathematics since its inception but in 1985 it began the process that led to three significant documents on curriculum and evaluation (NCTM, 1989), teaching (NCTM, 1991), and assessment (NCTM, 1995). Dossey and Usiskin (2000) claimed that although throughout the twentieth century various groups had made suggestions relative to what the US school mathematics curriculum should look like, none combined the scope and detail of these three documents. In 1989 NCTM produced the Curriculum and Evaluation Standards which provided a listing by grade level bands (K-4, 5-8, 9-12), of the mathematics that students should know about. These included problem solving, reasoning, communication, connections, and various content aspects of mathematics relevant to those grade levels. Similarly, no previous document had described teaching in as much detail as the 1991 document, the Professional Standards for Teaching Mathematics. The teaching standards asserted that concepts, procedures, and relationships were best developed in contexts that warranted students to develop knowledge themselves under the guidance of the teacher and to engage in discourse about the knowledge. Correspondingly, in 1995, the Assessment Standards for School Mathematics reflected a deeper understanding called for in the curriculum and its teaching through multidimensional assessment methods.

The visibility of the above standards led to a greater interest among groups within the mathematics and mathematics education in the revision that began in 1995 and culminated in the release of the Principles and Standards (NCTM, 2000) in April 2000. During the revision phase, NCTM solicited feedback from individuals and organizations by first developing a draft of the Principles and Standards and then holding a nationwide year of discussion on the draft. This process enabled them to consider all feedback and revise the Principles and Standards accordingly.

The Principles and Standards (NCTM, 2000) are guided by six principles. They are:

1. equity – excellence in mathematics education requires equity, that is, high expectation and strong support for all students;
2. curriculum – it must be coherent, focused on important mathematics, and well articulated across the grades;
3. teaching – effective mathematics teaching requires understanding what students know and need to learn and then challenging and supporting them to learn it well;
4. learning – students must learn mathematics with understanding, actively building new knowledge from experience and prior knowledge;

5. assessment – assessment should support the learning of important mathematics and furnish useful information to both teachers and students; and
6. technology – technology is essential in teaching and learning mathematics, it influences the mathematics that is taught and enhances students' learning.

Despite all that goes into developing a sound and rigorous school mathematics curriculum by NCTM, it remains as a resource and guide for the nation. At the state level, although all states set graduation guidelines, they differ in the extent to which they set curriculum guidelines for mathematics and the steps they take to ensure that the curriculum is implemented. Within states, local school districts make the decisions regarding which materials to use. Some states have textbook adoption practices, while others do not where the teacher is free to use any materials he or she deems suitable.

Curriculum Implementation

The teacher is the mediator between the curriculum and the child, and any attempt to change the curriculum must consider the teacher's role. Teachers can be implicated in curriculum development in two related ways; as participants in the process or as users of the product. In Japan, curriculum implementation uses both the top-down and bottom-up approaches (IFIC and JICA, 2004). The top-down implementation consists of three stages. The first stage is when the MOE publishes commentaries on the Courses of Study (COS). The second stage is when lectures are given by subject examiners to expound and explain the published commentaries to the users of the COS. The third stage is when guidelines for the teaching of the COS are disseminated to teachers through guidance documents. The bottom-up approach of curriculum implementation is essentially of three types: administrative leadership type, autonomy type, and the textbook publishing company intervention type. An example of an administrative-leadership-type approach is when research is conducted among designated schools and the results are made public to encourage and inform other schools of the effectiveness, perhaps, of the new curriculum. An example of the autonomy type is when collaborating persons such as teachers who understand fully the revised curriculum become key persons and leaders who would conduct research on teaching methodology and other topics that move the curriculum implementation forward. An example of the textbook publishing company intervention is when textbook companies ask teachers who have deep understandings of the revised curriculum to write textbooks or teaching guides that provide a fresh perspective of the methodology and contents of the revised curriculum.

The Fife Mathematics Project of Scotland in the 1960s as described by Howson *et al.* (1981). Approaches for curriculum implementation may be top-down, bottom-up or both. The roles of teachers in each of these may be distinct. The example from Japan illustrates the roles of the teachers in both a top-down and bottom-up approach. In contrast the Fife mathematics project highlights the role of teachers in a bottom-up approach.

Curriculum Reform

Curricular reforms may result from innovative projects or well-researched documents of school mathematics. Some of these curricular reforms have made tremendous impact. The Realistic Mathematics Education (RME) project is an example of a sustained reform in school mathematics curriculum. Developed by researchers at the Freudenthal Institute the theoretical framework of the project is guided by the didactical belief propagated by Hans Freudenthal. Three tenets of mathematics characterize the framework:

1. the starting points of instructional sequences should be applications experientially real to students;
2. the starting points should also be justifiable in terms of the potential endpoints; and 3. instructional sequences should involve activities in which students create and elaborate symbolic models of their informal activity (De Lange, 1996: 60–61). The success of this curricular reform can be seen not only in the Netherlands but also through the adoption of RME in many other countries around the world.

The open-ended approach of teaching mathematics (Becker and Shimada, 1997) that started in Japan in 1971 has also sustained its momentum in Japan as well as made its way into classrooms around the world. This method engages students in mathematical thinking through instructional activities that promote varied problem-solving approaches. The Agenda for Action, a position paper by NCTM released in 1980, is an example of a well-researched document that brought to the forefront the need to prepare students in mathematics classrooms to be problem solvers. This document initialized change around the world with one country after another emphasizing mathematical problem solving in their curriculum.

Curricular reforms may arise from global trends in mathematics education. The 1989 publication of the Curriculum and Evaluation Standards in mathematics by NCTM certainly led to many more countries articulating their intended curriculum in the form of standards. The years following the first publication of the Curriculum and Evaluation Standards documents saw how countries such as Australia, New Zealand, Canada, and Singapore followed suit. The Philippines recently put out the working

draft of its own Curriculum Framework and Teacher Education Framework in mathematics. A more recent mathematics reform has been created by the consistently high performance of Singapore's students in the TIMSS – 1995, 1999, and 2003. For example, Israel and parts of the United States have adopted Singapore's school mathematics curricula, in particular, textbooks used in schools, thereby engaging in reform of mathematics curriculum.

Glossary

Models-based instruction – A means of aligning subject matter and teaching styles with learning outcomes. Examples of instructional models in physical education are sports education and teaching games for understanding.

The development of the curriculum for physical education has tended to be most strongly influenced by local forces within state and national educational systems. This feature has led to much unevenness in the forms of physical education that exist in countries around the world. Nevertheless, there have been some commonalities of curriculum development that can be grouped around three main trends: a trend toward national and state curricula, where physical education has been caught up in developments affecting the school curriculum as a whole; a trend toward examination and matriculation in physical education in the middle and later years of secondary schooling; and a trend toward the construction, implementation, and increasingly widespread dissemination of a models-based approach to instruction, incorporating a number of specific pedagogical or instructional models.

The initial impetus for each of these trends dates to the 1970s and a time when internationally physical education had begun to take shape as a multi-activity, sports-based curriculum. This multi-activity form of curriculum was the outcome of a dramatic shift that took place in the years immediately following World War II, a shift that overturned some 50 years or more of domination of the curriculum of physical education by various forms of gymnastics, at least within systems of state-provided education. In some countries, such as England, sports were played in schools serving the social elite from much earlier than the 1950s, although there is some dispute over whether these activities might properly be referred to as physical education.

This article considers the selection, development, and implementation of the curriculum of physical education. It focuses particularly on how each of the three trends – national and state curricula, examination in physical education, and models-based instruction (MBI) – provide contexts for the development of particular versions of physical education. In each case, the forms of physical

education curricula that result inevitably signal the perceived worth of some knowledge over other knowledge in, through, and about physical education.

National and State Curricula

The emergence since the mid-1970s of state curricula in a number of countries, including Australia, England and Wales, New Zealand, Scotland, Canada, and Ireland, has had important consequences for curriculum development in physical education. Although the original rationale for these developments is not always made clear, it would appear that most rest on a version of the core curriculum concept advocated by writers such as Dennis Lawton and Malcolm Skilbeck, which itself drew heavily on the educational philosophizing of Richard Peters and Paul Hirst. The core curriculum was intended to encapsulate the essential learning that all young people should experience during the compulsory years of schooling.

In the United States, Rink and Mitchell (2003) argue that physical education has most often been excluded from state educational reforms, damaging, in the process its credibility as an educational activity and further confirming its marginalization in the school curriculum. Elsewhere, physical education has been included in state curriculum reforms, with varying outcomes.

For example, Scottish educational reforms for the curriculum of years 3 and 4 of secondary schools, published in the report of the Munn Committee (Scottish Education Department, Consultative Committee on Curriculum, 1977), drew explicitly on the core curriculum concept, and provide a vivid example of the significance of such developments for physical education. The first of two rounds of national examinations (the ordinary grade) were typically taken in year 4 at age 16. Curriculum reform in years 3 and 4 which supported these high-stakes examinations was therefore controversial. In this context, as a nonexaminable, practical, and as the report of the Munn Committee described it, “non-cognitive” subject (Scottish Education Department, Consultative Committee on Curriculum, 1977), physical education’s place in the core curriculum was not guaranteed. Scottish physical educators of the time were much exercised over the prospect that students could cease to participate in their subject after year 2, at age 14 (Scottish Education Department, Consultative Committee on Curriculum, 1977).

The arguments presented to the Munn Committee during its review of the curriculum provided competing and alternative views of physical education, one humanities based and sponsored primarily by women physical educators, and another science based and supported primarily by men. The Committee was eventually persuaded by the men's arguments and a science-based physical education gained a place in the compulsory curriculum of years 3 and 4, an outcome that irrevocably damaged the humanities-based form.

In a review chapter, Penney (2006) argued that studies of state curriculum reforms, such as the National Curriculum developments in England and Wales and the development of a national framework of curriculum Statements and Profiles in Australia, have provided evidence of a number of common trends in the development of physical education. She notes that in the process of producing curriculum texts such as syllabi, a range of competing interests and multiple discourses is exposed. The reform of physical education in England was impacted by interest in sporting excellence, reducing childhood obesity, developing socially valued behaviors that could transfer to other settings, such as work, and combating antisocial behavior. In a similar vein, there were claims in New Zealand that reforms of physical education aspired to inoculate young people against the risk of drug use, alcohol abuse, low self-esteem and stress, sexual activity, and spiritual decline.

At the same time, Penney (2006) argues that these competing interests are shaped through the curriculum construction process to support broader government agendas, thereby revealing the power relations at play in the development of curriculum. A study of the writing of the National Statement and Profile for Health and Physical Education in Australia illustrated how the selection of the writing team, their remit, the processes of consultation, and timescales all worked to produce a particular curriculum. Penney and Evans (1999) suggest that the careful selection of pro-sports members of the first National Curriculum committee in England and Wales produced a form of physical education that sought to restore sport's place at the center of the subject.

As Penney (2006) notes, while these common trends are discernable across countries and educational systems, there are also important cultural specificities that militate against casual generalizations, for example, the enduring prominence of traditional team games in the England and Wales National Curriculum, and also, almost paradoxically, the assertion and inclusion of a distinctive Welsh culture as the curriculum is applied in Wales. In Australia, during the early to mid-1990s, subject areas were radically recast as key learning areas (KLAs), with physical education finding a home in the Health and Physical Education KLA alongside nutrition and home economics, health, ethics, and religious studies. As the National Framework of Statements and Profiles for KLAs were reworked within state

education systems, considerable differences appeared in terms of the selection of subject matter and its various combinations. Meanwhile, in New Zealand during the late 1990s, distinctively different Maori and Pakeha conceptions of health had to be reconciled in the construction of the Health and Physical Education curriculum.

Examination and Matriculation in Physical Education

Formal examinations first appeared in secondary school physical education in the 1970s in England and Australia, initially at the end of the compulsory stage of schooling at age 15 or 16, and later at the post-compulsory stage (up to age 19). The post-compulsory examinations in both England and Australia and later in Scotland and New Zealand could be counted toward university entrance or matriculation. The arrival of examinations in physical education can be attributed to a confluence of factors, key among them were state-level initiatives to modernize the secondary school curriculum, on the one hand, and on the other the growing academicization through the 1960s and 1970s of physical education in higher education which fueled the ambitions of physical educators to reduce their perceived marginality in schools and to protect their subject from exclusion (Carroll, 1994).

Formal examinations were not, necessarily, welcomed by all members of the physical education communities in these countries, and there was through the 1970s and 1980s, at times, a vociferous debate centered on their necessity and their likely impact on physical education programs at other stages of schooling. A particular concern was that participation in practical physical activities such as games, sports, swimming, and gymnastics – subject matter that was the mainstay of secondary school physical education programs from the 1950s to the 1980s – would be replaced by classroom-based, theoretical study of sport and human movement.

This debate did little to halt the spread of formal examinations which, by the early 1990s, were well established in England and Wales, in the Australian states of Queensland, New South Wales, and Victoria, and in New Zealand. By the end of the 1990s, Green (2005) reported that examination and matriculation in physical education in England and Wales was the second fastest growing subject in the secondary school curriculum at a rate for an A level of 57.4% between 1997–98 and 2002–03, compared with 6.9% for biological sciences over the same period. Similar growth was observed in Queensland and other Australian states, while examinable physical education appeared for the first time in the curriculum of Scottish secondary schools in the 1980s, followed by a matriculation-level syllabus in the early 1990s. More recently in Ireland, a syllabus for matriculation in physical

education has been developed and may soon be implemented as part of the Leaving Certificate.

This substantial growth can be attributed in large part to the continuing influence of the two factors that lead to the introduction of examination for physical education in the 1970s. The liberalization and broadening of the secondary school curriculum in these countries has occurred as governments have sought to entice young people to stay at school beyond the compulsory leaving age by offering interesting or attractive subjects for study. The continuing and powerful growth of the field of physical education/sport and exercise science/kinesiology has also been a significant driver of developments of the secondary school curriculum. It is around this latter source of influence in particular that debates within the physical education community have continued, despite the growth and popularity of the subject.

A major point of debate among physical educators has centered on the shift, predicted by early opponents of examination and matriculation in physical education in the 1970s away from engagement in practical physical activities and toward classroom-based theoretical study. During the 1990s, at least one examination board in England and Wales offered an advanced level (A level) version of physical education that required no participation in physical activity at all. At the same time, this trend away from practical knowledge has not been universal. In England and Wales, revisions to A-level specifications required all four examination boards to include engagement with practical physical activities as a necessary component of syllabi. In Queensland, during the mid- to late 1990s, the integration of theoretical and practical knowledge was a guiding principle in the construction of assessment tasks in the Senior Physical Education program.

A second and equally troublesome issue for some contributors to the debate has been an apparent scientization of the physical education curriculum. In the late 1980s, Fitzclarence and Tinning (1990) became involved as writers of the Victoria Certificate of Education physical education curriculum in introducing a socially critical dimension to the subject to counteract what they saw as its dominance by biophysical science knowledge. A study of the Scottish Higher Grade Physical Education also noted the absence of any social science material in the syllabus. In another study of Senior Physical Education in Queensland, researchers found that the curriculum required equal amounts of time to be spent on psychological, biomechanical, physiological, pedagogical, and socio-historical subject matter, while there was a wide range of sports, games, and other physical activities from which schools could choose to construct their programs.

Models-Based Instruction

Metzler (2000) identified an important trend in the selection, development, and implementation of curriculum of

physical education, starting in the 1970s, which he conceptualized as MBI. MBI involves the statement of outcomes for learning and then the selection of teaching styles and subject matter which will facilitate the realization of these outcomes. Central to this concept of MBI is the interdependence and alignment of learning with teaching styles and subject matter. In elaborating this concept, Metzler was building on over 20 years of development of specific forms of MBI, including sports education (Siedentop, 1994), Teaching Games for Understanding (TGfU; Bunker and Thorpe, 1982), personal and social responsibility (Hellison, 1995), and health-related exercise (Whitehead and Fox, 1983), among others.

Of these models, the development and implementation of Sports Education (Wallhead and O'sullivan, 2005) and TGfU (under various nomenclature) (Oslin and Mitchell, 2006) have been the most widely researched, although the development and implementation of the others listed above have begun to be informed by a substantial research literature. Each of the models uses some form of organized physical activity as its subject matter, although with different learning outcomes in mind facilitated by a variety of teaching styles, in various combinations.

Sports Education

Sports education originated in the work of Daryl Siedentop and colleagues affiliated with the Ohio State University (Siedentop, 1994). The impetus to develop sports education came from Siedentop's dissatisfaction with the ways in which multi-activity physical education had from the 1950s through the 1980s offered young people a generally superficial and fragmented experience of sport. The principal aim of sports education is to develop young people as competent, literate, and enthusiastic sportspeople (Siedentop, 1994). In order to achieve this outcome, sports education requires the physical education unit of the curriculum to be recast as a sports season, with the following selected features of sport:

- sports education operates in seasons of length considerably longer than most physical education units, between 8 and 16 lessons;
- players are on teams and stay on that same team as a persisting group for the entire season, in order to promote affiliation and membership;
- seasons are bounded by formal competition, which is interspersed with student-directed practice sessions;
- there is a culminating event to mark the conclusion of each season, which includes festivity;
- there is extensive record keeping and collection of information; and,
- in addition to experiencing the role of players, learners also take on additional roles such as team coach, referee, equipment officer, record keeper, timekeeper, team captain, warm-up coach, journalist, and sports panel member.

The earliest documented research on sports education in school physical education appeared in the early 1990s. In addition to the United States, sports education has been studied extensively in New Zealand and Australia, and has recently attracted some attention in England. Sports education has been examined at primary, secondary, and undergraduate levels and with specific attention to low-skilled pupils, high-skilled learners, and at-risk pupils.

While games have tended to provide the activity context, there are examples of sports education units using gymnastics, dance, volleyball, softball, and athletics. Kinchin's (2006) review suggests that sports education has promoted breadth and balance in the physical education curriculum, with more recent studies reporting the use of bicycle safety and outdoor adventure activities. He also notes evidence from research studies to suggest that sports education is popular with students since they develop an affiliation with their team over an extended period of time, that the additional roles promote ownership, responsibility, and accountability for learning, and that competence develops across the ability range. Some teachers are reported to have found some difficulty in adapting their teaching styles to suit sports education, while others have over time embraced the facilitation style required by this model.

Kinchin also notes the development of variations of sports education, including empowering sport which sought to incorporate elements of personal and social responsibility, cultural studies which aims to question assumptions and values in sport, Sport for Peace, developed for urban schools in the USA and aimed at conflict resolution and fostering personal and social responsibility, and sports education as situated learning, which has been concerned with the authenticity of the experience sports education provides, and possibilities for transfer of learning.

Teaching Games for Understanding

Most of the game-centered approaches to teaching physical education have their origins in the work of Bunker and Thorpe (1982) on TGfU at Loughborough University. Bunker and Thorpe (1982) argued that too much games teaching, at the time they were writing, aspired to develop techniques ahead of learning to play the game. They developed a model that placed the learner and the modified game at the center of the curriculum, with the modified game forming the context in which game appreciation, tactical awareness, decision making, and skill in execution could be learned. In addition to providing a basis for a new form of MBI, Bunker and Thorpe's original work inspired the construction of various systems of classifying games in the curriculum, and variations on their model such as the Tactical Games Model, Play Practice, Game Sense, and developments of the Bunker–Thorpe

model itself (Oslin and Mitchell, 2006). Research interest in new approaches to games teaching and coaching has also generated new models in France and Francophone Canada and in Germany.

The earliest studies of TGfU and its derivatives sought to compare the game-centered model with technique-led approaches to games teaching. Rink *et al.* (1996) noted that this research reported positive learning outcomes for students using TGfU. The most powerful finding across the studies reviewed by Rink *et al.* (1996) was that students taught from a TGfU perspective tended to perform better on tests of tactical knowledge than those taught from a technique-led perspective. Some studies suggested that a TGfU approach may be perceived by students to be more enjoyable than the technique-led approach, and so students may be more highly motivated to participate. Reviewing 13 studies carried out between 1995 and 2003, Oslin and Mitchell (2006) reached similar conclusions, noting that until 2001 all studies sought to measure skill development, game performance, and a variety of other variables such as decision making, motivation, and knowledge, and were informed by an information-processing theoretical perspective.

Rink *et al.* (1996) also noted that, despite some positive findings, the earlier studies reviewed could not provide conclusive support for TGfU over technique-led approaches, a complaint echoed by Oslin and Mitchell (2006). Both sets of authors argued that this was due to different research designs, which made comparisons difficult because studies varied according to the game chosen, the age of participants, the length and nature of the intervention, the variable chosen for investigation, and the ways in which these variables were measured.

Since the late 1990s, research on TGfU and its derivatives has eschewed comparative study designs and has instead adopted naturalistic designs to investigate how teaching experiments and other interventions impact on teaching and learning (Oslin and Mitchell, 2006). These more recent studies have adopted multiple theoretical perspectives, including cognitive, ecological, and situated learning approaches, and have tended to be concerned with cognition, knowledge, and game performance (Kirk and MacPhail 2002; Rovegno *et al.*, 2001).

Oslin and Mitchell (2006) report on two other lines of research relating to TGfU and its derivatives, one focusing on how teachers (predominantly) have responded to this model, and the attempts to measure game performance. In the former, they identify a trend in the reports of studies that found initial resistance to TGfU and other game-centered approaches from practicing teachers and student teachers, to growing acceptance once the model had become familiar. In the latter, they review the development of two instruments, the Game Performance Assessment Instrument (GPAI), developed by Oslin *et al.* (1998), and the Team Sport Performance Assessment

Instrument (TSPA), developed by Grehaigine *et al.* (1997), and conclude that the instruments have the potential to provide a better appreciation of the complexity of game performance, with application perhaps more appropriate to elite levels of performance.

Conclusion

This analysis of the selection, development, and implementation of the curriculum of physical education suggests the trends toward national and state curricula, examination in physical education, and MBI have resulted in some common features across countries and contexts, and some variation in what counts as physical education.

While the trend toward examination and matriculation in physical education would seem to be strongly supported by student interest, making the study of secondary school physical education in some countries one of the most popular school subjects, this form of physical education curriculum nonetheless presents some challenges to the notion that physical education is a form of practical knowledge requiring participation in physical activities. Developments of national and state curricula show least uniformity across countries and seem to be most affected by local forces within education systems and initiatives to reform the school curriculum. The trend toward MBI is by far the most fluid factor influencing curriculum development in physical education, existing as it does outside the jurisdiction of official curriculum authorities, and supported by a strong research base.

There is little evidence of rational curriculum planning in any of these trends, even those directed by government agencies. At the same time, there is clearly no shortage of ideas for developing physical education. We might conclude from this observation that the selection, development, and implementation of the curriculum is a process of socially constructing physical education, in which ideas of physical education and their practice reflect particular and somewhat different configurations of values.

Glossary

Information communication technologies (ICTs) –

ICTs provide access to the Internet and its associated digital literacies, navigating the Web, multimedia, and so on.

Inoculation approach – The misinformed notion that provide reading instruction in the primary grades is sufficient for older readers' comprehension of subject-matter texts.

Subject-matter – The curricula and content areas, such as science, social studies, mathematics, and English language arts.

The reading curriculum for the primary-school-emergent readers and older elementary/middle-grade readers divides roughly at grade 3 (approximately age 9) in many countries (e.g., Canada, Chile, China, Malaysia, Nigeria, and the United States), though not all (e.g., Poland and Switzerland, where primary school ends much later). The rationale in selecting grade 3 as the dividing point between primary and elementary/middle grades reading rests largely on Barr's (2001) review of the research on teaching reading, which distinctly divided developmental beginning-reader issues from other issues in comprehending more complex texts in the upper grades. This divide, however, does not signal support for the cliché that first children learn to read and then they read to learn. Separating the act of reading from one of its functions – reading to learn something – makes little sense. Developmentally, emergent readers are different from skilled readers, but the difference lies more with the subject-matter materials than with the groups' purposes for reading.

Primary Reading

Curricular divisions in primary reading, especially where alphabetic languages dominate, tend to center on decoding and comprehension. This rather arbitrary divide between deciphering print and meaning-making masks two other aspects of reading. The first is concepts of print, a set of fundamental but complicated understandings about how print works in the world. An emergent reader demonstrates concepts of print by holding a book correctly, directionally

tracking print, knowing how to turn the page of a text, and other such behaviors that may seem obvious to more experienced readers but are basic to more advanced understandings of print. The second is fluency. A fluent reader comprehends texts of various types with speed, accuracy, and appropriate expression, similar to how a coherent speaker uses phrasing, tonal, rhythmic, and pacing conventions to communicate orally. When fluency is emphasized over meaning-making activities in the curriculum, students often become word callers rather than readers for comprehension.

Decoding typically points to two curricular areas of beginning reading: phonemic awareness and phonics. Phonemic awareness requires being mindful of the smallest units of sound that allow speakers of a language to differentiate among words (Snow *et al.*, 2005: 68). The primary reading curriculum includes activities involving alliteration, rhyming, and listening for sounds that make up a word (e.g., /b/ and /a/ and /t/). For the most part, these activities do not include matching sounds to letters or phonemes in print; they are usually restricted to the level of auditory and oral awareness. Phonics instruction, however, is the educational move from sound to letter-sound correspondences. These correspondences can be at the letter, phoneme, onset/rime, and word levels. Although phonics emphasizes sound and letter patterns, it is necessary to acknowledge the times when those patterns do not apply. For example, in the English language, approximately two-thirds of the words do not follow expected patterns.

Comprehending a text requires background knowledge and vocabulary. Although theoretical differences exist as to the source of meaning in a text, in the primary grades, reading comprehension is typically defined as “the process of simultaneously extracting and constructing meaning through interaction and involvement with written language” (RAND Reading Study Group, 2002: 11). One theory posits that the meaning of a text lies in the print that is on the page, and the reader is called to discover the meaning presented by the author. Another holds that a personal meaning of the text is constructed by the reader. Still another maintains that meaning is created as a transaction among the author, the reader, and their surrounding contexts. Underlying all of these theories is the assumption that a reader brings relevant background knowledge to the task of comprehending. When such knowledge is incomplete or when it departs radically from an author's intended purpose, a reader's comprehension will also be incomplete (Pearson *et al.*, 1979).

Curricular concerns related to vocabulary development at the primary grade level are well founded. When common words that most children know and use daily take on specialized or technical meanings in subject-matter classes, they can cause confusion and lead to problems in comprehending information. Consider for example, the common word *table* and its specialized meanings (a water table, a multiplication table, to table a motion, and so on). Children learn words through independent reading, listening to texts and oral language, direct instruction of specific words, context clues, and morphemic cues. Estimates of the number of words beginning readers need to know vary greatly. The range can be large (e.g., between 2562 and 26 000 words for first graders) and can also vary according to a family's socioeconomic status (White *et al.*, 1990).

Issues in Primary Reading

Policy has increasingly affected curriculum at the national, regional, and local levels. For example, the United Kingdom's National Literacy Strategy introduced in 1997–98 promoted a reading model that assumed a diverse range of instructional approaches to be preferred over a developmentally sequenced reading curriculum. Heavy critiques of this model (Rose, 2006) have led to a more defined reading curriculum being incorporated into the revised primary framework for literacy (House of Commons Education and Skills Committee, 2005). Similar trends toward more systemic reading instruction can be seen in countries such as the United States, with its legislated No Child Left Behind Act of 2001 (Pub. L. 107-110) and Singapore with its definitive national language syllabi (Curriculum Planning and Development Division, Ministry of Education, 2001). Curricular imbalances in favor of reading skills, such as decoding and comprehending, over reading for pleasure have potentially important implications for students' lifelong literacy (House of Commons Education and Skills Committee, 2005).

National policies in other countries have also created tensions by mandating instructional reading materials. For example, in Brazil, the official textbook for poetry instruction focuses young readers' attention on the structure of the genre over the deeper meaning that could be developed by making connections from the poem to themselves and to their world (Malloy and Botzakis, 2005). Although access to digital technology in literacy curricula may be dependent on region and socioeconomic status (Mallozzi and Malloy, 2007), reading domains require redescription for a clickerati generation who explore digital technology without fear (Turbill, 2004: 356). Concepts of print skills such as directionality of print and sequential page-turning are not the most effective mode of understanding how digital print works for

emergent readers exposed to more diverse sources of print; these young readers of a digital age may be better served by a more elastic reading curriculum. Devising and maintaining a reading curriculum is a challenge when the definitions and practices of reading are constantly changing in a politicized and globalized economy.

Elementary/Middle-Grades Reading

Beyond grade 3, the elementary/middle-grades reading curriculum increasingly focuses on the disciplinary or subject-matter aspects of acquiring information from a variety of academic materials (both print and nonprint). Typically, this focus is intended to deepen students' appreciation of reading for purposes of organizing and sharing ideas, revising one's thinking, inquiring more fully into a subject area, and so on. Key curricular questions at this level, which typically consists of grade 4–8 (or children approximately 9–13 years of age), include the following: (1) what role does self-efficacy play in elementary/middle-grade students' willingness to engage with reading in their subject-matter texts? and (2) to what degree is the new information communication technologies (ICTs) an influence on how the elementary/middle-grades reading curriculum is addressing the issue of student engagement with reading?

Elementary and middle graders' perceptions of how competent they are as readers, generally speaking, will affect the degree to which they are motivated to engage with learning in the core curricula (e.g., science, social studies, mathematics, and literature). In pre-adolescence as in earlier and later life, it is the belief in the self (or lack of such belief) that makes a difference in how competent an individual feels when faced with a challenging task, such as reading primary source materials in social studies class or comprehending a math word problem. Although the terms self-concept and self-efficacy are sometimes used interchangeably, they actually refer to different constructs. For example, a student may have a generally good self-concept of herself as a reader, but her answer "Not very" to the question "How confident are you that you can comprehend a primary source on the Battle of Gettysburg?" would indicate low self-efficacy for that particular task (Pajares, 1996).

In an extensive review of how curricular decisions affect elementary and middle-grade students' reading engagement and academic performance, Guthrie and Wigfield (2000) concluded that various reading strategies, while important, do not directly impact student outcomes (e.g., the time they spend reading independently, their performance on high-stakes assessments, and their beliefs about reading). Instead, it was the students' level of engagement in subject-matter reading that was the mediating factor in improved student outcomes. Guthrie and

Wigfield's conception of the engagement model of reading calls for a curriculum that fosters, among other things, self-efficacy and self-monitoring while reading subject-matter texts.

An emerging trend worldwide is a call for considering the multiple realities of ICTs on reading in the elementary/middle-grades curriculum. Based on the results of a survey sent to international literacy research correspondents covering fairly broad regions in South America, Europe, Africa, Pacific Asia, and North America, Botzakis and Malloy (2005) reported that the majority of respondents in all regions were positive in their descriptions of how new ICTs are influencing students' engagement with reading and hence the reading curriculum. At the same time, there were regional differences reflected in some of the respondents' reports. For example, in Argentina and Chile, most teachers who completed the survey indicated that they recognized the importance of electronic media and tried to use new technologies in making reading assignments. On the other hand, they also reported that "many computer labs in schools were scarcely used, except in instances when transcribing or searching for general information were the goals" (p. 113).

The extent to which ICTs are viewed as a positive influence on the elementary/middle grades-reading curriculum hinges in part on perceptions of their usefulness and issues of access. For example, some respondents from Estonia raised a question about whether or not print literacy and the literary curriculum were being diluted due to the influence of electronic media. A lack of access to ICTs was reported as a hardship in certain areas of South Africa, Malaysia, and Brunei. By way of contrast, respondents from Singapore pointed out the ministry of education's role in investing and promoting the use of new ICTs, while respondents in Hong Kong claimed that it was difficult to add anything new, including ICTs, to an already packed curriculum.

Not surprisingly, the key questions and issues that were identified as pertaining to the elementary/middle grades-reading curriculum apply to the secondary level as well where reading demands only increase in intensity and complexity. As Biancarosa and Snow (2004) have noted, "secondary school literacy skills are more complex, more embedded in subject matters, and more multiply determined" (p. 2). Adding to this complexity, particularly in the United States as a result of No Child Left Behind, is a culture of assessment that is essentially rewriting the face of the reading curriculum at the secondary level with little or no regard for input from local educators (Fecho *et al.*, 2007) or for learning through other than traditional print-based texts. On a global level, too, the push for higher standards and improved student achievement in reading is often grounded in print and reflected in a narrowing of the curriculum through overzealously adopting what Luke and Luke (2001) have referred to as an inoculation

approach to curriculum reform (but see the website of Literate Futures, for an exception to this critique).

International comparisons of reading achievement, such as the Program for International Student Assessment (PISA), administered by the Organization for Economic Cooperation and Development (OECD), indicate even more broadly the interest in measuring secondary students' performance levels and their implications for curriculum reform. A case in point is PISA's first report issued in the year 2000, which subsequently has had considerable influence on curriculum development in reading for 15-year-olds among the 32 participating nations, and particularly for those in Central and Eastern Europe (Meredith, 2004). In 2009, the date set for the next PISA survey of 15-year-olds' ability to analyze, reason, and communicate effectively about what they read, the assessment will involve reading electronic texts (OECD, 2007) – a stark contrast to the 2009 Reading Framework of the National Assessment of Educational Progress, a US assessment that will involve reading only traditional print texts. Perhaps advances in technology use may yet be perceived in some areas of the world as undermining long-standing assumptions about a reading curriculum.

Most researchers would agree that science learners engage in a process of making sense of diverse information by looking for patterns and building on their own ideas (Bransford *et al.*, 1999; Bruer 1993). Linn *et al.* (2004) describe this process as knowledge integration and show that students benefit from curricula that elicit ideas and encourage linking and connecting information, seeking and evaluating new ideas, as well as revising and reorganizing scientific ideas to make them more comprehensive and cohesive. They note that designing curriculum materials to support and guide the process of knowledge integration has required creative innovations along with many cycles of trial and refinement. Recent progress in synthesizing design knowledge (Brown 1992; Bransford *et al.*, 1999) has generated principles and patterns that give new designers a head start on creating materials that promote knowledge integration.

In spite of extensive research showing that students learn using knowledge integration processes, textbooks, lectures, and even hands-on activities reflect a view of learners as absorbing information rather than attempting to integrate new ideas with their existing knowledge. Too often students learn isolated facts from science courses, form conjectures based on experience or observation, and gather information from peers or media, but do not sort these ideas out (e.g., Roseman *et al.*, 2001). Students frequently fail to connect ideas learned in science class with observations made in other contexts. Designing curriculum materials that promote knowledge integration requires consideration of the many ideas that students develop. Effective designs encourage learners to compare their ideas, formulate criteria for promoting one idea over another, and link ideas into arguments. However, the translation of what we know about how people learn into curriculum materials is not obvious. Our theoretical knowledge is too abstract to help curriculum designers make important decisions (Kali, 2006). Recent efforts in the area of science curriculum design seek to bridge this gap.

Described here are two complementary approaches for synthesizing science curriculum design knowledge: the design principles approach and the design patterns approach. Both trajectories view learning as a knowledge integration process and aim to synthesize design knowledge from a variety of research projects to make it useful for curriculum designers. We show how the two approaches complement each other by analyzing the design principles

and design patterns in a thermodynamics curriculum unit. Then, we illustrate how the two approaches were used in a curriculum design and development course for graduate students. We also suggest ways in which they can be used in a curriculum design process. We conclude with a discussion of ways to make design knowledge useful.

Curriculum Development and Design-Based Research

Curriculum development is based on epistemological views of the designers. Designers have ideas about how learning takes place, such as a theory or a perspective on learning. They have epistemological assumptions about the nature of knowledge in a specific scientific domain. A good design process is sensitive to the needs and requirements of the users. A needs-analysis stage is therefore an important preliminary step in any curricular design process (Dick *et al.*, 2001). This stage is usually followed by a careful trial and refinement process, until the learning goals of the designed curriculum are met.

Design-based research is an emerging methodology for synthesizing the lessons learned from this trial and refinement process. To draw conclusions from these studies, researchers contrast multiple versions (Barab and Squire, 2004; Collins *et al.*, 2004; The Design-Based Research Collective, 2003). Design-based research studies contribute to what we know about how people learn. They also widen the body of design knowledge available for future curriculum development. To make this body of knowledge, which is sometimes referred to as design knowledge, become useful for curriculum designers, researchers have sought to abstract general guidelines that are based on large numbers of studies, and can assist curriculum designers to make important decisions (e.g., Brown, 1992; Quintana *et al.*, 2004; Merrill, 2002; Mor and Winters, 2007; van den Akker, 1999).

Design Principles and Design Patterns: Complementary Approaches

Researchers have begun to develop two approaches, which use different lenses to analyze promising curricular innovations, find common productive design elements, tie

them with theory, and articulate them as guidelines for future curriculum designers. Described below are two approaches which show how they can be used together in a curriculum design process.

The design principles approach

The design principles approach uses design principles as an organizational unit for synthesizing design knowledge (Merrill, 2002; Quintana *et al.*, 2004). Bell and co-workers describe design principles as:

...an intermediate step between scientific findings, which must be generalized and replicable, and local experiences or examples that come up in practice. Because of the need to interpret design principles, they are not as readily falsifiable as scientific laws. The principles are generated inductively from prior examples of success and are subject to refinement over time as others try to adapt them to their own experiences. (Bell *et al.*, 2004: 83)

Based on this approach, the Design Principles Database (Kali and Linn, 2008) was developed. This database is a mechanism to support researchers and curriculum designers to share their design knowledge in the form of design principles, exemplified by descriptions of features from learning environments. The database is an infrastructure for participants to publish, connect, discuss, and review design ideas, as well as to use these ideas to design new curricula. Thus, it serves as a collaborative knowledge-building tool as well as a mechanism to support design-based research (Kali, 2006). The current entries in the Design Principles Database represent the contributions of over 60 individual researchers. The database includes more than 100 features (mainly from physical, life, and earth sciences), connected with several dozen design principles.

For example, one feature in the database is labeled “Multiple representations in WorldWatcher”. This feature of WorldWatcher software provides scientific visualizations for the investigation of weather data. Students can explore weather data using visualizations that are similar to those found in environments that scientists use (Edelson *et al.*, 1999). The feature displays two-dimensional global data in the form of color maps with latitude and longitude markings and an optional continent outline overlay. A constantly updated readout follows the user’s mouse as it travels over an image, displaying the latitude, longitude, country or state/province, and temperature data value. Different types of representations of the data (such as textual representations of temperature, color schemes representing temperature, location of a mouse on the continent outline, and textual representations of the location as latitude and longitude) are linked, and changed synchronously as the mouse moves.

The feature “Multiple representations in WorldWatcher” is linked in the database to a design principle named “Use

multiple-linked representations”. This principle connects to about ten other features in the database. It provides a general rationale, theoretical underpinning, and important considerations, such as pitfalls, trade-offs, and limits of practical use, to help designers benefit from the many examples. This principle is applied in the thermodynamics curriculum unit described below.

The design patterns approach

The second approach for synthesizing design knowledge to support curriculum designers is the design patterns approach. A design pattern is a sequence of activities in a curriculum, followed by teachers and students in a classroom (Linn and Eylon, 2006). Design patterns based on knowledge integration involve four basic processes: (1) eliciting student ideas, (2) adding new, pivotal ideas, (3) developing criteria for distinguishing among ideas, and (4) sorting out ideas. Linn and Eylon (2006) illustrate how these four processes play out in ten design patterns, which research has shown, can promote knowledge integration (right column in **Table 1**).

For example, one of the ten patterns is “Experiment”. This pattern captures successful sequences of activities that support students in learning from experiments. It describes a recursive process of defining and refining an inquiry question, generating methods for investigating the question, carrying out the investigation, evaluating the results, and using the findings to sort out students’ own repertoire of ideas. When students use activities designed with the experiment pattern, they make decisions about what is a good experiment and what can be learned from an experiment. Students learn to select among varied data collection procedures, distinguish causal from correlational results, and link methods of investigation to the validity of findings (Linn and Eylon, 2006). The experiment pattern can help designers find ways to take advantage of hands-on learning.

This pattern appears in a curricular sequence of activities in the Learning by Design project (Kolodner *et al.*, 2003). Activities in this project interweave design and experimentation cycles. In the experimentation cycle, students begin by clarifying the question to be addressed and make a hypothesis. Then, they design the investigation by identifying conditions that need to be controlled, the variables that will be varied and their values, the steps to be carried out, the number of trials, and what to measure. Finally, students carry out the investigation, record data, analyze results, and present their findings in a poster session (Kolodner *et al.*, 2003).

To illustrate how the design principles and the design patterns approaches complement each other, in the following section we analyze a specific curricular unit in thermodynamics, using these two lenses. The juxtaposition of the two lenses highlights the different ways in which each of the approaches guides design of science curricula.

Table 1 Intuitions in sequences designed by students (left column) and design patterns that provide alternatives (right column)

<i>Intuitions in sequences designed by graduate students in the Kali and Ronen-Fuhrmann (2007) research</i>	<i>Design pattern providing an alternative along with relevant guidance</i>
Focus on flow of content rather than student engagement. Students' sequences focused on which content should be learned first and how to communicate a hierarchy of knowledge. They did not think enough about how to engage learners.	Pattern: <i>orient and elicit</i> . Instructors use the orient-and-elicited pattern to increase interest in a scientific phenomena, define the scope of the topic, connect the topic to personally relevant problems, link the new topic to prior instruction, gauge student interest, and identify the learner's entering ideas.
Providing instructions rather than diagnosing possible confusions. Students tended to start their sequences with instructions, instead of designing guidance that diagnoses learners' possible confusions, or enables learners to link to specific instructions when and if these are needed.	Pattern: <i>diagnose and guide</i> . Instructors use the diagnose-and-guide pattern to elicit the learner's ideas, identify confusions, and determine which ideas to add to stimulate knowledge integration. This pattern promotes knowledge integration by motivating instructors to analyze student thinking and select the more effective new idea.
Providing information rather than supporting inquiry. Students tended to provide information rather than support inquiry; providing learners with answers was often supported by visualizations, but these were usually designed to inform, rather than enable learner-exploration of phenomena.	Pattern: <i>predict, observe, explain</i> . The predict, observe, explain pattern involves providing a demonstration of a scientific phenomenon, eliciting predictions, running the demonstrations, and asking the learner to reconcile contradictions. Pattern: <i>explore a simulation</i> . The explore-a-simulation pattern enables learners to try out their ideas using simulations, virtual worlds, or scientific models. Simulations elicit ideas, support the testing of ideas with feedback, and encourage learners to monitor their performance, often in relationship to their peers or an ideal performer.
Seeking expected answers rather than encouraging negotiation of ideas. Students sought to provide a typical correct answer, or process, rather than illustrate a variety of ideas, and encourage negotiation of those ideas among peers.	Pattern: <i>illustrate ideas</i> . Using the diagnose-and-guide pattern described above, instructors illustrate their ideas by contrasting various perspectives – including those held by their audience – and discussing how a learner could go about distinguishing among them. Pattern: <i>collaborate</i> . In this pattern learners generate their own ideas, learn from the ideas of others, respond to group ideas, determine methods for distinguishing ideas, articulate warrants for their views, and reach consensus. Pattern: <i>critique</i> . In this pattern learners are asked to evaluate both established and potentially invalid, misleading, persuasive, or confusing information presented in Internet resources, textbooks, articles, models, experiments, arguments, or peer reports. Pattern: <i>reflect</i> . In this pattern learners are encouraged to analyze the connections they make and consider their prior ideas. The reflect pattern promotes knowledge integration by encouraging students to stop and analyze their own repertoire of ideas.
Recreations rather than enabling learners to design their own artifacts. Students tended to engage learners in predefined activities and rarely enabled learners to design their own artifacts	Pattern: <i>create an artifact</i> . The create-an-artifact pattern involves refining a question, selecting or using methods for creating an artifact, creating a draft artifact, evaluating the results, using the findings to improve the artifact, and connecting the results to views of the topic.

Design Principles and Patterns in the Thermodynamics Curriculum Unit

“Thermodynamics: probing your surroundings” (Clark and Sampson, 2007) is a curriculum unit for seventh- to ninth-grade students, which is part of the Technology-Enhanced Learning in Science program. The unit, which requires about 1 week of instruction, and uses the Web-based Inquiry Science (WISE) infrastructure, is designed to assist students to connect their observations (such as noting that metal feels cooler than wood at room temperature), and the explanations of these phenomena at the molecular level.

The design of this unit can be analyzed using design principles as well as design patterns. This dual analysis is described below and summarized in **Figure 1** (see below). The design principles and patterns are concisely summarized here. Information about each of the principles can be found in the Design Principles Database. The design patterns are explained in more detail in Linn and Eylon (2006).

The first activity in the unit, named “What do you think?” (**Figure 1**), introduces a driving question and elicits students' ideas about thermodynamics. (People talk about objects being naturally hot or naturally cold – what do they mean?) Students make predictions about the

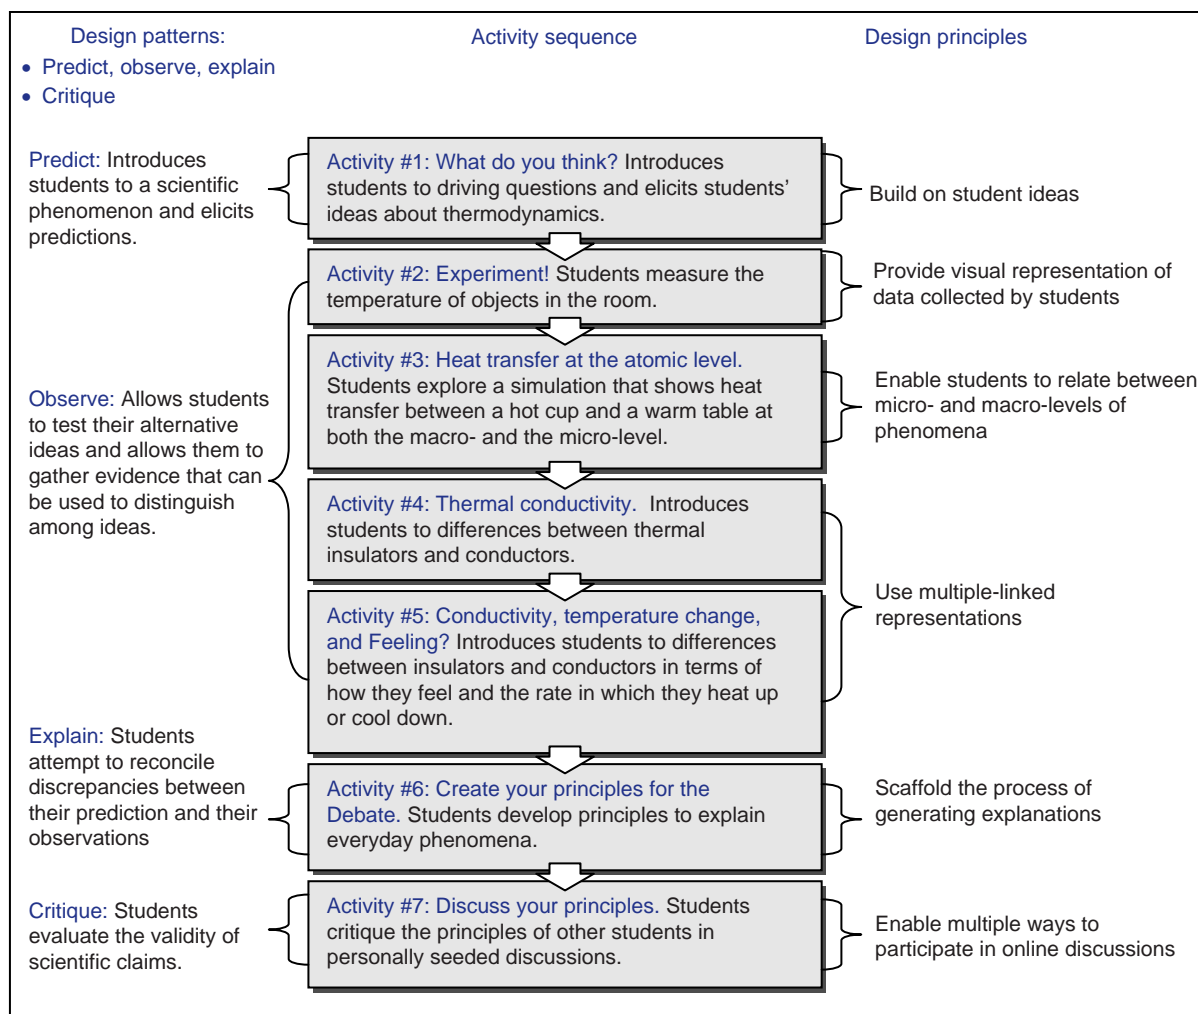

Figure 1 The sequence of activities in the thermodynamics curriculum unit described in terms of design patterns (left) and design principles (right). From Clark, D. B. and Sampson, V. D. (2007). Personally-seeded discussions to scaffold online argumentation. *International Journal of Science Education* 29, 253–277.

temperature of various objects in the room, and record them online. If we analyze this feature with a design principles lens, we can see that it employs a most prominent principle for designing scientific curricula called “Build on student ideas”. This design principle calls for designing instruction that encourages students to build on their ideas to develop increasingly powerful and useful scientific ideas, rather than isolate new information from existing knowledge. This first activity (**Figure 1**) also illustrates the design patterns approach. The activity realizes the predict part of a design pattern named “Predict observe explain” (**Table 1**). The other segments (observe and explain) follow in activities as the unit progresses.

In the second activity of this unit, students measure the temperature of the objects and compare the measurements to their predictions using a feature that graphically presents predicted versus actual temperatures. From a design principles view, this feature follows the principle “Provide visual representation of data collected by

students”. The tool enables students to easily represent data they collect (temperature, time, and data from surveys) in interactive dynamic representations. Graphing data collected by students can promote their understanding of the phenomenon they are studying. Using tools that automatically graph data collected by students decreases the workload involved in graphing. From a design patterns view, this one, and the next three activities represent the observe section of the “Predict observe explain” pattern described above (**Figure 1**; **Table 1**).

Students’ exploration continues in the third activity with a simulation that shows heat transfer between a hot cup and a warm table at both the observable and molecular level. The simulation applies the design principle “Enable students to relate macro- and micro-levels of phenomena”. This principle calls for creating features that help students see the connection between their observations and molecular processes by animation that allows students to zoom into the phenomena until molecules

can be seen. Then, in the fourth and fifth activities, students learn about the differences between thermal insulators and conductors. They choose different objects with various conductivities and different starting temperatures for each object, and view animated graphs showing how their temperature changes as they heat up or cool down. This animation realizes the design principle described above – “Use multiple-linked representations”.

The sixth and seventh activities, which culminate the thermodynamics unit, enable students to develop their own principles for explaining everyday phenomena in terms of concepts in thermodynamics, and to discuss these principles with their peers. Using a tool called “Principle maker”, students create general principles that summarize their understanding of simulations and of data collected in previous stages of the project. The students use a series of pull-down menus in order to construct a principle. Each pull-down menu gives a list of possible phrases to choose from. Finally, the principles created in activity 6 are used as seeds for online discussions between students in activity 7.

Activities 6 and 7 represent curriculum features that employ two design principles: “Scaffold the process of generating explanations” and “Enable multiple ways to participate in online discussions”. From a design patterns view, when students use the “Principle maker”, they accomplish the explain section of the “Predict observe explain” pattern, followed throughout the sequence of activities 1–6. The online discussion, seeded with students’ principles in the final activity, represents a new pattern – the “Critique” pattern, which guides designers to create sequences of activities that support students in careful examination of any information they encounter, including ideas brought to the discussion by their peers (Table 1).

The above analysis is only one example of ways in which a curriculum unit can be analyzed using design principles and design patterns. Curricular features and sequences can realize more than one design principle or design pattern. Principles and patterns can be embedded into one another. For instance, activity 3 in the thermodynamics unit is part of the “Predict observe explain” sequence and also implements the “Explore a simulation” pattern as part of the observation. This pattern enables designers to create sequences of activities that specifically support students in making sense of new science ideas represented in scientific models and simulations (Table 1).

Using Principles and Patterns to Guide a Curriculum Design Process

Researchers are beginning to tap the potential use of frameworks, such as the design principles and design

patterns described above to improve the design process. Research highlights the affordances and challenges they pose for designers. To assess the use of the design principles approach, Kali and Ronen-Fuhrmann (2007) developed a course to guide graduate students in designing technology-based curricula using the Design Principles Database. Students use the database when they: (1) write a needs and analysis document for the curriculum they are designing, (2) brainstorm ideas for features, (3) create a flow of activities, (4) design the features in the activity flow, and (5) evaluate each others’ designs.

Initial enactments of this model in graduate courses showed that design principles were useful to students in several of these stages. For instance, the use of design principles at the brainstorming stage helped students to widen the scope of their design. Students were more likely to include socioconstructivist features than before they used the principles. Additionally, after students figured out a sequence of activities for the curricula, the Design Principles Database helped them design innovative features for each activity in the sequence and, thus, build on ideas tested and refined by other design-based research studies. However, designing the sequence of activities was a challenge for many of the students. They tended to rely on their intuitive absorption model of the learner and: (1) create a hierarchical flow of content rather than engaging students, (2) provide instructions rather than diagnose possible confusion, (3) provide information rather than support explanation, (4) seek predefined answers rather than encourage negotiation, and (5) create actions rather than enabling learners to design artifacts (Kali and Ronen-Fuhrmann, 2007; Table 1).

To remedy this problem, the next version of the course will employ design patterns. Table 1 illustrates how the patterns approach could help graduate students, in the Kali and Ronen-Fuhrmann (2007) study, consider alternative approaches and analyze their intuitive designs from another perspective.

The above analysis shows the benefit of using design patterns in the create-a-flow-of-activities stage of the design process. Recently, the design patterns have been added to the publicly accessible Design Principles Database, so that novice curriculum designers will be able to use design principles as well as design patterns throughout their design process.

Summary and Next Steps

Current curriculum materials, including textbooks (Roseman *et al.*, 2001) and lectures (Linn and Eylon, 2006), fail to take advantage of advances in understanding of the learner and of effective instruction. Since the 1990s, researchers have sought learning principles (Brown, 1992)

and design knowledge (diSessa, 1992) to remedy this situation. With the advent of technology-enhanced learning environments, many research partnerships have used embedded assessments to gather detailed accounts of student learning of complex science concepts (e.g., Clark and Sampson, 2007; Kolodner *et al.*, 2003). These research programs feature trial and refinement of curricular materials using evidence from student learning (The Design-Based Research Collective, 2003). Efforts to synthesize which refinements succeed have typically involved generating design principles (Collins *et al.*, 2004; Dick *et al.*, 2001; Linn *et al.*, 2004; van den Akker, 1999) or design patterns (Linn and Eylon, 2006).

Recently, researchers have begun to study ways to synthesize design knowledge so others can use it. Kali (2006) created the public Design Principles Database and engaged the community in contributing its design knowledge. Kali and Ronen-Fuhrmann (2007) created a curricular design course for graduate students and studied the role of principles in the design process. Based on analyses of student designs, they found that principles were not sufficient to help students take advantage of research on instruction. The most recent version of the course and the Design Principles Database now also includes design patterns. These first steps toward creating effective, proven designs suggest promising practices for all designers. Future research must apply this rigorous, evidence-based approach to the design of widely used materials, such as textbooks.

Bilingual Learning (Learning L1 and L2 in an L1 and L2 Environment)

Introduction

With the growth of the global economy, more and more countries are recognizing that bilingualism is a national resource that can provide economic, social, and cultural advantages. Nations, local communities, and individuals are examining how the growth of bilingualism can be cultivated. Significant research has been conducted to examine how to help individuals to acquire multiple languages and how to improve bilingual learning in multilingual and multicultural environments. The opening section of this article discusses how multilingual environments for language learning can be created through the implementation of different models of bilingual education in public schools. Then, the article discusses how bilingual language acquisition can occur in homes, neighborhoods, and community-based heritage-language schools. In addition, since the acquisition of biliteracy is important for those who want to use their language abilities in formal contexts, such as higher education and the workplace, the article also examines theoretical models and practical techniques for developing biliteracy. While bilingual learning is embraced by many, there are still significant misconceptions about how the acquisition of two or more languages in a multicultural environment will influence overall linguistic and cognitive development. Thus, this article also examines language transfer, codeswitching, and cognitive development in bilingual individuals and shows how the research in these areas supports the idea that the acquisition of bilingualism is helpful for overall personal and academic growth.

Models of Bilingual Education

The bilingual learning of school-age students is strongly influenced by the organization of bilingual education in the formal educational contexts in which the students receive their elementary and secondary education. Bilingual learning is assisted by schools that provide extensive opportunities for students to achieve high linguistic proficiency through studying in two or more languages. Bilingual education can be provided in weak or strong forms. An example of a weak form of bilingual education is a program that provides a transitional bilingual education. The goal of these programs is to have students begin to study in the majority language as soon as possible. These programs are often seen as a track for low-achieving students or as a remedial program. Weak bilingual programs usually provide students with only a limited number of years of bilingual instruction (usually 2–3 years) before exiting the students into a monolingual educational environment.

In contrast, strong models of bilingual education, often referred to as enrichment bilingual programs, have a goal of helping students to achieve a high level of proficiency in two or more languages. These programs generally provide students with bilingual instruction throughout the students' time in the school, provide content-based instruction in multiple languages, and also seek to help students to become biliterate and bicultural. While there are many variations in how to organize bilingual education programs, there are three models of enrichment bilingual education that are frequently adopted. These

models include developmental bilingual education programs, immersion bilingual education programs, and two-way bilingual programs.

Developmental bilingual education programs, also known as maintenance or heritage-language bilingual education, provide students from language minority groups with a program that uses the minority language as the medium of instruction about half the time, and provides content-based instruction in both languages. This form of bilingual education is most often used where there are populations of recent immigrants, but it is also a popular model to encourage the maintenance of indigenous languages, such as Navajo in the United States (McCarty and Bia, 2002) and Maori in New Zealand (May, 2004).

Second, immersion bilingual education programs are designed to develop bilingualism in language majority students who are provided with intensive language-learning experiences and content-based instruction in a new language through multiple years of schooling. Most students enter immersion programs with little or no knowledge of the second language. Many of these programs offer early total immersion where students study in the new language for 100% of their first years in preschool and elementary school. While immersion programs are used around the world, this model of bilingual education has been particularly popular and successful in Canada (Johnson and Swain, 1997).

Third, two-way bilingual education programs, also sometimes referred to as dual-language or dual-immersion programs, are designed to educate balanced numbers of students from two language backgrounds. These programs allow students who are native speakers of different languages to study together so that all students develop high levels of proficiency in both languages as well as authentic cultural understanding. Research on these programs has shown that they not only aid students in becoming biliterate and bicultural, but they also often succeed in elevating the status of minority languages and their speakers in the community (Freeman, 1998). Dual-language classes are most effective when there are a balanced number of students from each language group in the class, and the languages are kept separate in the classroom. Language separation can occur in several ways. In some dual-language classes, two teachers can be used in the program and each teacher instructs the students using only one language. Other dual-language classes divide language use by time of day or by subject matter. There are different models of language use in dual-language programs. Some programs use each language 50% of the time in each grade. Other programs adopt a 90/10 model where the minority language is used for 90% of the time in kindergarten, but the use of the majority language increases in each grade so that the school day has a 50% language allocation for each language by the end of elementary school. Dual-language programs have increased rapidly in the last decade, and these programs have been shown to be the most effective of the types of bilingual programs.

The Importance of Families and Communities in Bilingual Learning

While schools may be one important site of bilingual learning, the home and community environments of bilingual learners also play a large part in the acquisition of competence in two or more languages. This section of the article reviews bilingual language acquisition at home and in the neighborhood, community heritage-language schools, and how local funds of community knowledge can be used to enhance bilingual language learning in formal educational settings.

Bilingual Language Acquisition at Home and in the Neighborhood

While the school can be a site of bilingual learning, the access to bilingual linguistic input in the home environment also plays an essential role for many learners by providing extensive exposure to multiple languages. Bilingualism in the home is especially important for the language acquisition of young children who often spend most of their time with their primary caretakers. While it is frequently reported that doctors or preschool teachers or other professionals have recommended to parents who are speakers of minority languages that they do not speak their native language with their young children, it is increasingly being recognized that early use of two or more languages in the home environment can provide children with advantages in language acquisition. Through using multiple languages for conversations in the home, sharing folklore or traditional stories, being exposed to multiple languages in religious settings, or taking part in ordinary daily activities such as letter writing to relatives, children can achieve a high level of bilingualism even if they are not exposed to a bilingual school environment.

One additional, and often-overlooked, setting for bilingual language acquisition is the interactions that learners have with their peers. As children get older, the peer group becomes a more important resource for bilingual learning. Older siblings often teach younger siblings vocabulary and other language forms that they can use to take part in games or sports with other children in the neighborhood, purchase needed items at local stores, and complete daily chores. One interesting example of research on how peers can positively influence bilingual language acquisition is described in Long (1997) who gives an account of how her daughter learned significant amounts of Icelandic from interactions with her peers after the family moved from the United States to Iceland for a year. She shows how her daughter acquired Icelandic through play experiences with her friends and from her participation with her peers in extracurricular activities after school. Certainly, a substantial amount of bilingual language learning can occur in the social environments of the home and community.

Heritage-Language Instruction

Heritage-language instruction in the community can be an important support for bilingual learning in the family and in the regular school classroom (Fishman, 2006). Heritage-language schools outside of the formal public school system often have classes that meet after school or on the weekend. These schools are organized by a number of different types of organizations, including religious groups, foreign governments, and local community ethnic associations. While heritage-language schools often concentrate on early childhood and elementary school children, some community heritage-language schools also teach teenagers and adults. One reason why community heritage-language schools are important is that they provide instruction in lesser-known and indigenous languages that are not included in the public school curriculum. They often also focus on transmitting cultural knowledge, a sense of cultural identity, and respect for the cultural traditions of the community. Thus, they often use activities such as dance classes or cooking programs as a vehicle for language instruction.

Local Funds of Knowledge

In recent years, substantial research has been done to demonstrate ways that the linguistic and cultural resources of the home and community environment can be drawn upon to improve students' educational experiences in public schools. It has been found that bilingual learning in schools and formal educational settings can be enhanced by using the local or household funds of knowledge that students have gained from participating in their families and communities. Funds of knowledge include the information, methods of thinking and learning, and the practical skills that are related to a community's everyday life. This knowledge can include linguistic and factual information about a variety of topics, including agriculture, economics, household management, medicine, scientific knowledge, and religion. Utilizing local funds of knowledge can allow parents to participate more fully in their children's education, and encourage students to place a higher value on the languages and knowledge that is taught to them in their homes and communities. Research also suggests that utilizing community knowledge and languages allows students to participate in activities and produce written products that they would be unable to produce if they were forced to utilize only traditional academic knowledge in completing their assignments (González *et al.*, 1995).

Funds-of-knowledge research has been carried out in a variety of different cultural and linguistic settings, and this type of research has added to our knowledge of the wide variety of vernacular and home literacy practices that can be linked to school learning. For example, Martin-Jones and Saxena (2003) researched how classroom bilingual teaching assistants in northwest England used their knowledge of the

students' home languages and cultures to create a variety of culturally appropriate literacy events. The teaching assistants used activities such as cooking chapattis and telling stories about the Sikh New Year to teach students academic content knowledge and literacy skills.

Biliteracy

For many learners, especially those who will use two or more languages in academic and work environments, developing biliteracy is an essential element of bilingual learning. Bilingual learners have opportunities to become biliterate when they are exposed to activities or literacy events where two languages are used for reading and writing. This section first discusses a major theoretical model of how bilingual learners acquire biliteracy and then discusses how an integrated approach to bilingual learning can aid learners in achieving competency in reading and writing in two languages.

Continua of Biliteracy

There are many important factors to consider when attempting to create a home or school environment that aids the acquisition of biliteracy. For example, decisions have to be made about whether to expose learners to the written forms of the two languages simultaneously or whether to teach reading and writing first in one language before introducing the writing system of the second language. In addition, bilingual learning can focus primarily on being able to read literary texts from the majority language or instruction can include vernacular texts and texts that include cultural content and information from the minority language culture as well. The model of the continua of biliteracy is a framework that suggests different possibilities for the acquisition of biliteracy by bilingual learners. The model suggests that the more a learning context allows learners to draw on the entire continuum of possible linguistic varieties, modes of expression, and types of knowledge in learning events, the greater is the chance of the learners to develop their bilingualism and biliteracy to the fullest extent possible. One important aspect of this model is that each continuum consists of weaker and more powerful ends, and the continua thus recognize that all modes of expression and types of knowledge are not viewed as equally powerful by society. This framework has been described in great detail and applied to many different educational situations in a recent edited volume (Hornberger, 2003).

Integrated Approach to Biliteracy

In addition to the major theoretical contributions that have added to our understanding of biliteracy, contributions

have also been made in creating an integrated approach to the teaching of biliteracy in bilingual classrooms. One text that gives a wealth of information about teaching reading and writing in two languages in a classroom context is *Learning in Two Worlds: An Integrated Spanish/English Biliteracy Approach* (Pérez and Torres-Guzmán, 1996). This text provides information about how to develop biliteracy in learners who have many different levels of proficiency, including emergent biliteracy, the development of basic reading and writing skills, and advanced proficiency including the reading and writing of content-area texts.

There is also research available that gives examples through case studies or samples of student work of how biliteracy can be developed and the high levels of biliteracy that can be achieved by some learners. Cox and Boyd-Batstone (1997) present three detailed longitudinal case studies of children's biliterate development between first and fifth grade, and also give a detailed account of how the classroom teachers used literature and various types of reading responses to increase the students' acquisition of English and Spanish in a school setting. In addition to content-area reading and writing, there has also been some research conducted in how biliterate individuals can use reading and writing for creative expression. Ada and Campoy (2003) describe how they have used bilingual children's literature and a variety of creative writing activities to help students draw on their cultural knowledge and their authentic life experiences. The text describes ten thematic units that are each based on a different genre of creative writing. One of the key features included in this text is the engaging examples of creative writing by teachers, parents, and students. Many of these are pictures of home-made books with illustrations or poems that show the high quality of writing that can be produced by young biliterate authors.

Common Misconceptions About Bilingual Learning

Among the general public, there are some misconceptions about the effects that bilingual learning will have on the linguistic and cognitive development of young bilingual learners. This section introduces three common concerns of parents and teachers who are considering whether to provide children with a bilingual education. People are often concerned that perhaps bilingual learning will cause learners to mix up the two languages that they are learning or will have negative overall cognitive effects. This section discusses how recent research findings demonstrate that bilingual learning is not detrimental in any way to language acquisition or overall cognitive development, but instead can confer an educational advantage for the bilingual learner.

Language Transfer

A common myth of bilingual learning is that the acquisition of multiple languages simultaneously will cause difficulties in language learning, especially in learning to read and write. However, researchers have shown that instead there is significant transfer of linguistic skills that actually gives bilingual learners an advantage in language acquisition. Many different language skills can be transferred, including a general understanding of how print works, reading comprehension strategies, spelling, a familiarity with the characteristics of specific genres, and an understanding of pragmatics (how language is used in context). The importance of language transfer was demonstrated in a foundational study by Edelsky (1986). Edelsky's research focused on how first through third-grade students in an English and Spanish bilingual program transferred the writing skills they had gained in one language to the second language that they were acquiring. This study also demonstrated how the students' bilingual competence gave them the ability to write for varying audiences in a larger range of genres.

While there is evidence of linguistic transfer in bilingual learning with many combinations of languages, recent research shows that there is a greater advantage in biliteracy acquisition when the two languages that are being learned share a similar writing system (Bialystok *et al.*, 2005). When languages have similar writing systems, it has even been shown that sometimes students can develop spontaneous biliteracy, that is, the ability to read in a second language even when they have received no substantial formal literacy instruction in the language. However, even when languages use varying writing systems, there is still the possibility for transfer to occur. For example, when researchers in England asked students who were in Saturday supplemental heritage-language programs in Chinese, Arabic, and Spanish to teach their classmates the additional writing systems that they were learning, it was observed that 5- and 6-year-old students understood the key differences between the writing systems they were acquiring, including the differences between alphabetic and logographic writing systems and the differing directionality in various writing systems. In addition, the heritage-language students were able to share this information clearly and in creative ways with other children (Kenner *et al.*, 2004).

Codeswitching

Codeswitching is mixing one language with another when speaking or writing, and it occurs frequently in environments where bilingual individuals share the same set of languages. Monolinguals often view codeswitching as something that indicates a lack of language proficiency. However, research has shown that codeswitching is a

complex use of language, and there are specific linguistic rules for what types of mixing can occur between languages in a sentence or conversation. Codeswitching can be utilized by bilingual learners for many purposes. While it is possible that bilingual learners may utilize codeswitching when they are unsure of a vocabulary word in a language, codeswitching is also used to show an affinity with others who speak the same language varieties or it may be used to emphasize a particular point in a conversation. One part of bilingual learning is acquiring an understanding of when it is appropriate to codeswitch and what type of codeswitching is appropriate in a particular linguistic and cultural context. One additional complexity in codeswitching is that in many cases, interlocutors utilize a range of dialects as they are codeswitching. For example, in Zentella's (1997) research of the language use of a low-income Puerto Rican community in New York City, she found that the children she was studying codeswitched between a whole range of linguistic codes, including standard Spanish, nonstandard Puerto Rican Spanish, standard English, Hispanized English, and African-American vernacular English.

Codeswitching has also been studied as part of a larger set of practices that can enhance bilingual learning. In some learning situations, it is possible for bilingual teachers and learners to purposefully draw upon multiple languages, semiotic modalities, and participation structures in a single lesson or learning experience in an organized and principled way. This mixing is sometimes referred to as hybridization or hybrid literacy practices. Gutiérrez *et al.* (1999) give an example of hybrid literacy practices in their analysis of an after-school program. Their research describes how elementary school students describe their activities and learning in daily e-mails to a fictional bilingual character, El Maga. The undergraduate students who answer these e-mails purposefully use both Spanish and English in a strategic way to help the bilingual students develop their literacy skills in both languages, and develop a strong bond with El Maga. This example shows how specific hybrid literacy practices can be used to reinforce learners' identity as bilinguals who are able to use codeswitching effectively.

Cognitive Effects of Bilingualism

Until the 1960s, it was commonly believed that bilingual learning had a negative effect on cognitive development in children. However, there are now many studies that show that children who acquire a second language may actually have cognitive advantages over their monolingual peers. These advantages occur when learners have reached a threshold level of proficiency, a level of basic proficiency, in both languages. It has been shown that children who are

bilingual tend to show a heightened metalinguistic awareness, especially during early childhood. Bilingual children are able to more easily understand certain linguistic concepts, such as phonological awareness or the ability to count the words in a sentence, earlier than monolingual learners. Research also suggests that bilingual language acquisition can improve creativity in children and increase their ability to complete tasks which require divergent thinking in order to solve problems.

Summary

With increasing levels of migration and internationalism, the number of multilingual communities is expanding and the need for bilingual individuals is increasing. Research has shown that creating opportunities for bilingual learning is possible and that bilingualism confers individual and societal advantages. Despite this, much work remains to be done to learn how to apply the best practices in organizing school bilingual programs, increase opportunities to use multiple languages in home and community settings, and develop teaching techniques to help students achieve full academic biliteracy. The potential to achieve societal bilingualism and protect indigenous languages is not fully realized, often because individuals have misconceptions that bilingualism might have negative effects on the development of children or on the solidarity of the nation. However, the large amount of research in bilingual learning environments from all around the world shows the incredible creative potential that exists and the high levels of bilingualism that can be achieved when schools, communities, and families work together to build and maintain environments that promote bilingualism.

Curriculum and Complex Systems Theory

W-M Roth and J Thom, University of Victoria, Victoria, BC, Canada

© 2010 Elsevier Ltd. All rights reserved.

I am inclined to think . . . that unlike the basic question of computability itself, the issues of complexity theory are not quite the central ones in relation to mental phenomena. (Penrose, 1989: 145).

Educators are increasingly engaging in a discourse that includes terms such as chaos, complexity, emergence, and fractals to understand, describe, and provoke teaching and learning situations (e.g., Davis, 2004). These terms are founded in scientific and mathematical fields where modeling phenomena such as weather, the shape of ice crystals, galaxies, or mountain ranges has contributed to the development of, among other things, film animation and video games (Mandelbrot, 1983). However, actual mathematical modeling of curriculum development, curriculum as a process, or curriculum as praxis rarely, if ever, occurs in terms of the complex systems theory, although the mathematics of nonlinear dynamical systems may be the most appropriate tool. (At the time of this writing, the ISI Web of Science database did not list any educational publication under this search term.) There may be two main reasons for this. First, sociocultural phenomena such as real classrooms are so complex that they exceed the capabilities of the mathematical models and computers that generate them. In addition, if classrooms are more complex than any other type of natural system or ecology (Costanza, 2003), then the developmental speeds of sociocultural phenomena exceed those of natural systems by orders of magnitude. Second, to make sense of and to subsequently model even the simplest of complex systems necessitates not only the conceptual mathematical competency of the educator, but also his or her procedural mathematical competency.

Given the enormous complexity of social systems, some may argue that concepts from the complex systems (complexity and chaos) theory be used primarily for analogical purposes, though the apparent simplicity underlying the models of complex systems appear to make it suitable for social systems as well (Guespin-Michel, 2005). However, as research on analogical reasoning shows, the user still has to understand the structures of both the source system and the target systems for any analogy to exist and be productive. For instance, if in the context of a fourth-grade lesson on electricity, the analogy linking a continuous train on the track to the electrons in the wire only proves conceptually effective when all the corresponding structural elements are precisely matched (track/train/people in station pushing/resistance and wire/current/battery/light bulb). Alternatively, one might

assume that the terms from the complex systems theory are to be used for metaphorical purposes, thereby drawing on the power of metaphors in understanding (Lakoff and Johnson, 1980). Even if this is so – and often, this is the case – using such terms for descriptive purposes does not eschew the need for assessing how these metaphors mediate one's conceptions and enactions of curricula. Furthermore, if the meaning of a metaphor is not communicated and comprehended appropriately, it does nothing but hide or obscure, rather than explicate the structural relations among sets of concepts. For instance, second-grade students learning about geometrical objects will find it difficult to understand and even memorize the word cylinder if they do not know that it comes from the ancient Greek term for roller. Having such knowledge would allow them to relate the term to their experience of rolling cylinders down an inclined plane or rolling it between their two hands.

The upshot of these considerations is that the use of concepts from the complex systems theory makes sense only if the speakers and their audiences know the source phenomena (the models related to them) and the target phenomenon (curriculum development and enacted curriculum). If this is not the case, one can use any imagery and does not have to refer to the complex systems theory at all. For example, it is possible to use the imagery of a branching tree and not have to refer to fractal geometry (e.g., Davis and Sumara, 2000) that allows producing a family resemblance between computer-generated images of trees and trees that can be touched and climbed. If we do not understand the underlying mathematical processes at least conceptually, it does not make sense to refer to the complex systems theory, fractals, or chaos, or to choose its associated images as metaphors. Thus, the addition of fractal does not make the metaphor anymore effective.

Modeling the Complexity of Social (Classroom) Interaction

Curriculum as a process (praxis) and curriculum development continue to be thought largely in terms of linear theories, whereby teachers translate a planned (written) curriculum into their classroom actions with the result of achieving specific learning outcomes in students. This is the case although every educator has had experiences where the planned curriculum and the curriculum that is actually lived out or enacted are not the same thing;

where plans or instructions – for example, recipe, assembly instructions, or modes of operation – led to very different sets and trajectories of action. Failing to implement one's own plans for making a dinner, or for operating a new gadget, points to the complexity of life. That said, one can only imagine how much more complex social actions are, such as a teacher bringing forth and carrying off a lesson in the company of a classroom of students. The linearity that underpins many accepted planning models does little to reveal the complexity of nature generally and, specifically, the many orders of greater complexity that is human life. This linearity, as should be clear from this article, underlies the fundamental inappropriateness that teachers experience in university classrooms or the irrelevance of the lesson plans they make to actual classroom events.

Complexity is or at least it should be assumed inherent in the term curriculum itself: one might be talking about a planned curriculum or an enacted one, with its different references to history, syllabi, classroom discourse, intended learning outcomes, and actual classroom events. Questions that arise include: which of these aspects is to be described and represented as a complex system and in terms of associated theories? How do the complex systems models for the different aspects of curriculum relate to one another? In which cases or for which phenomena do metaphors or analogies with complex systems hold true and under which conditions do they break down? In this article, two relatively simple examples – a parent–child exchange and the decision making concerning the (non) inclusion of a concept in a curriculum outline – are used to illustrate both modeling and complex-systems-theoretical thinking about curriculum-related issues. The article concludes with a critical interrogation of the limits and limitations of any analogy or metaphor derived from the complex systems theories.

As a way of introducing the readers to the modeling of complex systems, consider the following exchange that also serves as a model of a simple teacher–student transaction and, therefore, for curriculum as process (praxis):

Example 1

On the way from home to the vacation spot, a child (C) initiates an exchange with her parent (P).

Episode 1

- 1 C: When are we on vacation?
2a P: We are on vacation.

In this situation, we recognize the exchange as a question–answer pair. The parent (patiently) responds that they are on vacation, where the emphatic *are* indicates that the vacation has already started. Naïve analysts might think that the child asked a question. Such an analysis does not allow constructing a model for all possible next instances

that evolve from the child's utterance. That there are other ways of performing a next utterance leading to a different turn pair is evident from the parent's reply later during the 3-day voyage following the same utterance by the child.

Episode 2

- 1 C: When are we on vacation?
2b P: Stop bugging me.

This time, the parent interprets the child's utterance not as a question but as a form of annoyance. Of course, the parent could have responded in the same way as in episode 1, which is what happened throughout the trip between episodes 1 and 2. These instances illustrate that it is impossible to know in advance what the function of an utterance is until it actually occurs. In the first episode, the conversation unfolds as a question–answer pair; in the second instance, it is an annoyance–warning pair. Of course, many other forms of pair completion can be imagined. Any reader not yet convinced of this is encouraged to think of all those situations where an utterance was met with a response like “You hurt me!” and to which the initial speaker replies, “It was a joke” or “I didn't mean to hurt your feelings but . . .” How can this multiplicity of turn pairs emerging from the same utterance be modeled, and how might this diversity be realized in a model that takes into account the complexity of social relations?

A Model for Representing Social Processes

As a first explanation, one may draw on the catastrophe theory (Thom, 1979) as a framework that allows modeling the complexity articulated in the above episodes. The catastrophe theory is both a precursor and a parallel theory to the more popular chaos theory. It combines qualitative and quantitative mathematics to provide an easily intelligible way of modeling the two event categories.

Figure 1 presents a two-state system for completing the child's utterance as raising a genuine question versus aggravating the parent. To the right of point A, the system has but one state where the two turns together constitute

Figure 1 A simple catastrophe theoretic model for the complexity of social life.

one question–answer pair. To the left of point B, annoyance occurs as expressed in the singly possible annoyance–warning pair. Between A and B, two stable states are possible and simultaneous (the dotted part of the curve denotes unstable states of the system): genuine question and bugging. The interesting aspect of this situation is that we cannot know what response will follow the utterance of “when are we on vacation?”; that is, whether we are on the upper or lower branch until the event has taken place. The child’s utterance constitutes a bifurcation point where, for a moment prior to the parent’s reply, the system exists simultaneously on both branches and either response can occur; therefore, it is only when the parent replies that these possibilities collapse into one real event. Moreover, the system may jump from one branch to another in unpredictable ways, brought about by an infinitesimal change in conditions. We can see this as being the case when, at some point along the journey, the system flips and a different outcome results in episode 2 with the parent’s reply; or, equivalently, we can say that the reply flipped the system from one state into another.

What becomes clear when relating this simple example to everyday events is that social life is so complex that we never know whether we are to the left of point B or to the right of point A, though habits may make us think we are in either place. The unpredictability of soci(et)al situations, therefore, suggests that we are always between A and B; however, in relatively predictable (stable) cases, we are closer to A (on the upper branch) or B (on the lower branch). Here, only two actors and two possible states are considered, whereas in real classrooms, there are 20 or more individuals and the possibilities for next turns are large and, likely, infinite. Moreover, because interactions are contingent in the sense that one person never knows what another is up to, real (complex) systems such as classrooms are not only contingent, but also exist in states of instability, which makes them unpredictable even with respect to their immediate future. The best we can do as educators then, is to develop curricula that anticipate what could be as opposed to ones that prescribe what (we believe) is (e.g., Pirie and Thom, 2001).

A Second Model for Representing Social Processes

To model and better understand such complexity, one may use an analogy with another system (e.g., animal population) where complexity arises from recursion – a process of repetitive application to something, for example, a number. The simplest recursive system that leads to rather complex phenomena and can be used to model real events is given by the iterative equation

$$x_{t+1} = k \cdot x_t \cdot (1 - x_t) \quad [1]$$

where the value of some variable x_t at some point (in time) t is fed back into the equation to calculate its value x_{t+1} at the next instant ($t+1$). The end result of this iteration depends on the constant k value. When $k < 3$, x will always asymptotically approach one value (Figure 2). However, at $k = 3$, the system goes through a point of instability: to the left ($k < 3.0$), the animal population always stabilizes at one value, whereas to the right of the point ($k > 3.0$), the population oscillates between two values (i.e., attractors (Briggs and Peat, 1989)). Point $k = 3$ is then considered to be a bifurcation point and infinitesimal perturbations – which in computer simulations arise from rounding errors – are sufficient to change the observable behavior of the system: it is nondeterministic (Prigogine and Stengers, 1979). As k increases, there will be further bifurcations where there are 4, 8, 16, and so forth stable values of x until an infinite number of asymptotic $x_t = \infty$ are possible (Figure 2); here, periodicity ends and the population jumps unpredictably from one value to another. However, subsequently, with further increase of k , a small number of equilibrium states of x emerge from chaos. As a system moves through bifurcation points, it develops its own particular and contingent history, arising from the intertwining of deterministic laws of change (e.g., motion) and indeterminate (chance) fluctuations.

This model (i.e., eqn [1] and Figure 2) directly relates to the conversation between the child and the parent. It is, in fact, equivalent to the catastrophe-theoretical model presented earlier and depicted in Figure 1 for $3 < k < 3.45$, where x jumps between two values. The model allows us to understand the situation right after the child utters his/her sentence and prior to the parent’s response. At this point, the function of the child’s utterance in the collectively constituted conversation is not yet clear, and two possible responses are possible. For any k , therefore, the diagram provides the possibility space; as soon as the next person (parent) acts, the possibilities are reduced

Figure 2 A bifurcation diagram for eqn [1]: depending on the value of k , there are 1, 2, 4, . . . values that $x_{t=\infty}$ takes.

to certainty and the value of x is certain. Readers will immediately realize that any moment in a real classroom situation corresponds to the situations with $k > 3.6$, where there are innumerable possibilities of the next answers setting up new situations and each will have innumerable possibilities of continuation. As k increases, windows (white panels (**Figure 2**)) open up, within which three stable numbers appear, followed by period doubling to 6, 12, 24, and so forth. These period doublings resemble the original image, but now occur at a new scale (insert in **Figure 2**). This is what is denoted by the terms self-similarity and scale invariance. In the classroom, these qualities could be observed where a whole-class discussion about a chaotic event mirrors the discussions that previously occurred in smaller groups where each group came up with its own explication of a phenomenon of interest (e.g., Roth and Duit, 2003). Self-similarity of content is evident across the different discussions and scale invariance exists as a result of the discussions emerging on both whole-class and small-group levels.

It is also important to note that real human life situations do not correspond to stable k values that ecologists, for example, use to model repeating size patterns of animal populations; rather, human life is so complex that it corresponds to (unpredictable) changing values of k , and because of this, it is impossible to be absolutely certain what the effect(s) of our (discursive and practical) actions will be. In more poetic words, Frost (1966) makes the same point in “The road not taken”; there are always more than two roads and we can never know which one we are placing our first step on. Each time, we immediately find ourselves at another bifurcation point with similar complexity. In addition, regardless of the scale (e.g., at a microlevel) at which we examine a human event, for instance, what a student focuses on during a science demonstration, the complexity is so great that we cannot be certain about how many different ways even the simplest of science demonstrations might be perceived by the students (e.g., Roth, 2006).

A Third Model for Representing Social Processes

Such perception phenomena can be modeled using morphodynamical (catastrophe-theoretical) models, which combine qualitative (typological) and quantitative (topological) dimensions. The discontinuities (e.g., in perception, seeing, hearing, and categorization) are the result of complex, continuous, dynamic, and, therefore, inherently unstable processes. Qualitative discontinuities are recovered mathematically as dynamic events of bifurcation (Petitot, 2003), where complex systems radically change their expression, here in a qualitative difference, for example, in the perception of a color, an edge, and so forth. These models therefore

synthesize objectivism and subjectivism into a dialectical identity of nonidentical entities.

Language and speech are other important nonlinear (complex) dynamic systems that are of importance in curriculum theory. What a second-grade student hears during a reading lesson, for example, when her teacher utters what linguists transcribe as “bəa” – bare, to bear, or bear (animal) – is a function of context. Each of the different possible hearing constitutes an attractor (Gaudin, 2005) similar to those that are observable in **Figures 1** and **2**.

A Fourth Model for Representing Social Processes

Educators (teachers) who come into contact with the chaos theory frequently liken curriculum and the process of developing it to strange attractors where the trajectories of learning cannot be predicted but, in the end, captured in the potential of one or the other attractor, only a small number of possible learning outcomes – one in the extreme – are achieved. To illustrate how this model is used as a form of scientific representation, let us examine a high school experiment involving a magnetic bob that moves back and forth across two magnets after it begins at a certain position in space and with some initial velocity (Roth and Duit, 2003). This constitutes a two-state system in motion in which its endpoint is unknown because even infinitesimally minute influences along its trajectory change not only the trajectory, but also the endpoint. Thus, the only certain prediction we can make is that the system will end up near one of the two attractors. What we cannot predict is where the bob ends up – because over many trials and everything else being equal, the probability of it ending up at one or the other magnets is the same, that is, $p = 0.5$.

To study this system’s behavior as it moves from left to right and right to left, changing its speed (i.e., magnitude of velocity) as it approaches and recedes from the magnets, requires scientists and mathematicians to plot its trajectory in phase space – a set of variables that completely describe the system. In this instance, there are two one-dimensional variables, position and velocity, and, together, they create a two-dimensional phase space (**Figure 3**). The figure shows how, beginning with the same position and velocity, the pendulum is caught at one point of time in the left attractor (A_1), whereas it is caught in the other attractor (A_2) at the end of another run.

Although such a model provides an entry point for high school students’ understanding of chaotic systems (e.g., Roth and Duit, 2003), it is a very limited analogy for understanding anything about curriculum planning or the enactment of it.

A Fifth Model for Representing Social Processes

A more realistic system consists of a simple model for how people make decisions, such as choosing one of two options or classifying an object into one of two categories. For example, let us imagine a group of curriculum developers attempting to decide whether to include a particular concept in a curriculum (i.e., phase space). A model that is based on parallel distributed processing, and used for artificial neural networks, allows us to represent such a decision as constraint satisfaction (McClelland and Rumelhart, 1988). Each statement made in the decision-making process describes an aspect of the curriculum as a node (**Figure 4**); three statements support the inclusion of a particular concept under discussion (**Figure 4**, see 1–3) and three statements are made not to include the concept. Some statements support each other explicitly and are modeled as reinforcing links between the nodes (+). Some pairs of statements are contradictory, each supporting a different decision, which is modeled as links between

Figure 3 The trajectories of a simple chaotic system in phase space. Although the system begins at the same place and with the same velocity, its trajectory is unpredictable and, yet, the system will end up near one or the other attractor.

Figure 4 A simple model for decision making (categorization) that relates each statement supporting one of two decisions (gray, white statements). When a statement is supported by another, it is positively linked to it, whereas when another statement contradicts it, it is negatively linked. The strength of support or contradiction corresponds to how emphatic the statement is presented in the meeting.

nodes that weaken each other (–). Some statements do not relate to others and these are characterized in the model by the absence of a link. The final model consists of a network of statements, about a proposal, which mutually reinforce, weaken, or are neutral to one another. The outcome of the process is a solution with the least constraint in the network. Mathematically, the system finds itself somewhere up on a mountainside in a six-dimensional space and is moving (could we say flowing?) down the steepest gradients of the slope until it ends at some lowest place (lowest state). (Mathematically, the problem is the same as in eqn [1], the only difference being that there are now six mutually influencing variables rather than one.)

The dynamics of the system in six dimensions (its phase space) is impossible to envision; however, the (Euclidean) distance that the system has from the two end states (yes and no) can be calculated, yielding a representation of the systems dynamics in two dimensions, which constitute the interpretation or decision-making space (Hutchins, 1995). The left panel of **Figure 5** shows the trajectory of the decision-making process for different scenarios. In scenarios 1–3, the curriculum committee starts mildly favoring a decision to include the concept. However, because of different ways in which the same propositions are affecting others, the curriculum committee quickly comes to a supportive decision (trajectory 1), after initial consideration to the contrary (trajectory 2), or, during the considerations, shifts to support not including the concept (trajectory 3). The two end states – inclusion or noninclusion of the concept – constitute attractors where the system does end up.

There is a third attractor, which does not constitute an absolute minimum (relaxed state of the system) but a local minimum in which the system can be trapped. (Imagine a dip somewhere on our six-dimensional (fractal) surface that can trap the system in its course.) Scenarios 4–6 (**Figure 5**, right panel) model the different situations in which the curriculum committee is hung because both decisions (inclusion and noninclusion) are concurrently being supported and, therefore, a consensus cannot be reached. The different trajectories model the different ways in which the committee reaches the state of indecision. In scenario 6, despite the almost certain starting position of not including the concept, the curriculum committee moves toward a state where both funding and not funding are supported equally well.

Despite the complexity of the possible outcomes that this model can handle, it is still simplistic when we compare it to real-life social-psychological processes. Although it represents the changing strengths of the propositions 1 through 6, it cannot express the relation between them; it models all statements as if they arise simultaneously rather than unfolding over time, continuously modifying the context in which future statements are made; and it only models six statements as opposed to what is more realistic,

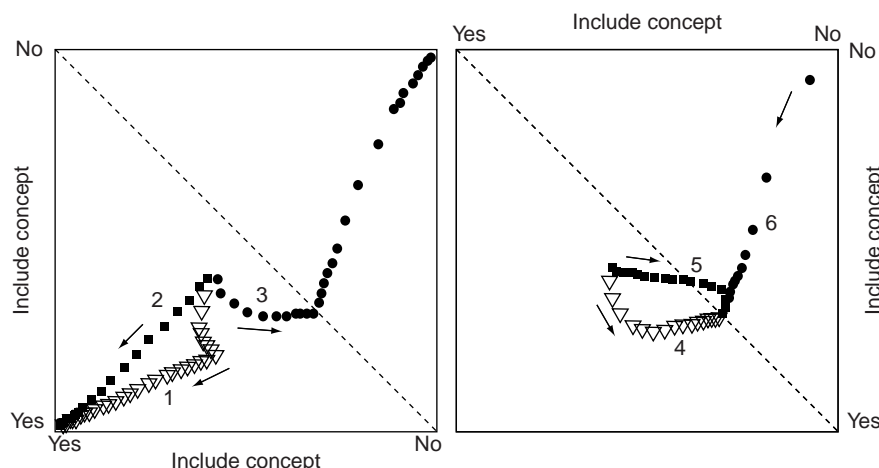

Figure 5 Modeling group decision making when some propositions favor including a concept in the curriculum (1, 3, and 5 (Figure 3)) and others favor not including the concept (2, 4, 6 (Figure 3)). Slight variations in emphasis with which arguments are made lead to the inclusion (1, 2) or noninclusion of the concept under consideration (3). Sometimes, even with extended discussion, the decision-making group ends in a stalemate (4–6).

a potentially infinite number of statements committee members might make in the process. Nevertheless, the strength of this particular model is that it underscores the notion that minor variations in initial conditions can lead to substantially different outcomes – one decision over another. This model also sufficiently captures the complexity of classroom events in that it demonstrates how, once all statements made in some situation are known, the possible ways in which concrete classroom conversations come to a conclusion (Roth, 2001).

Limitations of Analogies and Metaphors in Curriculum Theorizing

In this article, different models and situations are presented to exhibit the suitability of complex systems theories to curriculum theorists. It has been suggested that the mathematical models and graphical representations may be used in metaphorical and analogical ways. However, the effective use of metaphors and analogies requires knowledge not only of source and target domains, but also, and importantly so, the instances in and conditions under which the relationship breaks down. This is also the case for ideas, concepts, and theories from the domain of complex systems. All too often, concepts are taken from the complexity theory, applying them in loose ways that lack rigorous analysis but abound with generic advice (Fenwick, 2004).

From this articulation of different models, it is reasonable to conclude that the complex systems theory for actual physical, sociocultural, and cultural–historical contexts may be very different from the one that appears in the simple models presented here and elsewhere, and which figures prevalently in the educational literature. We do not know whether the phenomena of interest in the curriculum

show scale invariance, such as the one depicted in Figure 2. Do terms such as self-similarity and recursion allow us to expand possibilities for curriculum theorizing or restrict such actions? Current thinking across many disciplines, including landscape and physiological, paleo-, freshwater, and estuarine ecology, population interactions, meteorology and climatology, as well as global change, suggests that this is not precisely the case: to forecast the evolution of the complex system, one needs to take into account the particular scale chosen or involve the required scaling rules that, however, have not yet been developed (Costanza, 2003). The influence of scale, resolution, and hierarchy between different levels has not been investigated to any extent and remains a key question in developing coherent models (theories) of complex systems. Thus, although some curriculum theorists use the notion of scale invariance, even the inventor of the concept of fractal geometry takes a more differentiated view: “no one believes that the world is strictly homogeneous or scaling. . . . One should not be surprised that scaling fractals should be limited to providing first approximations of the natural shapes tackled” (Mandelbrot, 1983: 18 and 19). What, if so, are these limits? To what extent do models for simple constructed phenomena such as question–answer pairs scale up and capture truly complex and real events that arise moment to moment in classrooms, schools, and the field of education at large? In what manners do these theoretical frames allow us to understand events such as test taking, differential achievement, or the similarity in transnational curriculum comparisons?

In mathematics, the complexity theory is concerned with solving classes of problems (algorithms), some of which are vastly more difficult to solve (compute) than others. It is concerned not with the difficulty of solving the problem (algorithm), but with “infinite families of

problems where there would be a general algorithm for finding answers to all the problems of a single family” (Penrose, 1989: 141). In curriculum theorizing, we need a similar field concerned with tracking the solution(s) of infinite classes of problems. Fundamentally, the ideas that appear in much of the literature on complex systems are grounded in an epistemology of the same – recursion produced by some mathematical algorithm, the algorithm itself, self, similarity, self-similarity, and scale invariance are all terms that begin with the ideology of sameness and construct difference as the opposite, not the same, lying outside the boundaries of the same. The idea of the curriculum as a strange attractor, though implying the unpredictability of different trajectories, also implies one or more common endpoints that some enacted curriculum or curriculum committee might arrive at. Precisely here lies a problem that difference, which any real physical and cultural–historical system displays, is not modeled as a positive phenomenon, that is, as a phenomenon in and for itself. It is therefore necessary for the complex systems theories that have any value for describing and explaining real systems of interest to begin differently and recognize that any similarity is the outcome of a (decision making) process rather than *a priori*; sameness and similarity are human productions and not inherent characteristics of nature or culture (Deleuze, 1994). For example, although cooking pots and children’s cups that have a pair of handles appear to us as two different entities that are also substantially distinct on a practical level, from a mathematical perspective, they are considered to be topologically the same; that is, it is possible to morph one into the other without severing or reattaching any of its parts. Consequently, this raises an additional need for educators’ questioning and careful consideration of these forms of mathematics and the models they belong to as suitable structures to constitute the source of analogical thinking about curriculum.

The examples and models presented here – social interaction and decision-making processes – are complex and unpredictable. They serve to highlight just how non-simplistic the real world really is. At the very least, the complex systems theories provide us with ideas that are suggestive of how intractable the world is given that the simplest of phenomena already involve enormous and, perhaps, incalculable complexity.

Curriculum and Constructivism

B Davis and D Sumara, University of British Columbia, Vancouver, BC, Canada

© 2010 Elsevier Ltd. All rights reserved.

Perhaps more than any other categories of learning theories used to inform educational practice, constructivist discourses challenge the commonplace separation of what one is taught from how one is taught. Indeed, an oft-cited quality of constructivism-informed practice is that learning is an elaboration of what is already known; hence, the suggestion that content or tasks might be selected independently of learners is regarded as antithetical to a constructivist mindset.

One might say that a constructivism-informed curriculum is more a path laid while walking than a preselected route, echoing the notion of *currence* as developed by Pinar and Grumet (1976). They noted that the root of the word curriculum has to do with the running of the course rather than the “course to be run, or the artifacts employed in the running of the course” (p. 18). As they develop, the ongoing process of meaning making entails a constant recovery and reformulation of one’s embodied history. Curriculum, in this sense, arises in the moment of engagement.

We elaborate this suggestion in this article, starting with a brief overview of some of the more prominent constructivist theories. We then foreground and contrast metaphors for curriculum employed by nonconstructivists and constructivists, highlighting that the title constructivism is often misappropriated in popular conceptions of learning and knowledge. Finally, we highlight some of the more prominent and more thoroughly researched suggestions for formal curricula that have been proposed by constructivist theorists.

Constructivist Theories

Over the past 40 years, there has been a proliferation of constructivist theories of learning that, on the surface, seem to have little in common beyond a rejection of behaviorist, cognitivist, and/or transmission-based emphases in education. The apparent disparities among these theories are rooted in the fact that they are concerned with such varied phenomena as individual understanding, collective process, cultural knowledge, and social justice. When one looks beneath these explicit interests, however, some shared convictions and deep compatibilities emerge, including the following:

- they all highlight the vibrancy of their particular interests, usually by invoking bodily and/or ecosystemic metaphors (e.g., body of knowledge, student body, and body politic);

- they tend to describe systemic dynamics in terms of adaptation and evolution (i.e., notions rooted in biology) rather than cause and effect (i.e., notions drawn from physics);
- they focus on fit (coherence) rather than match (correspondence) in their accounts of how agents or ideas arise and persist, arguing that the criterion for survival is not optimality/efficiency but adequacy/sufficiency (if something works, it will probably endure); and,
- they all embrace the notion of structure determinism, according to which learning is determined by the learner’s own complex history, not by experience or pedagogy (more colloquially, learning is dependent on but not determined by teaching).

More generally, these theories are focused on the manner in which agents in a system must cohere in order for the grander system to remain viable. The nature of an agent varies from one theory to the next, depending on the system under examination. For example, agents might comprise a set of ideas (as in the case of an individual’s understandings), customs and laws (for a society), or species (for an ecosystem).

The major point of departure of these frames from earlier theories of learning is that they are organized around the assumption that what really matters is internal coherence, not external correspondence. For a system to be viable, its parts must hold together. That is, the robustness of an understanding (or whatever the agent might be in the system under examination) is not measured according to how closely it matches, reflects, represents, models, or otherwise corresponds to a reality external to the system. Rather, the measure of an idea is the extent to which it fits with/in the knower’s network of understandings.

In popular parlance, the learners and knowers are most often understood to be individuals, and so it is perhaps unsurprising that the most prominent constructivist theories deal with the question of how individuals make sense of the world. Sometimes qualified with adjectives such as radical or subject-centered, these constructivisms are typically traced to the work of French biopsychologist, Jean Piaget. His project might be described as an effort to construe personal learning through the metaphor of emergent biological forms. He suggested that the development of understandings is analogous to the growth of living systems, and so his theory of personal learning foregrounds principles of contingency, adequacy, adaptation, and fitness. In brief, Piaget (1955) argued that

learning is a continuous process of updating one's sense of the world as prompted by new experiences. The learner is constantly construing and reconstruing in an effort to maintain a coherent system of interpretation.

In other words, for subject-centered constructivists, the biological body is not a structure through which one learns, but a structure that learns. Individual learning is not a brain-based phenomenon, but an ongoing process of embodying one's history. For this reason, bodily action is not seen as a demonstration of internalized understandings; rather bodily action is understanding.

Another strand of constructivist discourse is known as social constructivisms – a term that comprises constructionism, sociocultural theory, activity theory, situated learning, communities of practice, and actor-network theory (among others). The common interests across these frames are interpersonal dynamics and collective activity. They generally address the sorts of phenomena that subject-centered constructivisms set aside as context or circumstance, including language, artifacts, social status, cultural background, and disciplinary knowledge.

The major point of departure from these more collectivist theories is an extension of the notion of a cognitive unity. Social constructivists do not regard the individual as the locus of learning but as a learning system within a grander learning system. For the social constructivist, human cognition is diffuse, distributed, and collective. In this frame, mind is understood not as an individual possession but as a product of shared human interest that arises in an environment that is both social and physical. Much less preoccupied with individual sense-making, social constructivist theories focus on conversation patterns, relational dynamics, social habits, prevailing technologies, and other aspects of collective possibility. In this frame, cognition is always collective: embedded in, enabled by, and constrained by the social phenomenon of language; caught up in layers of history and tradition; confined by well-established boundaries of acceptability; defined by joint interests, shared assumptions, and common sense.

The most commonly cited influence across social constructivist theories is Russian sociopsychologist Vygotsky (1986), whose core metaphor (reflecting the Soviet context of his research) was shared labor rather than biological coherence. This emphasis is preserved in some branches of discussion, particularly those that are organized around notions of apprenticeship and communities of practice. However, biology-rooted notions of bodies, coherence, and fitness have also come to be pervasive across social constructivist theories.

For the most part, discussions of constructivism within education are bounded by the bookends of the individual's construal of the world and the self-maintenance of the social collective – which is perhaps to be expected. Through most of the twentieth century, the bulk of educational research was focused on individual learning and social contexts and

was oriented by theories drawn mainly from psychology and sociology. However, through the 1960s and 1970s, as researchers with backgrounds in anthropology and philosophy entered the field in larger numbers, increased attention began to be given to issues such as cultural context and the social implications of schooling. One might say that the conversation was broadened to include issues of the body politic. Furthermore, while this part of the conversation is not often associated with either subject-centered or social constructivist theories, it shares the tendency to invoke body-based metaphors and to describe events in terms of evolutionary dynamics. A major difference, however, is that cultural and critical theories tend to delve into issues of morality and ethics – seeking, for example, to uncover the ways that schooling contributes to (or, more hopefully, might interrupt) social stratification, gender roles, and other cultural habits of differentiation. In other words, cultural and critical constructivist theories are principally concerned with deeply entrenched habits of interpretation and implicit associations that support social constructions of gender, race, class, sexuality, ability, disability, opportunity, and so on. A parallel focus has to do with the manners in which certain domains, such as mathematics and science, have been given privileged voices in the contemporary academic world. One might say that cultural and critical constructivist discourses attempt to shift the topic of conversation from the individual's efforts to shape an understanding of the world to the manners in which the cultural world shapes the understandings of the individual.

Metaphors and Images of Curriculum

Over the history of the modern school, different images have been employed to describe curriculum. Most commonly, curriculum has been characterized in terms of progress along a linear path (always forward, usually upward) toward a prespecified, fully articulated goal.

The notion of the spiral curriculum rose to prominence, first proposed by Bruner (1960) (who is often identified alongside Piaget and Vygotsky as one of the principal authors of constructivist theory). The idea was that, rather than proceeding through topics sequentially, students should be introduced to concepts gradually, revisiting topics each year to elaborate understandings. The spiral image was intended to embody a sense of what might be referred to as dynamic sufficiency – a notion offered in opposition to assumptions of the static deficiency of learners. Rather than positioning learners as essentially fixed beings with inadequate understandings that must be completed by schooling, the spiral curriculum was prompted by the realization that human knowers can never be finished, yet are always strangely sufficient. The process of formal education, then, is not to complete

learners, but to present opportunities to expand horizons of possibility.

This point is perhaps better expressed in terms of underlying visual metaphors. In both the classical (sequential) and the more recent spiral models of curriculum, the images are line based and oriented by a desire to converge onto pre-specified objectives. Constructivist interpretations inject senses of contingency and emergent possibility, and thus lean more toward images that involve branches ramifying into new branches. Typical images include fractal trees (see **Figure 1**) and waterfalls, the latter of which highlights the importance of context in defining emergent possibility. In essence, learning and the production of knowledge are understood in terms of opening up spaces of possibility by exploring the spaces of the existing possible. These recursively elaborative processes do not completely reject notions of directionality and preselection of learning outcomes; however, they do reject the assumptions that paths of learning can be predetermined and that there are best methods for structuring curricula.

This point – that is, that there are no best, merely good-enough approaches to education – has been identified as one of the most troubling aspects of constructivist theories. In effect, these theories do not indicate what should, must, or can be done to affect learning systems; rather, they are more focused on what cannot be done or should not be attempted. In particular, they emphasize that teaching should not be construed as causing learning and that curriculum should not be construed as any sort of deliberate constructive process. This latter suggestion has the ring of a paradox: How can it be that constructivist theories reject curricula that are understood in terms of processes of construction?

The underlying issue here has to do with a problem of translation and multiple meanings. In English, the word construction most often calls to mind notions of foundations, platforms, rigid frameworks, hierarchies, planning, and so on – in brief, precisely the sorts of images that are associated with linear and spiral curricula. In French, the language of Piaget's theorizing (and, more significantly, the language of the structuralist philosophy that influenced his work; see Davis and Sumara (2002)), construction has two distinct meanings, and the more common of which is a biological sense of ever-evolving possibility that is both reasonably stable and subject to sudden

change. This meaning is better preserved in the English cognates *strew* and *construe* and is more readily associated with the notion of an emergent curriculum.

This issue is of vital importance in distinguishing current constructivist theories from trivial and naive constructivisms that are often encountered in contemporary discussions of educational practice. Mantras, such as everyone constructs their own understandings and learning is based on experience, are commonly deployed as indicators of constructivist sensibilities, yet these notions have actually been part of the educational literature for centuries. Locke (1960/1976), for example, asserted “No man's knowledge can go beyond his experience” (bk. 2, ch. 1). An upshot is that a constructivism-informed curriculum is not a straightforward matter of a rich learning environment, an attentive teacher, and open-ended outcomes.

Curriculum Informed by Constructivist Theories

It would be impossible and irresponsible to suggest that there is any sort of consensus around what might constitute a constructivism-informed curriculum. However, there are a number of commonly mentioned elements. Several of these are discussed below. In order to contextualize the discussion, and to be attentive to the core principles of situatedness and embodiment of learning, we illustrate the discussions through a specific example – namely, the topic of day and night, explained in terms of the Earth's relationship to the Sun.

Trans-Level Learning

Considered as a cluster of overlapping and intersecting frames, the family of subject-centered, social, cultural, and critical constructivisms call for attentiveness to the manners in which individual, social, and cultural forms unfold from and are enfolded in one another. Rather than getting trapped in dualistic arguments in which, for example, the interests of the individual are pitted against the interest of society, these frames are oriented by a more all-at-once mindset and thus gesture toward a curriculum that might be described as transphenomenal. A guiding question is

Figure 1 Common visual metaphors for curriculum: sequential, spiral, and emergent.

how the topic at hand reaches across various levels of learning/adaptation.

For example, working from the premise that personal knowledge is anchored to experience in the world, a subject-centered constructivist frame might prompt attention toward the various ways that individuals might interpret or explain day and night. Most popularly, as evidenced by phrase such as the rising sun, daybreak is described in terms of the sun transiting the Earth's sky (rather than the Earth spinning out of its own shadow). A curriculum that is sensitive to such interpretive tendencies might include suggestions for activities through which individuals physically engage with different models (e.g., involving flashlights, balls, and elliptical paths). Such activities would be selected and designed not only to address the topic of day and night, but also in a manner that sets up related topics such as phases of the Moon, the Sun-centered solar system, and seasons – in brief, aimed at the articulation of a coherent set of principles that provide the learner with some significant conceptual reach.

On the more collective level, prompted by social constructivist theories, a curriculum might incorporate topics around the production of scientific truth. The contested nature of early heliocentric models provides a good opportunity to address issues around the ways scientific theories are developed, presented, defended, accepted, or rejected. Conversely, the classroom collective might be organized as a community of inquiry in an attempt to reflect the exploratory and collaborative work of scientists. Whatever the case, the orienting principle is that science (or whatever domain) should not be reduced to a collection of pre-given facts to be mastered. Rather, it should be represented and experienced as a specific and very social orientation toward addressing questions of shared interest.

As for cultural and critical constructivist theories, the historical transition from a geocentric to a heliocentric model marked a dramatic shift in Western sensibilities. It occurred at the dawn of the scientific era and was accompanied by the rises of capitalism, industrialization, urbanization, and European imperialism – and these movements were likely influenced by the displacement of the Earth from the center of creation to the status of minor planet orbiting a typical star. Cultural and critical constructivist theories might highlight the need for curriculum topics that include interrogations of a male-dominated, Eurocentric science on religion, global politics, and cultural genocides. In brief, explanations of such simple phenomena as day and night are neither innocent, nor isolated.

Cognitive Conflict

Further to the matter of the need to provide individual learners with opportunities to engage physically with objects in their worlds, since the early 1980s there has been a pronounced emphasis among subject-centered

constructivists on cognitive conflict. Underscoring that curriculum should address students' suppositions, the suggestion that experiences should be organized in ways that compel learners to be attentive to (and, if necessary, to reconfigure) understandings. This emphasis is framed by the principle that learners will hang onto an interpretation, no matter how limiting it may be, until the effort required to maintain it exceeds the effort required to revise it.

In the 1980s, this principle was most often discussed in terms of learner misconceptions, which by the early 1990s was redubbed alternative conceptions (reflecting the conviction that knowledge is about internal coherence, not external correspondence). The advice is to develop sets of experiences that lead to surprising results, so that learners question their frames of interpretation and (hopefully) revise them. This emphasis has been described in various ways, including the introduction of cognitive obstacles, structuring of discrepant events, and deliberate attempts to prompt disequilibrium. By way of specific example, the sorts of activity suggested in the previous section (e.g., involving flashlights and spheres) might be structured in ways that anticipate and challenge common, but limiting interpretations (e.g., introducing the question of phases of the Moon alongside day and night to highlight the conceptual contortions needed to maintain a geocentric model).

A problem here is that learners often generate auxiliary explanations and strategies (e.g., "In this case, use this rule") rather than revising understandings. In more general terms, the strategy of introducing discrepant events has been tied to the topic of transference of understandings across contexts and experiences. Seeking to address the commonly noted problem of isolated learnings, curriculum developers are also urged to consider the ways concepts might be taken up across disciplinary realms and within the variety of contexts in which learners find themselves. By consequence, curriculum should not be conceived in terms of a collection of parallel strands, but as a set of interlacing discourses with multiple opportunities to address and elaborate topics introduced in other contexts.

Rethinking Errors and Evaluation

Linking two points mentioned in the preceding sections, constructivist theorists call for a reconsideration of the notion of error. Commonly, errors are understood as mismatches between internal and external worlds. For constructivists, all actions are rooted in a coherent interpretive system – and so an interpretation that works well for the individual (such as a belief that the Sun goes around the Earth) cannot be construed as a mistake on the level of the individual.

However, on the level of social action, it can and must be understood as an error. Otherwise, there is a risk of

interrupting or disabling collective action. Note that the point here is not that education must seek to ensure everyone holds the same set of ideas. On the contrary, as noted in the section titled “Collective learning,” tension among views held by individuals in a knowledge-producing system is important for its survival. However, while some idiosyncratic beliefs are valuable and others can be ignored, there are some that prevent collective action. When that happens, they are justly treated as errors.

Further as suggested in section titled “Cognitive conflict,” the teacher’s responsibility here is not to fix a student’s error, but to make sense of the web of associations that render the interpretation a sensible one to the student. Working from an appreciation that the student’s action was part of a coherent worldview, the teacher would attempt to involve the learner in new sets of experiences that might support the construal of more appropriate interpretations.

By implication, methods and structures of evaluation must be attentive to the particular contexts of student action. Thus, in constructivist terms, contemporary approaches to standardized examinations are rife with problems. Not only do they ignore the necessarily experiential and contextual dimensions of understandings, but they also introduce a new level of organization in which new categories of error might arise (i.e., actions that might not be treated as errors on the individual or classroom levels could potentially emerge as errors on the level of a standardized examination). Further, they promote a curriculum organized around mastery rather than engagement. Significantly, however, the point is not that standardized examinations are wrong. Rather, the issue is that they may not (and perhaps cannot) test what they are assumed to test, since they are necessarily inattentive to intermediate levels of educational organization and activity. In turn, this issue raises questions around what it might mean to standardize a curriculum.

Collective Learning

With the interest in collective knowledge production across social, cultural, and critical constructivist theories, it is not surprising that there tends (as in the point developed in the section titled “Trans-level learning”) to be a strong emphasis on incorporating topics such as standards of verification, political dimensions of disciplinary realms, and unanticipated consequences of privileged discourses. In recent years, an added dimension of collectivity has risen to some prominence, and it is an issue to highlight inseparability of pedagogy and curriculum.

Oriented by the conviction that the word learner can refer to any context-sensitive, adaptive, and self-maintaining phenomenon, one might argue that classroom groupings might properly be construed as learners – that is, not as collections of learners, but as collective learners – capable of producing and acting on their own knowledge.

For the most part, traditional classroom structures and emphases do not support the emergence of a knowledge-producing collective in any significant sense, in large part owing to the structures of activities that organize their engagements (cf. Surowiecki 2005). In particular, and in contrast to productive knowledge-producing communities, there is often an overemphasis on redundancy (e.g., preset objectives, determined independent of learners, based principally on age) and an underemphasis on diversity (e.g., opportunities to pursue idiosyncratic interest or to bring specialized knowledge to bear on a real issue). To address these matters, a variety of researchers and theorists from across subject areas have called for curricula that, simultaneously, enable the development of necessary redundancies among learners and provide opportunity for the articulation and elaboration of diverse interests – all within the context of shared projects.

In this frame, redundancy is understood to refer to those competencies that enable individuals to work together. These elements might be thought of as the basics – where one is mindful that this phrase only makes sense when considered in relation to era and location. Redundancy contributes to the robustness of a system as it facilitates communication, frames interests, and enables individuals to fill in for one another. The notion encompasses not only matters of conceptual knowledge, but also problem solving, communication, and other social competencies.

Its complement, diversity, might be interpreted as the basis of the collective’s intelligence. Varied interests and expertise provide the pools of possibility that a learner might draw on in order to address more complex problems. To this end, commonly identified aspects of curriculum tasks include variable entry points (i.e., that allow individuals to negotiate the difficulty to suit their interests and levels of conceptual development), authenticity (usually taken to mean relevant, or able to be made relevant), and possibilities for digression (i.e., opportunities to pose new problems).

Of course, such structures present an issue that represents a challenge to traditional curriculum structures: There exists the possibility of generating knowledge and pursuing topics that are not explicitly sanctioned by the official program of studies. As such, there is a concomitant need for a sort of decentralized control, not only in the classroom, but also at jurisdictional and ministerial levels.

Participation

In a strong sense, the notion of a participatory curriculum might be used to collect together the above points. Constructivist theories are, in effect, participatory epistemologies. They understand knowledge to inhere in interactions – that is, to be embodied or enacted in the ever-unfolding choreography of action within particular contexts at particular times. This orientation compels a certain mindful attendance not only to what one knows, but also to the

consequences of one's knowing. Education in this frame is more about becoming aware of emergent possibility and corresponding responsibility than about acquisition or mastery. From this it follows that a curriculum must not only allow for participation, but also be organized around participation.

As for the future of constructivist theories in curriculum development, there would seem to be both significant challenge to overcome and significant promise to be realized. On the side of challenge, it often seems that more effort is given to identify differences among particular constructivisms than to examine their deep complementarities. By consequence, the range of contemporary constructivist theories might be interpreted as too dispersed and conflicted to be of much practical use. On the side of potential contribution, most constructivist theories are explicit in their embrace of evolutionary dynamics and self-organizing structures – emphases that align these discourses with transdisciplinary discussions of complexity and ecology. They thus offer advice not only for the content of curriculum, but also for its enactment, its ongoing development, and its place in the grander contexts of cultural and biological worlds.

Glossary

Capitalism – An economic and political system based on market competition, profit, and individualism.

Hegemony/hegemonic – The ruling ideas and social interests within a country.

Ideology/ideological – Beliefs and ideas that distort the truth, but represent the interests of a particular group.

Modernism – The belief that society and social institutions can be improved by the application of rationality.

Political economy – A focus on how institutions are shaped by capitalist economic interests and arrangements.

Postcolonial theories – The theories concerned with the effects of colonization or domination within a country on identities.

Reproduction theory – A theory that schooling and curriculum reflect the social structure and produce outcomes that continue that structure in its existing form.

How a society selects, classifies, distributes, transmits and evaluates the educational knowledge it considers to be public reflects both the distribution of power and the principles of social control. (Bernstein, 1971: 47)

Bernstein's much-quoted aphorism is a classic statement of a critical theory perspective on curriculum. In its historical and narrow sense, critical theory is the term given to a body of mid-twentieth-century, neo-Marxist European social theory (the Frankfurt School), whose writings analyze culture and hegemonic power. Education theorists drawing on this tradition were interested in the ways that curriculum functions as an ideological apparatus of the state by serving and maintaining the power of the dominant social groups and contributing to the subordination of others. Critical theorists analyze curriculum as an institutional set of arrangements that includes policies, contexts, identities, and pedagogy as well as explicit curriculum documents. They see curriculum as a social construction that works to produce ways of thinking and distributions of opportunity in which some social groups are powerful and others marginalized. They attempt to work toward new approaches and agendas for the

curriculum that might produce fairer and less subordinating social outcomes.

Over time, the range of activities and theories that might be considered to constitute critical theory has expanded, particularly in the prominence of feminist and critical race perspectives in the work, and in the taking up of some aspects of poststructural theory into the critical agendas. However, broadly, what distinguishes curriculum work bearing a critical tag is its ongoing concern with the relation between curriculum and broader social forms and its attempt to challenge social inequalities and differences and state hegemony as these function in and through curriculum.

Sociology of Knowledge and Curriculum as Ideological

In the critical theorizing of curriculum that flourished from the 1970s through the mid-1980s, two key ideas were prominent: that sociologists should investigate curriculum, and not simply school inputs and outputs, in order to understand how success and failure are distributed in schools; and an attack on the view that curriculum knowledge could be neutral. Curriculum was seen as serving the interests of particular social groups, and, more broadly, as serving an ideology of capitalism that represents different economic rewards as simply the outcome of individual effort and choice.

In the UK, the most influential text of this period was *Knowledge and Control: New Directions for the Sociology of Education* (Young, 1971). This signaled the beginning of a new prominence of specifically sociological perspectives on knowledge, and a fierce debate with philosophers of curriculum and with traditions of theorizing curriculum in terms of questions about the educated man, or the disciplinary forms of knowledge, or in terms of analytical distinctions about education versus indoctrination or socialization. It began an era of considering curriculum questions in terms of whose interests are being served by particular selections and forms of knowledge and assessment.

In the USA, influential works in the 1970s took a political economy approach: that is, they were concerned with economic determinants of education, curriculum as ideology, and education as a means of producing docile workers for the capitalist system. Bowles and Gintis (1976) argued that the hidden curriculum of schooling systems was designed to discipline populations for docile work in factories.

They were critical of the way differential school outcomes were attributed simply to internal factors of teaching and student effort, and, in a footnote, suggested that a more appropriate way to consider the achievement of schools would be to introduce a value-added measure that took account of their socially differentiated inputs – an idea that is now widely used in conservative education policy in many countries. Apple's (1979) work took up the economic interests of textbook publishers, and the ways these served the interests of capitalism by regulating what counts as curriculum knowledge in the USA.

Similar currents of work focusing on curriculum as a mechanism of social reproduction were being developed in many national settings in this period, including Sweden, France, Canada, and Australia. In Australia, for example, a major empirical study of working-class and ruling-class schools (Connell, *et al.*, 1982) identified the competitive academic curriculum as the lynchpin of the reproduction of class inequalities in education, and called for working-class schools to work with their communities to build different forms of knowledge and outcomes for them.

The critical theory approach is particularly associated with sociological work on curriculum; however, a few philosophers also took up a Marxist perspective on school knowledge, and from the 1980s and beyond, feminist philosophers played an important part in fundamentally critiquing perspectives of knowledge as objective or neutral. In the USA, some critical theorists would see a legacy from Dewey in their work, and also in the work of John Rawls. The use of the label critical theory is usually restricted to work that assumes an explicit critique of the current form of society as a foundation from which the analysis of curriculum begins.

In the 1970s, many radical books taking up particular elements of this broad critical approach to curriculum were widely circulating in general bookstores. Paulo Freire contrasted banking knowledge in which curriculum is conceived as a set of deposits to be transmitted to the learner, and which would inevitably reproduce power and advantage in its present form, with dialogical knowledge in which the teacher would work with the students to find key concepts for them, and begin to build these into more powerful (socially critical) ways of understanding their situation and the way to change it. Freire was later Minister of Education in Sao Paulo and his approach has been widely influential internationally, especially in literacy teaching.

Curriculum Theories: Bernstein and Bourdieu

Two important new theories of curriculum, by Bernstein in the UK and Bourdieu in France, were first developed in the 1970s and have had an enduring impact. Each has been widely used and elaborated by curriculum researchers in

many countries. Both bodies of work were built on a range of empirical studies of classrooms and school systems; however, both also developed more abstract formulations of curriculum and its relation to social forms and social inequalities, and the causal mechanisms that govern this relationship.

Basil Bernstein's work was interested in the relationship between social class-differentiated modes of language, identity and home socialization, experiences of curriculum in school, and forms of social structure being produced from school. In a series of important works, he used the concept of codes to develop a structural account of knowledge making and the ways of knowing developed by different social groups and curriculum arrangements. Bernstein's initial line of work focused on how the forms of language developed in different social class settings (restricted and elaborated codes) generated different forms of relationship and power in the classroom. Bernstein then turned his attention to the forms of school and university curriculum in different countries, and to the debates between advocates of integrated (or progressive) subject arrangements, and more traditional formal subject-based curriculum, which he named a collection code. By tracing what was open and what was closed in the different arrangements, Bernstein produced a highly generative schema for analyzing relationships and power of the teacher and student in different arrangements, effects of class difference, types of identities produced, and emerging new social forms (e.g., the knowledge and identity needs of the new (professional) middle class).

Pierre Bourdieu's work first became known to English-speaking readers primarily as a highly schematic account of schooling as a mode of social reproduction (Bourdieu and Passeron, 1977), and subsequently as a series of detailed investigations of the socially differentiated working of cultures and education institutions. His concepts of cultural capital, habitus, and intellectual field have been widely drawn on. Some key ideas in Bourdieu's work that have been important for curriculum are that family and community habitus (cultural, economic, and interpersonal environment) produces ways of learning to be in the world that are not only about language or what one knows intellectually, but also about physical and emotional presence and orientations to what one notices in the world (dispositions). For Bourdieu, the elite curriculum reproduces social elites because, through the curriculum and examination system, it asks of other groups what they cannot give, that is, it asks groups who are not of the elite to have already formed the tacit tastes and educational orientations of the elite.

Feminist and Critical Race Theories

From the 1970s on, feminist and critical race theories have been a core presence in critical curriculum theory, and

critical theory approaches have also been taken up by writers and activists concerned with disability and sexuality. In one sense, the work here expands and strengthens the critique of curriculum as representing the dominant interests of a capitalist/patriarchal/racist society. However, the new voices are each associated with social movements that do not simply emerge out of critical theory perspectives on capitalism and class that have been described to this point, though they do draw on these. They bring additional conceptual agendas and begin to challenge and reshape what is taken up as a critical theory perspective on curriculum.

In the most obvious sense, feminist theories expand the attention to a class-structured society by seeing society as structured by gender, and curriculum as a vehicle for transmitting inequalities and subordination related to gender; and race theories see society as structured by race, and curriculum as a vehicle for the reproduction of race and ethnic ideologies and outcomes. Both moves have been important in curriculum in mounting a critique of sexist and racist language and images in textbooks. At first, these concerns were often dismissed as a radical approach to curriculum; however, now, a modest form of that interest in representation is found in mainstream curriculum development and in instructions for textbook publishing, including in subjects such as math and science.

In practical terms, these movements expanded attention not just to what was in the curriculum (ideology of the mainstream or dominant class), but what was not in it as well. A feminist critical perspective was not just about adding women in to a curriculum story or an array of subjects that remained unchanged. It raised questions about what counts as public knowledge or history or science or academic achievement, and about the emphasis on a particular concept of rationality and individualism as the heart of education (Martin, 1994; Walkerdine, 1988). McCarthy and Crichlow (1993), Ladson-Billings and Tate (1995), and others developed similar challenges from the perspective of race issues.

Critical theory is overtly political in its orientation. Its concern is with processes and mechanisms that work through institutions, such as schooling, to covertly produce power and advantage, and discrimination and subordination for different social groups, and that work against democratic ideals. However, the development of feminist and critical race approaches has altered and challenged the way in which it is possible to think about the critical theory. They raise new ideas about what power or subordination looks like, and about the mechanisms or processes by which such social discriminations are reproduced.

Fraser (1997), for example, has named two different trajectories for understanding the politics of social justice: distribution and recognition. Distribution refers to the ways different groups gain or are excluded from economic goods in society. This is a formulation that has been

particularly associated with attention to class inequalities and poverty (though distribution concerns about curriculum are also part of the agenda for gender and race), and with the way school curriculum and assessment set up the conditions for success and failure of different social groups. Recognition is an issue that Fraser associates particularly with feminist and postcolonial movements, and it might be translated as the ways in which groups are, or are not, represented and acknowledged as part of the social polity, or as equally human. These are themes that have been particularly important in seeing school curriculum (or in Apple's phrase, official knowledge) as sexist or racist. Recognition (creating some groups as other, as lesser) is seen as an important discriminatory effect of curriculum, regardless of whether it has measurable outcomes in terms of immediate school success and failure.

Critical Theories and Poststructural Theories

In moving into these broader conceptualizations, the distinction between critical and poststructural theories of curriculum is not a sharp one, and the precise categorization a matter for debate (as is the question of whether feminist and postcolonial theories of curriculum are simply subcategories of other theories, or more appropriately seen as curriculum perspectives in their own right).

Traditionally, critical theory has been seen as a modernist form of theoretical and political activity. That is, it has been seen as an approach that is avowedly normative, one that believes truth (or at least more powerful or less-distorted understandings) can be obtained, and that wants to enhance the role of schooling as a form of social improvement. Poststructural theories (and postmodernism) are associated with a view that there is no single objective truth, that claims to truth are claims to power, and that the role of theoretical work is to unpack how truths and identities come to be constituted. In relation to curriculum, the critical theory has historically been more strongly associated with theories about the curriculum's distributional processes, and poststructural accounts with what kinds of identity formation and ways of being in the world are being produced by curriculum. However, especially with theories associated with feminist work, and with a widespread move to use the concept of discourse rather than ideology, the dividing line between these categorizations is not clear-cut.

One of the ways we might consider the distinction between these approaches for curriculum is to consider their form as theories. The early critical theory writing was clearly neo-Marxist in its foundations. That is, at least in its starting points, the work uses a causal form of explanatory theory grounded in showing a regularity of relationship between material practices (work and

family life) and ideas or ideology. The aim is to begin to reveal mechanisms for misrecognition and reproduction of social inequalities embedded in curriculum, and to find ways for nondistorted understandings of real social and individual interests to flourish. This is a political project as well as a set of theoretical perspectives, and one of its best-known forms in practice as well as theory, is the work of Paulo Freire.

With feminist work and work grounded in concerns about race, there is often less faith in a single explanatory theory as the potential solution to understanding curriculum effects, and less belief that a sphere of objective knowledge or undistorted communication can be attained once the distorting ideology is revealed. Rather, more diverse empirical and theoretical works are seen as needed to describe what is happening, and to take account of different conceptions of oppression. Much of the work here is critical of the single, big theory explanations and of neglect of the person, gender, and subjectivity in some other strands of critical theory work (Ellsworth, 1989; Luke and Gore, 1993).

Foucault's work is usually associated with a poststructural perspective on education, one that is interested in how people come to discipline themselves to serve the interests of a self-regulating polity, and that replaces the idea of a stable human subject who acts on the world with the concept of a subject positioned in discourse. However, much work that has been influenced by Foucault might also be seen as an extension of a critical theory approach, in that it develops from an interest in curriculum as a form of governance of the population that has particular disciplinary effects, both generally (e.g., in relation to neoliberalism) and for particular groups such as working-class children, or women. Feminist theorists of curriculum have had a particular interest in how consciousness and identity or subjectivity is constituted since the idea of the personal being the political has been a key conceptual agenda in feminist work.

The developments here are drawing poststructural perspectives into critical theory agendas in two ways: by developing a critical account of contemporary social forms and the role of curriculum as a mechanism of governing and disciplining identity; and by expanding attention to the interplay of desires and socially formed subjectivities with forms of curriculum. Subjectivity was traditionally a more central interest of feminist work; however, it is notable that many critical theorists, including Bernstein, Wexler, and others have also, in recent decades, focused more strongly on identities, and the role of curriculum in constituting them.

Power, Agency, and Action

One of the matters that has been of central concern for critical theory approaches to curriculum is how to

understand power and the scope for action by human subjects. The early phase of work that was labeled reproduction theory was subsequently much criticized for its overdeterminist picture and its apparent portrayal of human subjects as mere ciphers who reflect those mechanisms of schooling, and this led to some focus on resistance (i.e., studies of students from subordinated groups and the logic inherent in their refusal of the official knowledge schooling attempts to convey to them) and on collaborative action projects to produce change.

Critical action research has always been an important line of work within the critical theory (Carr and Kemmis, 1986). This work takes the position that moving to a more democratic or less ideological curriculum is not something to be worked out in the abstract by academics or bureaucrats, but requires collaborative work with teachers and students, and an ongoing cycle of identifying issues and working on and reviewing these. Other work (Giroux and McLaren, 1986) uses the term critical pedagogy and draws feminist and postcolonial agendas into its approach to change. In this approach, there is interest in the embodied person and in subjectivity as part of the terrain for critique and action.

As an avowedly political approach to curriculum, an intention of critical theorists has been not just to describe the world, but to change it as well. In practice, theorists who might come under this label take a wide range of positions in their work, with some operating almost entirely in terms of producing critical readings of curriculum, others working to develop new approaches to curriculum policy and teacher education, and yet others developing collaborative critical action research and critical pedagogy. A belief that the sources of curriculum and curriculum effects lie beyond the intention of individual subjects remains important in the work, but so also does attention to the subjective experiences and actions of groups who have been marginalized. In practice then, many different kinds of approaches to curriculum research may be found within the broad frame of critical theory: historical and demographic studies, textual and policy analyses, local qualitative small-scale studies, and action research.

Recent Directions

In the past few decades, critical theory in curriculum moved from an almost exclusive focus on class or poverty to a period when gender and race became central issues, and attention to language, identity, and discourse as the means by which human subjects were formed in curriculum assumed greater importance. The question of whose interests are being represented in the curriculum remained strong, but so did questions about how young people were being shaped to fit new forms of society.

Recently, three further developments have been notable. One is a reemergence of interest in class, this time incorporating some perspectives from feminist and critical race work, and particularly taking an interest in the power of middle class parents in shaping the curriculum (Dolby and Dimitriadis, 2004). Second, there are some signs of moves by sociologists to try to work beyond critique and somewhat relativist perspectives on the social construction of knowledge to a new critical realist position on knowledge and learning (Young, 1998). Third, there has been an upsurge of work post 2000 concerned with the socially discriminatory effects of the contemporary emphasis on evidence and scientifically based research in government policies, especially in the USA. An important part of this work is interested in global forces on curriculum and, especially, the sources and effects of international forms of educational measurement and ideology as a frame for curriculum work. (Dale, 2000) Another important component of this critical analysis of contemporary curriculum directions has been Apple's (2006) work on the conservative public constituency, including religion, which underpins these conservative directions.

Critical Theory and Curriculum Development

Since a critical theory perspective works from a critique of the social *status quo* (especially related to inequalities), and because theorists in this tradition do not see education as the only source and potential remedy of the inequalities and subordinations they critique, the contribution of critical theory to curriculum is not always or primarily about developing a new foundation for curriculum development. Rather, maintaining a critical watch on curriculum, revealing undesired social effects that are produced by it, is a central concern of this approach. However, contributing to social change and to better forms of education is also a concern associated with this approach. In both forms of contribution, a critical theory approach may work on the big picture of how a particular curriculum configuration is an effect of particular historical traditions and purposes and interests, or may work on a micro- and local level, concerned to identify the subjective making of curriculum by particular groups of students and teachers in particular circumstances.

Curriculum and Poststructuralist Theory

Glossary

Deconstruction – Often misunderstood as well as incorrectly attributed to Jacques Derrida as the originator of the word, deconstruction illustrates that language works not because there is a correspondence between a sign and a thing or because of presence, but because there is a difference, an absence. Deconstruction shows how a discursive system functions, including what it excludes or denies.

Differance – Central to Derrida's theory of deconstruction, this term combines the sense of the English verbs to differ and to defer. Thus, in the concept of differance, meaning is produced through the dual strategies of difference and deferral.

Discourse – In Foucault's conceptualization, it means the discursive practices that themselves form the objects of which they speak, consisting of written or spoken words that are grouped according to certain rules established within the particular discourse.

Many of those involved in curriculum studies and practices worldwide still consider Ralph Tyler's basic principles of curriculum and instruction, also known as the Tyler rationale, to be the model that primarily guides curriculum development and design. However, many curriculum critics decry various reductions of Tyler's intentions into a factory model of education, a model grounded in a behaviorist psychology that conceives curriculum as bits of information and universally agreed upon knowledge that supposedly can be arranged in a linear order and transmitted to the learner. In such a model, curricular development, design, and, most importantly, curricular meaning are determined by relationships among Tyler's sequential steps of developing educational purposes or objectives, as well as educational experiences, and then deciding how these can be organized and evaluated in terms of learners' attainment of the predetermined objectives.

In contrast, poststructuralist theory is utilized by curriculum scholars who wish to challenge forms of Tyler's schema that appear to them as singular, predictable, ahistorical, ideologically neutral, linear, sequential, and measurable versions of what and how one might acquire what is regarded as subject-area-specific content knowledge. That knowledge most often is considered to be stable

and universally accepted as the truth or best knowledge about a particular topic and is presented as such in classroom textbooks and teachers' curriculum guides. However, moving away from a technical-rational emphasis on curriculum development, where curriculum is only conceived as predetermined content to be covered in accumulative and additive ways, curriculum theorists and developers who work from poststructuralist perspectives assume curriculum development to be a political act, with incomplete, fractured, and deferred meanings constantly shifting and reconstructing versions of particular content knowledge. Poststructuralist curriculum theorists and practitioners, especially, are invested in developing and proliferating a multiplicity of views on any given field of knowledge.

Specifically addressing issues of power, poststructuralist curricularists further examine not only what and whose determinations and creations of knowledge count, but also how and under what conditions particular discourses come to shape what gets constructed as curriculum. They especially attend to what cultural and social practices as well as discourses constitute, reproduce, or call into question what is generally assumed to be the content – or what educators often generically refer to as the curriculum – as well as how and in what sequences it supposedly might be learned. From poststructuralist perspectives then, it is impossible to conceive of curriculum design, development, and evaluation as totally knowable, predictable, and universally applicable processes. Instead, poststructuralists argue that, given wildly varying social and cultural educational contexts, participants, and discourses, there is no one best way to proceed. For, to state any curriculum content, process, or activity as definitive is to insist on an ultimate meaning and a predetermined way.

Poststructuralist curriculum theorists also argue that educators' and students' subjectivities – the unconscious and conscious emotions and thoughts of individuals, their senses of themselves and their varying ways of understanding their relations to the world – are always in process, contradictory, produced historically, and reconstituted in discourse each time they think or speak. Indeed, poststructuralist theory posits that subjectivities, including perceptions, biases, and desires, rather than being considered inherent and part of a constant essence in humanist conceptions of the individual, are socially constructed in language, and thus can be considered sites of both struggle and potential change (Weedon, 1997).

Poststructuralist curriculum scholars argue that the subjects' perceptions, biases, desires, and identity constructions,

as well as their assumptions about what knowledge is of the most worth and what therefore should constitute the curriculum, are framed by and formed within particular educational discourses. The political elements of the processes of such formations are the focus of many poststructuralist curriculum scholars and practitioners. These educators often examine concomitant influences of psychosocial experiences in and out of schools as well as social and cultural contexts, including, for example, positionings in relation to normative constructions of gender, race, ethnicity, age, sexual orientation, and ability. Within these framings, the individual is a subject – subjected to dominate discourses that often impose predetermined meanings and thus guide educational processes, such as curriculum development, which are usually based on generally accepted assumptions about what knowledge is of the most worth. At the same time, in relation to content that might be studied as well as to others with whom the teacher or learner might interact, the individual student or teacher is a potential site for a wide range of possible forms of subjectivity, and thus might generate fresh and unanticipated versions of knowledges and identities that cannot be predicted or controlled.

Poststructuralist Theory and the Field of Curriculum Studies

In the late 1960s and early 1970s, a group of curriculum scholars in the United States began questioning positivist, social efficiency, and managerial assumptions that had undergirded the early-twentieth-century origins and development of the field of curriculum. These scholars working in the late 1960s and 1970s were loosely connected through their opposition to narrow conceptions of curriculum as able to be determined and sequenced by lists of behavioral objectives as well as students' absorption of that content as able to be measured by evidence that standardized tests supposedly provided. Working differently within the movement known as reconceptualization, from a variety of theoretical and ideological perspectives, these scholars attempted, early on, to expand conceptions of curriculum to include examinations of both political and autobiographical aspects and lived experiences of curriculum conceived as both content and process. Those involved in the reconceptualization were united only in their attempts to call attention to the interrelatedness of individuals who were differently situated in varying social, cultural, and political contexts and discourses, and they were determined to examine implications of the situated and discursive nature of any construction of curriculum and pedagogy.

Structuralism and Poststructuralist Theory

At approximately the same time, a new wave of philosophers primarily emanating from France, although differing in their

theoretical and disciplinary foci, became known collectively as poststructuralists because of their major and sustained critiques of structuralism. Structuralism is the intellectual movement and philosophical orientation often associated initially with the Western discourses of Levi-Strauss, Marx, and Althusser, for example, who claimed to analyze and explain invariant structures in and constitutive of nature, society, and the human psyche. Structuralism challenged the humanist and the Enlightenment projects, which regarded history as progress, placed humans at the center of creation, and privileged rational thought and the Western culture. The linguist Ferdinand de Saussure and the anthropologist Claude Levi-Strauss, among others, argued that structuralism could explain how certain cultural content (elements of kinship systems and stories told in varying cultures, such as myths and fairy tales) could be considered models of invariant structures.

Thus, those associated with structuralism claimed that cultural phenomenon could be examined according to the underlying formal systems out of which these phenomena emerged. It was argued that language and culture acquire meaning as they were intertwined in complex abstract relations. In addition, structuralism, in great part due to Saussurean linguistics and the subsequent development of language as a field of study, regarded language as a transparent and mirror-like medium through which societal regularities reveal themselves and are taken as constituting reality. Aiming for and acquiring the status of a scientific view of language and culture, structuralism thus assumed a systemic center that organized and sustained an entire society and its sets of relations.

Poststructuralist theories, although not amenable to full explanation, are more modes of cognition than sets of propositions that can be listed in a linear, rational manner. Poststructuralist thinking was an outgrowth of structuralism in that it incorporated structuralism's attack on humanism and the Enlightenment project. For example, many, although not all, of its theorists supported the psychoanalytic work of Lacan, especially his decentering of the humanist subject through the construing of the conscious and unconscious mind as products of language, of the symbolic. At the same time, poststructuralist theories offered sustained critique of structuralism. One of the major poststructuralist breaks with structuralism involved theories that highlighted how the underlying systems that structuralism analyzed were themselves caught up in language. Michel Foucault's work, in particular, conceptualizes discourse – discursive practices that themselves form the objects of which they speak – as consisting of written or spoken words that are grouped according to certain rules established within the particular discourse. Unlike structuralism's foundational sets of relations and systems, Foucault asserts that discourse is historically, socially, and culturally contingent, and that major analyses should focus not on what a particular discourse means, but rather, on investigations of how it works,

under what conditions, and how discursive formations and practices are part of nondiscursive practices. Discourses thus have both disciplinary and disciplining effects. Discourse, according to Foucault, defines fields of inquiry and knowledge as well as how rules within those fields govern what can be said, conceived, and acted upon (Foucault, 1975/1977, 1980).

Jacques Derrida, in his early work, also criticized structuralism's presumption that language could be described as a static set of rules. His work demonstrated how those rules could be examined for their contingency and their dependence on temporality, for example. Derrida further concerned himself not only with the regulatory nature of discourses, but also with cultural texts and the impossibility of their intrinsic authority as accounts of truth. In particular, he insisted that the act of reading extends from literary texts to films, popular culture, political scenarios, and to works of art. Derrida's notion of reading insists that our ability to understand relies on our capacity to interpret signs that come to signify in ways that no particular author or speaker can constrain in advance through intention.

Thus, in questioning Saussure's claim that signs have an already-fixed meaning recognized by the fully conscious and rational speaking individual, Derrida shifts from the Saussurean focus on speech to concerns with reading, writing, and textuality. He replaces the fixed signifieds of Saussure's chains of signs with a concept of *différance*. The concept of *différance* is central to Derrida's theory of deconstruction and combines the sense of the English verbs to differ and to defer. Thus, in the concept of *différance*, meaning is produced through the dual strategies of difference and deferral. In theorizing the problem of difference, Derrida wrote the term as *différance*, not only to mark the way that signification works – one term referring to another, always relying on a deferral of meaning between signifier and signified – but also to characterize an ethical relation, the relation of sexual difference, and the relation to the other. For Derrida, then, there are no fixed signifieds (concepts). Signifiers (sound or written images), which have identity only in their difference from one another, are subject to an endless process of deferral. Thus, any representation, in which meaning is apparently fixed, is only a temporary retrospective fixing. The name that we have for something, for ourselves, and for an other, is precisely what fails to capture the referent (as opposed to making or constructing it). Further, signifiers are always located in a discursive context, and any temporary fixing of meaning in a specific reading of a signifier depends on this discursive context (Butler, 2004; Weedon, 1997).

Conceptualizing any encounter with or construction of social and cultural worlds as discursive text with no original meaning, Derrida further argued that every structure – whether it be literary, political, religious, educational, or economic, for instance – that organizes our experiences within that particular structure, is constituted and

maintained through acts of exclusion. In the processes of developing curriculum, for example, by adding in certain presumed facts or content, something else inevitably gets left out. Such exclusions, often predicated on reified notions of difference, are the focus of Derrida's conceptualization of deconstruction. Deconstruction, often misunderstood as well as incorrectly attributed to Derrida as the originator of the word, illustrates that language works not because there is a correspondence between a sign and a thing or because of presence, but because there is a difference, an absence. Deconstruction shows how a discursive system functions, including what it excludes or denies (Derrida, 1998). At the same time, deconstruction cannot by definition be defined since it presupposes the undecidability of all conceptual or generalizing terms. Like any method of interpretation, it can only be exemplified, and the examples will all differ.

Deconstruction, then, according to Derrida, is only what happens if it happens because it is not a philosophy, a doctrine, a knowledge, a method, a discipline, and not even a determinate concept (Derrida, 2001). If it does happen, deconstruction enables one to critique structures that are held together by identity and presence, concepts that, in Western philosophy, represented transcendental order and permanence as manifested in beliefs and ideas such as the unified subject, the essence of an individual, and consciousness. Derrida utilized deconstruction not to dismantle, reject, or take things apart (as the term has come to be generically and incorrectly used), but rather to reinscribe them in another way. In particular, deconstruction allows one to challenge any notion of foundational center that creates binaries in which the first term of the binary most always indicates presence and power and, subsequently, to attempt to reconstitute that which has been previously inscribed. In addition, the reconstitution must then, in turn, be deconstructed. Derrida understood that social and political transformation is an incessant project, one that can not be relinquished, co-exists with encounters with the other, and insists on a reading of the rules by means of which a society constitutes itself through exclusion or effacement. Feminist theorists Gayatri Spivak and Judith Butler, in particular, consider deconstruction to be an affirmative political practice in that it enables us to rewrite the world and ourselves over and over again (Butler, 2004; Spivak, 1974).

Curriculum Reconceptualized in Relation to Poststructuralist Theory

In particular, the translation and dissemination of the work of Michel Foucault and Jacques Derrida in North America during the 1970s and 1980s enabled some curriculum scholars to take up major aspects of the French poststructuralist theory by addressing the central role of language, power, and discourse in any model or conception of curriculum

theory, development, and design. The further dissemination of this theory throughout the world, including the work of French feminists Helene Cixous, Luce Irigaray, and Julia Kristeva, encouraged curriculum scholars, within a variety of social and cultural contexts, to pursue poststructuralists' particular goal of troubling both discursive and material structures that limit or reify conceptions and enactments of curriculum.

Some of the earliest poststructuralist work in curriculum, especially theorizing in the United States that grew from the initial movement to reconceptualize the curriculum field, drew on the theories of Foucault and, secondarily, on the work of Derrida and Lacan in order to challenge essentialist notions of gender identity and examine various gender discourses that often were linked to the very same oppressive discursive systems they sought to dismantle. Explorations of the ways that discourse creates and is substantiated by the body and the unconscious followed, as did work that staged, in writing, deconstructive and poststructuralist performances of thinking about and enacting versions of curriculum that defied dominant positivist and behavioral metanarratives about what knowledge is of the most worth and how it should be presented in textbooks as well as in pedagogical strategies. Such critique became emblematic of contemporary contentions that currently characterize the field of curriculum studies, writ large, in terms its functions, philosophical and ideological commitments, and manifestations of those commitments for curriculum development and design in schools.

By the late 1980s and early 1990s, curriculum scholars were conducting studies of curriculum as phenomenological and deconstructed texts that emphasized multivocality, multiperspectivity, and the lived aspects of textbooks and classrooms. Some explained and analyzed poststructuralist theory in relation to structuralism. Others explored how curriculum as a field of study might now be characterized by ideas and metaphors from the new sciences of complexity, uncertainty, ambiguity, open systems, process, and transformations. A major poststructuralist line of inquiry in curriculum contrasted the behavioral orientation of the Tyler rationale and other positivist approaches to curriculum development with postmodern possibilities of a curriculum that is composed of complex and spontaneous interactions among students and teachers, and content both created from and with/in those interactions. Threaded throughout such poststructuralist curriculum work are constant critiques of any totality of representation that reduces learning to information transmission. Poststructuralist curricularists argue that such reductive narratives of education continue to foster the bifurcations that ignite racism, patriarchy, homophobia, colonialism, and classism. At the same time, others, working from still dominant neo-Marxist positions in curriculum theorizing, argue that the central tenet of poststructuralist theory and postmodernism, writ large – that there can only be

incredulity toward metanarratives (Lyotard, 1979) – is itself a grand narrative. Building upon these major influences on as well as upon critiques of the introduction of poststructuralist theory into curriculum theory, development, and design, a number of scholars have further explored poststructuralist theories from a variety of angles and for a number of educational purposes.

Women academics within the field of curriculum studies and practice began their poststructuralist work by attempting to conceptualize a multiple, indeterminate female subject. Multiple manifestations of this initial work have contributed to one aspect of what, some would argue, is now a major influence on the field of curriculum – the work of feminist poststructuralists.

Contributions of Feminist Poststructuralist Theorizing

Poststructuralist versions of feminism almost always advocate social change and, at the same time, mark a turn away from projects that promote humanist assumptions about progress, identity, and fully conscious selves who can attain, once and for all, freedom from oppression. Most poststructuralist feminists are concerned with gender power relations, in particular, and how those relations are constituted, reproduced, and, possibly, contested. A proliferation of work produced by feminists working in the field of curriculum as well as education, in general, has altered ways in which educators must now attend to issues of language, discourse, and power in all aspects of curriculum conception and development, as well as in the ways that curriculum is enacted, experienced, and created in the classroom.

A number of feminist scholars, especially in Australia, the UK, and the US, have drawn on the work of Foucault, in particular, as they work to understand and then to critique how modernist, humanist conceptions of a woman have been constructed through and by dominant discourses in societies in general, and in the field of education in particular (Baker and Heyning, 2004; Luke and Gore, 1992; Tamboukou, 2003). Many have relied on Foucault's work in their analyses of gender, the category woman, and constructions of woman and girl as subject and object in curriculum and pedagogy discourses. Some feminist scholars have studied how children, especially girls, are constituted as subjects within what are typically named child-centered curricula and forms of pedagogy (Walkerdine, 1990). Influential work, focused on Foucauldian issues of power, discourse, discursive practices, and the production of selves, has also centered on qualitative studies of preschool children and gender, as well as on children reading and writing beyond gendered identities (Davies, 2003).

Further, in investigating, from a variety of subject matter areas and disciplinary perspectives, a woman's subjugated positioning within educational discourses that focus on

binaries such as normal/abnormal or active/passive, many feminists utilize Foucault's insistence on historical analyses as well as attention to the ways in which attempts to assert legitimate claims to knowledge are often caught up in the very essentializing and patriarchal discourses that women wish to combat. Exploring additional ironies to which poststructuralist theory points, feminist curriculum scholars also have investigated how radical discourses in education, including feminist pedagogy, paradoxically operate as regimes of truth, to use Foucault's conceptualization. Some feminists, especially, have utilized aspects of Foucauldian poststructuralist theory in order to challenge essentialist and unitary notions of voice and dialog, two prominent components of critical pedagogy as well as of some versions of feminist pedagogy (Ellsworth, 1997; Orner, 1992).

Another major arena in which feminist poststructuralists have had and continue to exert a major influence on is qualitative curriculum research methodologies and practices. By addressing issues such as power relations with subjects in the field, the crisis in representation, and the stuck, unpredictable, and unknowable places and spaces of qualitative research, especially in relation to difference, feminist poststructuralist work has influenced curriculum scholars who wish to explore such issues within educative contexts. These feminists, for example, simultaneously, both use and immediately trouble typical categories of qualitative research, such as validity and generalizability, and move toward methodologies that foreground ambiguities, uncertainties, contradictions, and incoherences (Lather, 2007; Pierre and Pillow, 2000). In addition, some feminist poststructuralist curriculum theorists continue to grapple with how to conceptualize self, woman, teacher, researcher, or curriculum, not as permanently essentialized or naturalized through humanist and positivist educational discursive practices and regimes, but rather, as sites for cultural critique and social change (Miller, 2005).

Toward Further Ruptures

The wide-ranging areas of curriculum theorizing and inquiry that fall under the general heading of poststructuralist theory and curriculum have expanded rapidly in the late 1990s and into the twenty-first century. Major contributions of poststructuralist curriculum scholars, teachers, and curriculum developers have highlighted how poststructuralist theorizing challenges master narratives, postulates that all meaning is discursively constructed, and insists that we, as educators, examine how and under what conditions particular discourses come to shape what gets constructed as knowledge. At the same time, it is impossible to claim definitive and static manifestations of or future directions for poststructuralist theory in relation to curriculum theorizing and development.

What is possible to note here is the proliferation of those involved in the work of curriculum, writ large, who

are searching for ways in which to confront the reemergence of mechanistic, technical-rational approaches to teaching, curriculum conceptualizing, and development, and of standardized tests as the major tool for the evaluation of students' knowledge and teacher effectiveness. A number of curriculum scholars and practitioners are looking to the poststructuralist theory in order to call into question, for example, universalized versions of school reform efforts and educational policy mandates. Indeed, the poststructuralist theory offers perspectives that enable curriculum workers who wish to work toward creating ruptures, toward asking "... questions about necessary complicities, inadequate categories, dispersing rather than capturing meanings, and producing bafflement rather than solutions" (Lather, 2007: viii) to pose challenges to the educational *status quo*. The poststructuralist theory itself challenges all those involved in the curriculum field to interrogate our taken-for-granted assumptions as we investigate the discursive practices and relations of power that underlie any one answer to the classic curriculum question, what knowledge is of the most worth.

Glossary

Classification – An analytical concept which refers to the power relations that result from the strength of boundaries between contexts.

Code – An orientation to meaning into which children are socialized at home and at school. Home codes may or may not be congruent with school codes that communicate knowledge at different levels of abstraction.

Framing – An analytical concept which refers to the social relations of control between teacher and pupils in a pedagogic practice.

Horizontal discourse – Meanings relating to a particular context, understood experientially and through the senses.

Realism – Realist social science is the understanding of society in terms of social mechanisms that structure but do not determine outcomes.

Structural functional linguistics – A socio-semiotic approach to language that analyzes how grammar realizes meanings through the functions language is required to serve. It is associated with M.A.K. Halliday and the Sydney School.

Structuralism – A theoretical approach that explains the social world in terms of law-like patterns of relations, rather than in terms of individual actions or individual consciousness.

Vertical discourse – Meanings that operate at a general principled level. Nonempirical meanings that are generated through deductive and inductive reasoning. Meanings not derived experientially from immediate contexts.

During the 1960s and into the 1970s, structuralism as a theoretical style became influential in a number of disciplines in the humanities and social sciences. While several lines of descent can be traced, this article focuses on the two most directly relevant to the structural turn in the sociology of curriculum. The first derives from Durkheim and his contention that society exists over and above the individual, nested in the relationship between the social base of society and its production of consciousness (Davies, 1993). The second derives from the structural linguistics of Ferdinand de Saussure, which viewed language as a system

of signs and investigated the underlying set of laws (langue) by which signs combine into meanings that make speech acts possible (parole). This led to the practice of treating the social world as a set of semiotic patterns with a logical law-like basis. Linguistic structuralism thus examines the underlying systems of relationships which order forms of social life, treated as though they are homologous with those of language. Taking these two lines of descent together, the curriculum is treated as an object produced by social relations which order consciousness in determinate ways, and which are related in turn to the social division of labor in society.

The 1960s was a time of rapid increase in public expenditure on schools and universities and increasing differentiation of educational systems. Concern arose as to whether educational investments were efficient or equitable, prompting government-funded research initiatives ranging from a political arithmetic approach that calibrated the chances of children of different class origins reaching various educational destinations, to causal models of attainment difference based on environmental and genetic/intelligence differences, and to psychometric testing. These studies were widely regarded as atheoretical black box studies.

Structuralist sociologies of education were one notable reaction against this policy-driven empiricism. A prominent variant was the work of Pierre Bourdieu and his group in France. In this article, we examine the structuralist sociology of curriculum of the British sociologist Basil Bernstein, and the theoretical and empirical work he has subsequently inspired. Bernstein went against the grain of conventional orthodoxy in that he viewed language (environment) and not intelligence (genetics) as making the difference to educational chances. While what came to be known in Britain in the 1970s as the new sociology of education is characterized by a number of sociological approaches (phenomenological, structuralist, and neo-Marxist) that shared a common concern about the relation of curriculum and pedagogy to social class and academic achievement, it is particularly the work of Bernstein and his longstanding dialog with systemic functional linguistics (SFL) in the work of Michael Halliday and Ruqaiya Hasan that best exemplifies the structuralist turn in sociology of education and in sociological curriculum theory in particular. Even though Bernstein identified himself as a Durkheimian rather than as a conventional structuralist, his work should arguably be located within the structuralist tradition and related to a French rather than an Anglo-American reading of Durkheim

(Atkinson, 1985). The remainder of the article is thus dedicated to a brief exposition of two major components of his theoretical work, namely the theory of codes and of knowledge structures and the fruitful avenues of research that these have opened up.

The Theory of Codes

For Bernstein, the basic unit of socio-educational analysis is not the individual but the communicative relation and its control (Bernstein, 1990). All communication has a pedagogic (or formative) effect on consciousness. The key regulator of communication is the code.

Bernstein's early work on communicative codes examined the production and reproduction of meaning systems in the home and the school, with class relations taken to refer to inequalities in the distribution of power (Bernstein, 1990). The communicative relation in the home is the primary socializing context, which creates for each child a primary orientation to meaning, or semantic style. This style is either in harmony with the style favored by the school code, which is an advantage; or it is not, which is a disadvantage. The school code in all formal schooling favors a semantic style that is elaborated, context independent, and capable of generating abstraction, generalization, and explanation, all of which are generic modes required by formal learning. The home code comes in one of two modal types: an elaborated code variant typically found in middle-class homes, and a restricted code variant typically found in working-class homes.

This appellation of restricted turned out to be a most unfortunate one, and early code theory was all but derailed by socio-linguists such as Labov and Rosen who took the designation as impugning the capacity and dignity of the working class. Two facts have seen it survive this early critique. The first is the enduring feature, discernible in virtually all formal schooling settings, of working-class under-attainment, for which code theory still offers one of the best socio-cognitive explanations. (Cuba may just be the exception that proves the rule.) The second is the subsequent empirical work of structural functional linguists such as Hasan, Cloran, Painter, and Williams (see Hasan, 2005), who have fleshed out in rich detail the semantic features of the communicative code of mother-child talk in the early years. This group of linguists has shown that:

Mothers from different social groups systematically vary the types of meanings they communicate to their children, which decisively affects the child's orientation to meaning/semantic style. Where the 'formative' maternal style leads to a communalized cultural style and personal orientation, the 'informative' style leads to an individualized orientation that fosters a far greater sense of individual control over the manipulation and extension of meanings; and,

This home-learned orientation to meaning has long lasting effects on the child's receptivity to types of meaning expected at school. It does this by creating certain semantic expectations (recognition rules) by which children understand what is required of them, and understand what constitutes an adequate performance (realization rules). These semantic styles can be adapted, but only under certain communicative / pedagogic conditions, as we shall show below. (Hasan, 2005)

The study by Holland (1981) provides a graphic display of these orientations. He asked two sets of 7-year-old children, one working class and another middle class, to group pictures of foodstuffs and to give reasons for their grouping. They were then asked to repeat the task. Holland found that working-class children invariably used context-dependent, everyday criteria for grouping the foods (e.g., 'I like those things'; 'That is what mother cooks for breakfast'), whereas the middle-class children, recognizing the request as pedagogic, classified first on the basis of a general principle (e.g., a food category like dairy or vegetable) but in the second round also tended to give local, context-dependent criteria. He concluded that the middle-class children had been taught at home to recognize and realize abstract classification, while the working-class children did not recognize this as the requirement and thus supplied only their everyday categories. In other words, while the middle-class children had already been introduced to the elaborated school code at home, the working-class children had to acquire it virtually from scratch when they got to school.

Anatomy of the School Code

Bernstein's further work explored the modalities of elaborated code transmitted in schools. While much of the work that was being done in the sociology of education in the 1970s and 1980s investigated pedagogic communication as a relay for power relations external to education (class, race, gender, and religion), his work focused on power and control relations within education itself. His question was: "If pedagogic communication is a relay for patterns of domination external to education, what makes the relay possible?" (Bernstein, 1990).

In order to answer this question, Bernstein developed a specialized language with which to distinguish more precisely between modalities of elaborated codes as relayed by pedagogy. The features of any communicative context are represented by two principles: a classificatory principle and a framing principle. The classificatory principle creates specific recognition rules whereby a context is distinguished and given its position in relation to other contexts. The degree of insulation determines the degree of specialization of a communicative context and of the knowledge

transmitted, with strong (C+) or weak (C-) classification indicating the strength of the boundary.

Framing is about who controls what at the level of pedagogic practice. At the instructional level, framing refers to the nature of control over:

- selection of the content of the communication;
- its sequencing (what comes first, what comes next);
- its pacing (the rate of transmission and expected acquisition); and,
- criteria for its evaluation.

Like classification, framing can be strong (F+) or weak (F-). Where framing is strong, the teacher explicitly controls features of the framing relation; where framing is weak, the pupils apparently have more control over the selection, sequencing, pacing, and evaluation of the knowledge transmitted. At the regulative level framing refers to whether the hierarchical relation between teachers and pupils is explicitly controlled by the teacher (strong framing over teacher-pupil relations), or implicitly and apparently controlled by the students (weak framing over teacher-pupil relations). The strength of both classification and framing can vary independently of each other. It is, for instance, possible to have weak classification and strong framing of certain or all of the features of the communicative context, just as it is possible to have strong classification and weak framing. Framing values can also vary independently of one another. Framing over evaluative criteria could, for instance, be strong while framing over pacing is weak.

For Bernstein codes are not only mechanisms for social reproduction; they are also sites of contradiction, challenge, and change (Bernstein, 1990). The re-description of the fundamental relation between the social division of labor (classification) and forms of pedagogic communication (framing) in code form provides researchers of classroom practice with the means to link empirical evidence to a theoretically generated network of related concepts to make visible how power and control translate into principles of communication and "how these principles of communication differentially regulate forms of consciousness with respect to their reproduction and the possibilities of change" (Bernstein, 2000: 4).

This opened up the way for a series of empirical studies of great significance because it marked a major theoretical advance that provided a tool with which to investigate what it was that rendered the expectations of the school code so peculiarly invisible to children from working class homes. In an earlier iteration of the theory, Bernstein had distinguished between two modal types of pedagogic communication – visible (strong classification and strong framing) and invisible (weak classification and weak framing) – and had shown that the invisible mode communicated well to the middle-class children; in other words, the requirements were not invisible to them but left the working-class children struggling to discern what was required.

The proto-concepts of visible and invisible pedagogies left the theory with a description of the consequences of different pedagogic modalities, rather than with a stipulation as to what exactly it was that was visible or invisible. Was it everything? (i.e., should everything be strongly classified and framed to render the invisible visible?) This was never going to be happily accepted by the pedagogic community at large, who were by the mid-1980s and 1990s deeply in the impress of Vygotskian constructivism and Deweyan progressivism, both interpreted as favoring an invisible pedagogy. However in any case, why should it be all or nothing? With this refinement of code theory, a series of studies, first by the ESSA Group (Sociological Studies of the Classroom) in Lisbon, later by others in Australia, South Africa, and the United Kingdom, explored the specific lineaments of a pedagogy that might successfully convey expectations equally to all children, but especially to those of the working class.

The ESSA group led by Morais was concerned mainly with primary school science acquisition (Morais and Neves, 2001). They developed the conceptual categories outlined above into an observational grid which captured values for each conceptual category on a four-point scale. They were able to use a variety of measures to show that a certain mixed pedagogic modality, together with a scientifically competent teacher who could retain the proper level of cognitive challenge, produced the fewest failures and the greatest degree of success across all classes. This modality combined strong and weak features in the same pedagogy.

As the systemic functional linguists have shown, the semantic orientation of working-class pupils coming to school is generally context specific, local, and communalized at the family level. This orientation ensures that the decontextual, abstract mode of much of school science and its requirements will be invisible to such pupils. Where should these requirements pre-eminently be made visible? The theory predicts that there are two places where visible signaling will be critical: first, in the curricular stipulations of the intended curriculum (i.e., strong framing over external selection); second, in the evaluation criteria which signal to pupils whether they have understood what was expected and have met the criteria for producing an adequate response (i.e., strong framing over the evaluation criteria). The first is the responsibility of the curriculum writers; the second, the responsibility of the teacher.

In order for the teacher to be able to communicate the criteria in a comprehensive way to pupils whose orientation to elaboration required careful nurturing, two other features of the pedagogic modality were necessary: time (weak framing over pacing) and a personalized attitude to the pupils (weak framing over teacher-pupil relations). The ESSA regression analyses showed that these four aspects (i.e., strong framing over external selection and evaluation criteria and weak framing over pacing and teacher-pupil relations) accounted for a significant part of the variance in

achievement outcomes. There are other features of the ESSA mixed pedagogy, but these four are the most significant: two traditionally seen as part of progressive pedagogy and two as part of a (supposedly opposed) more didactic mode. When the ESSA team trained teachers to teach to this mixed pedagogy, and compared their success rate with teachers teaching to other configurations, their expectations were confirmed.

In a number of subsequent studies this general pattern has been confirmed. Hoadley (2007), for example, looking at grade 6 mathematics learners in South Africa, found a very similar configuration linked to successful (in this case middle-class) pupil attainment; clear and explicit evaluation criteria, linked to weakened control over both pacing and teacher–pupil relations. Hoadley’s further finding is a little more sobering: she shows that not only the pupils but also the teachers from working-class homes come to the classroom with a communalizing orientation, which creates an additional barrier to the individualizing mode of teaching required for pedagogic voice specialization. The great virtue of this group of studies is to show that under the right socio-cognitive conditions, teachers can make a difference, and to point with some precision to the various dimensions of pedagogic modality that could bring this about.

Knowledge Structure

Code theory established the how of curriculum and pedagogy – the various modalities of transmission, but it remains silent on the what – the knowledge that is thereby transmitted. The theory maintains that curricular knowledge – the what of the classroom – is recontextualized from that produced in the laboratory and the library, real knowledge so to speak, but pursues the matter no further.

It was only late in his career that Bernstein turned to the question of what this knowledge was which was to be acquired, its structure, and its social base. Bernstein draws a strong distinction between two basic classes of knowledge: mundane or everyday knowledge and esoteric or universal, principled knowledge. These two classes of knowledge are intrinsic to language, and they exist in all societies, even though their content may vary historically and culturally. This is not to say that some knowledge is concrete as opposed to abstract but rather that there is a difference in the form that abstraction takes in relating an everyday, mundane world accessed through experience, to the abstraction of a transcendental world accessed through formal reasoning. The relation between these two worlds can be direct or indirect. A direct relation between meanings and a specific material base is termed horizontal discourse. In horizontal discourse meanings cannot transcend their immediate context and so always refer to everyday or mundane contexts. Vertical discourse, by contrast, requires systematic ordering principles for the generation of meaning.

The knowledge bits fit together in a time and space not given by a specific context.

Context-independent meanings take two distinct forms. One is through what Bernstein calls a hierarchical knowledge structure, where general propositions and theories integrate knowledge at lower levels into a higher level in the hierarchy (as in the natural sciences). A second is horizontal, taking the form of a series of specialized languages that lie next to one another (as in the social sciences and humanities). Through a principle of recontextualization, competent members of vertical discourse can give an explicit account of the way in which they have arrived at a specific position and they can retrace their steps and show how they have made the recontextualized objects hang together (Muller, 2000).

By taking disciplines such as science and history for example, the structural functional linguistic Sydney School has explored knowledge structure variation in terms of register and lexical specialization. They isolate grammatical metaphor as the “critical linguistic resource . . . for the construction of vertical discourse” (Martin, 2007: 60). Other advances in the theory of knowledge structure include the Moore (2007) work on the production of esthetic judgments that suggests conditions for progress in knowledge in the arts and humanities, and the Gamble (2004) study of the tacit base of craft knowledge as a horizontal knowledge structure.

Knowledge and Curriculum

The theory of knowledge structures brings to light the differential coherence relations of different knowledges: vertical coherence relations in hierarchical knowledge structures and connective coherence relations in horizontal knowledge structures. Curriculum theorists soon made the connection between these arrangements and the arrangements of the curriculum specified by code theory. In particular, what would be the consequences of, say, a C+/F+ or C-/F- pedagogical modality for the learning of school subjects that are either vertically or connectively coherent? The empirical research has so far concentrated on the consequences of a weakly classified and framed pedagogy for vertical coherence subjects such as mathematics and English. The theory would predict that such a modality would render invisible the sequential or necessary steps of the vertical structure to be acquired. If the evaluation criteria require competence in all the sequential steps, and are also weakly framed – that is, weakly specified – then learners might very easily get to the final examination only to find that they have not traversed the expected vertical steps. The discussion above would suggest that working-class learners are most at risk in such a modality.

Outcomes-based curricular systems like those found in Australia and South Africa have tended to favor weak

specification of content (weak intra-discursive classification), weak framing over sequence and pace, and weak framing of evaluative criteria – this latter a consequence of evaluation criteria specified in skill terms. In short, this modality disguises the what from both teachers and acquirers. When teachers are knowledgeable (Morais and Neves, 2001), this can be offset; when they are not, as is often the case in South African schools, the pacing slows down, and critical parts of the curriculum are not covered. In a vertical coherence subject such as mathematics, this freezes further learning (Reeves and Muller, 2005). In Australia, it has similarly been found that weak specification of the what has tended to disguise the vertical spine of school subjects. Christie and her Sydney School collaborators have rendered visible the verticality of subjects such as English by reconstructing a linguistic meta-language to specify the operations students should master to meet the invisible (weakly framed) evaluation criteria successfully (Christie and Macken-Horarik, 2007). What these and other studies show is that determinate structural forms of a particular knowledge field place distinct limits on effective curricular structure.

Conclusion

In the light of the discussion above, it may be useful to revisit in what way this approach to the sociology of curriculum should be regarded as structuralist. The Durkheimian and linguistic influences are clearly apparent. There is however a deeper sense in which this approach can be distinguished from the empiricism of current approaches to both school effectiveness and textual cultural critique. In a way that could more properly be called realist (Manicas, 2006), Bernstein and those using his theory are engaged in a search for explanatory mechanisms (structures) for reading the world. With the theory of codes, and in a less elaborated form with the theory of knowledge structures, researchers are able to create a powerful and precise language for modeling pedagogic modalities and explaining their effects. This search for explanatory mechanisms is what distinguishes this approach to the sociology of curriculum, whether we call it structuralist or realist.

Curriculum Reform

R Gilbert, The University of Queensland, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

Curriculum reform is not a precise term. While it commonly refers to creating or revising curriculum documents, policies, or practices in order to improve what is taught and learned in educational programs and institutions, the term's limits are less clear. For instance, in his study of the history of curriculum reform in the twentieth century, Kliebard (2002) distinguishes the terms curriculum and pedagogy, yet nonetheless includes pedagogy and assessment in his history, implying either that curriculum is an all-inclusive term, or, more likely, that the three elements of the process of schooling are so intertwined that they must simply be discussed together. Similarly, curriculum reform, school reform, and educational reform are all discussed in Kliebard's history, despite the fact that the latter two terms include aspects of schooling, such as teacher characteristics or school resourcing, which lie outside any viable concept of curriculum.

The influences on curriculum reform are diverse, and its effects have consequences for students, teachers, and the community which go far beyond the curriculum's intended outcomes. In many respects, the broader elements of education reform, such as school organization and administration, teacher education and supply, facilities, technology, and class size, can be seen as means to curriculum reform, reinforcing the centrality of curriculum to the entire educational enterprise. The focus in this discussion is on the reform of the intended curriculum and its manifestations in institutional practice, that is, the specification of what is to be taught and learned in any educational program, and the processes by which these intentions are operationalized.

Curriculum reform occurs at a range of scales depending on the context and the type of reform under consideration. The term can refer to a change in a particular institution, where the case or unit of reform may be a university or school department; it can refer to improvements in the intended outcomes of a particular field, such as a school subject in science or citizenship; or it can encompass the educational programs provided for particular groups, such as differentiations by age level or phase of schooling in the middle years or early childhood curriculum.

However, curriculum reform is also and more commonly used to describe the general process of curriculum change or development at the system level. This general process of curriculum reform is the main focus of this discussion, and the concept of curriculum underlying it is well defined by Moreno:

Curriculum is a socio-historical construction which is expressed through general systems of knowledge characterization and hierarchy; these systems are in turn translated and transformed into legislative and administrative regulations, academic achievement standards, textbooks and teaching aids, and the practice of teaching and learning in classrooms and schools. (Moreno, 2006).

This somewhat linear view needs to be combined with the recognition that curriculum specifications are selections from the culture whose meanings are articulated in social practices. Curriculum knowledge is constantly interpreted and reinterpreted in contexts of conception, production, and implementation, and an understanding of curriculum reform must address this semiotic and indeterminate dimension of the curriculum. This in part accounts for the perennial controversies around curriculum reform, since curriculum decisions involve value judgments about the purposes of schooling and the most-valued forms of knowledge, and how they are related to the cultural practices of different social projects and interests. This recognition highlights the tendentious, or at least aspirational, connotation of the idea of reform, since curriculum reform, as distinct from curriculum change, refers to explicit attempts to improve the curriculum; but just what constitutes improvement is contentious. Curriculum reform in America has been compared with religion, with "periodic crusades, and occasional bouts of zealotry and apostasy" (Ravitch, 2004). Consequently, it is a contested area of educational policy and research.

Contexts and Elements of Curriculum Reform

Curriculum reform seems to be a popular cause, with interested parties from governments to academics to various community groups promoting change in the name of social, economic, or some other form of improvement. Yet, observers have a generally pessimistic view of the experience of curriculum reform, illustrated in McCulloch's claim that "longer term curriculum reform has generally failed to generate educational change of a fundamental kind" (McCulloch, 1998). Some commentators have pointed to curriculum change as an erratic or fortuitous process dominated by fads and pendulum-like swings from one ideology or theory to another (Good *et al.*, 1997; Ravitch, 2001).

Conversely, there is also a considerable and increasing degree of international consensus on the desired outcomes of education and the kinds of curricula which will achieve them. Reform in school systems is influenced by diverse sectoral, national, and international contexts, but governments are also subject to common economic and political influences which lead to convergence of educational policy decisions. Rosenmund analyzed curriculum elements of 102 national reports on education, and identified consistent and increasing emphases on a student-centered approach to learning, interdisciplinary knowledge, life skills and competencies, and values of rights, individualism, and identity. These emphases were seen to be driven by rationales based on concepts of the self-directed, competent, and rational individual, and societal development (Rosenmund, 2006). The desire for international competitiveness is often cited as a cause of this consensus, which is thought to be facilitated by the globalization of markets and information networks as influences on global curriculum change (Waks, 2003).

The importance of the teacher's role in interpreting and implementing the curriculum has been the rationale for reforms advocating a teacher-led approach to curriculum innovation and development, on the grounds that the curriculum that matters most is the one enacted by teachers and experienced by students (Elliott, 1994). Recent research has highlighted the ways in which teachers' involvement in innovation involves personal, social, and emotional responses to change which influence their commitment to reform (Zembylas and Barker, 2007). However, while the school-based curriculum movement and its associated action research approach to curriculum development provided important bases for such an approach, the early hopes for teacher-led curriculum reform underestimated the constraints of their environments (McCulloch, 1998). In the centralized, top-down approach of current standards-based approaches, this is an important issue, for the influence of teachers on the implementation of curriculum reform is well demonstrated.

Two Examples of Curriculum Reform

Many of the features of curriculum reform can be illustrated by reference to two recent examples: the outcomes-based education (OBE) movement, and the standards-based approach to curriculum and assessment. OBE was a reform driven by a desire to focus the curriculum development process more directly on the ultimate goals of schooling, rather than on inputs of course credits, class hours, or subjects taught. The belief was that the contribution of these inputs to the ultimate goals of education in students' later lives was taken for granted, and that school curricula were not succeeding in providing all students with the

learning required for contemporary society. This would be corrected through a process of clarifying the ultimate intended outcomes of schooling and designing the curriculum from them (Glatthorn, 1993; Schwarz and Cavener, 1994). This seems a logical process; however, in questioning established practice and traditional assumptions about curriculum and teaching, such as a normal distribution of student achievement, the universal grading of classes by age, or the subject-based curriculum, the OBE movement challenged convention. It also promoted an approach to curriculum and teaching which was not well established in either research or practice, and which therefore lacked exemplars or experience. After being enthusiastically promoted, OBE has stalled in the face of criticisms of its practicability as well as its ideology (the latter from both right and left).

Critics of OBE argued that its departure from traditional subjects and its focus on instrumental outcomes and contemporary relevance threatened the quality of what was learned. A countermovement developed which took the name standards-based curriculum (SBC), a largely rhetorical label typified by an emphasis on the subject-based curriculum, a closer specification of academic content, and an accountability process established through large-scale centralized assessment (McLaughlin and Shepard, 1995; Wixson *et al.*, 2003). This is an increasingly technical and bureaucratic return to the traditional means-end approach to curriculum.

Along with this development, the concept of alignment has become a key component of curriculum reform, where curriculum, teaching, and assessment are tightly controlled to increase their congruence with each other. If applied in a certain way, where the test specifies the outcomes and teaching programs, and strategies are aligned to it (known as the backloading approach to alignment), then the test effectively becomes the curriculum, and the process of curriculum development itself is undermined (Wraga, 1999).

Criticisms of the standards-based approach look at the emphasis on centralized standardization as a corruption of the curriculum process (Delandshere and Petrosky, 2004). On the other hand, the potential in the standards-based approach for clarifying curriculum emphases has been argued to improve teaching and learning, including for educationally disadvantaged groups. Schoenfeld (2002) points to problems with the approach if it is not introduced in a comprehensive and well-supported manner, but argues that it holds great promise for improving educational outcomes as a result of the clarity and clear guidance it provides. However, clarity of outcomes is a separate matter from the potential corruption of curriculum through an intrusive centralized testing regime. Au (2007) surveyed 49 studies of the effects of high-stakes testing on curriculum, and found that, with some exceptions for certain kinds of tests in some subject areas, the

primary effect of high-stakes testing was to narrow curricular content, to fragment subject knowledge into test-related pieces, and to increase teacher-centered pedagogy.

The examples of outcomes-based and standards-based approaches to curriculum well illustrate the conflicted nature of the curriculum reform process. They point to aspects of reform which, by virtue of their controversial nature, complicate the prospects of success of any reform.

The Efficacy of Curriculum Reform

The record of sustained success of curriculum reform is poor. This is often construed as resistance to change among relevant actors, resulting from cultural, social, organizational, or psychological barriers. Conflicts such as those illustrated above illustrate one aspect of the problem, where the significance of reform for long-held beliefs can be underestimated, or attempts at standardization provoke resistance from those wishing to protect local initiative. The sheer complexity of the curriculum process is another barrier to reform, and seems to have exacerbated the problem of unintended deleterious effects. The literature is replete with accounts of reform policies, which, whether or not they have achieved their specific goals, have caused new problems. The account by Fisher (2007) of post-16 reforms in the United Kingdom is a typical example. Fisher's study shows that reforms intended to broaden the curriculum by establishing parity of esteem for academic and vocational qualifications, and to promote participation and lifelong learning, led in implementation to more didactic approaches to teaching and an emphasis on knowing content at the expense of conceptual development.

McDonald (2003) reviewed three models of curriculum reform:

1. the top-down approach of the teacher-proof curricula of the 1960s and 1970s (which has reemerged in the standards-based approaches of recent times);
2. the bottom-up approach represented in school-based curriculum development and the action research movement; and
3. more recent approaches through collaborative partnerships of schools, professional associations, and other stakeholders.

McDonald suggests that these approaches have few prospects of success since they reflect modernist assumptions about knowledge and the role of students as consumers in a highly regulated institutional order, and that a more postmodern approach is needed. This would require more open and interactive learning contexts in which students have a more active role, with less bureaucratic control.

In similar vein, an OECD (OECD, the Organization for Economic Cooperation and Development) analysis of curriculum reform in a range of countries revealed "rather contradictory conclusions about the systemic reform endeavour," in which recognition of the organic and interconnected nature of the elements of reform contrasted with the "mechanistic, relatively static and linear" thinking of many reform proposals. The report concluded that the dominant metaphor of systemic curriculum reform 'owes too much to images of machines and of self-regulating systems drawn from the industrial production models. These characteristics mean that, despite its strengths, such proposals do not capture the complex nature of educational change' (Centre for Educational Research and Innovation 1998: 30).

The conflicts cited as explanations for the limited success of curriculum reform highlight its political dimensions, which range from internal institutional politics to the politics of national educational policy.

The Politics of Curriculum Reform

Rosenmund (2006) has pointed out that curriculum change cannot simply be seen as a planned technocratic reform to improve the productivity of the education system. It must also be understood as a political measure which reshapes relationships among individuals, institutions, and the nation-state through the selection and organization of school knowledge, and through the sorting and grading of students which result. It follows that the politics of curriculum reform can be seen as driven by broad ideological divisions, or by more specific political, economic, or other vested interests (Good *et al.*, 1997).

Curriculum reform is political not only in the conventional sense, but also in a deeply cultural way. Most visibly, reform will be driven by a motivating political source, with a corresponding agenda and implications for extant power relations (Hopmann, 2003). For instance, centralized initiatives may be resisted as undemocratic, lacking contextual authenticity, or representing a narrow ideological agenda. Local initiatives may be dismissed as parochial or irrelevant to broader central policy imperatives.

However, at its center, curriculum reform is a cultural process with a distinctly cultural politics. For instance, Paechter (2003) points to relationships among gender, power, and subject status as influences on the reform process. She shows that differential subject status is related to differential access to power and influence in the curriculum-change process, and that these relations are not gender neutral. From the perspective of cultural politics, curriculum reform will be successful only if it can link to significant beliefs about such values as inclusiveness, excellence, quality, and entitlement. Since these values are subject to different interpretations and emphasis, there is

potential for conflict – as when a new approach to knowledge is justified in terms of entitlement or progress, it may conflict with traditional interpretations of quality or excellence.

The idea of the educated person is founded in cultural traditions and values, and competing views of canonical knowledge. In contemporary curriculum reform, these cultural tensions are complicated by economic agendas, especially those driven by international competitiveness and global integration. In addition, curriculum reform is deeply implicated in issues of material well-being (involving the allocation of education as an economic good), social welfare (influencing cultural capital, status, and access to effective social participation), and personal identities (created through recognition of and incorporation in cultural patterns of knowledge and belief). The potential for disagreement in curriculum reform over priorities and programs runs deep, and its checkered history is likely to continue unless it is able to generate common understandings of and commitment to reform among its stakeholders. Consequently, to achieve its aspirational intent, curriculum reform must be part of a democratic project as both an end and a means. The democratic ideal must inform the intended outcomes of a curriculum for excellence for all which incorporates a wide range of community aspirations; however, it must be the basis of the reform process as well if it is to confront the cultural politics of the curriculum. The latter requirement is a key challenge to current large-scale approaches to curriculum reform.

Early Childhood Curriculum and Developmental Theory

S M-Y Lim, Nanyang Technological University, Singapore

The term curriculum refers largely to planned approaches to teaching and learning that are guided by theoretical and philosophical beliefs about the nature of learners and about the kinds of knowledge(s) that should be taught. From this perspective, a curriculum contains specific content knowledge, objectives and goals, teaching procedures, and assessment strategies. From another perspective, curriculum is less planned in advance and seen as developing through interaction between teacher and students. Regardless of the exact definition, it is generally acknowledged that no curriculum is ideologically neutral. Curriculum makers, like other educators, have philosophical, political, and pedagogical beliefs that underlie the curriculum they create (Apple, 2004).

Early Childhood Curriculum: Reflections of Images of Children

In the field of early childhood education (for children birth through age 8), there is a wide range of curricular approaches and models that are guided by different philosophical beliefs about young children as learners and beliefs about the kinds of knowledge that are worth teaching children. The field (as discussed below) may be characterized by multiple, sometimes opposing or overlapping, images of the child as learner:

- child as organism unfolding over time;
- child as scientific subject;
- child as creative player;
- child as active thinker; and
- child as relational and cultural agent.

These varied images of children have shaped curricular models for young children. Some models are closely guided by educational policies that serve specific groups of children, while others attempt to be more inclusively serving children with a full range of learning abilities and interests.

Child Unfolding: Early Conceptualizations of Curriculum

One of the earliest systematic conceptualizations of curriculum in the field was created by Johann Heinrich Pestalozzi, well-known for his school for mixed-age groups of orphans in Yverdon, Switzerland (established 1805).

Influenced by Plato's and Rousseau's images of the innately good child unfolding naturally over time, Pestalozzi founded the doctrine of *Anschauung* (direct, concrete observation), and capitalized on children's spontaneity and adult or peer-guided activity (Weber, 1984). Through object lessons that encouraged children to observe and explore objects collected from the natural environment, Pestalozzi's curriculum acquainted children with form, language, and number classifications and encouraged children to cultivate their own powers of seeing, judging, and reasoning. An underlying curricular principle was to introduce abstract concepts through concrete objects, always progressing gradually and cumulatively from the easier to the more difficult concepts.

It was Friedrich W. Froebel who documented a curriculum for young children in Germany in the 1800s, based on Pestalozzi's work. He also drew from the philosophical thinking of Plato, Rousseau, and Comenius, complementing his own religious beliefs and intuitive understanding of the child as a naturally creative and productive being (Weber, 1984). Froebel's enduring significance to early years of education was through his formulation of the kindergarten (a combination of two German words: *kind* [children] and *garten* [garden]) system with its emphasis on play and its use of gifts (didactic play materials) and occupations (hands-on activities). Singing, dancing, and gardening were included in order to develop the whole child, although much of the curriculum highlighted the learning of mathematical concepts and symbolic relationships through manipulative objects such as blocks, spheres, and cylinders. Froebel invented the kindergarten to prove that children under 7 years of age were capable of obtaining intellectual and emotional skills through structured forms of play and adult guidance.

The success of Froebel's model resulted in compulsory kindergarten education for all children in the Austro-Hungarian Empire by 1872. The gradual spread of the kindergarten movement can be traced across other parts of Europe and the USA in the second half of the 19th century. Its introduction into the USA is accredited to the efforts of educators such as Elizabeth Peabody and Susan Blow. With the establishment of free kindergartens in working-class neighborhoods in the 1870s, advocates of kindergartens in the USA began to suggest that the proper education of these children could eventually alleviate urban poverty.

Child as Subject: Scientific Views and Curricula as Early Intervention

At the turn of the twentieth century, the child study movement began in the USA. Seminal publications in psychology and philosophy that influenced early childhood education included G. Stanley Hall's *Contents of Children's Minds* (1883), Edward L. Thorndike's *Animal Intelligence* (1898), and John Dewey's *The School and Society* (1900). Influenced by scientific observation methods, especially those of Darwin in *The Origin of the Species* (1859), Hall advocated the use of systematic and direct observations of individual young children to inform curriculum. Arnold Gesell expanded on Hall's work by examining the correlation of ages and developmental stages and charting growth gradients of individual children. Such scientific studies of young children in the burgeoning field of developmental psychology appealed to many early childhood educators who subsequently propagated the generalized theoretical belief that there was an optimal period in the early years in which learning would be most effective.

The Froebelian kindergarten curriculum was to remain popular until the 10-year debate (1903–1913), which marked a turning point in early childhood curricular approaches. The debate was between those who supported Susan Blow and Elizabeth Peabody who argued for the continued relevance of the Froebelian kindergarten curriculum in the twentieth century, and progressive educators such as Patty Smith Hill who were influenced by John Dewey and Edward L. Thorndike arguing for curricular revision in order to keep up with the shifting sociopolitical context of society in the USA (Weber, 1984). Curriculum influenced by Dewey's educational philosophy placed social studies at the core of the curriculum since the purpose of education was for life in a democratic society. In contrast, Thorndike's behaviorist theory came to underlie the image of child as subject in the context of curriculum and of standardized testing.

Progressive educators increasingly influenced curriculum from the early 1900s and their work also drew upon a growing body of knowledge contributed by developmental psychologists. An example of one of the earliest eclectic curricula written by an educator of the progressive movement was the *Conduct Curriculum for Kindergarten and First Grade* (1923) by Patty Smith Hill at Teachers College, Columbia University. The curriculum was influenced by the theories of her contemporaries such as Thorndike and Dewey and was a culmination of her years of experimentation in loosening what Hill considered to be the rigidities of the Froebelian curriculum for children. The Conduct Curriculum combined elements of Dewey and Thorndike, respectively: it encouraged both social cooperation and democratic social responsibilities

(a response to the changing American society at the time), and it was a plan for systematic classroom instruction to modify children's thoughts, behaviors, and feelings (i.e., develop desirable habits).

Outside of the USA, in Italy around 1916, Maria Montessori (the first female doctor in her country) began advocating for her educational method for children who were then considered cognitively defective and those who lived in extreme poverty in Rome. Enduring initial dismissal by educators, including progressive educators in the USA, the Montessori approach is ironically still popular around the world among some middle- and upper-class communities, both as an academically focused approach in private schools and as a homeschooling method (Goffin and Wilson, 2001). It has also been modified to suit individual culture's values and needs while maintaining its emphasis on the training of young children's senses for intellectual development.

Child as Creative Player: A Psychodynamic and Developmental View

In contrast to child development study that focused on observable behaviors and outcomes, Freud's psychoanalytic theory encouraged early childhood educators to focus on the inner worlds of young children as biological and sexual beings. Over time however, his theory was modified and neo-Freudian psychodynamic classrooms featured curricula that encouraged children's self-expression and creativity through messy play with materials such as paints, clay, blocks, sand, and water. Lawrence Frank, a prominent American linked to the Laura Spelman Rockefeller Memorial Fund, built on the image of the child as an emotional being and highlighted the importance of free play in the curriculum for healthy socioemotional growth. Influenced by the theories of Erikson and Freud, Frank believed that emotional security and personality adjustment were keys to developing confident, social, yet independent learners. He advocated that teachers recognize individual differences among children, synthesizing psychodynamic work with the theory of Jean Piaget (Weber, 1984).

By the 1930s, in part because of Frank, many child development institutes and their corresponding lab schools had appeared in the USA. The research carried out at these institutes contributed to normative views of children's growth and abilities (e.g., in areas such as motor development, language, and adaptive behavior). Thus, such knowledge of average or normal child development became foundational in teacher education textbooks and guided the development of early childhood curriculum. Teachers planned curricular activities that would suit the assumed needs and abilities of the average child of a certain age group.

Child as Subject Redux: Concern for Economically Poor Children in the USA

In the 1960s in the USA, several scientific studies challenged the dominance of the fixed intelligence theory established earlier in the century by psychologist Alfred Binet, by showing how children's abilities could be enhanced by positive environmental influences (Goffin and Wilson, 2001). These studies eventually supported the inception of the federally funded Head Start program as part of the War on Poverty to provide academic skills and knowledge (e.g., language-based and numeracy skills) to children from low-income populations across the country. Interestingly, the motivation for the program was similar to Montessori's a half century earlier: to counter the impact of poverty through early education. Indeed, a curriculum based on Montessori's methods was one of a number of models that researchers and educators implemented as they tried to demonstrate positive effects of Head Start.

Another curriculum offered by Head Start was the Bereiter–Engelmann model (later developed into the direct instruction model) to help disadvantaged children catch up academically with their middle-class age mates. In this approach, work and play were on opposing ends of the curriculum as children were rewarded by food, tokens, or praise, when they accomplished academic tasks, that is, they got the right answers. Since the Bereiter–Engelmann model aimed to help Head Start children to attain some of the same skills and knowledge as their white, middle-class peers, it has been viewed as a deficit model that disregarded any of the children's own cultural knowledge and experiences. In the early twenty-first century, the direct instruction approach has been foregrounded again in the USA, due to the impact of the legislation known as No Child Left Behind. Funds associated with that legislation support scientifically based curricula. Thus, highly structured lessons that are clearly taught and whose outcomes are easily measured remain popular, especially in reading instruction, and in some special education approaches, for example, the reading curriculum Open Court and the applied behavioral analysis approach to special education.

Child as Active Thinker: Piagetian Theory and Its Curricular Offshoots

The 1960s also gave rise to curriculum models inspired by Jean Piaget's cognitive developmental theory that children's cognition develops through the sensorimotor, pre-operational, concrete, and formal operational stages. For those persuaded by psychodynamic and developmental approaches, Piaget's comprehensive theory was a better fit than behaviorist approaches to improving the education

of young children. A number of influential programs were based on Piagetian theory, the best known of which is the High/Scope cognitively oriented curriculum, initiated as an experimental program by David Weikart, offered as a Head Start model in the 1960s, and now incorporated into the Head Start curriculum. The curriculum encouraged children's active learning and independent knowledge construction. Other curricula, such as the Constance Kamii-Rheta DeVries constructivist approach and George Forman's constructivist approach, demonstrate different interpretations and applications of Piagetian theory. Constructivist activities capitalize on children's interests and provide physical experiences with objects, logico-mathematical experiences, and interactivity (e.g., experimentation with peers).

Developmentally Appropriate Practice and Its Critics

By the 1980s, another great debate occurred in the early childhood education field. This time, some leaders in the field spoke out against behaviorally oriented curriculum models such as direct instruction. Through the National Association of the Education of Young Children (NAEYC), these scholars published a position statement on developmentally appropriate practice (DAP) in 1986 (expanded in 1987) for standardizing the diverse range of practices found in an array of early childhood education provision (e.g., nursery schools, child care, Head Start, and kindergartens). The guidelines proved to be unexpectedly successful at the time as a much needed tool to provide uniformly high-quality services for young children and families. It was supported by a few longitudinal studies that verified the positive outcomes and benefits of High/Scope, a developmentally oriented curriculum. Such scientific support appealed to policymakers and public school leaders. The concept of DAP became a trendy phrase that was eventually taken up by some proponents of the direct instruction approach in the primary grades. The DAP guidelines were revised a decade after its first publication to accommodate the newer sociocultural perspective in developmental theory.

Just as there was a major debate that created a turning point in Froebelian curriculum in the early 1900s, a significant debate in the last decade of the twentieth century centered around DAP (see Charlesworth, 1998; Lubeck, 1998). Cross-cultural studies have also shown that adults in different cultures could have different views of what young children should learn or behave (see Tobin *et al.*, 1991; Tobin *et al.*, 2009). These studies point to the need to expand notions of what is meant by DAP, rather than to fixate on a search for the one best or most appropriate curriculum.

The Child as Relational and Cultural Agent

The Influence of Sociocultural Perspectives

Critics of Piagetian theory have argued that children do not merely construct knowledge in isolation from their social and cultural contexts. In the 1990s, proponents of the Russian psychologist, Lev Vygotsky, provoked educators to consider a sociocultural view of teaching and learning. Central to Vygotsky's theory is the belief that human development is inseparable from social and cultural activities. Thus, children's development of higher mental processes involves learning to use the tools of culture, such as language and symbols, through the guidance of other people who are more skilled in the use of these tools. Other American psychologists who became aligned with this view included Jerome Bruner and Barbara Rogoff. The sociocultural view led teachers to use tools and strategies to cultivate the latent abilities that lie within each child's zone of proximal development (ZPD). Such a curriculum includes extended blocks of time for free play, thereby encouraging children to advance their play behaviors to utilize symbolic representations and actions, multiple and complex themes and roles (e.g., doctor theme merged with a restaurant theme) through the use of language to create pretend scenarios (Bodrova and Leong, 2007). Props and play materials in the classroom are to be iconic and simple rather than realistic. The curriculum should also allow children to create and review their plans for play, to problem solve, and to learn from one another as a way to extend their individual ZPD. According to the Vygotskian approach, learning is believed to lead development, contrary to the Piagetian notion that development is a prerequisite for learning to occur. These differences in perspective have inevitably shaped curricular approaches.

In the early 1980s, some scholars from the USA began studying programs for children from infancy through age 6 in the small Italian city of Reggio Emilia. Although the Italian educators do not consider their curriculum to be a model, many US educators have studied and tried to implement or adapt the approach. Although the approach is often characterized as focusing on art, founders emphasize representational art as only one of many modes of symbolic representation, which they refer to as languages (Edwards *et al.*, 1998). Integrated learning through extensive project work is impelled by both teacher planning and children's interests in their environment. Teachers' respect for children's strengths, careful documentation of children's work, and collaborative relationships with families led some early educators to cite Reggio Emilia as an exemplar of blending developmental and sociocultural approaches, embedded in both Piagetian and Vygotskian theories. The approach maintains an international following, as educators visit, and are inspired by, the program's centers and schools.

The sociocultural emphasis of the Vygotskian approach has also been used to further the work of multicultural educators. Various multicultural curricula aim to foster an understanding and appreciation of cultural diversity, and to promote intercultural relations that may lead to constructive social action in communities. Inherent in multicultural education is the notion that there are diverse ways of constructing and acquiring knowledge and that one's cultural heritage, home language, and personal experiences are legitimate funds of knowledge (Ramsey and Williams, 2003). Thus, the notion of school knowledge is broadened beyond white, middle-class European-American cultures and histories, and children are viewed as active and interactive agents who not only learn but are capable of creating change. Examples of established multicultural curriculum in the USA include the Anti-bias curriculum (Derman-Sparks and ABC Taskforce, 1989). Outside the USA in New Zealand, the national Te Whariki curriculum (Ministry of Education, New Zealand, 1996) is an example of how policymakers and educators are determined to encourage bicultural early childhood curricular practices by empowering Maori, Pacific Islander, and white European-origin peoples.

Summing Up: Developmental Theories and Their Influence

Looking back historically, we have noted that educators in the field of early childhood see the roots of developmental psychology in the ideas of Pestalozzi and Froebel, who believed that children's abilities would unfold over time. Pestalozzi introduced careful observation, and both thinkers specified curricular choices attuned to children's interests and needs. Following the introduction of the kindergarten in Europe and the USA, the discourse of developmental psychology was built on the successes of nineteenth-century physical sciences inspired by the Darwinian revolution. Like their predecessors, developmental theorists of the twentieth century such as Piaget constructed universalist trajectories of human growth as dynamic, systematic, and irreversible processes.

Developmental psychology's prominence in early childhood curriculum, especially in the USA, was traced back to the 1920s and 1930s when a number of child development institutes were established around the country. These centers served to provide enrichment programs through nursery schools for young children from both middle- and low-income homes and gave developmental psychologists opportunities to further examine the role of the classroom environment, including curriculum, on affecting individual intelligence. After the inception of Head Start in the USA in 1964, part of the work of developmental psychologists was to assess the effectiveness of

early intervention programs for young children from disadvantaged backgrounds.

In the early twenty-first century, some theoretical and curricular stances seem to have cycled back to the 1960s as the discourse of developmental psychology gives way once again to a deficit orientation toward child learners. The legislation known as the No Child Left Behind Act has revived the child as subject, who learns best through scientifically based behaviorist curricula. This image of the child has persisted for about a century and is not likely to fade away. Interestingly, however, early childhood professionals such as those on both sides of the recent debate about DAP have resisted this image and consistently represented curricula as broad enough to include child choice and agency. In other words, they have opted for a definition of curriculum that is interactive, dependent on the knowledge of both children and teachers and not on published curricular scripts.

Postmodernist Critique: Limitations of Developmental Theory and a View toward the Future

Within an international context, many societies are heading toward global capitalism, and are faced with much tension created by the clash of global and local knowledge(s) and cultural values. For some scholars, educating citizens in an increasingly globalized age is not simply about training a skilled workforce capable of creating economic growth and technological advancement, it is also about educating citizens who are intellectually versatile, open minded, socially responsible, and who want to achieve greater global tolerance and understanding of differences in cultures and values (e.g., Burbules and Torres, 2000; Ryan and Grieshaber, 2005). Thus, many have argued for a reconsideration of early childhood educators' reliance on child development theories in curriculum design because they limit one's view of what young children ought to learn.

Within the field of developmental psychology itself, the assumption about the predetermined and cumulative nature of human development was critiqued as early as 1978 in the Presidential Address to the American Psychological Association's Division of Developmental Psychology, *The American Child and Other Cultural Inventions* (Kessen, 1983). Related critiques were taken up by educators and psychologists in the 1980s and 1990s (e.g., Burman, 1994). They urged a reconceptualization of early childhood curriculum so that there would be less focus on individual psychological differences and more on diversity within and across cultures (e.g., Kessler and Swadener, 1992; Mallory and New, 1994).

Postmodernist critics have continued to challenge taken-for-granted essentialist and scientifically biased assumptions about human development and learning and its view of the child as individual and self-contained

(Ryan and Grieshaber, 2005). Indeed, curricula that have been categorized as multicultural may offer the scope needed to encompass the diversity of views of children and curricula globally. Some scholars argue that the most flexible curricular approaches combine a constructivist theory of learning and development with a multicultural and activist orientation toward social justice. With a view of children as relational and cultural agents, adults teach about issues of equity and social justice and then encourage children to act to change communities (e.g., to create equitable rules for boys and girls within the classroom; start a recycling center in the school). The range of issues addressed could extend beyond race/ethnicity, class, and gender to include religion, spirituality, dis/ability, sexual orientation, technology and media, consumerism, environmental degradation, and economic exploitation in global communities. In short, there is an increasing need for more inclusive curriculum for all children.

Studies have shown that high-quality education for the early years is not entirely dependent on the curriculum model that is used, despite the continued preoccupation with such models. Instead, teacher quality is the most important factor (Goffin and Wilson, 2001). The way forward, then, is to stop searching for the one best model – to pause and evaluate the images of children that underlie value-laden teaching practices. From a postmodern perspective, socially just curricula (e.g., Grieshaber and Cannella, 2001; MacNaughton, 2004; Silin, 1995) require teachers to take the time to understand and situate individual children's cultures and the knowledge(s) to inform their curricular choices (i.e., content, perspectives, collaboration, strategies, and assessment). School leaders and policymakers, too, have the responsibility to encourage teachers to be knowledgeable enough to integrate a variety of teaching approaches and strategies instead of being implementers of fixed or scripted curriculum models.

In sum, early childhood curriculum will continue to be influenced by divergent theories of learning and development and contrasting images of young children. Thus, children and families around the globe will rely on the professional judgment of teachers and school administrators to choose curricula that are flexible enough for children's unique heritages and the funds of knowledge each child brings into the classroom. Maintaining such flexibility is no small task; but it is a challenge that must be met, as the increasing diversity within groups of children locally and globally make identification of one best curriculum for all an impossible and undesirable task.

An Evaluation Framework for E-Learning Effectiveness in the Arab World

W AbuSneineh and M Zairi, University of Bradford, Bradford, UK

© 2010 Elsevier Ltd. All rights reserved.

Despite the valuable contribution of each of those studies, a holistic framework for evaluating the quality of e-learning could not be found (AbuSneineh and Zairi, 2007a, b). Developed frameworks either addressed the quality of e-learning programs with an emphasis on the classroom environment only (see, e.g., Cohen and Ellis, 2004) or overlooked some important aspects – such as the impact of the institution on the quality of e-learning programs (see, e.g., Cashion and Palmieri, 2002).

This article is based on a study which attempted to fill the gap, identified in the literature, by developing a comprehensive framework that addresses the critical factors for evaluating quality of e-learning programs from an all-encompassing perspective. The study explores critical factors for evaluating the quality of e-learning programs based on extensive literature review. As a result, 26 factors were identified and categorized under five dimensions, namely, pedagogy, faculty, technology, learning support, and institution. Each represents an important area in the e-learning environment. The 26 factors have been validated and tested at The eTQM College in Dubai – in an Arab cultural context.

Although the sample size of the surveyed learners and faculty is relatively small, the overall findings of this study conform – to a large extent – with what has been reported in the literature in this field and, therefore, support the appropriateness of the implementation of such framework in the e-TQM College.

Introduction

At present, higher education is experiencing new challenges driven by many emerging trends – among which is the introduction of means of online learning. Accordingly, many universities – all over the world – are adopting different moves to cope with the new-era requirements; some universities were established as purely online learning providers, other conventional universities launched new online programs, and some introduced online learning components to enhance some of their already existing programs.

e-Learning redefines the teaching/learning processes and the overall learning environment. It directs the old university to a new set of practices by introducing significant changes in the roles of its main key players – learners, faculty members, and the institution as an entity (Mendenhall, 2001).

The many changes e-learning brings to higher education – accompanied by its vast distribution as an accepted learning-delivery mode – has always been questioned by opponents who tie this type of learning to poor quality. Therefore, studying the different aspects of evaluating the quality of e-learning has been arising as an issue worth researching and enhancing (Zhao, 2003; Kistan, 2005; Wirth, 2005).

This article includes a thorough review for the literature to explore what has been recognized by the researchers and practitioners, of this field, as key factors that affect the quality of e-learning programs and institutions and,

therefore, should be used to evaluate this type of learning. To do so, many studies and researches were taken into account – whether they tackled the issue from a single aspect or went further to address multiple aspects.

Critical Factors

The evaluation model is based on a set of critical factors found to have significant impact on the quality of e-learning. Based on an intensive literature scanning and review, the authors constructed a framework that consists of 26 factors categorized under five dimensions; pedagogy, faculty, technology, learner support, and institution. The dimensions are highly interrelated and do not function independently. The following sections present a brief description of each of the framework dimensions.

Pedagogy

The reason why pedagogy always comes first when the quality of e-learning is discussed is that e-learning is about learning in the first place. Pedagogical issues are one of the first things educators address when they plan to teach.

To start with, pedagogy is a term which originated from Greece and means the art of teaching children (Ciavarelli, 2002). The definition – in the context of higher education – means, generally, the science or art of teaching. Sonwalker (2002) defines pedagogy as “the method by which educational content is exposed to learners.”

To understand the significance of this dimension, it is imperative to introduce the issues that program pedagogy usually addresses:

1. The learner and his characteristics.
2. The subject to be taught.
3. The organization of the content.
4. The strategy for content presentation.
5. The sequence of the topics in the course.
6. The delivery strategy of the content.
7. The assessment of the taught subject and its fulfillment of the teaching objectives (Ciavarelli, 2002).

Pedagogy, therefore, relates to four main components: faculty member, learner, tasks, or exercises that need to be completed with the help of faculty members, and, eventually, knowledge disseminated and gained by the learner (Boettcher, 1999).

Interestingly, the aforementioned pedagogical issues do not limit the learning and teaching processes to any specific time, place, or medium.

In order to understand, briefly, what is meant by learning styles – a major component of the pedagogy – the following section addresses this component and its most familiar theories and principles.

Learning Styles and Their Impact on the Quality of e-Learning

The behavioral, cognitive, and constructive learning theories are referred to as the main principal schools of learning styles (see, e.g., Ally, 2004; Ciavarelli, 2002; Boettcher, 1999).

The Behaviorist school of thought – influenced by Thorndike, Pavlov, and Skinner – hypothesizes that learning takes place as a change in behavior, caused by external stimuli in the environment (Skinner, 1974).

Ciavarelli (2002) explains that it is the change in behavior that bears on its ability to indicate whether or not learners have learned according to the Behaviorists. This is done through shaping learner's response to a set of stimuli – by focusing on skills development through practical means.

The behaviorists' learning theory was criticized by many educators who saw the learning process as being about more than a change in behavior, and that learning consists of elements that cannot be observed. As a result, there was an evolution of a new learning theory – the cognitive school of learning (Ally, 2004).

Craik and Tulving (1975) explain that the cognitive school of learning, on the other hand, relies on the processing capacity of learners and the depth and maturity of the processing. It claims that learning takes place through the use of learners' memory, motivation, thinking, and reflection.

The cognitive theorists believe the instructor is responsible for the information-input process. However, the learner is also an active participant in the learning process, where he/she is responsible to process information (input), store it, and retrieve it (Boettcher, 1999).

The third learning style, discussed in this section, is Constructivism. Cooper (1993) explains that, according to constructivists, learning takes place through learners' observation, processing, and interpretation. This theory is well-known for its argument that learners contextualize the information and personalize it into their personal knowledge and reality.

Learners – according to the constructivists – play a more active role, according to this theory, where they act as the creator and processor of the learning experience. This is why this theory emphasizes the learner-to-learner interaction which is claimed to enrich the learning process (Boettcher, 1999). The teacher – on the other hand – is the facilitator of the learning process, who guides learners in their learning experience, encouraging them to engage in active learning situations whether individually or in groups.

Appropriateness and Relevancy of Learning Styles to Course Goals and Learners' Needs

Although the aforementioned learning styles are the most popular so far, new learning styles are evolving, at present,

with the progress of research in this area. Educators, therefore, have to consider the appropriateness of the learning styles they use for course content to meeting learning goals of the e-learning course they teach (Ally, 2004).

At present, the question becomes: Are the traditionally used learning styles relevant to the pedagogical needs of faculty members and learners? Are they capable of delivering quality learning under today's new conditions where learning environment is more liberating and learner-centered and when more specialized resources are accessible to learners than ever before? (Beaumaster and Long, 2002).

The quality of e-learning is highly dependent on the course content. Learning styles cannot be taken without questioning anymore. Instead, faculty members have to adjust course content by selecting appropriate learning styles based on their conformance to achieve course goals and learners' and needs (Coffield *et al.*, 2004; Gillani, 2000).

Therefore, many researchers have highlighted that the continual review of programs pedagogy, courses' content, and learning styles is a very important tool that helps educators judge the relevancy of learning styles to achieve planned objectives. Bates and Poole (2003) even argued that the appropriateness of using learning content to program goals and objectives should be assessed by educators who were not involved in the design of the pedagogy to guarantee objectivity.

Howell *et al.* (2004) believed that the review of courses' content and learning styles does not only improve the quality of courses, but also helps faculty members to experiment with different approaches to the teaching/learning process and to establish faculty communities that can produce more relevant learning to learners' needs. This is why this factor is usually discussed in association with faculty innovation and engagement.

Clarity of Course Goals

Not surprisingly, there has been consensus in the literature of pedagogy design that, in order to assure the quality of the teaching/learning process, designing a course should start with explicit outcomes that identify the expectations from learners and faculty from the very beginning (e.g., Stone *et al.*, 2001; Bates and Poole, 2003). Learning outcomes – which usually drive the effectiveness assessment process of courses – should also be challenging and linked directly to the institution's overall goals and objectives (Mayer *et al.*, 2001; Watkins and Kaufman, 2003).

Diversity of Learning Styles to Meet Course Goals and Learners' Needs

Ally (2004) claims that with the overlap in existing learning styles and the progressing ones, no styles can be used in

isolation from others. Quality of pedagogy and course content depends, therefore, on using a combination of all appropriate styles – each one to serve a specific course goal or requirement and also learners' needs and wants. The same argument was also advocated by Sonwalker (2002) as discussed below.

In this context, Hughes (2004) argued that the comprehension of learners' needs – such as their readiness to e-learning, familiarity, accessibility and competency of technology, individualized learning styles, individualized career and educational goals, language, and cultural issues – are among the aspects that should be addressed when designing courses and learner-support services.

Pedagogy Is Not Only about Learning Styles

The development of e-learning, introduction of associated infrastructure, and changes hit the interface of education; all led to a reinvention in the pedagogy concepts.

At present, classrooms are being replaced or significantly supplemented with asynchronous and synchronous Web-based and Web-supported learning environments; therefore, methods by which educational content is disseminated to learners are also changing (Sonwalker, 2001).

In this study, components of the pedagogy dimension adopt Sonwalker's (2001) classification that considers pedagogy does not consist of learning styles only; it is a function of another two components – the multimedia and the interaction. The three components form a three-dimensional (3-D) cube – where each axis represents one of those dimensions.

The *x*-axis of the pedagogical learning cube represents the different learning styles, while the *y*-axis represents the multimedia elements used as part of the course content – such as the text, graphics, audio, video, animation, and simulation – and the *z*-axis represents the interaction component which refers to the interaction among faculty and learner, learners among themselves, and learners and content material using tools such as system feedback, adaptive remediation and revision, e-mail exchange, discussion groups, and bulletin boards (Sonwalker, 2002).

Sonwalker (2002) argued that the effectiveness of the pedagogy to meet certain goals and objectives increases with the diversity and the use of a wider range of learning styles, a wider range of multimedia elements, and interaction as well.

Many believe that engaging learners in active learning, allowing them to inquire about what they are learning, reflecting on it, and relating it to personal experiences and real-world issues is the only way to achieve learning outcomes (Laurillard, 1993). Diversity of learning styles, multimedia, and interaction will realize such learning experiences.

Similarly, Graham *et al.* (2001) argued that the use of learner-centric different styles of pedagogy has a direct impact on the achievement of learning outcomes and hence the quality of e-learning programs. Learner-centric pedagogy refers to the use of different learning styles and objects such as projects, challenging tasks, and sample cases to accommodate for the different needs and talents of learners.

Interaction

Interaction is one of the most widely mentioned factors in the literature, in relation to its impact on the quality of e-learning programs (Moore, 2002).

Diversity of Interaction

Simpson and Galbo (1986) defined interaction as

... behavior in which individuals and groups act upon each other. The essential characteristic is reciprocity in actions and responses in an infinite variety of relationships: verbal and nonverbal, conscious and non-conscious, enduring and casual. Interaction is seen as a continually emerging process, as communication in its most inclusive sense.

Interaction in the e-learning environment compensates for the loss of direct and face-to-face contact between learners and their faculty member or colleagues.

Moore (2002) has identified three types of interaction:

1. interaction between faculty and learners – which is considered to be the most vital component that creates an effective learning environment upon which the other two types depend and are facilitated through;
2. interaction between learners among themselves; and
3. interaction between the learner and content material.

Chickering and Gamson (1987) believe that learner motivation, involvement in the learning process, and, hence, the quality of e-learning are affected, primarily, by the learner–faculty interaction – whether inside or outside the class. Faculty's constant communication with learners keeps them engaged actively in learning. The authors also believe learning can be significantly enhanced when group interaction is taking place among the learners themselves – where involvement in active learning is increased, learners' thinking is improved, and knowledge understanding is deepened.

Prompt Responsiveness of Faculty Feedback to Learners

However, quality of interaction – rather than its quantity – is what really matters; Graham *et al.* (2001), for instance, has

identified the promptness of feedback from faculty members to learners as a critical factor that affects the quality of learning. Timely and prompt feedback helps the learner understand the learning content and also helps individualize the learning process (see also Rovai and Barnum, 2003; Roblyer and Ekhaml, 2000).

Vrasidas and McIsaac (2000) stipulate promptness of feedback from faculty members to learners – whether in the form of comments on assignments, homework, class contributions, or overall progress – as one of the critical factors that affect the quality of e-learning and compensate for the loss of the availability of projects, group discussion, or brainstorming activities linked to the desired outcomes of an e-learning program that has a positive impact on the effectiveness of learning.

Relevance of Interaction to Course Goals

Using an innovative rubric to evaluate the quality of interaction, Roblyer and Ekhaml (2000) also emphasized the importance of interaction relevancy to course goals and outcomes – whether during faculty–learner feedback or through learners' projects. The authors considered this link as one of the main factors affecting the quality of learning in the e-learning environment.

Flexibility of Interaction Time and Place

Offering flexibility for time and place of interaction has also been highlighted, by the literature, as a critical factor that affects learners' satisfaction and, therefore, the quality of the e-learning experience.

Through an empirical study conducted by Cashion and Palmieri (2002), it was found that flexibility was rated topmost among the factors affecting learners' satisfaction. This result is not surprising due to the fact that many e-learners usually have other obligations, such as full-time employment, families, etc.

Multimedia

Diversity of Multimedia Components

Similar to the other two components of the pedagogy – that is, learning styles and interaction – the diversity of multimedia components is one factor that affects the quality of the pedagogy, hence the quality of e-learning programs (Sonwalker, 2002).

Relevancy of Multimedia Components to Course Goals

Research on the quality of e-learning programs outlined that effective multimedia components are those which are highly

in conformance with – and explicitly linked to – course learning goals and objectives (Roblyer and Ekhaml, 2000).

Graham *et al.* (2000) have also identified four main technical components pertaining to how multimedia affects learners' and hence quality of e-learning programs; these are:

1. *Consistency of page layout and design.* This is necessary for allowing learners to recognize the graphic language of the interface, use and re-use their knowledge in different applications, and retrieve information easily.
2. *Clear organization and accessibility of information.* This allows learners to accomplish their tasks effectively when understanding the relationship among the media elements, without being distracted by irrelevant features.

In this context, accessibility is identified as "arrangements giving people the opportunity to study in an institution, in particular, the requirement to offer learners from unconventional backgrounds, those with traditional low take-up of Higher Education, or those with disabilities, the maximum opportunity to access education courses" (LTSN, 2004).

From the above definition, accessibility of multimedia content considers disabled learners and their rights for an equal use of content material (Foley and Regan, 2002).

3. *Navigation consistency and ease of use; if not consistent.* Navigation can place a heavy mental load on learners and, therefore, hinders their learning process.
4. *Attractiveness of design and graphics.* In this, learners – who are studying multimedia elements or using the learning interface – can be encouraged to spend longer hours by attractive design and graphics.

In conclusion, elements of the pedagogy act as a jigsaw – the quality of which can be evaluated by the factors outlined in **Figure 1**.

Figure 1 Critical factors for evaluating quality of e-learning programs.

Faculty

Faculty Competency

The amount of literature that addresses this aspect is enormous, where a broad consensus on the positive direct link between the competency of faculty members and the quality of e-learning programs seems to exist (Howell *et al.*, 2004; Caplan, 2004; Frydenberg, 2002; Bower, 2001; Graham *et al.*, 2000; Fredericksen, 2000; Hartman, 2000; Clay, 1999).

Although the competency of people is a general critical factor that has been emphasized heavily by different quality-management standards such as the ISO 9000 or excellence models such as the EFQM Business Excellence Model, yet – and perhaps – due to the rapid introduction of e-learning, institutions might assign online courses to faculty members without proper training, causing many painful experiences whether to the faculty, learners, or the institution itself.

Educators who seem to be very confident with their skills and abilities to deliver quality teaching are, sometimes, hindered by the new infrastructure, new skills required, and their new assumed role; therefore, development programs for faculty members are deemed to be necessary for quality e-learning programs.

According to a study conducted by SUNY (Fredericksen, 2000), faculty competency does not only impact the quality of the entire learning experience by affecting many aspects – starting from course designs to delivery practices. Faculty competency also affects the overall satisfaction of the faculty themselves. Faculty satisfaction has been identified as a critical measure that indicates the quality of e-learning programs (Bourne and Moore, 2003; Hartman *et al.*, 2000).

Faculty competency, according to Fredericksen's study, refers to many aspects, among which are:

1. Awareness of online teaching and learning, in general.
2. Awareness of the new role of faculty and also learners.
3. Required technical knowledge of the Internet and technology to work with and administer applications necessary during the teaching/learning process, during the design of courses, or following completion of courses.
4. Awareness of guidelines and resources related to courses development and planning.
5. Information of all support services and facilities offered to faculty members.
6. Familiarity with the program taught.
7. Familiarity with the policies and procedures pertaining to e-learning, such as copyrights, workload, etc.
8. Access to previous experiences of other faculty members.

Clay (1999) also considered the need to educate faculty members on how their involvement in e-learning programs fits with the overall strategy and mission of the institution. He also added that discussing faculty members' issues and concerns with regard to this type

of learning is also very important to increase levels of awareness.

The success of e-learning courses depends on the type of development offered to faculty members. The following three areas of development have been considered, by Caplan (2004), as the most crucial requirements due to their impact on the success of e-learning programs:

Pedagogical proficiency

This is where faculty members are introduced to – and experience – the classroom environment, requirements of course design, and delivery.

Administrative skills

An area in which methods of classroom management and identification of the support needed and offered by the institution are among the topics addressed in this area.

Technical skills

This includes learning basic and more advanced technical skills as needed and learning more about the technology, its benefits, and barriers.

In the same context, Bower (2001) suggested that faculty-development workshops should introduce faculty to varied e-learning pedagogical approaches, allowing them to explore the online environment and to take informed decisions during the design and the delivery of courses.

In addition to increasing faculty members' satisfaction, faculty development affects the quality of online learning by (Hartman *et al.*, 2000):

1. Encouraging experimental learning and sharing of techniques, tools, and best practices among faculty members.
2. Transforming faculty members to lifelong learners who understand the needs and wants of their learners.
3. Creating meaningful discussions with regard to the teaching/learning process among faculty communities, and allowing evaluation of successes and failures.

Improving competency of faculty members in e-learning institutions has high impact on the pedagogical critical factors discussed in the previous section. According to Hartman *et al.* (2000), faculty-development programs incite their innovativeness to create pedagogical styles and environments that embrace active learning suitable to learners needs.

It is important to mention that developing the competency of e-learning educators should be considered as an ongoing process, which should be evaluated periodically to judge its effectiveness. Surveying of faculty members can be used to generate the perception on a development program to enhance it (Clay, 1999).

Faculty Engagement

Faculty engagement refers to their involvement – in different academic and nonacademic endeavors – guided by the e-learning institution. Faculty engagement is argued to be a very good tool that minimizes faculty resistance, resulting from concerns about the quality of this type of learning. It also creates a cooperative culture that increases faculty motivation, awareness, and confidence (Bower, 2001).

A study – carried out at the University of Central Florida – showed there is a direct positive relationship between faculty engagement and faculty satisfaction, which proved to be a very vital measure that indicates the success of e-learning programs, and hence affects the quality of e-learning (Hartman *et al.*, 2000).

Faculty engagement is also seen as an important input for faculty innovation. Faculty who participate in more e-learning-related conferences and share experiences with colleagues develop high potential for innovating new teaching/learning methods and tools (Howell *et al.*, 2004).

Faculty Innovativeness

The emerging changes in higher education raise more and more questions, everyday, concerning the validity of the learning styles that have been used for decades and their ability to cope with the new educational interface. At present – with the association of technology to learning – faculty members are the best candidates to challenge and validate the existing learning/teaching methods and to innovate new styles that equip learners for such new environments.

As part of today's new educational frontier, the innovation opportunity for faculty has never been this wide; educators, therefore, have to respond with more courage to experiment with the learning environment and learning styles and to create and innovate. The literature on this subject has highlighted that e-learning institutions, at present, require more involvement and more innovation from faculty members to be effective and to produce quality learning (Laurillard, 1999; Conole *et al.*, 2000; Howell *et al.*, 2004).

According to Conole *et al.* (2000), the level of innovation in technology should be associated with a matching level of faculty innovation on aspects of teaching and learning to assure the quality of this type of learning. The authors argue innovation in teaching and learning should be the main purpose for advancement in information technology (IT).

A project, conducted in Pennsylvania State University, supported the argument that faculty innovation in teaching and learning has a direct and significant impact on the quality of e-learning. Through forming platforms of multidisciplinary teams of faculty and instructional

designers, faculty members were encouraged to re-examine their pedagogical approaches and come up with learning/teaching methods that enable learners of today (Oblinger and Maruyama, 1996).

Howell *et al.* (2004) argue effective learning – along with research promotion – can both be achieved if faculty members consider their e-learning experiences as an opportunity for experimenting and innovating new teaching and learning methods, as well as a part of their research efforts.

Faculty Recognition

Faculty satisfaction and motivation and, hence, quality of e-learning programs are also affected by the level of recognition received by faculty members (Clay, 1999; Srikanthan and Dalrymple, 2002).

Many argued that as e-learning demands faculty to develop new skills and assume different roles, setting appealing incentive structures for faculty members is, then, essential (Cashion and Palmieri, 2002; Graham *et al.*, 2000; Hartman *et al.*, 2000).

The argument of the importance of faculty recognition becomes more valid with the existence of research and studies, proving the fact that e-learning exerts extra workload on faculty (Moore, 2002). Therefore, effective and proper compensation should be made to maintain faculty motivation and satisfaction.

Institutions should demonstrate support to faculty members engaged in the design and delivery of e-learning program through a variety of recognition forms that acknowledge extra workload compared to, for example, traditional courses and intellectual contribution. The practice of existing universities indicated that recognition can take different forms – such as financial compensation, upgrade in office computer equipments, adjusted salary and workload, public recognition, notes of appreciation, special privileges (Bower, 2001), or even administrative support, privilege to attend related conferences, or appreciation letters and awards (Clay, 1999).

Researchers also demonstrated the necessity of higher education institutions to revisit their faculty incentive and promotion schemes to include stipends that accommodate for faculty innovativeness (Conole *et al.*, 2000; Oblinger and Maruyama, 1996).

It is, therefore, the reason why faculty compensation and recognition have been highlighted as a critical factor that affects faculty satisfaction and motivation and, hence, the quality of e-learning.

Technological Infrastructure

Appropriateness of Technology to the Pedagogical Requirements

e-Learning is about learning and not technology; the purpose of academic programs is learning and not offering

the most modern or impressive technological facilities. The success of e-learning programs, therefore, depends on how the technology is geared toward achieving the teaching/learning purpose of the program (Bates, 2000).

Bates (2000) added that, in order to provide quality learning, technology should not be planned or implemented in isolation from the operation in the institution, its structure and processes, and – most of all – the pedagogical needs and requirements of its programs.

The appropriateness and usefulness of technology to achieve its desired objectives have been emphasized, in general, and not just in the educational context. The ISO 9126 standard for selection and evaluation of software has put this factor first on the evaluation list and called it “functionality” – which refers to the ability of the technology to accomplish a specific task and provide the desired results, interact with other systems, adhere to necessary standards, and prevent unauthorized accidental or deliberate actions (ISO, 2002).

Similarly – in his well-known model for evaluation of technology – Davis (1989) highlighted the first and fundamental determinant for selection and acceptance of technology depends on its perceived usefulness, referring to its functionality and ability to achieve certain objectives.

Commencing by addressing the pedagogical needs of e-learning program when developing the technological infrastructure is very useful in achieving at least the following (Davis, 2004):

1. Building the suitable learning system.
2. Designing the learning assessment system.
3. Determining the degree of prior preparation needed before starting the course learning journey.
4. Assessing and evaluating the quality of programs and its component courses.

It is not surprising, therefore, to find an increasing amount of literature in the field of e-learning, stipulating that enhancing the e-learning experience and the achievements of its outcomes are also dependent on the appropriateness of technology to pedagogical requirements and needs.

Reliability

Reliability of technology refers to the capability of the technology to perform a required function and maintain a certain level of performance under stated conditions for a stated period of time (ISO, 2002).

Reliability of technology has been highlighted as one of the most important factors that essentially impact the quality of the learning experience and the success of online courses (Cashion and Palmieri, 2002; Moore, 2002).

Faculty members and learners can be easily distracted from the continuation of a teaching/learning task which usually causes high level of frustration due to unreliability or instability of technology (Hartman *et al.*, 2000).

Initially, many concerns with regard to the future and substantiality of online learning were raised – resulting from the doubts concerning technological reliability and its impact, not only on the quality of e-learning but also on the survival of the entire concept.

Technical shutdowns – faced by learners and faculty members – during virtual sessions, discussions, and even assignments were among those issues, and, therefore, reliability and stability of technology was rated topmost, in many studies, as a critical factor that affects the success of the e-learning experience (Fredericksen, 2000; Bates, 2000).

Accessibility

In this respect, accessibility refers to the ability of learners – of varying technical means and technical limitations related to computer power, bandwidth, or hardware limitations – to have equal opportunity of access to course material similar to other colleagues (Bates and Poole, 2003).

Schrum and Hong (2002) argued there is a substantial relationship between the number of learners dropping their online courses and the difficulties they face trying to access the technological tools and equipments. Accessible technologies, therefore, represent a distinct advantage for learners to study according to their convenient time and pace; otherwise learners will spend their time trying to solve technical problems, instead of engaging in the learning experience.

Therefore, an understanding of the technological and financial limitations of learners, their preparedness, and ability to participate equally in the learning experience is necessary for the success of e-learning. In addition, it is important to select appropriate technological infrastructure that enables learners to focus on their learning (Davis, 2004).

At present, for this reason, many e-learning institutions offer their learning content using online and offline tools (compact disks (CDs) and digital versatile disks (DVDs)) to accommodate those who have no access to high-speed connectivity.

Learner Support

The first audiences is of learner-support services are, usually, the prospective learners – through whom they learn about the program objectives, admission criteria, learning and teaching philosophy, their readiness for e-learning, required technology, and technical competence. Learner support then continues with learners throughout their learning journey, with services such as the academic advising, the library, and the technical support helpdesk until following graduation with alumni services.

Appropriateness of Support Services to Learners' Needs

There is no doubt with regard to the importance of learners' support services which, usually, complement the learning/teaching process and enhance their learners' experience. Many authors have highlighted the importance of learners' support and its impact on the quality of e-learning programs (Hughes, 2004; Goss and Prakash, 2003; Cashion and Palmieri, 2002; Frydenberg, 2002).

Although many higher education institutions claim awareness of the needs and wants of their learners, they actually do not. Cashion and Palmieri (2002) explained that many institutions go wrong by assuming learners' needs are only pedagogical and, therefore, learners' support is exclusively limited to pedagogical support.

For instance – and despite the assumption that many of today's learners are aware of the technological tools and facilities – the level of learners' awareness of educational technologies is still not up to the mark. Many of today's learners might be exposed to e-learning courses, for the first time, at the higher education level; therefore, the preparation of learners to cope with the requirements of study, to understand the new role they have to assume, and also to understand the technology they will deal with during their study is necessary for learners before they engage in their learning experience.

Schrum and Hong (2002) claimed that technical support provided to e-learners reduced the pressure on them and released their fear from the inability to use technology. Learners who feel technical support will be provided when necessary are more able to concentrate on their study and experience a more successful learning experience.

According to Hughes (2004), learner-support tools should exceed pedagogical needs, and should be extended to include:

1. information and administrative support;
2. technological support;
3. study-skills assistance – such as time management, balancing personal demands and study pursuits, information about usage of Web content, and plagiarism;
4. educational counseling; and
5. program advising and digital library.

Responsiveness of Learner Support

Responsiveness to learners' enquiries, suggestions, or complaints has been also highlighted as an important factor that affects learners' satisfaction and, therefore, impacts the quality of learning (Hughes, 2004; McNaught, 2002; Meyer, 2002; Srikanthan and Dalrymple, 2002).

According to Harvey (2002), responsiveness of learning-support tools and staff to learners' enquiries can increase their tolerance and satisfaction; hence, increasing the quality of their learning.

Most often, a high percentage of e-learners usually comprises busy senior professionals or full-time employees who would value and appreciate the timely response to their enquiries and the availability of support when needed. Smith (2004) outlines that the availability of responsive learners' support can be demonstrated in three forms:

1. The ability of learners to get in touch and to make contact with the person to whom they wish to speak.
2. The reassurance of learner support staff that, if a message is left or an e-mail is sent, this will at least be acknowledged.
3. The prompt-actioned response, wherein if the action cannot be taken immediately, the information of actioned support will be received promptly by the learner.

Institution

Leadership Commitment to Effective Learning

According to Barker *et al.* (1999), effective learning requires a whole-institution approach that pays enough attention to the teaching/learning processes, facilitates the work of faculty members, and provides necessary support to faculty whenever necessary – starting from its leadership.

e-Learning institutions – according to the author – cannot be successful without leadership commitment to set, maintain, and share a clear direction for the institution, with a focus on its teaching/learning processes.

Setting up institutional priorities in favor of the teaching/learning quality and providing support to develop competencies and infrastructure are some exemplary forms of leadership commitment for effective learning (Marcus, 2004).

Top management should, therefore, be involved in continuous monitoring, evaluation, and improvement of the institutions' academic performance; as part of that, e-learning institutions should continuously monitor learning effectiveness, learners' satisfaction, faculty satisfaction, efficiency, and cost-effectiveness (Bourne and Moore, 2003).

Pervasiveness of Commitment to Quality and Continuous Improvement

Quality commitment is an obvious factor for developing a quality culture in an organization and for assuring and maintaining continual improvement. This factor has been highlighted, generally, in many quality management and excellence standards or models – such as the ISO 9000 and the EFQM Excellence model.

Similarly, quality commitment at all levels of the e-learning institution – including top management, faculty, and staff – has been highlighted heavily in the literature as a precondition to the success of e-learning

institutions (Marcus, 2004; Frydenberg, 2002; Barker *et al.*, 1999; Mayer *et al.*, 2000).

Pervasiveness of quality commitment should be witnessed at all levels of the institution. Top management should create a shared vision for continuous improvement. They should also drive and support the institutional quality-assurance initiatives (Kistan, 2005). Faculty members and staff should demonstrate quality commitment by their involvement in the continual improvement directives, such as assessment of teaching/learning effectiveness, review, and improvement of courses and programs (Meyer, 2002; Moore, 2002).

Appropriateness of Processes to the e-Learning Environment

The changes that accompany the introduction of e-learning in a higher education institution should be associated with a new definition of processes which impact organizational structures, roles, and responsibilities of educators and staff.

According to Bates and Poole (2003), planning for e-learning programs by defining relevant and appropriate processes to the e-learning environment and changed roles and responsibilities of staff and faculty is considered to be a critical factor that impacts the quality of e-learning programs. Processes of e-learning are not quite similar to those of conventional learning; many additions have occurred to the day-work of institutions with the introduction of this type of learning. Instructional designing, dealing with intellectual properties, planning for and maintaining the technological infrastructure, program management, administrative support for faculty or learners, dealing with faculty workload and incentives, governance and decision-making processes, or pricing are only some examples of the processes that need redefinition or customization in the e-learning environment.

Among the changes e-learning introduces is the overall change of the needs and role of learners. In this context, Austin (2001) argues that the starting point for defining and shaping processes in an e-learning environment is an understanding of customers' needs (learners, families, employers, and society) who represent the input for the learning/teaching process. A change in the input will lead to a change in the definition of the process. He argues that appropriateness of processes to the e-learning environment and their integration to serve customers' needs is an important factor upon which the quality of e-learning programs depends as well as the successful implementation of processes and the potential improvement of them later.

Financial Feasibility and Sustainability

It is obvious that many elements in the e-learning type of education are costly and require more financial investments and support from higher education institutions.

Preparing learners to this type of learning through introductory and orientation programs, the necessity to offer different types of learning styles that accommodate the different learning needs and talents of learners – offering more flexible learning methods and timings, development of faculty competencies, compensation for faculty workload and copyrighted work, developing reliable, accessible and maintained IT equipments, infrastructure and multimedia components, the need for timely and responsive learners' support – are only few examples of what investment this type of learning would require.

For the aforementioned cost elements and many more, it is not surprising to know that cost structure and, consequently, the costing of e-learning programs is considerably different from conventional educational programs (Bartolic-Zlomislic and Bates, 1999).

Therefore, the financial management in e-learning institutions has been highlighted as an important factor that should be used to judge the quality of e-learning programs (Frydenberg, 2002; Moore, 2002; Bourne and Moore, 2004).

Financial sustainability which relates the cost of the program to its financial benefits (Bartolic-Zlomislic and Bates, 1999) is considered to be one of the factors that affect the quality of e-learning programs for the following main reasons:

1. The ability to support and sustain the program while it is running even if the number of enrolled learners did not match the expectation in order to protect the interests of learners.
2. The ability to re-invest in the program to enhance it and advance it.
3. The ability to offer affordable e-learning programs.

Financial planning and management of e-learning programs is a necessary activity that should be undertaken with a lot of consideration and responsibility to assure financial sustainability and feasibility of the program – maintaining sustainability of the institution and program quality (Moore, 2002).

Many practices have appeared in e-learning institutions to increase the financial benefits of a program or to decrease its costs such as offering for economies of scale and the re-use of learning objects and modules contents for different target groups or even different courses (Frydenberg, 2002).

Research Objectives and Methodology

The main purpose of this study was to develop a framework for the effective implementation of e-learning programs through investigating the 26 factors explained in the section above. It also intends to examine the relevancy and importance of such framework by investigating the experience of learners and faculty members of e-learning programs.

The research of this study adopts a methodological triangulation approach where a mixture of quantitative and qualitative methods is used. The study starts with a deductive approach where necessary literature review in the field of e-learning quality-implementation is conducted – to assure relevant work in the same subject is not overlooked and to generate a framework of factors critical for the effective implementation of e-learning programs. A case-study strategy was selected to explore the relevancy and importance of the framework factors, in which:

- Quantitative data is collected by surveying learners and faculty members' views using a questionnaire.
- Qualitative data is collected by interviewing a group of the questionnaire's participants to triangulate the data collected by the questionnaire means and to further investigate some of the findings from the questionnaire results.

The selected multi methods approach was beneficial for the study for at least the following reasons:

- helped generate a better understanding of the results collected;
- ruled out the effect of being dependant on one method; and, therefore,
- created greater confidence in the conclusion drawn.

Case-Study Analysis and Discussion

Average Comparative Ratings

Using the mean value for each factor, **Table 1** outlines the rank of each factor as perceived by faculty members and learners in addition to the study that supported it – which represents the average comparative rating of importance for each factor as viewed by both learners and faculty members.

As can be seen from **Table 1**, responses of the learners and faculty members do not follow a specific pattern of peaks and troughs; average comparative rates of importance (indicated by the mean value) do coincide in some of the factors, such as faculty–learner interaction and relevancy of interaction to learning goals; however, they also show some significant differences in importance perception.

Referring to Ehler's (2004) argument that the effective implementation of e-learning programs is correlated to the level at which higher education institutions are consistently satisfying their principle stakeholders – that is, educators and learners – the difference in perception of importance between faculty members and learners indicates both the impact of those factors on the quality of e-learning programs from a different perspective and the different priorities which would add more pressure on e-learning institutions to fulfill the different needs and demands both of faculty members and learners.

Common Top-Rated Factors by Learners and Faculty Members

Among the top ten factors rated by faculty members and learners, six factors were common. Those factors are believed to be critical factors to both faculty members and the learner when implementing e-learning and, therefore, e-learning institutions should tackle with extreme importance,

1. Reliability of the technology.
2. Accessibility of the technology.
3. Faculty competency.
4. Use of diversified learning styles to suit learners' talents and needs.
5. Faculty–learners interaction.
6. Relevancy of learning styles to learning goals and objectives.

Dimensions Analysis

Pedagogy

Positive and close responses obtained by both faculty and learners in this dimension supports the work of Sonwalker (2002) and Ally (2004), who stipulated diversity of learning styles is a powerful solution to accommodate for learners different needs and courses different goals and objectives. In addition, the responses support the importance of clarity of course goals (Stone *et al.*, 2001; Bates and Poole, 2003; Mayer *et al.*, 2001; Watkins and Kaufman, 2003) and the importance of appropriateness and relevancy of learning styles factor (Ally, 2004; Coffield *et al.*, 2004; Gillani, 2000; Freire, 1997).

Faculty

Faculty competency is one of the top-rated factors at all dimensional levels as per the views of learners – and as per the views of faculty members. Those results come to support the work of many researchers in this field such as

Howell *et al.* (2004), Caplan (2004), and Graham *et al.* (2000). On the other hand, many studies have argued that faculty members' engagement in the institute's e-learning activities, ventures, and communities is positively linked to faculty members' innovativeness (Bower, 2001; Hartman *et al.*, 2000; Howell *et al.*, 2004). This direct relationship was not seen, however, by the surveyed faculty members who highly rated faculty innovativeness, yet the majority of the surveyed faculty members perceived faculty engagement as not important.

Similarly, an enormous amount of literature has emphasized that the quality of faculty–learner interaction is what matters – urging the need for prompt and timely response from faculty to learners when needed (Graham *et al.*, 2001; Rovai and Barnum, 2003; Smith, 2004; Roblyer and Ekhaml, 2000; Vrasidas and McIsaac, 2000). Despite this, 50% of surveyed faculty believed prompt responsiveness of faculty feedback to learner does not affect the quality of e-learning programs.

Given this fact, this factor was among the highest-rated factors by learners at all dimensional levels; this area needs more investigation where the results of faculty members can be due to their lack of readiness or awareness for the need to engage in extra workload, or other reasons.

Technology

Despite the differences in views and perception of surveyed faculty members and learners on the level of importance of many factors; they agreed that technology reliability and technology accessibility were among the two top-rated factors. Those results support the findings of Cashion and Palmieri (2002) and Fredericksen (2000), who also concluded that technology-related factors occupy the highest priorities when it comes to learners' and faculty satisfaction.

The results also support the work of Schrum and Hong (2002), who suggested that the importance of technology

accessibility is an undervalued issue and is not taken into consideration by many e-learning institutions despite its impact on withdrawal rates.

This is not surprising – simply because e-learning cannot work without the proper technological infrastructure. Assume a situation where the institution has the best and fully engaged faculty member, the right pedagogy in place, all necessary support is provided, yet have technological infrastructure which fails to operate when needed, or have unreliable infrastructure that shuts down in the middle of a virtual classroom. The level of frustration caused to faculty and learners by inaccessible or unreliable technology, reported in the literature (Moore, 2002; Hartman *et al.*, 2000; Bates, 2000), is, therefore, not exaggerated according to the views of surveyed faculty and learners.

Learner Support

Learners placed a lot of emphasis on prompt responsiveness to their enquiries whether from faculty members or learners' support staff. This again supports the reported literature which finds timely responsiveness from e-learning faculty and staff compensates for the loss of face-to-face and social interaction (Vrasidas and McLissac, 2000) and increases learners' tolerance and satisfaction (Harvey, 2002).

Prompt responsiveness of faculty feedback to learners was highly repeated in the literature for its impact on the quality of e-learning programs and also received a lot of enthusiasm by the surveyed learners, yet was believed to be not important by a majority of faculty members.

This result contradicts the increasing literature that emphasizes the new role of faculty members. Faculty have more expanded roles than lecturing at present; they are facilitators of the learning process – mentors who assure the engagement of learners at all levels (Cashion and Palmieri, 2003; Mendenhall, 2001; O'Neill *et al.*, 2003). This realization cannot be achieved without full dedication of the faculty who should be available to learners with timely responses whenever needed. The literature has reported how learners can lose interest in the course if they do not receive timely feedback on their queries and progress (Smith, 2004).

Institution

There is a general assumption among many educators that e-learning programs can operate under the same conventional environment and support system as any traditional education program (Bates and Poole, 2003; Howell *et al.*, 2004). This, perhaps, explains why 66.7% of the surveyed faculty members did not see the importance of having appropriate processes for the e-learning environment.

Conclusion

The main purpose of this study was to explore the factors that are considered critical for the effective implementation of e-learning programs, to develop a framework of such factors, and to test the relevancy and importance of the framework's components in an e-learning institution in the Arab world.

In the development of the critical factors framework, a thorough exploration and review of the existing literature was carried out. A framework of 26 factors – categorized under five main dimensions – was developed as a result of interpreting and analyzing the present literature. The study then continued by testing the relevancy and levels of importance of each factor using a case-study approach.

The empirical research was, mainly, based on gathering qualitative and quantitative data using distributed questionnaires to learners and faculty members, as well as conducting semi-structured interviews.

As a result of this study, all factors included in the evaluation framework were found relevant and important by either faculty members or learners or by both. The findings of this study support the work of researchers upon which the framework was built.

Generally, there was a difference in perception between learners and faculty members on the level of importance of many factors. Yet – and despite the differences in views and perception of surveyed faculty members and learners – they agreed that technology reliability and technology accessibility were among the two top-rated factors.

In addition to the technology reliability and technology accessibility factors, learners and faculty members shared the perception of importance of: faculty competency, use of diversified learning styles to suit learners' talents and needs, faculty-learners' interaction, and relevancy of learning styles to learning goals and objectives.

It is crucial that e-learning institutions keep searching for novel processes, methods, and support systems to cope with today's new educational frontier and to provide quality education. Measuring and evaluating if the institution is capable of doing this is yet another crucial matter.

What have been identified in this study as critical factors for the effective implementation of e-learning will need to be continually reviewed and enhanced. e-Learning faces challenges to stay updated in a learning/teaching world that is changing faster than ever, supported by powerful tools, tendered by different types of teachers, and offered to more aware and educated learners.

Globalization and Social Justice in Higher Education

E Kimura-Walsh, Santa Clara University, Santa Clara, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Democratization – The shift from an authoritarian social or political system to one that provides democratic participation in which all people have legitimate representation.

Divest or divestment – A removal of funds from an area of investment, including higher education, corporations, etc.

Recuperated businesses – Businesses that were closed or under threat of being closed as a result of Argentina's 2001 economic collapse until workers took on collective ownership. They are part of a larger recuperated businesses movement.

Introduction

Scholars are developing increasingly complex – and, often, contradictory – understanding of globalization and its influences. Some scholars credit globalization with troubling results, such as exploiting the poor (McLaren and Farahmandpur, 2001) and westernizing the world (Altbach, 2005), whereas others note more progressive results including increases in foreign aid (Stiglitz, 2002) and opportunities for international scholarly collaboration (Altbach, 2005). Within the realm of higher education, scholars find globalization equally complex and contradictory. This article examines the current literature with regard to globalization's effects on higher education. Moreover, it suggests how higher education institutions can use the mechanisms of globalization to further social justice issues, locally and globally.

Globalization from Above, Globalization from Below

Kellner's (2002) critical theory of globalization is helpful in understanding the numerous and contradictory conceptions and consequences of globalization. Kellner (2000) notes that one must acknowledge that globalization has "progressive and regressive features, as well . . . as fundamental ambivalences" (p. 305). By encompassing both positive and negative characteristics, Kellner (2000, 2002) suggests a critical theory of globalization that

deconstructs and denounces oppressive and undemocratic features of globalization, while supporting and promoting the positive aspects of globalization that uphold justice and democratization. (Democratization refers to the shift from an authoritarian social or political system to one that provides democratic participation in which all people have legitimate representation.)

To further explore the contradictory nature of globalization, Kellner (2002) suggests that a distinction be made between globalization from above and globalization from below. Globalization from above – or neoliberal globalization – is the use of globalization to inhibit democracy, exploit and oppress the poor, and generate more power and wealth for the rich (Kellner, 2000, 2002). Neoliberals share the belief that liberalization of the market will create equality by removing human bias and promoting rationality and fairness in the allocation of goods and services (McChesney, 1999). As a result, they attempt to use the mechanism of globalization to create a hierarchical global structure that emphasizes capitalism, privatization, individualistic prosperity, free market values, and a weak state (Apple, 2000). These views are best known for guiding the policies of the World Trade Organization (WTO), World Bank, and International Monetary Fund (IMF) – the three primary institutions that govern global economy and trade.

Critics view these neoliberal ideals as advancing the exploitation of marginalized people and countries (Chomsky, 1999; Chua, 2004). They argue that, instead of providing for fair policies, the neoliberal agenda of the WTO, World Bank, and IMF has detrimental effects on developing countries and their citizens, while looking out for the interests of the G-7: the United States, Canada, Japan, France, Germany, Italy, and United Kingdom (Stiglitz, 2002). For example, these three organizations practice capital market liberalization, which requires poor countries seeking aid to liberalize their trade and financial markets as a condition for economic assistance. Similar policies contributed to Argentina's economic collapse when – as a result of opening their markets – their banking system became dominated by foreign banks that failed to fund domestic small- and medium-size businesses (Stiglitz, 2002).

In contrast, globalization from below describes anti-neoliberal global movements that are mainly concerned with challenging the liberalization of markets, establishing rules to govern the global economy, and ensuring the interests of all people are served (Torres and Rhoads, 2006). Moreover, globalization-from-below movements

resist neoliberal exploitation and oppression. They use the trends of globalization to empower marginalized people and counter global structures of domination and exploitation (Kellner, 2000). Globalization from below takes many different forms including environmental, human and labor rights, and identity movements (Brecher *et al.*, 2000; Torres and Rhoads, 2006). Examples of globalization-from-below activism include the Anti-Apartheid Movement (Altbach and Cohen, 1990); protests against the World Bank, IMF, and WTO (Smith, 2001); as well as the Group of Seventy-Seven (G-77) – a United Nations coalition of 131 developing countries that promotes the economic interests of developing countries and advocates for a shift in global economic decision making from the World Bank and IMF to the United Nations (Brecher *et al.*, 2000).

Higher Education and Globalization from Above

Kellner's (2002) concept of globalization from above and below is helpful in examining globalization's impact on post-secondary education. Globalization has mixed – often conflicting – effects on access and equity within and between national higher education systems, and individual institutions. The majority of literature exploring globalization's impact on higher education focuses on the consequences of globalization from above. Some of the effects most prominently noted in the literature include: increased disparities between post-secondary systems throughout the world, a trend of privatization within institutions, and the westernization of higher education research and teaching.

Hierarchies Intensified

Globalization has intensified long-standing hierarchies among various systems of higher education throughout the world (Altbach, 2005). The United States, Europe, and a few other wealthy countries have well-developed post-secondary systems with ample resources to fund teaching, research, and other activities. Developing countries, however, struggle to maintain and expand their colleges and universities. As a result of globalization, privileged higher education systems wield increasing international influence and have become the ideal to which other systems are compared. As developed countries become dominant centers of knowledge through research production, knowledge exchange (e.g., academic journals, conferences), and advanced training, it is more difficult for less developed higher education systems to catch up (Altbach, 2005). As a result of growing international competition, existing disparities have become more extreme, if not irreparable.

Moreover, the IMF and World Bank aggravate these disparities by promoting policies that force poor countries

to divest from higher education as a condition for further borrowing (Puplampu, 2006; Torres and Rhoads, 2006). (Divest or divestment refers to a removal of funds from an area of investment, including higher education, corporations, etc.) The IMF and World Bank promote these policies because they view higher education as having a low rate of return (Puplampu, 2006; Santos, 2006), and education as a private good that should be allocated through the free market. As a result, countries such as Mexico, Argentina, and Brazil have been forced to redirect funding from higher education to elementary and secondary education (Torres and Rhoads, 2006).

Similarly, in many African countries, the World Bank and IMF's structural adjustment packages resulted in state divestment from education, generally, and higher education, specifically (Puplampu, 2006; Santos, 2006; Shizha, 2006). Shizha (2006) argues the enactment of these neoliberal policies in Zimbabwe diminished access to education for the poor because tuition increased to supplement the state's declining financial investments. As a result of higher education's declining resources, institutions also face falling faculty salaries and scholars leaving to seeking more stable institutional environments. These trends have led to a shortage of academic personnel, and undermined Africa's knowledge production (Puplampu, 2006; Teferra and Altbach, 2004).

The WTO is also contemplating further imposition of neoliberal-influenced policies on higher education. As part of the General Agreement on Trade in Services (GATS), the WTO is considering including higher education in the open market. This agreement is still being developed; however, if it is carried out, developing countries would be forced to allow multinational educational providers (primarily those from G-7 countries) free access to their countries. Simultaneously, developing countries would be prevented from sufficiently supporting their own higher education systems, thus lessening their chances of competing with better-resourced, foreign educational suppliers (Altbach, 2005). Furthermore, without any stipulations to ensure mutually beneficial relationships between foreign providers and their host countries, GATS could weaken the social good purpose of higher education (Santos, 2006). This could occur in South Africa where affirmative action is utilized in higher education to integrate the society and advance opportunities for all. Foreign higher education institutions, that utilize selective admissions likely to favor whites, would undermine the country's use of education in the broader battle against racism (Santos, 2006).

Privatization of Higher Education

Universities are also engaging in more capitalist-oriented behaviors as a result of neoliberal divestment from higher education. Clark (2004) identifies this trend on an

international level, documenting entrepreneurial business-like activities at such diverse institutions as the University of Strathclyde in Scotland, Makerere University in Uganda, and Catholic University of Chile. In US institutions, the influence of market ideology has grown to the extent that Slaughter and Rhoades (2004) propose a major shift from a public good knowledge/learning regime to an academic capitalist knowledge/learning regime where higher education practices are increasingly driven by the market.

This neoliberal influence can be seen in the ever-increasing presence of private industry on college campuses. Higher education institutions are involved in patenting new knowledge and products, and their boards of trustees are largely made up of private industry executives (Slaughter and Rhoades, 2004). Private corporations also have a growing influence on academic research (Gumport, 1991). For example, the pharmaceutical company Novartis offered the University of California, Berkeley, \$25 million for the Department of Plant and Microbial Biology in exchange for two seats on the grants committee that determined which research to fund, and the ability to vet all inventions emerging from the department (Press and Washburn, 2000; Rosenzweig, 1999). (With the exception of research funded by other corporations.) Further, Novartis would also have the right of first refusal to license a fraction of the patents equivalent to the percentage of the department's funding provided by the company (Rosenzweig, 1999). Critics are concerned corporate intervention could taint academic research by potentially creating bias, and shifting its purpose to serve the private not public good (Press and Washburn, 2000).

Increasing Homogenization

At an international level, globalization has a homogenizing effect on higher education. As countries strive to develop world-class institutions in a global context, these institutions are likely to follow Western models. For example, Mohrman (2005) points out that China's leaders are failing to take advantage of their universities' strengths in the humanities and social sciences. Instead, they are attempting to catch up with Western universities' achievements in the natural and physical sciences – an ambition they have little chance of fulfilling.

Furthermore, research standards have also become biased toward Western values. The methodological practices of Western researchers are accepted as the norm, forcing non-Western scholars to adapt their research practices to be both accepted and understood in the international academic realm (Altbach, 2005). Additionally, the growing dominance of English in academic communication is also evidence of globalization's homogenizing effects (Altbach, 2005). As the most widely learned and used second language, English dominates academic journals,

cross-border degree programs, and international conferences (Altbach, 2005). This widespread use of English creates an advantage for English speakers and English-speaking countries in academe, while further marginalizing non-English speakers (Altbach, 2005; Puplampu, 2006).

Overall, scholars argue neoliberal globalization is having a detrimental effect on equity within higher education. These neoliberal policies engender a broad trend of public divestment from higher education which is contributing toward the privatization of institutions. Further, this divestment is increasing the divide between the haves and the have nots among higher education systems, and limiting access for the poor in developing countries to post-secondary education.

Higher Education as Globalization from Below

While scholars have identified the impact of neoliberal globalization on higher education, less has been written with regard to how higher education institutions can resist neoliberal globalization, and use the mechanisms of globalization to advance social justice. Higher education institutions in developed countries have a particularly pressing responsibility because of their privileged status (Altbach, 2005). As a result, there have been calls for universities – particularly in the United States – to engage in globalization from below by resisting neoliberal trends and addressing social inequality (Altbach, 2005; Kimura-Walsh and Allen, 2008). While literature on institutional participation in globalization from below has been limited, scholars have explored some ways institutions can advance the social good in the context of globalization.

International and Local Collaborations

Collaborations at the international and local levels offer an important means for higher education institutions to use mechanisms of globalization, in conjunction with existing resources, to benefit marginalized higher education institutions, countries, and people. Technological advances have enhanced worldwide communication and travel, thus making international research and scholarly collaborations more viable. Altbach (2005) argues US institutions and faculty are in an ideal position to pursue and promote global scholarly relationships. In this way, higher education institutions can “develop collaborative, mutually beneficial initiatives and policies, eschewing profit-making ventures that advance the hegemony of powerful academic institutions and systems” (Altbach, 2005, p. 64). If so motivated, US colleges and universities can avoid buying into and profiting from their dominance in the global higher education system. One natural link that deserves more exploration is potential collaboration between scholars

from developing countries who have migrated to developed countries, and higher education institutions or other organizations in their home countries. As technology expands, these scholars can maintain better contact with their countries of origin, and provide an important source of intellectual capital (Altbach, 2005; Teferra, 2000).

Higher education institutions and their constituents can also play an important role in local globalization-from-below activities. In addition to promoting a neoliberal agenda, the World Bank and IMF, often, fail to consider regional context (Kempner and Jurema, 2006; Slocum and Rhoads, 2009). As a result, local initiatives are necessary to address the unique economic struggles of developing countries because they take into account factors such as culture, values, community dynamics, and local economy (Kempner and Jurema, 2006). For example, Kempner and Jurema (2006) describe Integrar Institute – a collaboration initiated by Brazil's *Central Única de Trabalhadores* (CUT; Workers Central Union) with public universities in Rio de Janeiro, Campinas, and São Paulo. This program provides courses to union workers, managers, and unemployed citizens in areas such as basic education, management, planning, computing, and economics. Through these courses, participants improve their workplace skills and gain exposure to advanced educational opportunities. As seen in this example, universities in collaboration with grassroots organizations can address the economic challenges of their communities more effectively than global organizations while also undoing some of the negative ramifications of neoliberal policies.

In addition to institutional efforts, individual faculty and students can also play important roles in local movements opposing neoliberal globalization. Slocum and Rhoads (2009) examine ways faculty and students at Argentina's University of Buenos Aires (UBA) opposed neoliberal trends in the wake of the country's 2001 economic collapse resulting from IMF and World Bank policies. In addition to participating in social protest, faculty and students engaged in forms of "intellectual transference" (p. 99). They generated theory and research on the broad forces shaping the country which provided a new lens for marginalized groups to understand their experiences. Further, university constituents helped grassroots organizations, such as recuperated businesses with services such as accounting and technological assistance. (Recuperated businesses are businesses that were closed or under threat of being closed as a result of the economic collapse until workers took on collective ownership of them. They are part of a larger recuperated businesses movement in Argentina.)

Massification of Higher Education

In some cases, globalization has encouraged countries to increase access to higher education because of

the growing perception that post-secondary education increases competitiveness in the global market (Yang, 2002). While the increasingly market-oriented goals of higher education are questionable, the expansion of higher education offers a wider range of citizens more job opportunities, as well as social mobility, and improved lifestyles. For example, China expanded their higher education system to increase their economic competitiveness and stimulate the economy with families' educational savings. As a result, the proportion of the population attending college grew from 3.4%, in 1990, to 11%, in 2000 (Yang, 2002). Unfortunately, paired with this growth in access is a trend of increasing tuition which limits the opportunities of poorer citizens (Yang, 2002). As a result, we are seeing a global trend of massification – but not democratization – in higher education (Santos, 2006). As globalization heightens the priority placed on higher education, it is also important to consider how access can be more equally distributed among all citizens.

Engaging in Social Responsible Practices

Within a global context, university responsibilities extend beyond community and nation-state borders, and beyond the realm of education to include international human and labor rights issues. Using their global networks, universities can challenge neoliberal trends and promote the well-being of people throughout the world (Kimura-Walsh and Allen, 2008). For example, some US higher education institutions have signed on to the student-led anti-sweatshop and Sudan Divestment movements which promote socially responsible consumerism and investing, respectively, to advance specific social justice issues (Kimura-Walsh and Allen, 2008). It is important to point out, however, that often institutions are not eager participants. Many student activists have engaged in extended advocacy and protest activities to gain the recognition and support of their universities in furthering these causes. Once involved, higher education institutions engaged in globalization from below by using their global economic connections to advance both issues. In the case of the anti-sweatshop movement, institutions used their business connections with overseas factories to promote the welfare of apparel workers. They ensured their university apparel was manufactured in factories that upheld workers' basic rights. As a result, they challenged the liberalization of the market which undermines the well-being of developing countries and their citizens (Featherstone and United Students Against Sweatshops (USAS), 2002). In the Sudan divestment case, institutions used the mechanism of their international financial connections by engaging in targeted divestment from corporations that work in the Sudan. This strategy was undertaken to pressure the Khartoum regime to end the Darfur genocide (Sudan Divestment Task Force, 2004).

Conclusion

Literature examining the impact of globalization on higher education has, primarily, focused on the impact of neoliberal globalization on colleges and universities. Scholars have found that neoliberal trends potentially threaten institutions' ability to benefit the broader good. With a decline in public funding, countries as diverse as the United States and Zimbabwe are seeing tuition increases that prevent less privileged students from accessing advanced education (Shizha, 2006; Zusman, 2005). These declines in financial support also provoke more business-like behaviors within institutions, including trends toward entrepreneurialism (Clark, 2004), and collaborations with private industry (Slaughter and Rhoades, 2004). Lastly – in an increasingly global context – Western institutions have become the model to which everyone aspires and English the common language. This trend is contributing to a homogenizing of higher education institutions, and to disparities between Western and non-Western scholars.

An examination of the literature reveals that colleges and universities are doing little to advance globalization from below, despite being in an ideal position to promote social justice. These institutions are often in positions of privilege with a plethora of material and knowledge-based resources. Similarly, they are well situated to take advantage of the mechanisms of globalization – such as technology and international financial connections. They are, however, doing little with these resources to promote global social justice. One of the primary ways in which institutions could advance globalization from below is through collaboration. Altbach (2005) suggests that colleges and universities – particularly those in the United States – could benefit developing countries through international collaborations made more viable by increasing technology and travel.

Additionally, higher education institutions should engage in collaborations with local organizations to advance the betterment of community members disenfranchised by the global economy and neoliberal policies. The cases of Brazil's Integrar Institute and the University of Buenos Aires' (UBA) faculty and students in Argentina provide insight into the societal benefits that higher education-community collaborations can engender. However, in the case of Integrar Institute, the program was initiated by the unions, while – in the case of UBA – individual faculty and staff took action. It is time that universities take initiative to identify ways they can counter neoliberal globalization in their local communities. Moreover, Santos (2006) proposes institutions prioritize (1) action research in which participants play a central role in conducting research that addresses problems they face; (2) and the ecology of knowledge by reversing the knowledge exchange that has, historically, occurred within higher education. Instead, knowledge should be to travel from outside to inside the university.

Institutions must also identify ways to further democratize higher education by providing access to the diverse populations represented in their countries. While the growth of higher education in some countries is encouraging, in many cases, access continues to be granted to the privileged. Universities must consider how to enhance financial assistance to students, particularly in the form of scholarships (as opposed to loans); and develop affirmative action policies to address racial, ethnic, and class disparities. Further, universities must acknowledge and challenge their role in the colonial project which has excluded marginalized groups from educational opportunities and constructed knowledge about their inferiority (Santos, 2006).

Furthermore, higher education institutions must be conscientious members of society by engaging in socially responsible activities, and advocating for social justice throughout the world. The cases of the sweatshop and Sudan divestment movements offer insight into how institutions can use their global connections and prestige to advance critical social justice causes. However, these examples also reveal the limitations of colleges and universities; they failed to take the initiative in addressing these injustices. Instead, they followed student activists, who – in many cases – had to push, prod, and protest to convince these institutions to take a stand. As a result, the trend – at present – is that universities are followers in globalization from below movements. Higher education could learn much from students in becoming agents for social change.

With the increasing influence of colleges and universities in a global, knowledge-based society, it is essential that post-secondary institutions – particularly in developed countries – take an active role in advancing globalization from below. They are in an ideal position to use the mechanisms of globalization to help developing countries advance their higher education systems and increase access. Furthermore, they are equally well-situated to work for equity in their local communities and promote social justice throughout the world. Unfortunately, in most cases, post-secondary institutions have far to go in reaching these goals. Within the context of globalization, universities must broaden their social good purpose to reach out beyond nation-state borders and the boundaries of education.

Racial Inequality and the Economic Payoffs of Higher Education

S A Lachtman, University of Oxford, Oxford, UK

© 2010 Elsevier Ltd. All rights reserved.

In *The Republic*, Plato describes an ideal society where the elite receive educations that are complementary to their future roles and these leaders are recruited through both meritocratic and heredity criteria. In many modern industrial societies, including the United States, one concern has been that although ethnic minorities obtain elite educations and enter elite professions and industries, they do not move to the highest levels or positions in their societies and professions. The economic standing of college-educated Americans has been a concern of elite social scientists throughout the twentieth century, including W.E.B. Du Bois, Gunnar Myrdal, Peter Blau and Otis Dudley Duncan, and, more recently, Michael Hout and William Bowen. The social science literature highlights that national samples of college graduates have superior wealth, income, and labor-market outcomes than people with lesser levels of educational attainment. However, there is also general agreement that race-based income and employment inequalities are both historic and contemporary features of American society (Blau and Duncan, 1967; Bowen and Bok, 1998). In addition, social scientists have found the following mix of overlapping trends, to differing degrees:

1. some overall social mobility, but much less at the elite level;
2. higher-income returns for graduates of elite universities;
3. income penalties for ethnic minority alumni of elite universities compared to nonethnic minority alumni; and
4. substantial career penalties against ethnic minorities with both nonelite and elite educations.

Many intellectuals have described education as a key method for social uplift and as a key indicator of how meritocratic a society is. Social scientists throughout the world continue to ask: What are the relationships between the origins and destinations of citizens? How are advantages and disadvantages passed or not passed throughout the generations? Also, of what utility is education for the masses? In the United States, the query has most frequently been: Can education – or how much education does it take to – overcome low socioeconomic origins and racial inequality?

Scholars have articulated a theoretical and empirical link between higher education and substantial economic rewards for African Americans. A long line of social

science literature, beginning with W.E.B. Du Bois in the late nineteenth century, examines the comparative payoffs of education for different racial groups. Du Bois concludes that the fate of the black elite is tied to education and work and that their mobility is essential for social stability. Chronicling the black college alumni of the nineteenth and early twentieth centuries, he finds college-educated African Americans doing quite well, the vanguard of black social uplift and economically well-off property holders. While Du Bois describes education as a training field, he also notes how limiting ethnic stratification is for the life chances of educated blacks. He explains that college-educated blacks are social elites within the black community, holding both relatively high-prestige professions and substantial wealth as well as being occupationally diverse, including teachers, clergy, graduate students, lawyers, civil servants, businessmen, farmers or artisans, editors, secretaries, and clerks. To Du Bois, these statistics represent a watershed in occupational diversity, a change from the historic perception that clergy and teaching were the only choices for the educated black elite. However, Du Bois recognizes the stratification of the black elite in comparison to white America, and particularly the white elite.

In *An American Dilemma: The Negro Problem and Modern Democracy*, Myrdal (1944) equates African Americans to a caste because of their lack of social mobility and opportunity. Blau and Duncan (1968) provide a more nuanced, although very similar, picture in *The American Occupational Structure*, arguing that in the United States at the time, high status was less inherited than generations before and more dependent upon actual, normative achievement, with education serving as a central means for generational transmissions. However, their conclusion “that the American Occupational structure is largely governed by universalistic criteria of performance and achievement” is presented with the Myrdal-like caveat: “the notable exception of the influence of race.” They find African-American educational levels declining and stratification increasing with education. To them, this conclusion is especially surprising because the lower socioeconomic origins of nonwhites should make upward mobility, as measured through income and occupational prestige, more likely. They theorize that this indicates both the higher returns whites receive for education and the possibility of a widening attainment gap between whites and nonwhites.

In *Black Elite: The New Market for Highly Educated Black Americans: A Report Prepared for the Carnegie Commission on Higher Education*, Freeman (1976) finds dramatic changes in the labor market for black college graduates since Blau and Duncan's analysis. To analyze change over time, he notes that as recently as 1959, the income of white male college graduates was larger than their black counterparts by nearly 81%, far greater than differences between black and whites with lesser educational attainment. Moreover, almost 50% of black male college seniors at that time planned on teaching careers compared with one-seventh of whites. In contrast, Freeman finds that in the 1970s, starting salaries of black college graduates reached parity with whites and black male graduates had more increases in income than whites for the first time in modern American history. This ended a long historical trend of widening black-white income gaps with ascending education. Freeman connected the continuing income gaps among older college graduates to historical discrimination and was optimistic about future equality. He noted the then-recent increase of blacks in managerial positions as well as distribution of blacks and whites throughout the occupations were additional encouraging signs.

Michael Hout, in his examination of General Social Survey cumulative data files for 1972–85, finds that college degrees overcome disadvantaged origins. He not only describes a less-than-ideal situation where origin status affects workers without college education but also finds that education cancels out the effect of background status for college-degree holders. In *The Shape of the River: Long-Term Consequences of Considering Race in College and University Admissions*, Bowen and Bok (2000) analyze the College and Beyond Database, which tracked 80 000 undergraduates who matriculated at 28 selective colleges and universities in fall 1951, 1976, and 1989. They find that among the alumni of these highly selective institutions, gender and racial inequalities persist, as women earn less than men and black graduates less than white graduates, with especially significant racial earning differentials between males.

Intraracial benefits of graduating from a selective institution instead of a nonselective institution are also interesting. They find that black women from the cohort earn 73% (\$27 200) more than all black women with BAs, black men earn 82% (\$38 200) more than the average earnings of all black holders of BA degrees, and that white graduates of these selective institutions also have significant intraracial income advantages, but slightly less so than their black counterparts. In addition, they find large fractions of both black and white graduates from elite schools earning elite salaries, even at relatively young ages. Furthermore, for graduates whose grades were in the bottom third of their class, the black-white differential was outstanding, \$68 500–83 200,

while the top- and middle-level grade earners were about even. Quite clearly, there are income benefits for the alumni of selective institutions compared to alumni of less-selective institutions, but these degrees do not generate income equality among alumni with similarly selective credentials.

In addition, the nation where education is received is crucial in understanding some nonwhite income differences. For example, Zeng and Xie (2004) find no earnings difference across American-born white and Asian Americans compared to US-educated Asian immigrants. In contrast, foreign-educated Asian immigrants earn roughly 16% less than the aforementioned groups. We can thus infer that degree nativity matters.

Turning to another example of variation in the benefits of higher education, in *The Game of Life: College Sports and Educational Values*, Shulman and Bowen (2001) find that for all three surveyed cohorts of the College and Beyond Database, college athletes from top schools earn more than their student peers from the same elite universities. Furthermore, they analyze that the positive earnings differential is surprising because male athletes typically have lower test scores, lower socioeconomic origins, are more likely to belong to minority groups, and have lower college grade point averages (GPAs), than the average surveyed student, all of which are negative indicators of future earnings. Shulman and Bowen explain that athletes' greater presence in the for-profit sector and self-employment may explain a significant amount of the higher-earnings outcomes.

In their analysis of athletes, Shulman and Bowen do not mention the existence of racialized wage differences even though this is a featured section in Bowen's other co-authored book, *The Shape of the River*, using the same College and Beyond data set. Despite Shulman and Bowen's reluctance to explore the issue, other historic and current analyses demonstrate the probability of racially unequal benefits for collegiate athletes. Throughout several publications in the 1960s, sociologist Edwards (2002) surveyed the relationship of black athletes to universities as a site of exploitation, discrimination, and an instrument for maintaining inequality. To Edwards and others, what had resulted from attempts at integration was the creation of opportunities that did not essentially change racially unequal outcomes. This debate rages on, with recent surveys consistently finding that white and black athletes have unequal academic outcomes and graduation rates. Even among white and black athletes on the same collegiate teams, the racial difference in graduation rates are often severe and consistently point to intense racial inequality even among students of the same institutions.

In summary, both the historical and current social science literature have found college-educated African

Americans to be substantially better off than less-educated members of their race, but that they receive lesser income and occupational benefits than their white peers for their degree attainment.

The Experiences of Nonwhites in Corporate America

As reviewed in the previous section, the unequal payoff of a collegiate credential has been a persistent problem throughout American history, but some evidence indicates that the inequalities have lessened. In the literature, income and occupational prestige are consistently used to measure inequality. How ethnic minorities experience their workplace environment is important to understand the possible connections between education, income, occupational prestige, and, ultimately, economic well-being. This section thus reviews the social science literature covering ethnic minority work experiences. Success, failure, rewards, and/or the lack thereof are ultimately translated into long-term economic consequences for individuals, with work and career serving as the primary (and well-studied) mechanism through which the payoff and benefits of higher education are distributed.

There is a rich American literature analyzing ethnic disadvantage in relation to the experiences of the highly educated, upper class, and managerial elite. This literature suggests that ethnic minorities are intensely marginalized and pushed away from the power elite, despite their efforts to obtain such status. However, many argue that elite occupations have become more open since the civil rights movement of the late 1950s and 1960s, and that being nonwhite no longer disqualifies one from membership. This section surveys descriptions of nonwhite experiences in white corporate America. Edwards' characterization that attempts to integrate sports has resulted in limited islands of black opportunity appropriately summarizes findings about the integration experiences of nonwhite college graduates in the workplace.

Some scholars counter with arguments and findings of how nonwhites can now succeed in the predominantly white corporate world. In *The Declining Significance of Race*, Wilson (1978) argues that education, socioeconomic status, talent, and merit are becoming increasingly important to the life and career chances of African Americans. He argues that these historic changes are related to both national economic expansion and increasing quantities of white-collar positions, as well as to public pressures and affirmative action policy programs. Wilson, much like Freeman (1976) in *The New Black Elite*, argues that educational credentials and professional opportunities dictate one's circumstances more than discrimination. Consequently, this scenario envisions that for those with adequate human and social capital, including credentials, the opportunity to

succeed is an accessible and open door. Wilson's argument also insinuates that education should translate into economic opportunities that ultimately lead to wealth.

Wilson's 1978 thesis has many virtues, including its descriptive utility for contextualizing historical change (Wilson, 1978). However, it has been at the center of a social science debate since its publishing, and much research has contradicted it by outlining limited progress during the 1980s and 1990s as well as documenting black exclusion from elite economic rewards. In *How Capitalism Underdeveloped Black America*, Marable (1983) argues that blacks in white business, and even black businesses, all operate at the subservient pleasure of white interests. The combined total value of the 1060 black businesses in America with more than 20 employees was less than just the cash assets of a major individual white-owned and dominated corporation. Thus, according to Marable, black elites are especially vulnerable and subordinate to white businesses because black businesses are predisposed to failure because of their comparative lack of capital and limited market access to servicing larger white markets. Marable's assertions that the black corporate elite exist at the behest and pleasure of whites, and that they are comprised of less than 200 people, are powerful statements about segregation and exclusion at the top of the economic system. Marable's description of access to elite positions and wealth as closed to African Americans, regardless of qualifications and credentials (with the exception of the symbolic 200 beneficiaries), challenges the thesis of Wilson's *The Declining Significance of Race*.

In 1999, Zweigenhaft and Domhoff conducted a C. Wright Mills-inspired survey of the American power elite, with a detailed focus on the corporate elite. Their findings support the islands of opportunity model, in contrast to Wilson's depiction of expanding white-collar positions, and largely compliment Marable's thesis. Zweigenhaft and Domhoff (1991) find staggeringly low numbers of nonwhites in high-level management positions and much higher – although not populationally proportionate – representation on corporate boards. Concerning their outlook on the future, they cite data from 1990 that indicate that blacks in high-level management positions had increased from 0.2% to 0.6% from the 1980s to the 1990s. Subsequently, they recommend appropriating the glass-ceiling metaphor, first used to describe limits to the mobility of white women, and now to describe the continuing barriers for black men and women in the corporate world.

In addition, they find that Hispanics are less than 1% of all corporate directors, despite composing 10% of the population, while Asian Americans only rose from 0.2% to 0.5% of all corporate directors from 1992 to 1995, despite being a higher proportion of the population. Blacks may be better represented as board members than Latinos and Asians, (this representation is still less than proportional in

terms of population and does not extend to management positions) because of several reasons:

1. a lack of full participation in all areas of corporate life;
2. African Americans are manipulated by white executives for symbolic purposes, as Marable argues;
3. the success of targeted programs to promote minorities; and
4. the effect that interlocking directorates facilitate repeated appearances by the same black elite on multiple boards so that, as Marable describes, the same black elites are members of multiple corporations while few other blacks are high-level employees.

Zweigenhaft and Domhoff (1991) also conducted a study of 38 participants in the A Better Chance program, which places disadvantaged black youth from all over the United States at elite private boarding schools. While 99% of the participants in the program went to colleges, which is far above the national average for black youth, the program is commonly judged successful and lauded because so many alumni attended the most elite universities and were more successful than both their siblings and peers from their home communities who had not participated in the program. However, many alumni had changed positions, moved to work at black-owned businesses, or started their own businesses in order to escape the racial job ceilings they found in mainstream corporate America. This trend in the career trajectories of these highly educated blacks led the authors to conclude that the power elite will likely remain the least integrated segment of American society. Despite establishing substantial lifelong networks with whites at the most elite high schools and colleges, gaining the same elite education credentials and even having high intermarriage rates, these African Americans unequivocally believed that they were marginalized in the workplace.

These experiences are consistent with other findings. For example, in *The Marginalization of Black Executives*, Sharon M. Collins explores “the careers of 76 of the top-ranking black executives employed in Chicago white-owned corporations.” She finds that black upward mobility in the otherwise white management has been restricted, with these workers largely filling human resource and public relations jobs that were recently created in response to public demands. In sum, this situation leads to the black executives being marginalized away from central decision making and thus to dead-end careers. This undermines the intentions of the social and political pressures that employment opportunities would enable upward mobility for the educated black elite. Instead, highly educated and capable black executives experienced new, less obvious, but nonetheless substantial employment inequality.

Although Wilson argues that class and educational credentials are more important than discrimination in getting African Americans access to the means of production, a line of literature, including Collins, has found that African

Americans are systematically all but excluded from reaching the top of the corporate hierarchy. Similarly, this literature finds that African Americans who achieved upward promotion in the corporate sectors were often channeled into dead end, racially oriented jobs that not only did not match their qualifications, but also derailed their career trajectory by excluding them from power and decision-making roles. Such findings have many implications about the comparative economic well-being of college alumni. Exclusion from elite, decision-making positions indicates that African Americans are likely to have dissimilar career trajectories, and thus dissimilar incomes and wealth outcomes, than white peers with the same educational credentials. As a result, African Americans have a much lower chance of gaining extreme income or ever accruing extreme wealth. This directly relates to the literature on intergenerational transmissions of wealth, indicating that historically unequal intergenerational transmissions of wealth will likely continue, even among the educated elite.

Wealth and wealth inequality are the culminating consequences of unequal payoffs to education, effectively shaping long-term economic well-being. The literature has consistently found that income inequality is the tip of an economic inequality iceberg, with wealth inequality significantly greater than wage inequality. As discussed previously, many scholars have articulated a theoretical and empirical link between higher education and substantial economic rewards for African Americans, but some have called for more investigations into wealth to gain a fuller understanding of economic life, well-being, status, and the payouts to educations. Wealth has emerged as a holistic measurement of economic well-being in the social sciences. Racial wealth inequalities have been found to be exponentially greater than income inequality, to the extent that the highest-income brackets of African Americans are found to have the same wealth as the lowest-income earning whites.

Oliver and Shapiro (1998, 2006) provide the most recent and comparable analyses regarding wealth, race, and education. They find that African Americans with college degrees possess just 23 cents for every dollar of wealth owned by similarly educated whites. While blacks’ net worth increases with education, whites gain far more wealth with almost every level of additional degree attainment in both absolute and relative measurements over similarly educated blacks.

We can hypothesize that the intensity and persistence of racial wealth inequality even among college graduates is likely associated with different mechanisms of cumulative disadvantage as follows:

1. a stratified history of property relations, including racialized historic and persisting political, legal, and economic obstacles to home ownership;
2. systems of neighborhood segregation that devalue black-owned property and translates neighborhood

segregation into various disadvantages, hazards, privileges, and/or opportunities to residents according to their race and location;

3. unequal payoffs for higher education that are associated with the marginalization of and discrimination against nonwhites at the workplace; and
4. wealth mobility differs by race.

These mechanisms help perpetuate the racial stratification in wealth observed in national samples, regardless of education. As evidenced by the continued wealth disparity, even between families with similar incomes, it is necessary to look beyond income to understand economic well-being, racial inequality, and the payoffs of education. While the American higher education system strives to provide equal access and opportunities for all, college-degree attainment does not make its alumni economic equals.

Health and Education

Healthy People 2010, the US government's decennial statement of its national health goals, set a target for high school completion among persons aged 18–24 at 90% in the year 2010 (USDHHS, 2000), consistent with the national education goals. The inclusion of a high-school-completion goal in a government-agenda-setting publication for health underscores the well-established and enduring positive relationship between health and education. Dropping out of school is associated with increased risk of substance abuse, delinquency, intentional and unintentional injury, and unintended pregnancy. There is a dose–response relationship between health and education: the more years of education a person has obtained, the more likely they are to report being in excellent or good health. The relationship between health and education is positive independent of the effects of family income, age, or poverty status.

Although the relationship between health and education is enduring, evidence of a causal effect of one on the other is elusive. Health status is thought to affect educational attainment, while educational attainment has a clear impact on health. Instead of declaring either health or educational attainment as the causal agent, it is most accurate to describe health and educational attainment as intertwined.

There are three major hypotheses to explain the observed effect of child and adolescent health on educational attainment. The first is based on the status-attainment model that views both educational attainment (Sewell *et al.*, 1969) and child health (Aber *et al.*, 1997) as primarily dependent on parental occupation and position in the social hierarchy. This hypothesis argues that parental social status determines both adolescent health and educational attainment. The emerging field of life-course health development (Halfon and Hochstein, 2002) – which suggests experiences in critical life stages and cumulative life experiences affect adolescent and adult health – may hold some explanatory power for this hypothesis. Numerous analyses, however, have shown that the positive relationship between adolescent health and educational attainment endures after controlling for parental socioeconomic status.

A second hypothesis suggests that poor health has a negative effect on cognitive development and functioning, leading to lower educational attainment. The evidence to support this hypothesis, however, is weak and no systematic studies to examine the relationship between adolescent

health, cognition, and educational attainment have been conducted.

A third hypothesis posits that health limitations have detrimental psychological, behavioral, and social effects on children and adolescents, leading to lower educational achievement. Lower levels of self-esteem, attachment to school, commitment to schooling, and greater absenteeism have been associated with poorer health in adolescents. There is a growing literature on the psychosocial impact of poor health on adolescents and school performance, though the type and magnitude of effect varies by disease or behavioral risk factor.

Given the complex interaction among family context, school environment, and disease pathology, the effects of poor health on educational attainment take on any number of pathways. The health conditions and behaviors that adolescents deal with on a daily basis demonstrate how the general notion of poor health includes any number of specific impacts on educational attainment. Asthma, for example, has been linked to increased school absenteeism, with overweight and obese children more likely to have low self-esteem and higher rates of anxiety disorders, depression, and other mental health conditions. Insufficient or interrupted sleep is associated with reduced attention, memory, intelligence, and cognitive ability, and undernutrition is associated with poor concentration and greater irritability and apathy. There remains a paucity of research which looks directly at specific diseases and related morbidities as mediators between health and educational attainment. Emerging evidence, however, provides basis to believe the effect of health on educational attainment is mediated through diverse pathways.

School Health Education

With over 55 million and 95% of all children aged 5–17 years enrolled in American schools (Snyder *et al.*, 2009), school health education is a unique opportunity to improve the health and educational outcomes of children and adolescents. School health education is a subset of health education, a field concerned with educational interventions that can affect and facilitate adoption of behaviors conducive to health, which are focused on schools (Green and Iverson, 1982). Though in principle school health education is not limited to classrooms, didactic methods, and students, in practice, these are the settings, pedagogy, and audience that school health-education programs commonly employ and target.

Health education targets three categories of factors that affect health behavior (Green and Iverson, 1982): predisposing factors, enabling factors, and reinforcing factors. School health education typically focuses on affecting predisposing factors that orient adolescents toward a particular behavior. These include beliefs, knowledge, attitudes, and values. In, for example, school health-education programs to prevent tobacco use, predisposing factors such as knowledge of the health effects of smoking, beliefs about the acceptability of smoking among peers, and values toward exposing others to the dangers of second-hand smoke must be addressed. Changing predisposing factors like knowledge and attitudes is a necessary but insufficient component of school health education.

Enabling factors, such as skills acquisition, critical thinking, effective decision making, and management of peer influence, allow adolescents to carry out health-enhancing behaviors. In school smoking-prevention programs, skills such as reading cigarette-constituent labels, critical thinking about cigarette advertisements, and decision making on accepting cigarette-promotional items should be taught.

Reinforcing factors influence whether a behavior that has been tried will be repeated. They are material, emotional, and social in form, penalizing or rewarding individuals for engaging in particular behaviors. For example, peers can offer or withhold the benefits of social inclusion for smoking cigarettes. Reinforcing factors are considered more influential than predisposing and enabling factors on health behavior. Since they are the factors most beyond the ability of the school to control, school health-education programs are limited to helping students learn how to resist the array of factors that encourage adoption of unhealthy behaviors.

National Health Education Standards

In response to the absence of an explicit health goal in the national education goals, the Joint Committee on National Health Education Standards was formed to develop standards for health education. The committee was made up of representatives from the numerous health organizations and sponsored by the American Cancer Society. The resulting National Health Education Standards (NHES) provide a framework for health-education curricular development (Joint Committee on National Health Standards, 2007). Instead of approaching health education from the perspective of predisposing, enabling, and reinforcing factors, the NHES focuses on improving health literacy among students. Performance indicators for four age categories – pre-K through second grade, third through fifth grade, sixth through eighth grade, and ninth through twelfth grade – guide the development of age-appropriate health-education curricula.

School Health-Education Content Areas

The School Health Education Study, conducted from 1964 to 1972, introduced the idea of comprehensive health-education

programs. The results of the study identified ten content areas that provided the basis for health-education curricular development through the 1980s.

More recently, the US Centers for Disease Control and Prevention (CDC) has identified six health areas responsible for over 70% of illness, disability, and death among adolescents and young adults: intentional and unintentional injuries, tobacco use, alcohol and illicit drug use, sexual behaviors that cause unintended pregnancies and sexually transmitted diseases, dietary patterns that cause disease, and sedentary lifestyle (Kann *et al.*, 1995). As these areas are responsible for such a significant burden of disease among adolescents and young adults, they are priority-substantive areas for health-education programs.

Comprehensive Health Education Programs: Best Practice

Taking predisposing, enabling, and reinforcing factors; health literacy; and the core content areas together, the CDC has outlined a framework for developing a comprehensive school health-education program (Collins *et al.*, 1995):

1. A documented, planned, and sequential program of health education for students in grades K through 12.
2. A curriculum that addresses and integrates education about a range of categorical health problems and issues.
3. Activities to help young people develop the skills they will need to avoid behaviors that result in unintentional and intentional injuries; alcohol and other drug use; tobacco use; sexual behaviors that result in human immunodeficiency virus (HIV) infection, other sexually transmitted diseases (STDs), and unintended pregnancies; imprudent dietary patterns; and inadequate physical activity.
4. Instruction provided for a prescribed amount of time at each grade level.
5. Management and coordination in each school by an education professional trained to implement the program.
6. Instruction from teachers who have been trained to teach the subject.
7. Involvement of parents, health professionals, and other concerned community members.
8. Periodic evaluation, updating, and improvement.

Time allotted to school health education and appropriate training of health-education teachers are two critical areas for effective health-education programs. The exact amount of time needed for health-education programs to produce desired outcomes is unclear. But brief curricular exposure does not produce changes in behavior. Sustained exposure to a health-education program and follow-up sessions after program participation are needed for stable improvements in behavior. Estimates suggest that at least 1.8 h per week are needed for changes in student knowledge and attitudes. Health knowledge has been observed to

increase after 15 h of exposure to health-education programming. Behavior begins to change after 50 h of program exposure, and maximal change in knowledge, attitudes, and behavior occurs after 60 h of exposure.

As health-education teachers are not only expected to provide knowledge but also influence present and future behavior, well-trained teachers are integral to effective health-education programs. Training opportunities for health-education teachers are numerous. Professional associations are available for information regarding health teacher training. Professional development can be accessed through programs offered by universities and through conference attendance, professional journals, and online courses. Even with increasing access to opportunities for professional development, there is a shortage of health-education teachers with a background in health education.

Coordinated School Health Programs

Early health-education programs focused on hygienic behaviors that would help stem the transmission of communicable diseases. As the conditions that afflicted children and adolescents shifted to chronic, noncommunicable, multifactorial diseases and conditions, the limits of traditional health education became apparent. Didactic strategies alone could not meet the behavioral goals of school health programs. Over time, the economic, social, and political – as opposed to an individualistic and behavioral – determinants of health became more widely accepted as a part of health education. As they were, school health education became embedded within the broader framework of coordinated school health programs.

Coordinated school health programs approach child and adolescent health as a multisectoral enterprise to be shared by health, medical, educational, and social-service organizations. Working together, multiple agencies provide students with a comprehensive set of programs and services to prevent disease and promote health.

One model includes eight components in a coordinated school health program (**Figure 1**) (Fisher *et al.*, 2003). Access to health services through direct care or referral services allows for control and management of chronic diseases and provision of emergency services. Counseling, psychological, and social services provide resources to improve student mental and emotional health and ensure a healthy social environment. Health promotion for staff includes health education and activities that can improve health status, morale, and commitment to the school's overall health program. A healthy school environment ensures that the design and structure of the school environment is optimal, protects students from biological or chemical agents damaging to health, and enhances the psychological, emotional, and social culture of the school. Access to nutritious and appealing meals

that meet the nutritional needs of all students are part of appropriate nutritional services. A high-quality physical-education curriculum provides cognitive content and experiential activities in a variety of movements. Involvement of family and community actors helps build support for coordinated school health programs while helping to build reinforcing factors for healthy behavior outside of schools.

School health-education programs are most effective when they not only follow best practices but are located within the broader context of a coordinated school health program. The access to resources, school culture, organizational structure, and prioritization of health created by coordinated school health programs amplify the impact of school health education. Coordinated school health programs provide the context to effectively translate change among proximal targets of school health education – knowledge, beliefs, attitudes, skills, critical thinking, and decision making – into health-promoting behavior change.

Tobacco-Use Prevention in Schools: A Cautionary Tale

Consequences of Adolescent Smoking

As the leading cause of preventable death in the United States, tobacco use is a core content area for school health education. Every day, almost 5000 children in the United States try their first cigarette (Fisher *et al.*, 2003). Childhood experimentation often leads to adult addiction because of the presence of nicotine in tobacco. Concern over child adolescent tobacco use is threefold. First, tobacco use is associated with lower levels of educational achievement and school involvement (though the causal direction is unclear). Lower levels of achievement may be mediated by behavioral problems associated with smoking among adolescents, which include fighting, carrying weapons, attempting suicide, and engaging in high-risk sexual behavior. Second, the health effects of smoking include increased cough, higher risk for respiratory illness, increased likelihood of developing risk factors for cardiovascular disease, decrease in levels of physical fitness, and retardation of lung growth and optimal lung function. Use of smokeless (i.e., chewing) tobacco is associated with health concerns ranging from bad breath to oral cancer. Third, a vast majority of adult smokers begin before they leave high school. If students leave high school as nonsmokers, they are highly unlikely to begin smoking as adults. Thus smoking prevention among adolescents has enduring health and attainment implications into adulthood.

Tobacco-Use Prevention Programs

Educational interventions for tobacco-use prevention have evolved over the second half of the twentieth century (USDHHS, 2002). Early interventions relied on an

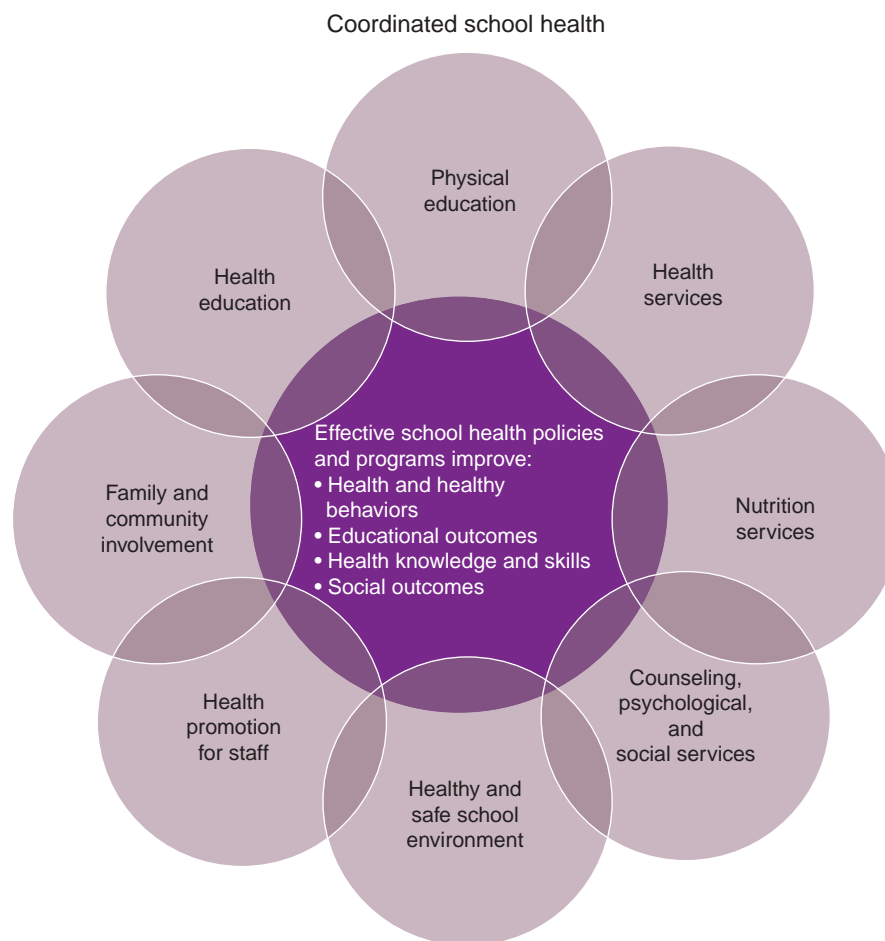

Figure 1 Coordinated school health programs. From US Centers for Disease Control and Prevention.

information-deficit model, assuming provision of information regarding the harms of tobacco use would prevent uptake and spur cessation. A second approach incorporated intrapersonal factors such as self-esteem and improving attitudes toward family, school, and community efforts to bridge information gaps. While programs based on both approaches were shown to increase knowledge, they were ineffective in preventing smoking initiation.

Over time, smoking initiation was found to be a social behavior influenced by peer smoking, smoking by others in the environment, and other social and psychological factors. These insights led to a third orientation to tobacco-use prevention programs called the social-influences model. Programs based on this model aim to equip adolescents with the skills and resources to help resist offers to take up tobacco use. Specific strategies include learning the short-term negative social and health consequences of tobacco use, reframing tobacco use as a behavior of a minority of students, recognizing the social influences of smoking, and developing skills to resist social pressures to use tobacco.

Although early social influences-based programs had limited effects, recent studies have shown more consistent

results. Contemporary programs using the social-influences mode begin during the sixth or seventh grade and utilize classroom activities over multiple sessions for a duration of between 1 and 3 years. The effect of these programs on smoking behavior has been larger and longer lasting than earlier studies, but sustaining program effects on behavior to the end of high school has been difficult.

Curricula focusing solely on skills training to resist peer influence may be ineffective. Modifying perceptions of peer and adult smoking and denormalizing smoking behavior have more powerful effects than skills training. Combined curricula result in the greatest impact. As a result, some tobacco-use prevention programs expand intense social-influence-based school programs to incorporate community education toward adults, mass media, parent education, and involvement in program activities and community organizing.

The CDC has issued seven recommendations for a school health programs to prevent tobacco use (CDC, 1994):

1. develop and enforce a strong school policy on tobacco use that is consistent with state and local laws;

2. provide instruction about the short- and long-term negative health effects and social consequences of tobacco use, social influences on tobacco use, peer norms regarding tobacco use, and refusal skills;
3. provide tobacco-use-prevention education in kindergarten through twelfth grade with more intensive education in junior high or middle school reinforced in high school;
4. provide program-specific training for teachers;
5. involve parents or families in school-based programs for tobacco-use prevention;
6. support cessation efforts among students and school staff; and
7. assess the tobacco-use-prevention program at regular intervals.

The Tobacco Industry and School-Based Programs

In 1997, the CDC concluded that the two curricula, Life Skills Training (LST) and Project Toward No Tobacco Use were effective in reducing adolescent tobacco use. This announcement was seized upon by the tobacco industry, in particular by Philip Morris (PM) and Brown and Williamson (B&W), to expand their youth smoking-prevention programs (Mandel *et al.*, 2006). The tobacco industry has a long-standing interest in promoting its youth tobacco-use prevention programs. They are public-relations tools to help ease public suspicion that the industry markets tobacco products to children. The industry also uses its voluntary youth smoking-prevention programs to stave off strong legislation to restrict activities of the industry with respect to adolescents, including advertising and promotions.

Tobacco industry youth smoking-prevention programs target youth, parents, tobacco retailers, and youth organizations, and are disseminated through multiple channels such as media campaigns, brochures, public gatherings, stickers and posters, and third-party organizations – including the National Association of State Boards of Education (Landman *et al.*, 2002). Tobacco industry documents reveal that youth smoking-prevention programs send messages consistent with their advertising campaigns and are used to displace more aggressive educational programs. They lack components, such as mass-media campaigns that de-normalize tobacco use, price increases for tobacco products, and smoke-free policies to decrease the social acceptability of smoking, which have proven to be effective in reducing youth smoking. Industry programs do not prevent, and may even encourage, youth smoking.

The promotion of the LST curriculum for youth smoking prevention followed the general pattern of industry youth smoking-prevention programs. It was promoted by PM and B&W because it steered attention away from programs focused on the manipulative behavior of the tobacco

industry, a theme of successful state programs in California and Florida. Instead, it wanted a program that stressed positive youth development and allowed the industry to be seen as a partner of health and education organizations, strengthen relationships with youth organizations, and build the industry's image as responsible and reputable. LST was particularly attractive because it had been endorsed by the CDC, a credible government agency, as an effective tobacco use-prevention program.

PM and B&W actively promoted LST among school superintendents, school board members, legislators, and educators using a public-affairs consulting firm. PM and B&W also set up a grant-matching mechanism for state departments of education or health to use money from the Master Settlement Agreement, a legal settlement between the tobacco industry and 46 state attorneys general, for LST.

As PM and B&W promoted LST, a second consulting firm provided data to the companies that showed that the LST programs they were sponsoring had a statistically significant effect on knowledge about the physiological effects of smoking, no impact on social acceptability of smoking, and reduced decision-making skills after 1 year. Results after 2 years of LST implementation were no better. PM and B&W were promoting a program they knew was ineffective.

On the face of it, PM and B&W's promotion of an LST, a CDC-approved tobacco-use-prevention curriculum, appeared to be a positive development to improve adolescent health. It was not, however, because the real-world effectiveness of LST was limited to improvements in knowledge compared to the highly controlled studies that the CDC used to deem LST an effective curriculum. Adoption of LST was also problematic because it supplanted the implementation of programs shown to be effective in real-world contexts. In the broader struggle between the tobacco industry and public health advocates, school health education was co-opted to serve the business goals of an industry with decidedly negative impacts on health.

The case of the tobacco industry and LST highlights three points about school health education:

1. *Careful attention must be paid to the development and implementation of school health education programs.* Curriculum development for health education differs markedly from other subjects because the aim is not only to impart knowledge but to change behavior. Yet, the low stature of health on the educational-research landscape results in a lack of proven and effective strategies to achieve health-education goals. Continued research must be conducted to improve school health-education curriculum. For example, anti-industry messages and de-normalization of tobacco use are effective approaches to tobacco-use prevention that fall outside of the standard social-influences model. Additionally, training of

schools and teachers to implement effective curricula must improve. In the case of tobacco and LST, highly controlled studies showed curricular effectiveness on behavior. But schools taking part in the PM and B&W program did not demonstrate equivalent results due to process factors.

2. *School health-education programs must be complemented with other activities outside of school.* School health education is useful for affecting knowledge, but is not sufficient to change adolescent health behavior. Health education must be embedded within a coordinated school health program to yield optimal results, with investment from family and community actors. In the case of tobacco, anti-industry mass-media campaigns have been effective tools for tobacco-use prevention as have tax increases on tobacco products and smoke-free policies in workplaces, schools, and other indoor areas. The knowledge impacts of tobacco-use-prevention programs can be expanded to behavior change when accompanied by other interventions.
3. *Schools must carefully select partners for health education.* When partnering with and finding support from individuals and organizations for health-education programs, schools must collaborate selectively. The case of the tobacco industry is an obvious case of conflict of interest and extreme deception. Though the industry portrayed itself as concerned about youth smoking, it did so for public relations and regulatory purposes with a goal of delaying, not preventing, smoking initiation. Schools must be aware of the competing interests of various organizations and develop school health education and coordinated school health programs with partners whose mission and purpose align with those of the school.

Summary

Good health is a necessary condition for educational achievement. The challenges to health for children and adolescents are complex and wide ranging, requiring coordinated effort on the part of health and educational systems to overcome. School health education is an integral part of this process. A solid conceptual foundation for effective school health education exists in national standards, prescribed best practices, and technical-assistance resources at the state and national level. When best practices are implemented, school health education can change predisposing and enabling factors needed to ensure adolescent health. But school health education alone is not sufficient to observe sustained behavioral change. A larger health-enhancing enterprise must be undertaken by schools to support the behavior-change goal of health education. As the case of school tobacco-use-prevention programs show, effective school health-education programs must be developed, correctly implemented, and complemented

with efforts in families, communities, and at the broader policy level to ensure that health does not act as a barrier to but enhances student-achievement potential.

Race in Science versus Race in Science Education

An examination of the role of race and racism in science education must begin with an understanding of the importance of race to the ideology and practice of Western modern science. Bell (1992) asserts racism is an enduring attribute of American culture that has maintained a prevailing position in the cultural milieu. America has a history of sustained racism that influences contemporary interactions. In other words, because racism has been a pervasive component of society at large throughout modern history, then many institutions are likely to reflect those racist patterns to some degree. This perspective

could lead to the question of how modern science, whose foundational epistemology relies on objectivity, free itself from the influence of racism.

The answer, of course, is that science has not been able to invoke immunity to racism. The fact that science is an inherently human activity means it is fraught with all the biases and tendencies humans bring into it. As a result, science as experienced in schools is impacted by issues of race and racism, much as any other Western cultural practice (Eishenhart *et al.*, 1996; Norman, 1998). Contrary to the reality of scientific practice, science education curriculum (and science education as a whole) tends to confer upon scientific practice an unwarranted mantle of 'objectivity.' By portraying the scientific enterprise and its

practitioners as objective, they have enabled racism in scientific ideology, practice, and pedagogy to hide behind the cloak of scientific objectivity.

It is the inherently contradictory notions of scientific objectivity and science as a human activity that stand at the heart of this article. Despite being influenced by racism, the science presented in schools is often viewed as objective, culturally neutral, and uninfluenced by racism. This culturally neutral representation of science continues to bring us to the same end as more overtly racist representations did decades ago. The myth of scientific objectivity enables racist conceptions of science to merely retrofit their previously overt constructions for more subtle alternatives. Specifically, it has the effect of rendering the societal structures that work against the participation of minority students in science, technology, engineering, and mathematics fields as invisible. In this article, we first argue that presentation of scientific practice as completely objective is inaccurate. We then demonstrate how scientific practice has historically been influenced, to a substantial degree, by racism and is apparent in both scientific ideology and scientific practice. We will also illustrate that historical influence, which is readily visible to the keen observer, is only a pretext for the current ideology and practices we witness today. Time has yielded little change at the core of scientific practice and ideology. Instead, it has given us a theoretically retrofitted version of science, such that it looks different on its surface, but remains unvarying at its core. We conclude with a discussion of the implications this presentation of science has for the contemporary practice and research in science education.

A History of Racism in Science

Historically, science has provided a wealth of insights and technological projects to advance contemporary culture. However, it has also served a role in marginalizing people on the basis of race and ethnicity. Norman (1998) describes how science has a history of being a marginalizing discourse. He argues that science, conducted in the name of promoted sociopolitical ideologies, needs to be framed as an alternative to science if scientific objectivity is to remain central to the construction of scientific knowledge. Norman explains:

The discourses on race and gender raise the question of scientific objectivity in very compelling ways. In the context of scientific literacy, it is absolutely crucial that the questions of fraudulent science in the interest of political ideology be treated separately from the more fundamental question of how problematic it is to achieve complete objectivity in science. (p. 371)

Norman's argument discloses how scientific research avoids addressing the sociopolitical subjectivity of the

scientist's intentions as a means to maintain the reified status of science. As a result, much science research and pseudo-scientific research designed to promote and sustain racial ideologies has been able to continue under the cloak of scientific objectivity.

Norman's assessment can be extended to science education as the perception of an objective science makes the cultural components of science invisible. Although nearly invisible in most science texts and curricula, science has historically been influenced by race and racism while being used to support racist ideologies.

Historical records of race and science extend as far back as Grecian cultures (Norman, 1998). Although the culture of the early Grecian times was more philosophical and metaphysical than empirical science, Hippocrates was accused of asserting that people with darker skin were perceived as less courageous warriors (Norman, 1998). Although not supported by scientific evidence, the biological basis of racist ideologies served as a foundation to these early philosophical Grecian arguments.

This traditional assumption formed the foundational ideology of Europeans for most of the eighteenth and nineteenth centuries (Norman, 1998; Gosden, 2006). In fact, Linnaeus provided one of the earliest conceptions of racial inferiority in his *Systema Naturae*. His 1758 text attempted to construct a systematic taxonomy of human beings. Linnaeus categorized blacks as "Sapiens Afer (the Black African) as 'ruled by caprice,' while Homo Sapiens Europeans were said to be 'ruled by customs.'" (Norman, 1997: 367). This characterization of the black African as 'ruled by caprice' (or impulsive) started the attempt of the scientific community to construct people of color as intellectually inferior.

Racial Evolutionist

After these philosophical constructions of race were presented, a series of attempts to construct Africans as inferior emerged through racial evolution theories (Norman, 1998; Morris-Reich, 2006). Racial theories embedded in the philosophy of science served to define much of the research on race in the 1800s. Arthur Schopenhauer offered theoretical perspectives that became essential to frameworks on literacy (Norman, 1998; Morris-Reich, 2006). Early scholars argued the growth of civilization was based on the contributions of whites and that led to the development of a refined north (Hasian, 1996; Larson, 1995; Norman, 1998; Morris-Reich, 2006; Tucker, 2002). This perspective completely ignored the early scientific contributions of the entire continent of Africa. Others made the argument that racially advanced whites migrated to the north in an effort to survive. They suggested that whites had to develop higher intellectual powers as a part of their struggle to survive the misery and challenges

of northern climates (Dubow, 1995). These racial evolutionist perspectives were used by early scientists to make an argument that attempted to establish whites as superior. These initial studies led to the development of more empirical approaches to research designed to ‘prove’ the racial inferiority of people of color.

Much of the pseudo-scientific research conducted by racial evolutionists was executed in an attempt to validate institutions of slavery and colonization. As a result, it framed Africans as physically gifted and sexual predators in an attempt to justify the cultural practice of slavery. Dubow (1995) describes the work of Linnaeus as an example of such a perspective. Dubow explains Linnaeus’ work in the following:

To each [race] he attached character descriptions. For example, Europeans were ingenious, inventive and governed by law; whereas Africans were crafty, lazy, careless and governed by the arbitrary will of their masters. (p. 26)

This perspective is customary of early evolutionist work that attempted to taxonomically categorize the African as inferior by means of physiological and mental differences. In fact, the racial evolutionist attempted to use physical observations as a means to justify racial ideologies about the scientifically proven inferiority of African people. Civis (1993) explained this perspective by claiming African people were inherently sweaty and pungent:

The Negro is eminently a sweating animal. The remarkable sweating capacity of the negro renders him objectionable in the cars, in the jury box, in the halls of legislation, in the crowds that assemble on the court green, but wonderfully fits him for his proper functions as a laborer in tobacco and rice fields and on the great cotton and sugar plantations of low latitudes. (p. 5)

Such an example attempts to attribute a physical characteristic (that is not empirically true) to an ability to perform cognitive tasks such as serving on a jury or participating in legislative activity. Civis goes on to express his opposition to advocacy of public school systems of “the doctrine of negro equality,” which aimed to prepare people of color for the “highest functions of public life” (p. 17).

In present times, such an argument would be met with great political opposition. However, at the time this perspective was so pervasive that other scholars strongly supported it. Thomas Jefferson’s (Jefferson and Peden, 1781/1982) *Notes on the State of Virginia* (see also Elkins, 1968; Elliott, 1969; Mellon, 1969) includes detailed provisions of such positions. One would think such perspectives were a relic of centuries ago; however, How’s (1971) argument to the General Synod of the Reformed Protestant Dutch Church attempts to reify this argument using contemporary language.

What becomes challenging about these perspectives is the manner in which they tend to reinvent themselves. Although

the early perspectives like racial evolutionists and racial taxonomies were nonempirical and greatly refuted, they continued to be reinvented and proposed using alternative methodologies. Scientists from Alfred Wallace (Osborne, 1980) to the founder of our modern taxonomical system, Carolus Linnaeus, all attempted to use taxonomical means to declare the African as physiologically inferior (McLeod, 1974). In fact, contemporary scholars argue these taxonomical perspectives still find their way into new media outlets (Chideya, 1995; Means-Coleman, 1998).

Given the attempts of racial evolutionists to frame African inferiority as biological, much of the early science research attempted to use classification as a way to establish Africans as cognitively inferior. However, with a few exceptions (e.g., Hernstein and Murray, 1994; Jensen and Johnson, 1994), the notion of genetic inferiority has been dismissed.

What becomes intriguing about how racism impacts science is the ways racial evolutionist perspectives have been retrofitted to adopt contemporary methodological means (Hernstein and Murray, 1994; Jensen and Johnson, 1994). Modern perspectives tend to frame these same assumingly biological characteristics of inferiority as psychological, cultural, or cognitive (Hernstein and Murray, 1994; Jensen and Johnson, 1994). The legacy of this early portrayal exists in the image of Africans as less capable beings or as Smith (1993) says ‘inferior others.’ Moreover, this image of Africans (and more recently African-Americans) can be traced throughout recent history and continues in retrofitted form in contemporary scholarship.

It is this image of blacks as inferior others that, we believe, remains central to how contemporary research is designed. Subsequently, African-Americans who are somehow able to conquer their inherent characteristics are able to escape characteristics of race that limit academic progress. The conception that those blacks who can appropriate white culture find it easier to achieve because they come from ‘good’ homes and have ‘white’ values, finds its roots in racial evolutionist perspectives. By contrast, assuming that underachieving blacks are less capable academically and have behavior problems as a result of cognitive differences is the result of the roots of racist science. This assumption is most notably found in the University of Chicago’s National Opinion Research Center’s study on race (Smith, 1990). Smith reported that racist views of blacks were so pervasive that the vast majority of respondents thought they were fundamentally less intelligent, less patriotic, and lazier than whites; and 78% said that Blacks prefer to live on welfare. Although these perspectives prevail, there is little research concerning the impact of a majority of Americans holding these views about African-Americans. We maintain that the sustained prevalence of historically constructed racial evolutionists models leave educational researchers unable to understand how the sociohistorical implications of these negative frameworks affect African-American students.

Craniometry and Physical Anthropology

Another paradigm in the recurring retrofitting of racist scientific ideology involved the use of the more empirically based craniometry and physical anthropology studies. During the 1770s, Camper measured human skulls in an attempt to justify racial differences. He used facial angles acquired by drawing a horizontal line from the nostril to the ear and the other perpendicular one from jawbone to the forehead to measure the intelligence of various species. This framework, which would later be known as craniometry would essentially reform the racial evolutionist perspective with a more empirical support. Camper proposed hierarchical differences between Europeans of 80°, Africans 70°, and the orangutan of 58° also reflected intellectual hierarchies.

The paradigm of physical anthropology reshaped the empirically based racial evolutionist perspective by attempting to use the physical patterns of skulls to argue for racial inferiority. Morton's (1839) *Crania Americana* measured the volume of the interior skulls to demonstrate that larger skulls yielded larger brains (Bruce, 2002; Fredrickson, 1972). He used these measurements to construct an argument that Caucasians were intellectually superior to Africans (Bruce, 2002; Fredrickson, 1972). Morton eventually attempted to retrofit earlier racial evolutionist perspectives by maintaining that skulls were reduced in size because of evolution. Morton's work eventually concluded that Egyptians were not actually African and should be considered European. Ironically, Ripley (1899) countered his argument by suggesting that Morton actually deceived his readers by stuffing skulls in an effort to justify his racist opinions. Despite contradictory evidence and counter-arguments, the result of this work was the reification of previously nonempirical theories of racial superiority with erroneous empirical data.

Racism in Medical Research

Another paradigm of racism in science involves the inappropriate use of minorities as participants in scientific research (Gamble, 1997; Lyles, 1994; Steinbrook, 1989). Scholars have asserted that inappropriate research on minority students is a practice which has been around for centuries. Based on the scientific research on racial bias, studies were designed that used African-Americans as test subjects (Gamble, 1997; Lyles, 1994; Steinbrook, 1989). Beech and Goldman describe this historical racism in science in the following:

Gamble (1997) traced the blatant and racist violations of medical research among African-Americans to the 1800s when Blacks were used as test subjects to promote race-specific stereotypes. A priority goal of such medical research was to provide scientific evidence for widely

held beliefs that African-Americans were physically, genetically, and intellectually inferior to whites. (p. 127)

This perspective discusses the premise that medical research has the potential to be influenced by racism in the form of deciding who is being studied, what illnesses are being studied, and how the participants are being treated.

In 1932 the United States Public Health Service (PHS) under the direction of Dr. Taliaferro Clark initiated its Study of Syphilis in the Untreated Negro Male. This study has since come to be known as the Tuskegee Syphilis Study (The Tuskegee Experiment). One of the most well-known instances of human subject abuse, the study has been the subject of several books (Jones, 1981), at least two feature films, stage plays, several documentaries, as well as academic, newspaper, and magazine articles (Bowman *et al.*, 1999; Corbie-Smith, 1999; Thomas and Quinn, 1991).

With this broad exposure, there is a great deal known about The Tuskegee Experiment. For example, it is clear over 400 men of African descent were known to be infected with syphilis and were observed to determine the means by which syphilis would ravage their bodies. We also know these men were denied treatment by the United States PHS, the US military, and other agencies (Bowman *et al.*, 1999; Corbie-Smith, 1999; Thomas and Quinn, 1991). In addition to being denied treatment, the participants were never told that they were actually part of the study. This study lasted 40 years and was wholly supported by the US government. The horrific abuse of these men, their families, and their communities was finally brought to an end in 1972 (Bowman *et al.*, 1999; Corbie-Smith, 1999; Thomas and Quinn, 1991). This is 125 years after the American Medical Association first published its medical code of ethics, 26 years after the Nazi party was excoriated for human subject abuse at Nuremburg, 25 years after penicillin had become the standard treatment for syphilis, and 8 years after the Declaration of Helsinki (Rothman, 2000).

What becomes clear from a case like The Tuskegee Experiment is the fact that it exemplifies a central aspect of the nature of Western modern science. It reflects how racism was central to Western science and that people of African descent were often the subjects of abuse. Incidents such as The Tuskegee Experiment are characterized as aberrations or the result of a few troubled practitioners who stepped outside the bounds of true and acceptable scientific practice. The reality, however, is people have endured every conceivable desecration at the hands of research scientists. Their corpses have been stolen for unauthorized autopsies and dissection; their bodies (both living and dead) have been put on public display; they have been exposed to myriad pathogens; they have been test subjects for experimental drugs and other products; they have endured experimental surgery (at times

without anesthesia); and they have been used as host vessels for the farming of blood and tissue. Washington's (2006) landmark text is the most comprehensive book to date on the medical exploitation of Africans in America and interested readers would do well to examine the complete history that she offers.

Monogenism and Polygenism

Another of the retrofitted paradigms of racist science involved the notions of monogenesis and polygenic research. In an attempt to dispute Africans and Europeans were not of a common origin, scholars developed the notion of polygenism (Nott, 1854; Ellis, 1988). Nott's (1854) *Types of Mankind* attempted to construct the argument that races from different regions actually developed from different species. This perspective contradicted the more widely held migration frameworks, yet enabled scholars to differentiate between the biological features of Africans and Europeans based on biological grounds. Although Darwin's notion of monogenism, or common origin, prevailed in the long term, science researchers attempted to debate about biological constructions of race rooted in past pseudo-sciences such as phrenology and craniometry.

Eugenics

Perhaps the most consistent form of retrofitted scientific racism involves the eugenics paradigm of scientific racism. Eugenics is a framework that states that the human gene pool can be improved by the removal of deficient minority gene pools (Glad, 2006). This perspective served as the foundation of the Nazi holocaust, American slavery, the Ku Klux Klan, and more contemporary problems of ethnic cleansing. These ideologies operated on the common eugenic assumption that a particular race of humans comprised of inferior gene pools must be addressed through various forms of social disorder and regulations. What remains central in these positions is the fundamental argument and baseless assumption that people are biologically inferior. Such a view finds its roots in the previously refuted taxonomical, eugenic, and polygenic perspective.

Unlike many other forms of scientific racism, eugenic perspectives continue to reinvent themselves well into the twentieth and twenty-first centuries. In 1901, Galton founded a psychometric science journal entitled *Biotrika* that promoted eugenic perspectives of race (Bulmer, 2003). Davenport's (1970) *Race Crossing in Jamaica* used psychometric research to argue that cultural and intellectual inferiority resulted from interracial childbearing.

Not surprising, this eugenic perspective was used as justification by the Nazis in World War II.

Psychometrics

Despite changes in the social position of race in American culture, research continued to attempt to affirm racist ideologies through psychometric research. Despite the fact that the research has been proven to be statistically inaccurate and lacking methodological sophistication to make the claims it is making, most contemporary studies that attempt to support racist ideologies find their home in psychometric research. Much of the early physical anthropological studies on race are now discredited as based on the methodological inaccuracies. However, this early psychometric work continued to reemerge in the form of intelligence quotient (IQ) testing during World War I. Much of the eugenics research attempted to use IQ testing to identify how Africans were genetically inferior. Valencia and Susuki (2001) critiqued this work by examining the culturally based assessment devices and methodological shortcomings. Morris-Susuki (1998) noted how the post-World War II denunciation of Nazi-based scientific research essentially discounted scientific research that attempted to use psychometrics to reify racist ideologies.

Perhaps the most famous form of intelligence research is found in Herrnstein and Murray's (1994) *Bell Curve*. They attempted to redesign previously discredited research to debate the intellectual superiority of Europeans. Despite being discredited a half century ago, the bell curve was supported by other works including Lynn's (2002) *IQ and the Wealth of Nations*, and Jensen's *The g Factor: The Science of Mental Ability*. Ultimately, the eugenics psychometrics movement has been able to sustain itself despite being discredited in each of its forms. What becomes clear is the fact that a number of researchers have attempted to use psychometrics as a means to argue for a racist perspective that believes biological differences are based in genetic inferiority.

The scope and depth of research conducted to prove racial theories is too detailed to address in a manuscript of this nature. Therefore, we have attempted to outline the major traditions in science research that have been used to sustain racist ideologies. Given this review, of a diversity of ways in which race and racism have influenced science, we hope to examine how making issues of race invisible in science education has limited the growth of the science education community.

Theoretical Retrofitting Scientific Racism

The history of racism in science shows a patterned progression of racial theories in science. Initially, the theories

are used to reify racist ideologies; they are refuted and removed from the science landscape until they are revisited years later with new methodological support. The transition from racial evolutionist, to craniometry, physical anthropology, racism in medical research, monogenism, polygenism, eugenics, and psychometric research, all reflect this pattern of the theoretical retrofitting of scientific racism.

Although the early racial evolutionist perspectives were philosophical and lacked any empirical support, they established an ideology of individual difference as the root of scientific research on minorities. The attempt to classify African-Americans as scientifically inferior was revisited in the craniometry and physical anthropology research paradigms. As a result, the notion that African-Americans were physiologically inferior remained central to how science viewed differences between African-Americans and Europeans. Despite the fact that craniometry and physical anthropology perspectives were empirically refuted, these views allowed the fundamental assumption about the perceived biological differences between races to pervade. Imagine any other arena of scientific study. How would science research that disputed previously held beliefs impact the intellectual landscape? In most cases, scientists would alter their perspective in favor of the new empirical frameworks. In the case of race and science, however, the research merely used newly discovered methods and tools to retrofit the previously held assumptions about minorities.

The eugenics, monogenism, and polygenism perspectives are fruitful examples of such a retrofitting process. With the emergence of genetic research and the establishment of insights regarding the human genome, scientists attempted to reify their racist ideologies about race by using the newly discovered information about genetics. Ultimately, such research has continued to be refuted, but the long-term effects of that type of research are enduring. In fact, these assumptions have become so reified that intellectual leaders like James Watson, one of the founders of DNA research, continued to make racist comments about African-Americans till as late as 2007. A recent article about Watson's perspective explains his argument in the following:

The 79-year old geneticist said he was "inherently gloomy about the prospect of Africa" because all our social policies are based on the fact that their intelligence is the same as ours – whereas all the testing says not really. He said he hoped that everyone was equal, but countered that "people who have to deal with black employees find this not true."

Comments like these from people who are central in the world's understanding of science enable racist ideologies to continue to reemerge in different forms. Watson's perspective is the same as the argument proposed by

Linnaeus and other racial evolutionists in the 1700s and continues to pervade the public opinion about Africans and science. Ironically, Watson's comments are incorrect. The research on race and intelligence argues there are no biological differences that account for performance differences. In fact, Watson has completely ignored years of psychological and educational research that addresses how differential academic performance results from stereotype threat and other psychosocial limitations (Steele, 1997). So in fact, the continuous retrofitting of racist ideologies under the cloud of science do more to shape racial differences than any biological factor. As a result, the continual process of using science to support racist perspectives has a profound impact on how people use, experience, and understand science.

Implications for Contemporary Science Education

We can understand how the history of race and racism in science had a substantial impact on science education if one appropriates a critical perspective on how race and racism can translate into science education. Science education has developed norms designed to reflect the norms of science (Fang, 2004; Halliday and Martin, 1993; Wellington and Osborne, 2001). However, these science norms reflect the impact of race and racism in defining discourse systems, funding priorities, and the presentation of images of what counts as science, and cultural expectations for who can become a scientist. The establishment of these science norms are Eurocentric and androcentric, which has the potential to frame how science is experienced by students. If a critical lens on race and racism is applied to understanding how these norms impact science education, one could consider the diversity of ways in which the issues of race and racism have ultimately impacted how science education is experienced.

Determining the Norms of Communication and Valued Contributions

Research that challenges the normative patterns of scientific communication has maintained a consistent role in science education research (Hildebrand, 1998; Lee, 2001; Warren *et al.*, 1994). Research on the genre of science discourse has established that using the language of science serves as a site for cultural conflict for many science students (Brown, 2004, 2006). Hildebrand (1998) argued that discursive practices of science education are hegemonic because they do not incorporate cultural ways of communicating in attempting to prepare students to learn the content and language of science. In the broader education community, scholars propose the use of native ways of communicating as a means to providing bridges through

which students are able to learn the discourse practices of academic environments (Lee, 2001b; Hull and Shultz, 2001). These new literacy studies essentially debate discourses that are inherently political and teachers must become skilled at providing students the ability to see the continuity between their native ways of communication and those they will learn in their classroom (Lee, 2001b; Hull and Shultz, 2001).

More recently, research that analyzes the impact of the discursive norms of science environments has argued that discursive practices of science serve as symbols of cultural mismatch for many minority students (Brown, 2004, 2006; Gilbert and Yerrick, 2001; Brown, 2005; Reveles *et al.*, 2004). Brown (2004) noted how students often avoided using science as a means to maintain their public identity. As a result, he argued some students developed misconceptions due to their inability to appropriate the discourse practices of the classroom. Reveles, Kelly, and Cordova explored how teachers attempted to design instructional practices to build bridges between their cultural modes of communication and those valued by science. Without an ideology that takes a critical approach to the role of race and the culture of science classrooms, issues of language and identity remain invisible to contemporary framework in science education.

How does research implicating the discourse practices of science reflect the racial history of science? Given the functionality of science discourse, learning to use the language of science is a critical component of learning science. In fact, Lemke (1990) states that learning science is essentially the process of learning to talk science. If science presents a culture-free and objective image of itself, and science education does not incorporate cultural ways of communicating in its approaches to teaching, the science classrooms reflect the cultural and linguistic norms of the cultural mainstream. Said differently, the ways of communicating in science reflect the culture in which they are designed. The great irony is that science has a history of being culturally biased and Eurocentric, yet the science education presented in schools proposes an image of science as a culture-free entity. Subsequently, minority students who attempt to study the subject find it to be discursively conflicting and culturally disconcerting. If people assume that all students experience science from the same cultural perspective and make no allocation for people from different cultures, then the culture of science may serve as a marker of cultural difference.

Access to Funding and Training

Another essential challenge in contemporary science education involves the current crisis in encouraging minority students to participate in science-related fields. If examined from a critical race perspective, one can analyze how

a history of retrofitted racism in science has impacted funding and training aspects of science education. Currently, there are over 100 historically black colleges and universities in the United States whose existence and legacy reflect the role of race in science. The very need for these universities reflects America's history of racism as they were designed to educate those who were not provided access to traditionally white colleges and universities. As a result, early research and training of African-American scientists was done by under-funded researchers who developed science programs at historically black colleges and universities.

Given this historical backdrop, one might ask how such a history of segregation impacts contemporary science education. First, a critical perspective on the influence of race in science suggests that access to science careers and science education at the secondary level was limited to a small number of African-Americans. More specifically, true access to careers in education was first made readily available after the desegregation of schools in the 1950s.

Second, one can argue that research on issues of importance to African-American communities has been limited due to the limited numbers of African-Americans conducting research. If minority students are not afforded access to research careers, and there are a limited number of minority researchers to advocate and propose scientific research of importance on minority communities, a disconnect may continue to exist. How can we expect students to matriculate into a science community that does not value their presence or their medical research challenges? Taken from this perspective, issues of underrepresentation in science education and the lack of medical research geared specifically to address the needs of minorities can be seen as a direct product of how science research and training was influenced by the history of segregation in America.

Another effect of racism on contemporary science education involves the issue of student isolation. Many students who choose to pursue careers in science find themselves experiencing isolation when they major in science careers. Students experience feelings of cultural mismatch at being one of few minority students enrolled in a science major at historically white universities. Research in higher education has documented these feelings of cultural isolation in a variety of ways (Solórzano, 1998). Solórzano (1998) describes how students experienced 'microaggressions' during their college experiences as a result of their being considered as representatives of their entire race. His argument suggests that students experience subtle forms of racism as teachers and other students make comments that are negative commentaries about the students' culture.

When issues of marginalization and microaggressions are extended to an analysis of science classrooms, one

could argue that feelings of peripheral membership are heightened due to the small number of minority students pursuing careers in science at traditionally white colleges and universities. This can be considered a direct reflection of years of cultural oppression and racial stereotyping that were reified through retrofitted racist science research.

Given the racial history of science and the evolving paradigmatic attempts to retrofit racist ideologies through scientific research, we assert failure to recognize the mythical objectivity of science education has prevented science educators from attempting to consider the impact of sociohistorical and racial issues in the career participation and classroom instruction of minority students. Lewis' (2003) exploration of how African-Americans pursued careers in science suggested the underrepresentation of African-American students is a direct response to failure of science educators to incorporate a thorough understanding of the sociohistorical impact of racial oppression.

This failure can be seen as a by-product of the fundamental assumptions that tend to frame contemporary research on minority achievement. Many scholars design science education research on minority students that fundamentally assumes minority underrepresentation as a result of erroneous choices of minority students. This assumption is made in a variety of ways. For example, Griffin's (1990) study implicated students' choices as a primary factor limiting their career decisions. Griffin argued "the incidence of career choices among ABC students" served as a central limitation (Griffin, 1990: 428). These decisions were not analyzed as the byproduct of larger sociohistorical issues or as potentially being informed by the failure of the science community to effectively market its careers to minority students. Post *et al.* (1991) were of the view that self-efficacy was fundamental in limiting students' matriculation into science. Post *et al.* described "how self-efficacy and interests related to consideration of math/science careers among Black freshman" were key factors in limiting students' pursuit of science careers (Post *et al.*, 1991: 179). Their study did not address how hearing rumors of racial inferiority may have negatively impacted the students' self-efficacy. Maple and Stage (1991) offered a more sociohistorically informed position as they sought to understand "what background, ability, and high school experience factors are related to choice of a quantitative major" (p. 42). However, they supported the fundamental argument that the failure of students to achieve success in their careers could be directly attributed to choices.

Our goal here is not to critique the theoretical findings of the studies cited earlier. Rather, our belief is that truly gaining an understanding of the impact of students' matriculation and experiences with science requires researchers to gain a rich understanding of the context in which those decisions are made. We contend that one cannot adequately understand the context of interactions of students and decisions without gaining a rich understanding of how

those contexts are designed and impacted by a sociohistorical past full of retrofitted racist scientific research.

The inclusion of the sociohistorical context of race is prevalent in other educational domains (Nasir and Saxe, 2003). In fact, Nasir and Saxe (2003) maintained that one cannot adequately understand students' identity without thoroughly considering the sociohistorical context framing the possibilities for identity development. We are quite concerned that the notion of scientific objectivity inherent in science has limited how science education research addresses issues of race in contemporary research.

A second theoretical assumption that tends to frame research on minority students involves perceived differences in psychological dispositions of students. This assumption treats disparities in performance of students and choice as the result of disparate psychological orientations. Post *et al.* (1991) applied Bandura's (1982) theory of self-efficacy to examine science career decisions of African-American college freshmen. They opined that a key figure in students' underperformance involved freshmen students' lower self-efficacy, interest, and overall consideration of mathematics and science careers. They compared students' lower self-concepts and self-efficacy without adequately exploring the sociohistorical effect of how social issues, like a history of American racism, impact how students develop psychological models. This assumption is derived without considering the wealth of research from psychology that details how a history of racism shaped a sense of self and self-efficacy in students (Steele, 1997; Cross, 1971, 1978). Their study and others like it (Gilleylen, 1993; Griffin, 1990, 1993; Maple and Stage, 1991) frame disparity in psychological terms pointing to psychological antecedents such as self-confidence, interests, and attitudes.

An additional assumption limiting contemporary research perspectives involves a fundamental assumption that the culture of minority students is embedded with deficient cultural characteristics that limit their success. These frameworks tend to position minority and white cultures in contrast; framing minority culture as culturally disparate containing traits such as family background and community values (Griffin, 1990), parental influence (Maple and Stage, 1991), cultural awareness and social support (Gilleylen, 1993), and students' interest in social service fields (Hager and Elton, 1971; Thomas, 1984). The studies presented here and the types of antecedents outlined are neither exhaustive nor mutually exclusive.

These studies are, however, representative of the larger body of literature aimed at explaining the underrepresentation of African-Americans in science and are useful in illustrating how contemporary science education research has not explained why or how race is operative in science career attainment and classroom performance.

Alone, each of these perspectives offers valuable insights by revealing different sides of a complex social

problem. Taken as a whole, however, this body of literature could be vastly improved by incorporating a framework rich in its understanding of how race and racism have shaped the sociohistorical context in which students develop academic identities. Ultimately, without adequately incorporating a framework that includes an informed perspective on the sociohistorical impact of race and racism, science education research is simply unable to assess how the construction of race, which has been a defining feature of Western culture since the sixteenth century, may serve as the foundation of the academic achievement gaps we are currently experiencing in science.

Sociohistorical Construction of Race

The sociohistorical construction of race is the fundamental assumption that humans are physiologically equal. Given that physiological equity, differences in their ways of thinking, academic performance, and cognitive modes reflect the influence of the way social context and social interactions have shaped individual identity development. If race is not biologically determined, then scholars must develop an in-depth understanding of how the sociohistorical construction of race had resulted in how people see themselves and define the possibilities for their identity development. Hacking (1999) argues that the primary use of 'social construction' is as a conscious-raising measure.

Those who adopt a sociohistorical framework of the role of race in science education offer an analysis critical of education research which attempts to measure characteristics of minority students that are assumed to be biological or inherent. Social constructionists argue certain issues do not need to exist, or would not exist if not for the impact of racism in society. For example, Steele's (1997) notion of stereotype threat states that academic differences are best viewed as purely sociohistorical phenomena that would not have existed due to biological differences, but rather are purely social effects resulting from years of racism. In contrast, sociohistorical theorists critique those who do not adopt a sociohistorical framework by arguing that they merely attempt to change the conditions under which socially shaped behaviors are developed. Said differently, they suggest that much of our contemporary research simply offers different treatments to conditions that are not biological but are rather sociohistorical. Therefore, without addressing the sociohistorical impact, one could design interventions and research that merely continue to assess the impact of sociohistorical racial difference in American culture.

In this sense, the social construction of race typically refers to the idea that race is not biologically determined, but is a social construction that must be studied accordingly. Seen this way, the very notion of race is not a matter of inevitable physiology but is rather a result of the impact

of social decisions. Social constructionists make the essential argument that scholars should engage in research that attempts to transcend racial classification as fundamental and explore the nuances of the sociohistorical influences which shape cultural interaction. In this way we may be able to improve our understanding of research if it transcends the assumptions it makes about race and culture. Ferrante and Brown (2000) provide an example of such a perspective as they attempted to use research that explicitly assigned meaning to racial categories rather than to be critical of the use of those categories.

Although, exploring a theory of racial construction is essential to this manuscript, we are not attempting to craft an alternative perspective on the sociohistorical construction of race. Rather, we argue that just as science has been influenced by the subtext of racial ideologies, science education has also been impacted by assumptions about what counts as race. Over the years, these perspectives continue to be retrofitted, but the primary assumption about a construction of race as physiologically or cultural inexorable remains the same. Therefore, defining a theory of racial construction is beyond the scope of this article. Instead, we assert that appropriating a sociohistorical perspective of the role of race in science education and recognizing the history of retrofitted scientific racism would illuminate how minority students, as a result of centuries of racial oppression, experience the discourse, artifacts, and knowledge and practices of science.

Schools of Thought

An expanded version was published in the (Fall, 2002) *International Journal of Africana Studies*, 8(2). An earlier version was published in Diamond, R. and Adams, B (eds.) (2000). *The Disciplines Speak: A Continuing Conversation: Rewarding the Scholarly, Professional, and Creative Work of Faculty*, pp 125–151. Washington, DC: American Association of Higher Education.

While some schools of thought within the field may be more or less intent upon counterbalancing the traditional Eurocentric bias characteristic of traditional American and European scholarship in the field, the central tendency of Africana studies is to investigate and illuminate the African world experience, in its own right.

As in any dynamic field, there are schools of thought in Africana studies. It is commonly agreed that the diversity of perspectives in the field is critical to its vitality and creativity. For example, there is an ongoing debate as to whether Africana studies is a field of study, a discipline, or something else. Some scholars declare Africana studies a discipline in that, like sociology, scholars look at different areas of the human experience, be it history, politics, family, etc., through the same lens. Such advocates call the discipline Africology. Some scholars consider Africana studies to be an interdisciplinary field of focused study to which, like the field of education, scholars bring a variety of disciplinary lenses, be they anthropological, psychological, historical, etc., to study the African-world experience. Still others would argue for a multidisciplinary or nondisciplinary label (for a discussion of the implication of terms, see Stewart, 1992).

We choose to use the term postdisciplinary as useful for describing the developmental trajectory of the field. It expresses a view of Africana studies as more than a territory to which scholars bring disciplinary lenses. It rather describes an evolving intellectual enterprise attentioning traditional, traditionally ignored, contemporary, and future ways of knowing. For example, one characteristic of the field's approach is the recognition of indigenous cultural knowledge which lies outside the traditional boundaries of humanistic and scientific discourse, such as that attainable through visual and oral accounts.

Central Tendencies in the Field

There is widespread agreement that many forms of cultural knowledge are necessary to understand the complexity of the Africana experience. In the sense that thought precedes speech and orature precedes literature, indigenous knowledge sometimes precedes scientific acceptance. For example, many folk remedies for illness have subsequently been found to have a basis in science and only then declared acceptable. Africana studies is open to other ways of knowing.

Another central tendency in the field is the rejection of the notion of pure objectivity as an attainable neutral space from which humans might analyze the human experience without bias (see Ani, 1994; Asante, 1990). While recognizing the value of the scientific method as a tool useful for minimizing bias, Africana scholars see danger in pure objectivity claims. The symbolic danger of such an illusion is akin to looking through a pair of binoculars from the wrong side and getting the illusion of distance. In short, we believe the use of traditionally recognized disciplinary tools, along with other ways of knowing, such as oral communications, spirituality, intuition, and reflections may generate richer and fuller descriptions of many phenomena.

There exists a positive creative tension within the field, within the units, and between the units even as Africana-studies scholars share both the pursuit of scholarly knowledge and social responsibility as the dual goals of the Africana-studies enterprise. Despite recognizing our common cultural roots, the presence of multiple cultural traditions in the field presents the challenge of shared and unique cultural visions as a consequence of different cultural experiences. We recognize that culture and color are not the same thing. While we generally agree on the ends, there is great variation in the means by which these dual goals are pursued. Given the change agent mission characteristic of many Africana-studies units, this tension perhaps becomes inevitable. This positive paradox may have been best expressed by Martin Luther King Jr. when he declared that no change is possible without creative tension.

Titles and Foci

The variety of labels under which Africana studies is included generally reflects different geographic areas of concentration such as African, African American, and African Caribbean Studies. Diaspora studies is sometimes used to describe studies of populations of acknowledged African descent not located on the African continent. The term acknowledged African descent is deliberately chosen to avoid unnecessary controversy about lines of human descent, as there is solid anthropological and genetic evidence that the human roots are common and African.

The variety of different geographical locations attended by the field provides challenges and a wealth of opportunities to explore continuity and change in cultural patterns within and between peoples over time and over space. Such scholarship is also engaged in by scholars located in traditional departments such as English, history, sociology, and political science. Scholars in the field also engage in specialized-area studies such as women studies and education (Aldridge, 1984).

Africana studies, the global term used throughout this discourse, is the term generally recognized in the field and used by the National Council for Black Studies to describe the field as a whole. The term unit is also used in this discourse to include the various structural labels, be they programs, centers, or departments, which Africana studies operates under in the academy.

Applied Scholarship

Due to the unique cluster of methodological approaches and emphasis on service to students and community espoused by and expected of scholars in the field, Africana studies challenges the traditional elite model of scholarship that, in our view, too often advocates scholarship for scholarship's sake. Africana studies, in contrast, generally seeks praxis in advocating what might be called applied scholarship. Thus, performance evaluations for tenure and promotion, when controlled by the units themselves, reflect this centrality of service to students and community. This difference in performance expectations and subsequent method of faculty evaluation has been a source of friction between the units and higher university-evaluation bodies over the differing criteria, especially when the Africana-studies unit has not acquired the autonomous rights associated with departmental status.

Historical Background

While the roots of the study of the Africana experience can be traced back to ancient Africa and ancient African universities, the formal emergence of the field is anchored in

the world of our elders in the nineteenth century, such as Anna Julia Cooper, Maria Stewart, Ida B. Wells-Barnett, George Washington Williams, Henry McNeal Turner, and Martin Delany. In the early to mid-twentieth century, many of the pioneers in Africana studies functioned largely outside the academy including W. E. B. Du Bois, J. A. Rodgers, Arthur A. Schomburg, Zora Neal Hurston, Amy Jaques Garvey, Carter G. Woodson, Lorraine Hansberry, Jacob Lawrence, Charles S. Johnson, and Alain Locke. However, the formal institutionalization of the field of Africana studies within and across disciplines can be linked to the work of W. E. B. Du Bois at Atlanta University, Charles Johnson at Fisk University, and especially the work of Carter G. Woodson with the Association for the Study of Negro Life and History (presently ASALH), the *Journal of Negro History*, and the Annual Negro History Week Celebration (currently Annual Black History Month Celebration) (Young, 1997).

The activities of all three of these historical giants in the field of Africana studies demonstrate a commitment to the integration of scholarship with a commitment to fostering constructive social change; one of the fundamental values of contemporary Africana studies. Useful perspectives on the historical foundations of Africana studies and the symbiosis between academic inquiry and social change can be found in a number of writings including Aldridge (1994); Anderson (1990); Hall (1999); Karenga (1982, 1993); Semmes (1992); Stewart (1992); Turner (1984); Turner and McGann (1976); and Harris (1990).

Competing Conceptions

There was a high degree of overlap of visions among the early advocates of Africana studies. Representative early discussions of the nature, goals, and future of Africana studies were produced by Blassingame (1969, 1972); Jackson (1970); McClendon (1974); Robinson *et al.* (1969); Rose (1975); and Russell (1975). At the same time, however, as noted by Allen (1974), three distinct views about the nature of Africana studies were espoused:

1. an academic conception, whereby the mission of Black studies is to research Black history and illuminate the contributions of Blacks;
2. an ideological political conception, whereby Black studies is seen as an instrument of cultural nationalism;
3. an instrumental political conception, whereby Black studies is considered a vehicle for social change with a functional relationship to the Black community.

While Allen's categorizations are useful, they mask the importance of ideologies other than cultural nationalism important in the early development of Africana studies, such as Marxism (see Alkalimat *et al.*, 1986; People's College Press, 1977).

The evolving nature of Africana studies as an intellectual enterprise at this stage of its development is open to interpretation. For example, as previously indicated, there has been much debate about whether Africana studies is a discipline, in the traditional sense, or an area of inquiry to that one brings tools from selected disciplines and applies them to a particular subject matter. Stewart (1981) discusses the philosophical implications of various conceptions of Africana studies. The general consensus has been that the field has had, as its developmental goal, the creation of an academic unit with a discipline-like configuration and mechanisms to link scholarly inquiry to social action and social change.

Black Studies Defined

Karenga (1982: 35–36) defines Black studies as an interdisciplinary discipline that has seven basic subject areas. According to Karenga, these intradisciplinary foci that at first seem to be disciplines themselves are, in fact, separate disciplines when they are outside the discipline of Black studies; but inside, they become and are essentially subject areas that contribute to a holistic picture and approach to the Black experience. Karenga suggests that the qualifier Black, attached to each area in an explicit or implicit way, suggests a more specialized and delimited focus that of necessity transforms a broad discipline into a particular subject area of inquiry. Karenga delineates seven basic subject areas: Black history; Black religion; Black social organization; Black politics; Black economics; Black creative production (Black art, music, and literature); and Black psychology. As previously indicated, use of terms such as interdisciplinary and multidisciplinary must be viewed with caution. For some scholars, these terms simply convey the idea of casual discourse among scholars trained in traditional disciplines. However, as used by many Africana-studies specialists, the terms have much more of a transformative interpretation. To illustrate, Hall (1996: 14) observes, “In theory, a body of knowledge or field of study that is truly interdisciplinary does not just cross conventional disciplinary boundaries, it obliterates them. In practice, however, the trend remains that most African American studies programs represent multidisciplinary approaches in that — disciplinary boundaries intact — scholars trained in history, humanities, or social science fields apply their particular disciplinary approaches to some piece of knowledge in relative isolation from the whole.”

Aside from the general issue of disciplinary intersections, there is also the question of which disciplines are especially germane to the mission of Africana studies. Karenga (1982: 32) suggests that, “Black Studies, as both an investigative and applied social science, poses the paradigm

of theory and practice merging into active self-knowledge that leads to positive social change.” In Karenga’s view, “Black Studies is a discipline dedicated not only to understanding self, society, and the world but also to critique them in a positive developmental way in the interest of human history and advancement.”

Despite the diversity reflected by these multiple linkages, for the purpose of this assessment, we use the term discipline to characterize the field because it has all of the characteristics of Kuhn’s definition of a paradigm or disciplinary matrix (see Karenga, 1988; Stewart, 1992). We recognize, however, that future developments may eventually produce an enterprise that differs significantly from existing disciplines.

African-Centered Thought

As previously indicated, all academic disciplines have different schools of thought that contribute diverse perspectives to the collective enterprise. There is, however, always an overarching worldview and a set of values, part of a disciplinary matrix that includes theories, research methods, etc., that is shared among schools of thought (see Kuhn, 1970). One value that links different schools of thought within Africana studies is the commitment to producing a perspective that reflects the beliefs, values, culture, and interests of peoples of African descent. The terms African-centered and Afrocentric are used in contemporary discourse to convey this value. Critics of Africana studies have attempted to denigrate the field by attaching specific interpretations of this value expressed by some particular authors. Such specific formulations are confused with the generalized value that constitutes an undergirding value for the discipline. These terms are used in a general rather than limited sense as suggested by Semmes (1992: 18) “Afrocentric or African-centered thought is solidly embedded within a historical tradition that can be understood by recognizing internal dialectics and contradictions over historical time within the field and the society.” Thus, it may be argued that Afrocentric or African-centered thought exists regardless of whether or not it is called Afrocentric or African-centered.

Each school of thought within Africana studies has its own particular interpretation of what constitutes African-centered thought and how that thought should be linked to other intellectual traditions. One schema representing the range of thought in Africana studies is presented in **Table 1**.

Within each school of thought, there are subtle but important distinctions. At the same time, it is possible to compare the treatment of core theoretical constructs and approaches to social change across different schools of thought.

Table 1 Categorization of alternative conceptions of Africana studies

1. Africana studies as a disciplinary matrix-driven enterprise
Kawaida theory (Karenga)
Africology (Asante)
2. Africana studies as a discipline constituting syntheses of traditional disciplines
Multidisciplinists
Nondisciplinists
3. Africana studies as an adjunct to Eurocentric metatheories
Marxism-paradigm of unity (Alkalimat <i>et al.</i>)
Feminism
4. Africana studies as a subcomponent of individual disciplines
History
Literature
Sociology
5. Africana studies as a component of nondisciplinary aggregates
African studies
American studies
Ethnic studies
Multicultural studies
6. Africana studies as expressions of selective emphases
Kemetologists
Melanists
Generalized folk approaches

Table 1 (Stewart, 1992) presents a classification scheme that clarifies the conceptions of the field discussed to this point. The framework articulated in the introduction is most closely associated with the first category, but, as discussed previously, the current state of development is also strongly identified with the second category. External evaluators tend to identify with the fourth and fifth conceptions. There is no doubt that what can be described as popular Afrocentrism has permeated various popular culture media, most notably film and music. However, this phenomenon has virtually no relationship to formal efforts to develop Africana studies into a disciplinary matrix-driven enterprise. Popular Afrocentrism draws heavily on self-published works produced by persons largely outside the academy. Although, as discussed previously, there is a long history of African-centered thought generated outside the academy, during the current period, the locus of development has been and remains solidly inside the academy.

The marginalization of peoples of acknowledged African descent and other similarly situated groups spurred the development of a school of thought heavily influenced by Marxist thought and practice. The collective of scholars associated with this school of thought were, in fact, responsible for institutionalizing the commitment of the National Council for Black Studies to the linkage between scholarship and activism as expressed by the organizational adoption of the motto “academic excellence and social responsibility.”

The categories presented here are sometimes overlapping and thus not presented as exclusive.

Gender Studies

The treatment of gender within Africana studies has precipitated increasing examination and debate. There are two distinct tendencies within this movement and both have been instrumental in exposing and countering the sexist tendencies of some Black nationalist ideologies. Some scholars have called for the application of feminist constructs for the analysis of the experiences of Africana women and have critiqued cultural nationalism as a belief system that is inherently nonliberatory because of what are perceived as inescapable sexist tendencies (see Hull *et al.*, 1982).

In contrast, many Africana womanist scholars urge the redefinition of the partnership between Africana men and women in pursuit of intellectual and political objectives (see Aldridge 1989, 1992; Gordon, 1987; Hudson-Weems, 1989, 1993). Proponents of this view generally identify with and contribute to the overall effort to establish Africana studies as a discipline.

Afrocentricity

Given the emphasis that has been focused on Afrocentricity as a key construct associated with the efforts to develop Africana studies as a disciplinary matrix-driven enterprise, it is useful to examine its content in more detail to examine the credibility of claims of limited coherence. **Table 2**, (Stewart, 1992), offers a framework for comparing schools of thought. The framework is useful for comparing elements of the disciplinary matrix of different variants of a given school of thought (in this case Afrocentric thought), and comparing constructs associated with different schools of thought (here Afrocentric and Marxist paradigms).

The variants of Afrocentric thought examined in **Table 2** are those generated by two of the most widely acclaimed scholars in the field, Molefi Asante (systematic Afrocentricity) and Maulana Karenga (Kawaida theory). The principal point is that there is an acceptable level of coherence within Africological thought and that systematic comparisons can be used to identify desirable research thrusts that would accelerate the development of Africana studies.

The National Council for Black Studies

The National Council for Black Studies (NCBS) was founded in 1975 and has been the premier professional organization dedicated to the professional development of

Table 2 Comparison of systems of thought associated with Africana studies

<i>Comparative criteria</i>	<i>Kawaida theory</i>	<i>Systematic Africology</i>	<i>Paradigm of unity</i>
Concept of Afrocentricity	In the cultural image and human interests of 'African Americans'	Placing African ideals at the center of any analysis that involves African culture and behavior	Unspecified
Treatment of gender	In the context of male/female relationships	Unspecified	As a biological category
Theoretical focus	Theory of culture	Theory of inquiry	Theory of social change
Theoretical emphasis	Social organization	Authenticity of knowledge and culture	Social dynamics
Key constructs	Cultural authenticity Nguzo Saba	Afrocentricity Nommo	Class relations Social cohesion
Treatment of race	Cultural (emphasis on consciousness)	Cultural (emphasis on language and symbols)	Social disruption Biological
Observational language	Partially transformed	Completely transformed	Standard Marxist
Subject areas	History, religion, social organization, economic organization, political organization, creative production, ethos	Society, communication, history, culture, politics, economics, psychology	Consciousness, society, economy, biology
Periodization scheme	Unspecified	Unspecified	Two-stage cycle
African emphasis	Classical civilizations	Classical civilizations	Traditional pre-slave trade

Africana scholars and the development of programs in the United States and around the world. The annual national and occasional international conferences sponsored by NCBS are notable because of their ability to bring together established and emerging scholars to deliberate on the African world experience. The motto, "promoting academic excellence and social responsibility," captures the past, present, and future direction of seeking to bring about social change through scholarship that informs social action. The organization remains centrally involved in monitoring and assessing the field in light of this dual goal.

Publication

Aldridge (1994) identifies approximately 40 000 Black/Africana studies publications in the discipline in the forms of books, monographs, articles, and special publications, along with several dozen new journals and texts. Of course, much of this research has reflected traditional methods and has been published in traditional organs. But, as noted previously, a distinct body of knowledge has been generated that is associated uniquely with Africana studies as a self-standing intellectual enterprise. Some of this work has been published in professional journals that have been created to serve scholars in the field, such as *Journal of Black Studies*, *Western Journal of Black Studies*, and *International Journal of Africana Studies* (the official organ of the

NCBS). Special issues or sections of other periodicals have also served as publication outlets such as *The Black Scholar*, *Journal of Negro Education*, and *Journal of Black Psychology*.

Africana-studies research has also been published in a variety of monograph formats including introductory texts (e.g., Alkalimat *et al.*, 1986; Anderson, 1990; Karenga, 1982, 1993; People's College Press, 1977); singly authored examinations of broad issues facing the field (e.g., Asante, 1986, 1987, 1990); single-authored works that provide the foundations for current research thrusts (e.g., Diop, 1974, 1990); and collections of essays designed either to complement texts or cover a range of critical issues (e.g., Alkalimat, 1990; Anderson, 1990; Conyers, 1997; Hayes, 1992; Turner, 1984).

It is interesting to note that the character of the research published has changed as the academic training background of faculty has changed. The first generation of faculty staffing Africana-studies units was trained solely in traditional disciplines, and they tend to approach the study of the Africana experience through their various disciplinary lenses, those who have developed other Africana ways of seeing have had to do so through self-development. Such scholars tend to publish both in traditional and specialized Africana-studies publications. However, as more graduate programs have recently produced new faculty trained specifically in the field, alternative methodologies are being introduced both in the classrooms and the journals. Some of

this new scholarship introduces ways of knowing and methods of analysis that either fail to meet or challenge, or transcend the expectations of traditional journals.

Thus, while bringing fresh and new energy and vision, Africana-studies scholars run the risk of not meeting traditional standards when measured by traditional criteria. Both the journals that would publish their works and the units in which they reside in the university remain suspect. This dilemma speaks to the need for Africana-studies units to retain or attain, whether through the attainment of departmental status or another arrangement, the right to make tenure and promotion decisions independently.

Creativity

Africana studies also endeavors to embrace the more creative work of the professoriate advocated in Dr. Ernest Boyer's (1988), *Scholarship Reconsidered: Priorities of the Professoriate*. The work is a model of the scholarship of "discovery, integration, application, and teaching that so urgently needs to be acknowledged and rewarded." To this end, the pursuit of external funding is reflective of the creative work or applied scholarship.

Teaching

The best pedagogical approaches associated with Africana-studies instruction at the undergraduate level are designed to expose students to the ideas, philosophical orientations, and benefits and liabilities of the variety of schools of thought. Instructional strategies are designed to transmit critical analytical skills that allow students to make their own informed decisions about the world. Instruction is generally delivered through organized units, usually departments, programs, centers, or institutes using faculty with various types of affiliations within the academy. The range and orientation of instruction generally reflect the mission, faculty expertise, and general focus of the academic unit, for example, African American or diasporic studies.

Africana studies courses are increasingly included in general-education curricula, expanding the numbers and variety of students in classes. Among opportunities offered in Africana studies for students, in addition to classroom exposure to a variety of professors and perspectives, are stimulating learning activities, conducted on and away from campus. Study-abroad opportunities in Africa and the Caribbean, and field experiences in local community service agencies are offered. Unique teaching models and strategies have been employed to provide students in Africana studies with a wide range of intellectual and personal experiences at home and abroad.

Study Abroad

Africana-studies units, like their counterparts in international studies and individual departments and/or programs, have developed study-abroad programs. However, the major global foci of Africana studies, Africa, and the Caribbean area tend to be neglected in traditional international-studies offerings. The opportunity for students in Africana-studies-oriented study-abroad programs to travel, to learn, and to experience the language, people, and culture of Africa is, according to participants, a profound world-view-changing experience. Not only do the students report upon return that their view of Africa will never be the same, their view of their home nation is simultaneously altered as they become citizens of the world.

This central benefit of the Africana-studies experience comes through the encouragement and, at times, insistence of Africana-studies units that college and university offerings have to be expanded beyond Europe, Latin America, and Asia, to include Africa and the Caribbean. Such programs have also differed from the Africana-studies-program experience traditionally provided, because they present an African-centered rather than European-centered exposure. The Africana view may sometimes be through a different, though equally valid lens. It is a critique from the inside out rather than from the outside in.

Conclusion

The continuing advancement of Africana studies requires, in addition to a well-managed interface with traditional disciplines, a well-developed intellectual core that both differentiates the enterprise from and connects it to traditional disciplines. In Stewart (1992), seven useful developmental thrusts are identified:

1. Development of a theory of history.
2. Articulation of a theory of knowledge and social change.
3. Delineation of a theory of race and culture.
4. Expansion of the scope of inquiry encompassed by the disciplinary matrix.
5. Expanded examination of the historical precedents to modern Africana studies.
6. Increased emphasis on applications of theoretical work.
7. Strengthened linkages to interests outside the academy.

The dual missions of student centeredness and applied scholarship, in combination with the too frequently ambiguous status of the units within the academy, make Africana studies unique and vulnerable in its relationship to the academy. This relationship will continue to present as yet unseen challenges. The field, nevertheless, remains as

innovative, adaptive, and optimistic as its founders and the peoples it educates, studies, presents, services, and defends in the intellectual arena called the academy.

The type of synthesis of ways of knowing pursued through Africana studies is actually at the cutting edge of a broader de-emphasis of science (as distinct from technology) as the only source of socially useful knowledge. This erosion of scientific influence is signaled by several developments. Within the scientific establishment itself, there is increasing soul-searching among practitioners in various social and behavioral disciplines regarding the value of the current incrementalist approach to knowledge. The growing prevalence of meta-analyses is a manifestation of a desire to generate broader interpretations from potpourris of small-scale scientific studies. Popular culture, with its decided sensate emphasis, has supplanted science as the major purveyor of cultural imagery, values, and, most important, sensory stimulation. This shift in attitude of mind finds its intellectual expression in deconstruction and cultural-studies paradigms that challenge both the claims of universalism and linguistic assumptions associated with scientific explanation. The growing significance of popular culture media is, of course, linked directly to the increasing commodification of culture and the associated scramble for profits in the global cultural marketplace. From this vantage point, one of the challenges of Africana studies is to preserve culturally specific sources of innovation and resist market tendencies to commodify cultural forms.

In addition to the increasing role of sensate approaches to understand reality, there are also ideational challenges to scientific discourse, including various new-age philosophies and resurgent traditional religious movements. Not surprisingly, many of the new-age philosophies borrow heavily from non-Western cultures. This resurgence of idealistic ways of knowing constitutes an expanded search for spiritual guidance in a rapidly changing world. Africana-studies research examining the spiritual and religious foundations of classical African civilizations provides an important cross-cultural dimension to this growing approach to the search for meaning.

Finally, technology plays an increasingly critical role in propagating these shifts in attitude of mind. In particular, new technologies of information acquisition and dissemination, especially the Internet and other rapidly growing instant forms of worldwide communication, are accelerating shifts in patterns of knowledge production and information acquisition as well as changes in patterns of human-human and human-machine interaction. It is critical that Africana studies prioritize the mastery of information technologies, not just as consumers, but as designers of computer-human interfaces and the design of systems to ensure that cultural diversity is reflected and respected in the foundations of this new and powerful technological force. Thus, emphasis on the serious

scrutiny of science and technology is a necessary and logical extension of the ongoing quest by Black/Africana studies scholars/activists.

The central mission of Africana studies is to advance knowledge that simultaneously facilitates scholarship and activism, toward advancing human liberation.

Beyond Black Nationalism to Black Internationalism: The Compelling Case for Examining Black Educational Challenges Globally

K Freeman, Southern University and A & M College System, Baton Rouge, LA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

- Black populations** – African descendants.
Cultural alienation – The process to isolate groups.
Cultural annihilation – The process to remove culture and eliminate groups.
Culture of exclusion – The process where groups are removed from settings – whether schools or other societal settings.
Internationalism – Collective, comparative, globalized group-focused.
Nationalism – A particularized country-specific focus, where groups experience challenges in isolation.

Introduction

With all the worldwide debates about the impact of globalization on every aspect of cultures, from the environment to technology to the economy and education, it is astonishing that – around the world – black populations (broadly defined in this article as African descendents) remain underrepresented at every level of schooling. Yet, the economics of education theorists have long ago (Schultz, 1962) documented the linkages between education participation, economic development, political participation, and environmental justice. With such documentation, it is surprising that there is such a dearth of research and/or focus on the comparative struggles that black populations share in their quest to participate in education.

Writers across disciplines (e.g., history and the humanities) such as Baldwin (2002) and Lorde (1992) have challenged the existing paradigm used to understand and examine the cultural link among blacks in the diaspora. However, educational researchers have been slow to see or move beyond the Black National model of examining educational underrepresentation. Consequently, the necessity of refocusing and/or shifting to a different paradigm to examine the comparative, common educational experiences black populations confront globally have been largely misunderstood and under-examined. This perspective – utilizing a broader, cross-disciplinary, and cross-boundaries approach – makes the case for moving

from a Black Nationalist model to a black internationalist model to examine black educational challenges globally.

A Black Nationalist model is a particularized model where African descendents in each country focus on their challenges in isolation – whether they are issues of education, economics, or environmental justice. A black internationalist model differs from a single-focus paradigm to one that builds on the collective, comparative experiences of black populations globally. Contrary to common perceptions that there are more differences than similarities between black populations, this research makes the case for an expanded paradigm to researching and developing an international agenda for better understanding educational challenges confronting black populations globally.

Different Countries, Similar Historical Experiences

As James Anderson has so rightly indicated in numerous writings and speeches (e.g., 1988 and 1999) – to understand the educational experiences of blacks, it is necessary to examine the historical context of their existence. Although, as Lorde has indicated, blacks in different countries have experienced particular histories – as it relates to their humanity and their pursuit of education – blacks across societies have had similar experiences. The common historical linkage among blacks in the diaspora is captured by Opitz *et al.* (1992) who wrote in reference to Afro-Germans: “In the course of colonial exploitation, enslavement, and domination ‘Negro’ (from Latin *niger*, i.e., black) became an especially negative epithet. The thinking underlying this label attempted to link physical characteristics with intellectual and cultural ones” (p. 7). That is, across cultures, being black has historically been thought of as being intellectually inferior and being without a culture or having a primitive or uncivilized culture.

While often not recognized, blacks have been a part of European societies – in most cases, longer than in America. For example, Fryer (1992) who wrote what would be considered the seminal work on blacks in Britain, indicated that African descendants have been in Britain for centuries, as a group they “have been living in Britain for close on 500 years. They have been born in Britain since about the year 1505” (p. ix). That would mean that, based on

American history, Black Britons – as a group – were in England more than a hundred years prior to the arrival of blacks in America in Jamestown, Virginia, in 1619 (Clarke, 1972). While Opitz *et al.* (1992) indicated that “there is no precise method of determining when the first Africans came to Germany and when the first Afro-Germans were born,” they indicated that “several paintings have survived from the twelfth century that depict Africans living in Germany” (p. 3). Although the exact arrival of blacks across cultures may be unclear, what is certain is that, by the mid-sixteenth and seventeenth centuries, blacks were settled in countries around the globe. For example, “in the mid-sixteenth century, one-tenth of the population in the Portuguese capital were Black, and, as in France and England, it was probably also true in Germany” (Opitz *et al.*, 1992: 3).

Blacks in different countries faced similar treatment in the portrayal of their culture. Blackness was associated with evilness, inferiority in every way, and subhumanism. In Britain, for example, “Africans were said to be inherently inferior, mentally, morally, culturally, and spiritually, to Europeans” (Fryer, 1992: 7). Likewise, in Germany, blacks were portrayed negatively. In general, “Africans were seen as the lowest human form, thought to be related to the highest animal form, the monkey” (Opitz *et al.*, 1992: 8). As well, “Most Portuguese seem to have thought that blacks as a people were innately inferior to whites in physical beauty and mental ability and moreover, that they were temperamentally suited to a life in slavery” (Saunders, 1982: 166). Although on a different continent, blacks in the United States were experiencing the same devaluation of their humanity. In the United States, this statement about the use of slave codes best captures how blacks were viewed: “There were variations from state to state, but the general point of view expressed in most of them [Slave Codes] was the same, that is: slaves are not persons but property, and laws should protect the ownership of such property, and should also protect the whites against any dangers that might arise from the presence of large numbers of Negroes” (Franklin and Moss, 1988: 114). This devaluation of the black culture by the nineteenth century, according to Clarke (1972), caused Africans the world over to begin to search for a definition of themselves.

Another similar link in the historical experiences of black populations was the exploitation of their labor. As Clarke (1972) indicated, “The story of the African slave trade is essentially the consequences of the second rise of Europe . . . They were searching for new markets, new materials, new manpower, and new land to exploit. The slave trade was created to accommodate this expansion” (p. xvii). Just as blacks in America were relegated to working the land and as servants to increase the wealth of this country, so were blacks in European countries. For example, according to Fryer (1992), “The majority of the 10,000 or so black people who lived in Britain in the

eighteenth century were household servants – pages, valets, footmen, coachmen, cooks, and maids – much as their predecessors had been in the previous century” (p. 73). Although working menial jobs, Fryer conceded that as a Liverpool writer declared in 1893, “it was the capital made in the African slave trade that built some of our docks’ and the price of human flesh and blood that gave us a start” (p. 66). Similarly in Germany, blacks were used for menial labor. In Germany, for example, blacks “were forced to cultivate export products or to work on the plantations and in the mines of whites” (Opitz *et al.*, 1992: 25). The same was the case in Portugal. According to Saunders (1982), “The nobility employed – or underemployed – large numbers of slaves solely as domestic servants” (p. 63).

Even when blacks were interested in working higher-status jobs, they were forbidden. For example, in London after 1731, blacks were not allowed to learn a trade. In fact, on 14 September of that year, the lord mayor of London issued the following proclamation prohibiting apprenticeships for black people:

It is Ordered by this Court, That for the future no Negroes or other Blacks be suffered to be bound Apprentices at any of the Companies of this City to any Freeman thereof; and that Copies of this Order be printed and sent to the Masters and Wardens of the several Companies of this City, who are required to see the same at all times hereafter duly observed. (cited in Fryer, 1992: 75)

Although there were some blacks in the United States who possessed some skills – especially the few slaves who lived in towns – the great majority of slaves’ responsibilities were divided between two distinct groups – the house servants and the field hands (Franklin and Moss, 1988). According to these researchers, slaves had little opportunity to develop initiative because their responsibilities were proscribed for them. Therefore, the idea that blacks did not want to work and thus played a role in having their skills underutilized was not the case.

Understandably, the exploitation of labor is – and has always been – intricately linked to lack of educational opportunities. To keep groups uneducated or undereducated has been a formula across societies for the underutilization of their talents. Nkrumah – the son of the late African leader – describes it as a sort of worldwide formula where African descendants everywhere have been relegated to the bottom educationally and economically. As such, the idea has been to prevent blacks from being empowered intellectually, culturally, and economically.

As Anderson (1988) has indicated, it is through education that individuals begin to feel empowered, and African-Americans were active agents in their right to be educated. From slavery until now, African-Americans have had to struggle to have the opportunity to participate in any form of education. According to Anderson,

"Blacks emerged from slavery with a strong belief in the desirability of learning to read and write" (p. 5). As an example of the intensity of anger that slaves held for keeping them illiterate, Anderson quoted a former slave: "There is one sin that slavery committed against me which I will never forgive. It robbed me of my education" (p. 5). Restrictive legislation was passed to prohibit slaves from learning to read and write (Fleming, 1981). According to Fleming, from 1850 to 1856, less than 5% of African-Americans out of a population of 4.5 million could read and write.

Just as blacks in America were forbidden to learn to read and write, the same was true in other countries where the controlling population was non-black. In Portugal, for example, Saunders (1982) indicated that very few blacks were able to read and write.

As Opitz *et al.* (1992) indicated as it related to Afro-Germans, "The limitations of educational opportunities concurrent with the favoring of some individuals led to hierarchical structures that undermined the solidarity of the community" (p. 33). In that sense, not only has lack of educational opportunities been utilized to limit the use of the talent and skills of blacks but education has also been used as a force to destabilize communities. That is, education as a commodity has been used as a means to favor some intra-group members over others as a way to undermine community relationships. In Portugal, for example, mulattoes were thought to be more conversant "with Portuguese customs, were supposed to be more gifted intellectually than were blacks from African" (Saunders, 1982: 172).

Therefore, the commonality of the black historical experience in countries where non-blacks are the dominant populations has been the underutilization of the potential of blacks by demeaning their humanity through the slavery experience, destabilizing their communities, exploiting their labor, and limiting their educational opportunities. However, even when blacks were allowed to participate in education, a process of cultural alienation and/or annihilation was implemented.

Cultural Alienation and Annihilation

According to Anderson (1994), one way that the use of power over a less powerful group takes form is "the group with the greater power annihilates the powerless group or drives them out of the territory" (p. 82). Thus, cultural alienation and annihilation can be defined as that process that controlling populations use to minimize or eradicate the culture of minority populations. Generally, this process is synonymous with assimilation, acculturation, or deracination (the term Mankiller (1993) used to describe the mission of boarding schools to annihilate the American Indian culture) – that is, the uprooting or destruction of a race and its culture. More specifically, she stated, "the

primary mission of Sequoyah and the other boarding schools was a full-scale attempt for the children to leave everything behind that related to their native culture, heritage, history, and language" (p. 8).

In order for blacks to assimilate into the dominant culture in different countries, they were often separated (alienated) from their own cultural group or an attempt was made to eliminate (annihilate) their culture altogether. Clear examples of cultural alienation and annihilation can be found across black populations. In Australia, for example, "Between 1910 and 1970 it [Australian Government] forcibly stole up to 100,000 aboriginal children from their families to live with whites in an attempt at forced integration – 'to breed the black out,' as politicians of the day expressed it" (Evenson, 1998: A10). As in other countries, particularly children who – through rape – had white fathers were taken from their families. Pilkington (1996), whose aboriginal name is Nugi Garimara, wrote an intriguing account of the assimilationist policy of Australia that took her mother and her mother's sisters – Daisy and Grace – away from their families. She wrote the following:

Patrol officers travelled far and wide removing Aboriginal children from their families and transported them hundreds of kilometres down south. Every mother of a part-Aboriginal child was aware that their offspring could be taken away from them at any time and they were powerless to stop the abductors. (p. 40)

The aboriginal experience was not unlike that of Black Britons and African-Americans. As it related to the experience of Black Britons, Fryer (1992) indicated that most black Londoners "had been torn from their parents and ethnic groups while still children. They were atomized in separate households, cut off from the cultural nourishment and reinforcement made possible by even the most inhumane plantation system" (p. 70). As a Black Briton recently stated in the popular press (15 August 1999): "I have done a lot of thinking about issues of assimilation and national identity. And I'm beginning to suspect that immigrants can only blend totally into their host environment if they are the same colour as the host or dominant population" (p. 58). Similarly, African-American families were divided. Franklin and Moss (1988) described the process of dividing black slave families in the United States: "Since the domestic slave trade and slave breeding were essentially economic and not humanitarian activities, it is not surprising to find that in the sale of slaves there was the persistent practice of dividing families. Husbands were separated from their wives, and mothers were separated from their children" (pp. 106–107). Although the dividing of families might have been justified for economic reasons, it also served the function of cultural annihilation and/or alienation. That is, when families were divided, they had to reconstruct their social institutions into new forms.

Education has been used as one of the primary channels through which cultural alienation and annihilation have occurred. As Pilkington (1996) noted about the Aboriginal girls who were taken from their family, the belief was that “part-Aboriginal children were more intelligent than their darker relations and should be isolated and trained to be domestic servants and labourers” (p. 40). In a like manner, in America, blacks were treated to educational opportunities differently by color. For example, according to Franklin and Moss (1988), mulattoes had more of a chance of schooling than others.

In addition to using education as a divisive tool based on color among blacks, cultural alienation and annihilation have occurred through the transmission of education. That is, the way in which education has been transmitted (teaching style) and the content of educational materials (curriculum) have discounted the social and cultural capital of black populations (consciously or subconsciously) and have, therefore, minimized the culture of black populations. Researchers such as DiMaggio and Mohr (1985) have suggested that cultural capital is typically specialized social behaviors that make one accepted at different levels of society. Whereas some theorists (e.g., Coleman, 1990) have indicated that while social capital is related to cultural capital, social capital is more related to relations among persons. For example, Coleman (1988) explains social capital as the networks that provide information, social norms, and achievement support.

In simplest terms, the concepts of cultural and social capital mean assets – in the form of behaviors – on which individuals and/or families can draw to meet a certain set of established values in a society (Freeman, 1997). As Freeman noted, these societal values are generally established by majority groups in society and encompass behaviors – such as the way individuals speak to the way they dress. The more individuals are able to meet these established standards, the more they are accepted by different institutions (e.g., schools) in society. There is no doubt, however, the cultural and social capital that students bring to the classroom have tremendous implications for how they will be accepted, treated, and provided necessary information. According to Cicourel and Mehan (1985), students are provided different educational opportunities because students arrive in school with different types of culture capital. Black students typically arrive in school with different cultural capital, and schools, therefore, attempt to eradicate their cultural values in order to make them assimilate.

Who has taught, what has been taught, and how it has been taught over time have severely eroded the cultural identity and educational opportunities of blacks. Although this has been the case historically, black educators and researchers – particularly in the United States – are currently extensively examining and discussing ways to undo the intellectual damage to black children by

demonstrating the importance of valuing the culture of blacks rather than eradicating their culture. For example, several researchers and educators have written about the impact of the influence of the curriculum (what is being taught) on the education of black children (e.g., Banks, 1988; Freeman, 1999; Hollins, 1996; King, 1995).

The school curriculum, as defined by Hollins (1996), is “in fact that package of knowledge, skills, and perspectives that prepares us to develop the attributes of thought and behavior that comply with the prescribed norms” (p. 82). When there are inconsistencies in the compliance of these norms by different cultural groups – in this case, black populations – this can lead to various group members questioning their identity, being turned off from learning, and/or under-performing academically.

The curriculum validates individuals’ culture, history, and sense of self – what is possible. Therefore, when black populations’ culture is not included in the very heart of school, this must create the feeling within students that something is missing. Banks (1988) says it best: “It is important for students to experience a curriculum that not only presents the experience of ethnic and cultural groups in accurate and sensitive ways, but that also enables them to see the experiences of both mainstream and minority groups from the perspectives of different cultural, racial, and ethnic groups” (p. 161). Searle (1994) – a Black British educator – mirrors Banks’ statement. Referring to the national curriculum of Britain, he stated:

The national curriculum, with its gradgrindian sequence of learning and testing, the narrow cultural chauvinism of its approach to knowledge and human experience and its blatantly racist exclusion of cultures, histories, languages and perspectives of Britain’s black people, is already creating a tedium and uniformity which will do nothing to spark the interest and motivation of young people to learn. (p. 26)

It is as though the fact that many black students have underachieved is completely divorced from the curriculum. Linkages have clearly been established between the curriculum and its effect on African-American students’ achievement (Hollins, 1996; King, 1995). As Hollins (1996) indicated, for African-American children the “discontinuity between the home-culture and school learning ultimately disrupts the learning process for many children and the resulting failure may lead them to reject the Euro-American culture and school learning as well” (p. 84).

Aside from what has been taught (the curriculum), as a way to stem the tide of alienation and annihilation of the black culture through education, Black educators have also more recently focused their research on who has taught and how black children have been taught. For example, researchers/educators such as Foster (1997), Irvine (1994), Ladson-Billings (1994), and Siddle-Walker (1996) have examined the role of culturally relevant pedagogy

and the relevance of the cultural perspective of black teachers in black students' achievement. More specifically, these researchers have suggested the importance of historically and currently understanding the role black teachers have played in helping black students achieve.

At the same time that black educators in the United States have focused their research on the inclusion of a black perspective and valuing black culture in the educational system, black researchers in other countries have also begun to address these same issues. Searle (1994) speaking on the British system stated: "The ignorance of teachers and the school system generally about the communities whom they serve is still a vital factor which promotes conflict and misunderstanding between teachers and students" (p. 25). Bridges (1994) – another British educator – supported Searle's assertion. He indicated that more black teachers were employed as a way "of counterbalancing the underrepresentation of black teachers in the borough and, through this, to attack the real problems of underachievement among black children" (p. 4).

Cultural alienation and annihilation have had a devastating effect on black students' participation in education. Over time, the process of trying to breed the black out (assimilation) – whether through the devaluation of the cultural capital of blacks or the what and who of the transmission of knowledge – has severely impacted on black students' sense of self and achievement. As such, there should be little doubt that cultural alienation/annihilation has led to a culture of exclusion for black populations globally.

Culture of Exclusion

Even when blacks have had the opportunity to participate in education, as it relates to black British, Searle (1994) indicated a culture of exclusion has existed. Searle describes culture of exclusion as it relates to Black Britons in this way:

There is much mystification surrounding the word 'exclusion' in education parlance. Schools do not refer to 'expulsions' now, even though almost all parents would know what that means. The preferred term is 'permanent exclusion', but it comes to the same thing. (p. 19)

Searle reported that secondary schools "in Nottingham, Reading, Bristol and the north London borough of Brent showed that black students were up to six times more likely to be suspended from school than their white peers" (p. 24). Drawing on the research of Searle and Bridges (1994), a culture of exclusion, then, can be defined as that process whereby black children are excluded from schooling, whether through suspension or expulsion or placement in the lower tracks of schooling – which would be referred to as "internal expulsion" (Bridges, p. 11).

Educational expulsion (suspension) is a phenomenon that is similarly faced by black populations globally. For example, the honorable Ka (1998) – in a report on the conditions of blacks in Portugal – indicated the following: "The black community in general – and the children and young people in particular – are victims of educational expulsion. The number of those that manage to complete compulsory education (up to the 9th grade) is frightfully low, and even worse if we consider the number of those who manage to complete secondary education (12th grade)" (p. 2).

In the United States – as in Britain and Portugal – a greater number of black children are subjected to suspension or expulsion. For example, a comprehensive study conducted by the Children's Defense Fund (1975) in the 1970s reported the following:

No one is immune from suspension, but black children were suspended at twice the rate of any other ethnic group. Nationally, if they had been suspended at the same rate as whites, nearly 50 percent or 188,479 of the black children suspended would have remained in school. Although black children accounted for 27.1 percent of the enrollment in the districts reporting to OCR, they constituted 42.3 percent of the racially identified suspensions. (p. 12)

In support of these earlier findings, in a more recent study, Morris and Goldring (1999) cited studies that concluded that "desegregation was often accompanied by an increase in the overall student suspension as well as a high disparity between black and white student suspension" (pp. 60–61).

However, the greatest numbers of African-American students are subjected to "internal expulsion." A recent report (Klenbort, 1999) in the Southern Regional Council periodical indicated, as an example, a statement from a high school sophomore who spent his schooling in the lower-level track: "You live in the basement, you die in the basement. You know what I mean?" Researchers, such as Oakes (1985), Wheelock (1992), and Braddock, II and Slavin (1995), support this student's description of tracking or what can be referred to as internal expulsion. Page and Page (1995) describe how tracking became the norm following desegregation: "Schools in the region [Southern region] became increasingly resegregated through the use of tracking, with the majority of African-American students assigned to lower tracks and the majority of Caucasian students assigned to higher tracks" (p. 73).

The way in which tracking can best be thought of as internal expulsion is best captured by Oakes (1985) and Braddock, II and Slavin (1995). For example, Braddock, II and Slavin indicated that the effects of tracking on students were striking. They found that students in lower tracks performed significantly less well than similar low achievers in untracked schools and were much more likely

to end up in noncollege-preparatory programs by tenth grade. This effect, they suggested, “being in the low track in eighth grade slams the gate on any possibility that a student can take the courses leading to college” (p. 8). Oakes suggested that “lower-track students are more alienated from school and have higher drop-out rates” (p. 9). These researchers also found that tracking hurts students’ self-esteem, causing them to feel inferior. Based on these researchers’ findings, then, the effects of tracking on students’ life chances is tantamount to being excluded. That is, black students who are in tracks are in school but because they are more likely to drop out or to have limited opportunities beyond secondary school, in a sense, the school has excluded them. Morris and Goldring (1999) in their study on disciplinary rates of African-American and white students in Cincinnati magnet and nonmagnet schools explained it in this way:

The overall effect of disciplining students, which involves removing them from the classroom, will drastically impact students’ acquisition of educational materials presented by the teacher. Other long term effects might include African-American students falling behind academically, or worse, dropping out of school altogether. (p. 64)

Whether internally excluded or suspended or expelled, black students globally share similar experiences. At least – as described in Britain, Portugal, and the United States – black students comprise the majority of students facing a culture of exclusion. This culture of exclusion has led to the underutilization of blacks in education which, in turn, has implications for societal and individual costs.

Blacks in Education: The Case for an Expanded Research Agenda

This research suggests that to more fully comprehend the educational dilemma of black populations in particular countries, it is important to examine their experiences individually yet collectively. As Lorde (1992) indicated, although particular histories have fashioned the experiences of blacks in different countries, similar historical experiences make the case for expanding the research agenda on black populations – intra-, inter-, and across cultures. This research suggests that a more in-depth comparison of the historical experiences and how the impact of these experiences have constructed the current educational phenomenon in which blacks find themselves, supporting James Anderson’s position to better understand the experiences of black populations. As pointed out in this research, blacks in different countries have had similar historical experiences, and it is important for these to be examined collectively in order to determine where similar programs and models might be instituted.

When cultural differences are taken in considerations, the wheel might not have to be reinvented.

Another agenda that this research suggests is that, not only is it important to expand the research agenda across borders to understand the black educational experience, but it supports the necessity of examining the educational experiences of blacks across disciplinary boundaries. That is better linkages between the different research agenda (whether K-12 and higher education or different aspects of educational phenomena) need to be established. This research demonstrates how each aspect of the black experience impacts on each experience and level of schooling.

To better understand the barriers constructed across cultures to underutilize the potential of blacks’ human potential in countries where non-blacks are the controlling populations, much more research needs to be conducted. In order to more fully understand this process, more research on each point where underutilization occurs has to be explored. This is to understand the costs – particularly the nonmonetary costs – as Bowen (1977) indicated, associated with the underutilization of black potential so that countries better understand how everyone is losing is an imperative. The quote from the Commission on Research in Black Education from Wendell Berry summarizes the imperative of countries to assess the underutilization of the human potential of Black populations: “If the white man has inflicted the wound of racism upon Black men, the cost has been that he would receive the mirror image of that wound into himself.”

Finally, although, it is not enough for countries to assess the costs associated with the underutilization of the potential of black populations, for, this research suggests that – at each point – blacks have been underutilized. At the beginning of the twenty-first century, countries will find it necessary to develop strategies to address the societal and individual costs associated with black populations’ underutilization while simultaneously increasing the utilization of the potential of blacks. Carnoy (1997) describes the way the process of increasing the spending on the underutilization of blacks should work: “The vicious cycle of increasing social costs will gradually break. Down the road, as early-childhood investment reduces spending on adult social problems, more public funds will become available for general education and other activities that improve worker productivity and growth rates” (p. 241). However, countries have not yet been able to develop a formula for assessing the individual and societal costs, therefore, to appropriately target their spending.

For globalization to be successful for individual countries and countries collectively, the potential of all of their citizens have to be utilized. In order to balance this imperative, different paradigms and players have to be a part of the research agenda and the agenda has to be expanded, particularly to address the educational challenges confronting

black populations. This must be done by utilizing the collective, comparative experiences of black populations globally, an internationalist model.

Beyond Racial, Ethnic, and Gender Bias in Education Statistics

J T Lott, Tamayo Lott Associates, Colesville, MD, USA

C Bennett, US Census Bureau, Suitland, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

In recent decades social statistics in federal and other statistical systems were used to measure the progress of the total population, selected racial and ethnic groups, and women. In societies composed of racial majority and minorities, measures are refined to comparing minority populations to the majority. (The term minority in the United States refers to historical racial minority groups (Black or African American, American Indian or Alaskan Native, Asian, Native Hawaiian, or Other Pacific Islander). The term minority also includes Hispanics who may be any race. It excludes non-Hispanic Whites.) When disproportionality or disparity exists and persists, the question of possible bias arises. Given the existence of equal opportunity policies and programs, including education ones, for several decades, it is time to consider the further utility of this disparity measure. This article suggests an alternative measure of productivity for the present and foreseeable future. A twenty-first-century perspective of education focuses on maximum productivity for each student which may include, but is not limited to, race, ethnicity, and gender. Twenty-first-century education will be multidimensional, engaging, and increasingly unbound by traditional paper media, requiring fluency in many languages. In today's global, knowledge-based economy, the economic growth and social well-being of nations around the world are increasingly dependent on a well-educated workforce and individual access to quality education. Shared knowledge, ongoing learning, and skilled intelligence are key factors defining education in the twenty-first century.

At the national level, the United States is a timely case to better understand relevant education and human capital for the twenty-first century and the role of bias. The evolution of racial, ethnic, and gender bias in education statistics is rooted in US legal and demographic frameworks. The US was founded as and continues to be a nation of immigrants and refugees. One-third of its population is minority whose share of the total population is projected to increase. The US joins other nations in addressing three major trends in twenty-first-century education: (1) the growing impact of electronic information, including statistical data, (2) continuing educational disparities despite greater choices, and (3) education beyond borders. At the international level, other federal statistical systems consider race, ethnicity, or gender as a proportion of the population and in measures of disparity and productivity. Globally, The Dakar Framework for

Action, Education for All: Meeting Our Collective Commitment of the World Education Forum reaffirms that education is a fundamental human right for all children and adults.

Toward a Twenty-First-Century Perspective of Education

Meaning and use of statistics and other data are based on context. The twentieth-century context for race, ethnicity, and gender in education statistics was the status of US minorities and females compared to white males. Traditional bias has focused on measures of inequity, specifically disparity between majority White men, who traditionally had greater access to education. This focus has become problematic as White men are a relative, not an absolute, standard of equality. In recent decades, access to education at all levels from preschool to postgraduate school is rising. In particular, minorities have increased their high-school graduation and college-enrolment rates. In the US and some majority White postindustrial nations, the addition of immigrants and foreign students/faculty form a sizable presence in higher education, particularly in the sciences, mathematics, statistics, and engineering. Regarding gender, the rising proportion of women in higher education has been accompanied by the decrease of men's enrolment in and graduation from selected degree programs. These shifts suggest an alternative twenty-first-century perspective of education on the role of racial and ethnic minorities and women that goes beyond closing disparities with White men. An alternative twenty-first-century perspective is to ensure education for all members of society that allows maximum productivity for an informed citizenry and competitive workforce beyond race, ethnicity, and gender.

We cite three trends that support such an alternative. First, ready access to electronic data means an increasing global capacity to collect more varieties and quantities of data. From a research perspective, this means going beyond historically labor-intensive longitudinal and cross-sectional survey data to embracing cutting-edge dynamic, real-time administrative, biometric, and geospatial data. From a societal perspective, the general public is inundated by statistics and other data 24 h, 7 days a week. Yet, higher expectations for accessible data continue. What are the implications for an educated society when individuals can

readily learn what they need, or think they need, online? What are the implications for the digital divide and thousands of years of fact-to-face and hands-on learning? These questions are addressed below in the section titled Growing Impact of Electronic Information, including Statistical Data. A second trend is that disparities across and within groups continue, despite greater educational choices and access. This occurs even as pluralism increases in the twenty-first century. In the United States, for example, traditional minorities were already becoming the majority in selected cities by 1990. At a global level more nations are becoming more pluralistic given greater migration. Are new disparities, biases, or other priorities arising from a change of relations? This question is addressed below in the section titled 'Continuing disparities despite greater choices and greater access'.

A third trend is that the concept of education in the twenty-first century has outgrown its twentieth-century meaning; in the twenty-first century, education is without borders. A strategic discussion in the twenty-first century is warranted on: (1) the idea of what is education; (2) what is the value and utility of education; and (3) who pays for it? These questions are addressed below in the section titled 'Education beyond borders'.

The Case of the United States: A Nation of Immigrants

For a better understanding of relevant future education and human capital, we use the case of the United States. From a demographic perspective, the US, has an over 200-year history of heterogeneous demography due to a variety of settlers from Europe, Africa, Asia and the Pacific, the Middle East, and the Americas. Except for Native Americans and African slaves, the US evolved from refugees, pioneers, and immigrants. Continued population growth and heterogeneity are due to open immigration and refugee policies based on family reunification, labor needs, and humanitarian concerns, and due to fertility rates at replacement levels or higher. Finally, as a nation with separation of powers between church and state, the US population tolerates various religions, languages, and cultures.

Local and state governments initiated universal public education in the nineteenth century for elementary and secondary education led by reformers such as Horace Mann. By 1870, every state provided free public education. Statistics on education was a natural response to the increase in the US population and the need for an educated labor force. The 1840 census was the first to include data on school enrolment. The 1870 census marked the first time that women were included in the labor-force count.

Civil rights statutes and educational/employment-opportunity policies also shaped data collection for a more diverse population and labor force. During World War II, women and minorities assumed positions traditionally reserved for White men in civilian and military occupations. Rosie the Riveter symbolized women's ability to do men's work. Minorities and women began their permanent expansion into nontraditional occupations. Integration of US military forces after World War II was the first postwar civil rights policy facilitating a multiracial labor force. This was followed by the 1954 Supreme Court decision *Brown versus the Board of Education* that struck down the policy of separate but equal public education between White and Black and other minority children. In 1965, the national-origins quota, which had maintained a White majority and non-White minority for decades, was abolished. With 1965, amendments to the McCarran-Walter Act, US born minority populations began to grow. Refugees of the Vietnam War further increased the growth of non-White population in the 1970s and the 1980s, especially in school enrolments from prekindergarten to high schools. These two processes of increased immigration, especially from Asia and Latin America and increased births of non-White populations were noted by careful observers at local, regional, and federal levels.

A steady increase in the proportion of females in higher education and in the labor force also occurred. The launch of Sputnik in 1958 awakened the US to the need to increase the pool of young Americans proficient in mathematics, science, and engineering. While young women in high school were encouraged to take higher level courses alongside their male classmates, they still comprised a minority in colleges in 1960. By the 1970s, affirmative action policies, notably Title IX of the Higher Education Act sponsored by Congresswoman Patsy Takemoto Mink, facilitated the admissions of women to higher education and professional schools traditionally limited to men.

Education was characterized by public funding, local and state control, separation of church and state, and an academic curriculum for an expanding industrial economy. Tuition was free or minimal in the public state universities. For example, through the 1970s, the University of California and state university systems did not charge tuition for undergraduates. University of California, Berkeley, the system's flagship, was and continues to be renowned as a world-class research center. American and foreign parents and their children actively sought, and many times sacrificed for, a US education. All the above, taken together, contributed to the rise of the US as an economic and intellectual world power.

Nevertheless, during the same period, two reports indicated that all was not well. In the 1970s, the US joined a growing list of nations including Canada, France, Germany,

Great Britain, Japan, the Netherlands, and the Philippines in producing social indicator reports (US Commission on Civil Rights, 1978). Such reports generally focused on indicators that measured production, consumption, and satisfaction. In its social indicators report, *Social Indicators of Equality for Minorities and Women*, the US Commission on Civil Rights (1978) focused on the degree of inequality in the distribution of resources in the society. The study analyzed data from the 1960 and the 1970 censuses and 1976 survey of income and education, a supplement to the current population survey. It focused on the underdevelopment of human skills through delayed enrolment, non-enrolment in secondary education; and nonparticipation in higher education. It examined rates of delayed education, being behind in school, high-school nonattendance rates, and educational attainment. In terms of labor-force participation, it looked at the lack of equivalent returns for educational achievement in terms of occupational opportunities and earnings, earnings for educational levels, and occupational mobility. The study found continuing and serious problems of inequality between women and minority men compared with majority men.

The second prescient report was the landmark *A Nation at Risk*, issued by the National Commission on Excellence in Education (1983). It identified major deficiencies in the overall quality of education in America and stated that “the educational foundations of our society are presently being eroded by a rising tide of mediocrity that threatens our very future as a Nation and a people” (1983). Further, it indicated that American students were no longer competitive with students in many other countries and “that individuals in our society who do not possess the levels of skill, literacy, and training essential to this new era will be effectively disenfranchised, not simply from the material rewards that accompany competent performance, but also from the chance to participate fully in our national life.” A high level of shared education is essential to a free, democratic society and to the fostering of a common culture, especially in a country that prides itself on pluralism and individual freedom. The report urged America to consider new approaches to public education while continuing to define public education as an institution financed and operated by the government.

In 2001, President George W. Bush addressed education reform with the No Child Left Behind Act. This Act called for education reform in public schools that ensures high standards and accountability to students with specific emphasis on mathematics and reading skills. Between 1972 and 2005, the percentage of racial and ethnic minority students enrolled in the nation’s public schools increased from 22% to 42%, primarily due to the growth in Hispanic enrolment (US Department of Education, 2007a). The number of children of ages 5–17 who spoke a language other than English at home more than doubled between 1979 and 2005. While Spanish is the predominant second

language in the US, many school systems have children from families speaking dozens of languages. For example, over 150 languages are spoken in the Miami-Dade School system. In Maryland, the second most frequently spoken language is Haitian Creole and in Iowa, it was Hmong. “It is clear that America must determine the manner in which we will manage this language diversity. But, in a real sense, we must also capitalize on these skills. National security concerns clearly call for a nation increasingly fluent in multiple world languages. With the diversity clearly present in our nation’s schools, these concerns can be addressed with our current population of students. America’s schools clearly face the challenge of including these children and to providing them with language acquisition skills necessary to function in an English-speaking culture. At the same time, we must understand that fluency in these languages is a cultural and economic benefit for the society as a whole” (National Association of State Boards of Education, 2008).

In 2007, the US population was estimated to be 301.6 million. The single-race White non-Hispanic population was 199.1 million or 66% of the total population and 34% or 102.5 million were racial and ethnic minorities (US Census Bureau, 2008a). According to data from the National Assessment of Educational Progress (NAEP), 33% of fourth graders and 26% of eighth graders scored below basic in reading. However, for both Black and Hispanic fourth graders, the percentages were greater than 50% and for eighth graders the figures were 53% for Blacks and 43% for Hispanics. At both the fourth and eighth grades, a higher proportion of males than females scored below basic in reading (US Department of Education, 2007b). A similar picture existed in mathematics. Eighteen percent of fourth graders and 29% of eighth graders scored below basic in mathematics. Similar to performance in reading, a larger proportion of Black and Hispanic students scored below basic in mathematics and males’ scores were less than that of females (US Department of Education, 2007c).

Have We Reached the Top? Educational Attainment Projections of the U.S. Population (Day and Bauman, 2000) illustrates some of the factors to be considered beyond race, ethnicity, and gender in educational attainment. These include age, cohort, immigration, and questionnaire effects. In answering the above question, Day and Bauman examined three major influences – the process of cohort succession, ethnic shifts in the US population, and immigration. These influences were also noted in an earlier report commissioned by the US Department of Labor, *Workforce 2020*. A major theme of both works is that minority education is directly tied to concerns about the quality of the American labor force. Day and Bauman found that the cohort succession rate remains powerful enough to raise overall education levels. They also noted, however, that if younger cohorts were to attain less education, then their

projections may be overly optimistic, and that any policy designed to address educational growth needs to be flexible enough to address the particular challenges facing various groups. This conclusion reinforces the complexity of understanding educational attainment, addressing disparity, and promoting productivity.

In summary, equal educational opportunities of women and historical minorities have expanded since the 1960s. Studies track growth in accession, retention, and graduation rates from high school and college. Of equal note is the growing presence of minorities and women as employees and managers in education professions, from school systems to flagship universities. Various indicators suggest that progress has occurred, especially among younger cohorts. Children of color and White girls have a range of educational and occupational opportunities open to them that were denied their parents and grandparents. Immigrants – both White and of color – continue to come to the United States so that their children can obtain a US education. At the same time, research suggests strengths and limits of educational data by race, ethnicity, and gender. Disparity gaps are closing in some areas but replaced by new ones. Progress is mixed. It is still important to be cautious concerning the explanatory power of data and possible misuse of statistics. They are limited given the paradox of diminishing competitive educational achievement amidst programs to close disparities. This is a crucial point as the United States shifts to greater proportions of minorities and women. At the global level, the parallel shift is migration of residents from the southern hemisphere to become immigrants in northern hemisphere nations, increasing their proportion.

Growing Impact of Electronic Information, Including Statistical Data

Past discussion on minorities and women in the US showed a dearth of data on these populations. That is not so in the twenty-first century with voluminous and various data sets. The challenge is to manage and make sense of data given the various research methods and formats and different definitions of these populations. Moreover, ready access to electronic data means an increasing global capacity and higher expectations to collect more varieties and greater quantities of statistical data 24/7.

Current debates on whether a digital world closes or widens disparities between haves and have-nots are not new. They mimic the debates on whether television was a medium for increasing public intelligence or shifting to the lowest common denominator of mediocrity. In *The Medium is the Massage*, McLuhan (1967), who also coined the term global village, illustrated that media are extensions of human senses, minds, and bodies. He noted

that worldviews and how humans process information are changed by the adoption of new media.

It is not yet clear what the implications are for an educated society when individuals can readily acquire what they need and want online particularly in the absence of universally adhered to standards and principles. What are the implications for the digital divide and thousands of years of face-to-face and hands-on learning? What is the role of wikis, blogs, and other nontraditional ways of creating, collecting, and verifying information and transferring knowledge that might suggest not just bias in educational statistics but also in what it means to be educated?

While technological literacy is crucial for an educated society and workforce, it does not replace the traditional human survival skills of critical thinking, processing of a wide range of knowledge and information, tacit knowledge, fluency in world languages, face-to-face group learning and communication, learning by doing, research and experimentation, and the apprentice-to-master learning tradition. Neither does it substitute for the tradition of scientific thought and method. Education is much more than quicker computation or easy information retrieval. Education entails interpretation, context, meaning, and reflection to appreciate and understand lag time between observation of phenomena and making sense of them.

Continuing Disparities Despite Greater Choices and Greater Access

The United States and other pluralistic societies are facing the paradox of continuing disparities despite greater choices for consumers, individuals, and groups. At a global level, more nations are becoming more pluralistic given greater migration. Much of this migration is primarily from Third World nations to First World nations. Nations such as China, Brazil, India, and Argentina comprise an intermediate group or second world emerging out of third-world poverty on the path to a sizable middle class. Are there new disparities and biases or perhaps other priorities arising when choices may not be limited to black and White, and to haves and have-nots?

For example, in the past 40 years, women have increased their proportion of undergraduate degrees. While they currently hold more than half of bachelor's degrees among adults 25 years and older in the US, men remain slightly more likely than women to hold at least a bachelor's degree (28% compared with 26%) (US Census Bureau, 2008b). About 33% of young women 25–29 had a bachelor's degree or more education in 2007, compared with 26% of their male counterparts. Yet these degrees are largely in female-dominant majors ensuring the continuing disproportion and segregation of women in traditional female occupations.

A second example is that, in 2006 about 49% of Asians aged 25 and older had at least a bachelor's degree compared with 30% of non-Hispanic Whites, 17% of Blacks and 12% of Hispanics (US Census Bureau, 2008b). The proportion of the foreign-born population with a bachelor's degree or more was 28% with 29% of the native population. However, the proportion of naturalized citizens with a college degree was 34% (US Census Bureau, 2008b). Other research indicates that Asian Americans equal, or surpass, Whites on standard achievement tests. Asian foreign nationals and other immigrants are disproportionately enrolled in and graduate from math, science, and engineering doctoral programs compared with Americans. On the other hand, other research raises the question of whether there is a quota on Asian Americans in admissions to first-tier schools.

Hirschman's life-course perspective and life-table research (Hirschman *et al.*, 2007) suggests that choices at various stages of an education do not occur in a vacuum. Individual educational behaviors are not isolated events. For example, dropping out of school is a significant milestone hindering access and ability to take advanced courses or graduating from high school let alone going to college. Tracing the enrolment status of cohorts of students through high school and the rigor of instruction they undertake in timely sequence provides new insights into the temporal dynamics of attrition, retention, exit, catching up, and reentry. Innovative work like that of Hirschman and his demographic colleagues provide integrated models that consider individual and systematic social background risk factors, actual school experiences, and cumulative decisions in the probability of educational success.

Students and their parents in the US find a wide array of competing choices. Superficially, such choices seem beneficial but they are not without consequences that may exacerbate disparities. For example, in recent decades, minority students have been recruited to attend first-tier universities so they can choose from a variety of colleges. One of the consequences has been creaming the historically Black colleges and universities and institutions traditionally serving Hispanic, American Indians, and Asian Pacific Islanders of top students and future leaders. Another choice is the heterogeneity of children in a classroom. This has gone from the legislative mandate to integrate White and non-White children in public schools to mainstreaming disabled children. Such heterogeneity can be overwhelming for students, teachers, and parents. Current consequences of such choice include placing gifted and talented magnet programs of primarily White students in primarily racial/ethnic minority schools or what some education critics call a school within a school. Other parents respond with counter-choices removing their children from public schools to private and charter schools or to home schooling. Along with public education, a host of private and corporate-education programs are now

available for a price. They provide certificates but not necessarily degrees. They may or may not be state certified. Another recent choice is that students have a range of faculty from tenured professors to lecturers. American universities more and more rely on teaching assistants and adjunct faculty. They may not have benefits and privileges or even an office in which to meet with students. This is a new disparity between first-tier and second-tier faculty, especially as the latter increase their proportion of total faculty. While more students can choose to go to college and earn a PhD, the reality is fewer numbers are being employed in tenure track positions. While there are more ways to fund an education, the reality is that undergraduate and graduate students even in public state universities incur sizable debt to attain their degrees.

These current practices and programs are being watched closely for new disparities, especially for students most at risk. Routine mechanical and clerical tasks are becoming obsolete and being replaced with computerized tasks. The new reality is that there may be more disparity as jobs in the twenty-first century will require critical thinking and problem-solving skills, not just multiple-choice or fill-in-the-blank mechanics. Employers in the twenty-first century require employees who possess an understanding of science, mathematics, and technology and the critical-thinking skills that underlie these topics. They look for employees with soft skills who possess diplomatic communication and team-building skills. They search globally for such employees.

Elimination of choices and access also occurs. Post-1996 research indicates that neighborhoods and schools are returning to levels of racial segregation witnessed in the 1960s. In California, in the aftermath of Proposition 209, the number of Black students on University of California or California State University campuses has declined or remained steady, while all other races increased enrolment over the decade. According to Allen and others, systematic reproduction of racial and ethnic disparities results in lower Black and Latino college enrolment; a negative climate for students of color in recruitment, retention, and achievement; the educational value of diversity not fully realized to benefit all students and faculty; and US competitive disadvantages in the global economy as producers and consumers (Allen *et al.*, 2004). Now, when the state most needs its public colleges and universities to educate the next generation of workers and to help boost economic prosperity, college opportunities are rapidly declining for African Americans and Latinos (Allen and Jaykuma, 2007).

In the twenty-first century, historical minorities and new immigrants from less-traditional areas including Latin America, Africa, the Middle East, and Asia provide a ready pipeline of human capital. This is imperative given the already high labor-force participation rates of American men and women. Racial and ethnic minorities comprise one-third of the population and are expected to

grow. Such experience may be instructive to other nations moving from a less-homogeneous society with a clear majority and minority in relationships of inequality. In the twenty-first century, postindustrial societies in a competitive global economy are dependent on a widely educated workforce that is composed primarily of women, traditional, racial, and ethnic minorities, and new immigrants from both very old and emerging cultures.

Education Beyond Borders

A third trend is that the concept of education in the twenty-first century has outgrown its twentieth-century meaning. It is time to move beyond measures of disparity by race, ethnicity, and gender to education beyond borders. A strategic discussion is warranted on: (1) the idea of what is education; (2) what is the value and utility of education; and (3) who pays for it?

The above are not academic questions. A parallel discussion is surfacing regarding bias/inequality in the labor force as employers shift from retirement systems with defined benefits to retirement systems with defined contributions. The notion of permanent jobs with a career ladder is giving way to serial, less-than-permanent jobs, and multiple careers with a growing contingent workforce; some of which is outsourced. In this new economic and global order, racial and ethnic minorities, and women are not only increasing their roles in education and the workforce, but they constitute the majority of intellectual and human capital required for a society's reproduction, productivity, and competitive capital as well. Traditional bias by race, ethnicity, and gender as depicted by statistics and other data based on twentieth-century theory and methods are insufficient to understand what is education and its value and costs to all.

Education takes place in conditions ranging from a one room, rural classroom with one teacher instructing students in many grades to individual students tapping into distance learning all over the world beyond physical borders. Degrees, credentials, and certifications connote a measure of formal education. For the twenty-first century, however, education is not necessarily synonymous with credits earned toward some finite degree or credential. Rather, ongoing learning and the sharing/creation of knowledge are lifelong processes for individuals and organizations. Increasingly, innovation, and creative productive capital demand a multidisciplinary approach, not specialization. That is, education is beyond borders.

This is not to say that there is no longer a role for formal education but to acknowledge the value of ongoing informal education and shared knowledge, especially performance-based knowledge and team work. For example, emergency and rescue workers and medical personnel continuously build upon formal education and training

by collectively adapting to real-life situations. They extend existing knowledge when faced with situations not covered in formal training. Formal and informal education contributes to shared institutional knowledge. Education in the twenty-first century builds upon a cumulative human heritage and legacy of shared creativity and innovation which requires multiple perspectives, interdisciplinary contributions, fluency in multiple languages, shared memories, and collective experience. As such, education is a fundamental public good for an informed society. It is inclusive not exclusive. It is accessible to all.

The case of California is instructive in this regard. Free public education for all was the prevailing philosophy of California for most of the twentieth century. For its historical agricultural and military industries and the emerging film/entertainment, aerospace, science, finance/banking, and silicon/electronic industries, investment in human capital defined the California educational system. Education was for all segments of the population. Access was through free public education from elementary and secondary levels to public higher education resulting in flagship public universities and world-renowned research centers. The state's exemplary system of public higher education provided a steady supply of college graduates for what was one of the country's most highly skilled labor pools. Educational opportunity was directly related to societal outcomes. A well-educated workforce was responsible for the economic success and competitive human capital of California. Nonetheless, with Proposition 13 in 1978, California reversed the earlier philosophy of education as a fundamental public good. Proposition 209 in 1996 went further with state voters amending the state constitution to prohibit state and local governments from discriminating against or granting preferential treatment to anyone on the basis of race or sex. In the first decade of the twenty-first century, not just in California, but in other public school systems and public universities, education is no longer free or readily affordable within many family budgets, except for the wealthy.

This is a serious dilemma for policymakers, educators, employers, and families. While education is not without costs, the lack of education is much more costly. Employers compete with one another for a finite global pool of skilled labor. Employers contend with employees who lack a work ethic. Teachers worry about teaching to the test and some students work only for a desired grade. Parents consider whether they will have to support their children in adulthood. Policymakers grapple with increasing children and adult-dependant populations, and a decreasing competitive workforce. Educational opportunity and access are related to societal outcomes. The cost of a poorly educated population in terms of workforce and citizenry can also go beyond borders. The challenge is to again view education as a public good and sound human-capital investment that appreciates.

The Case of the Global Village

The opportunities and possibilities of an educated world are boundless. From a data perspective, federal statistical systems are concerned with accurately describing human phenomena by demographic, geographic, social, and economic characteristics. They seek to address and measure in a better manner, the disparate and productive status of racial/cultural minorities and women through international conferences such as Challenges of Measuring an Ethnic World (Statistics Canada and the US Bureau of the Census, 1993). Such intellectual inquiry and civic accounting is part of the greater education of the global village. An electronically connected world with more rapid and frequent travel and residence abroad provides a greater proportion of the world's population to education beyond national or pedagogical boundaries. Study abroad, traditionally reserved for college student-exchange programs, is growing from elementary schools to corporations. Such exciting challenges and opportunities connect world citizens to different cultures, languages, and traditions of learning while sharing knowledge and affirming commonalities.

Migration across national boundaries, including the growing feminization of immigration, will continue due to needs of a global economy. Given the population imbalances by size, and age distribution between northern and southern hemispheres, new and younger workers from the latter will migrate to the former to attend to aging populations with growing dependency ratios.

Through individual nation's initiatives and collective ones, the global village is addressing the importance of education particularly for underrepresented and disenfranchised groups for the greater good. It still takes a global village to raise a child. *The Dakar Framework for Action-Education for All: Meeting Our Collective Commitment* was adopted by the World Education in Dakar, Senegal during 16–28 April 2000.

It is an example of a collective initiative drawn from education forums in sub-Saharan Africa, the Americas and the Caribbean, the Arab States and North Africa, Asia and the Pacific, and Europe and North America. The framework states that, "Starting from early childhood and extending throughout life, the learners of the twenty-first century will require access to high-quality educational opportunities that are responsive to their needs, equitable and gender-sensitive. These opportunities must neither exclude nor discriminate. Since the pace, style, language, and circumstances of learning will never be uniform for all, there should be room for diverse formal or less formal approaches, as long as they ensure sound learning and confer equivalent status" (UNESCO, 2000).

It further notes, "The right to education imposes an obligation upon states to ensure that all citizens have opportunities to meet their basic learning needs. Primary

education should be free, compulsory and of good quality. The education systems of tomorrow, however diversified they may be, will need to be transparent and accountable in how they are governed, managed, and financed. The indispensable role of the state in education must be supplemented and supported by bold and comprehensive educational partnerships at all levels of society. Education for 'All' implies the involvement and commitment of all to education." The cost and return on investment in education to individuals and society are being questioned nationally and globally. Productivity, rather than disparity, across populations nationally and internationally is a more realistic measure of returns on investment to education for current and future generations of a global village.

Summary

A twenty-first-century perspective of education focuses on maximum productivity for each student undemarcated by, race, ethnicity, and gender. It is inclusive of various learning styles complementing traditional time-tested ones with new innovations; greater access to, appreciation of, and facility with various cultures and languages; and teaching/learning through various media both low and high tech. Education will be multidimensional, engaging, and increasingly unbound by traditional paper media and traditional disciplines. Workers in the most productive and better paying jobs will be proficient in reading, writing, mathematics, and computer technology, while fluent in timeless soft skills of civility and world languages. Knowledge, learning, information, and skilled intelligence for the greater good will be the hallmark of education in the twenty-first century.

Glossary

Manu – A sixth-century Hindu scholar and philosopher. The laws of Manu consist of 2685 verses on topics interrelated in Hindu thought which is in sum an encompassing representation of life in the world, as it is, and how it should be lived.

Purusha – This finds mention in the Rig Veda in Hindu spiritual literature and in its most literal sense means man. This is not a generic for human, but includes the masculine sense and principle of the world. He was the source of all creation. It describes this form of his, as having countless heads, eyes, legs, manifested everywhere, and beyond the scope of any limited method of comprehension. All creation is but a part of him.

Varna – Taken from the Sanskrit word which means to choose from a group. Hindu society was divided into four *varnas*, the Brahmin, *Kshatriya*, *Vaishya*, and *Shudra* and these groups had social and occupational differences among them. Varna literally means color referring to distinctions between dark and fair.

Vedas – The Vedas are the ancient scriptures of the Hindu teachings which manifest the divine word. There are four Vedas: the Rig Veda, Sama Veda, Yajur Veda, and Atharva Veda. The Vedas contain hymns, incantations, and rituals from ancient India.

Introduction

India has attracted the attention of several scholars both national and international particularly in the field of sociology due to the intricacies woven into the country's social fabric. One among these has been the interest in a particular aspect of stratification, a term considered a unique feature of Indian society – caste. This stratification refers to a hierarchical division between people on various grounds like religion, caste, occupation, etc. Intrinsically woven into any system of stratification is the notion of superordination and subordination, one that divides society into different strata. In Indian social reality, the caste system emerged as a major base for stratification.

The multiplicity of definitions of the term caste suggests the wide interest in the concept and brings to light

different perceptions on the issue. While historically the effects of the caste system were seen in every sphere of life, today the same exists but mostly has subtle undertones. The word caste has Spanish and Portuguese origins and comes from the word *Casta* meaning lineage or race. It began to be used in the Indian context in the seventeenth century. Various definitions of caste brought forth a few similar key features:

- functional interdependence – economic, political, and ritual;
- rules that safeguard level of caste-group purity;
- hereditary occupation;
- no opportunity for members of lower groups to rise into the upper groups;
- backing of social institutions: as a subsystem and sub-subsystem;
- necessary justification provided for enforcement of caste duties and obligations by Hindu religion;
- ascribed status;
- closed system;
- endogamous;
- segmentary – divided into subcastes which are themselves endogamous;
- predicated on graded social inequality;
- purity–pollution; and
- hierarchy.

Origin of Caste

Many studies of caste have reached different conclusions about its origin. One theory was that of Divine Will indicating division of *Purusha* – the creator into the four main *Varnas*, the Brahman, *Kshatriya*, *Vaishya*, and *Shudra* (Table 1). Paralleling this theory and drawing from the Rig Vedic hymns was the law of Manu justifying social differences by laying out the tasks for each caste. Another explanation was the Aryan invasion of India wherein they defeated the dark-skinned indigenous Dravidians. Thus, it was believed that the Brahmins hailed from the Aryans whereas the *Shudras* hailed from the Dravidians.

One of the reasons why the caste system was able to exist was the functional interdependence in Hindu society, permitting a wide range of differentiation without hampering the social fabric. The religious basis given to the caste system made it easier for the upper castes to perpetuate the differences and enjoy the accruing privileges of suppressing the lower castes.

Table 1 Broad *varna* and caste categories with their occupational and social status and estimated population^a

<i>Varnas</i>	<i>Broad categories of castes</i>	<i>Social status and occupations</i>	<i>Percentage</i>
1. Brahmin	Brahmins (upper (high) castes)	Performing rituals and teaching	3–4
2. <i>Kshatriya</i>	Middle castes	Warriors and landlords dominant	20
3. <i>Vaishya</i>		Traders and moneylenders	
4. <i>Shudra</i>	Lower castes (OBCs)	Artisans Peasants	52
5. Scheduled castes (untouchables)	Lowest but out of <i>varna</i> system	Menial occupations Polluting status	16
5. Tribals		Primitive lifestyle Physical isolation	8

^aEach *varna* consists of several castes based on hierarchy among themselves and all of them practice untouchability with scheduled castes (SCs). SCs were constitutionally recognized after independence based on their polluting status, as untouchables with special provisions for their socioeconomic development. Even the SCs numbering 1092 have hierarchy and practice of untouchability among themselves. Untouchability was legally banned in 1955. Enumeration of SCs and scheduled tribes (STs) is done only by the Government.

The interpretation of caste saw heterogeneous conceptions. While some saw it as a division of labor, others such as Dr Ambedkar pointed out that it was in fact a division of laborers into water-tight compartments graded one above the other. The assertion of an individual's own freedom of expression is the way to social reform; if in fact this desire is thwarted and controlled by certain groups, it cannot lead to any kind of reformation. The caste system through its rigid control kept the lower castes from acquiring the intellectual and social inheritance that the upper castes were fortunate to have received.

Contemporary Indian society is also witness to social discrimination based on caste divisions. Disadvantaged groups in society today include the scheduled castes (SCs), scheduled tribes (STs), and the other backward classes (OBCs). Legally they have been referred to as follows, in the Constitution of India:

- Article 341: Scheduled Castes

1. The president may with respect to any state or union territory, and where it is a state, after consultation with the governor thereof, by public notification, specify the castes, races, or tribes or parts of or groups within castes, races, or tribes which shall for the purposes of the constitution be deemed to be scheduled castes in relation to that state or union territory, as the case may be.
2. The parliament may, by law, include in or exclude from the list of scheduled castes specified in a notification issued under clause (1), any caste, race, or tribe or part of or group within any caste, race, or tribe, but save as aforesaid a notification issued under the said clause shall not be varied by any subsequent notification.

- Article 342: Scheduled Tribes

1. The president may with respect to any state or union territory, and where it is a state, after consultation with the governor thereof, by public notification, specify the tribes or tribal communities or parts of or groups within tribes or tribal communities which shall for the purposes of the constitution be

deemed to be scheduled tribes in relation to that state or union territory, as the case may be.

2. Parliament may by law include in or exclude from the list of scheduled tribes specified in a notification issued under clause (1), any tribe or tribal community or part of or group within any tribe or tribal community, but save as aforesaid a notification issued under the said clause shall not be varied by any subsequent notification.

- Article 340(1): Other Backward Classes

The president may by order appoint a commission, consisting of such persons as he thinks fit to investigate the conditions of socially and educationally backward classes within the territory of India and the difficulties under which they labor and to make recommendations as to the steps that should be taken by the union or any state to remove such difficulties and as to improve their condition and as to the grants that should be made, and the order appointing such commission shall define the procedure to be followed by the commission.

- Article 340(2)

A commission so appointed shall investigate the matters referred to them and present to the president a report setting out the facts as found by them and making such recommendations as they think proper.

Adhering to Article 340, the first backward classes commission was set up by a presidential order on 29 January 1953 under the chairmanship of Kaka Kalelkar.

For identifying socially and educationally backward classes, the commission adopted the following criteria:

1. low social position in the traditional caste hierarchy of Hindu society;
2. lack of general educational advancement among the major section of a caste or community;
3. inadequate or no representation in government services; and
4. inadequate representation in the field of trade, commerce, and industry.

The commission submitted its report on 30 March 1955. It had prepared a list of 2399 backward castes or communities for the entire country and of which 837 had been classified as the most backward.

There was considerable divergence of opinion among the members of the commission as to what should be the criteria of backwardness. However, the commission in its final report recommended caste as the criteria to determine backwardness. However, this report was not accepted by the government as it feared that the backward classes excluded from the caste and communities selected by the commission may not be considered and the really needy would be swamped by the multitude and would hardly receive special attention. Thus, there was a need of second backward classes of commission.

The decision to set up a second backward classes commission was made official by the president and the commission was popularly known as the Mandal Commission, its chairman being B. P. Mandal.

The Mandal Commission Report of 1991 was in favor of reservations in higher education and government services for the other backward classes of India.

With a view to provide safeguards against the exploitation of SCs and STs and to promote and protect their social, educational, economic, and cultural interests, special provisions were made in the Constitution. Due to their social disability and economic backwardness, they were grossly handicapped in getting reasonable share in elected offices, government jobs, and educational institutions and, therefore, it was considered necessary to follow a policy of reservations in their favor to ensure their equitable participation in governance. Thus, a national commission for scheduled castes and scheduled tribes was set up in 1978. Consequent upon the Constitution (Eighty-Ninth Amendment) Act, 2003 (Annexure II of the handbook), the erstwhile national commission for scheduled castes and scheduled tribes has been replaced by (1) national commission for scheduled castes, and (2) national commission for scheduled tribes.

Castes and Education

India is a country with 1028.7 million as its population according to the 2001 census report, with 72.2% living in rural areas and 27.8% in urban areas. The sex ratio is 933 females per thousand males. The population of scheduled castes is 166 635 700 accounting for 16.2% and scheduled tribes is 84 326 240 making up 8.2% of the country's population. Exact figures are not available but the population of OBCs is estimated to be at 52% of the country's total population. Demographically a diverse population, India is sated with caste and class problems. While education began inducing the spirit of social transformation, inequalities in the system still in certain ways

strengthened the hold of the upper castes. The link between caste and education has been there since the time of inception of the caste system in India. Formal education was confined only to the study of the Vedas in schools which were established for this purpose. The state did not hold itself responsible for opening establishments for the study of the arts and sciences that concerned the life of merchants and artisans. In the absence of a formal education system, each caste managed to transmit to its progeny the ways of doing things it was traditionally involved in doing. Therefore, illiteracy became an inherent part of the caste system by a process that was indirect to Hinduism. The education provided was religious education in the classical language of Sanskrit and only the Brahmins could teach the same. It was a direct result of the rule relating to the rights to teach and study the Vedas. Brahmins, *Kshatriyas*, and *Vaishyas* could study the Vedas, Brahmins could teach, and *Shudras* could not study and were not even allowed to hear it. If *Shudras* disobeyed, the offence was punishable with direct penalties.

In the period from seventeenth to nineteenth century, the British East India Company took over the Moghul empire in India and exercised political power in order to manipulate and control trade in India to their advantage. While they had no interest in reforming the Indian society socially or religiously, their endeavors to introduce development strategies were for their own vested interests. Bearing witness to this was the emphasis on English education also considered as modern which was restricted to reserved sections of society like children of employees of the company (East India Company), Anglo-Indian families, and Indian upper-caste Christians. Introduction of these new forms of education in a way was perpetuating the caste system by restricting access to people from the upper castes.

Beginning of the twentieth century, there was a tendency of caste organizations and associations to enter into education to spread education through the establishment of institutes by building schools and hostels for their own children.

Postindependence, national progress was the aim of policymakers and in order to achieve this, formulation of national policies on education became the need of the hour.

The educational developments in the postindependence period can be divided into three main periods:

1. the first is the period between 1947 and 1965–1966 when there was no formal statement of a national policy on education;
2. the second is the period between 1965–1966 and 1977–1978 when the national policy on education (1968) was formulated and an attempt was made to implement it; and
3. with 1978–1979 begins the third period when an attempt was made to implement the draft on the national policy on education (1979).

Several policies and programs were continuously being developed since the time of independence and while they had their flaws, they contributed to the country being able to move ahead in the field of education. When India became independent, it committed itself to a socially just and equal social order. The constitution of the country, promulgated in 1950, recognized the scheduled castes and the scheduled tribes as the two most backward groups needing special protection. There are 1092 scheduled castes, 547 scheduled tribes and 150 million is the population. A number of provisions have been made in the constitution with a view to abolish all forms of discrimination and put these groups at par with others. According to the 2001 census, the literacy rate of schedule castes was 54.69% and that of schedule tribes was 47.10% as against the national average of 64.84%. In 2001, the Government of India introduced the 93rd amendment to make free and compulsory elementary education for children in the age group 6–14, a fundamental right. The reasons for illiteracy among various caste groups in the country including SCs/STs are various socioeconomic factors such as poverty, lack of awareness on the relevance of education, gender disparity, etc. To better understand the situation on caste discrimination with respect to education, one has to look at three levels of education – primary, secondary, and higher education.

Educational Problems

High dropout and lower literacy rates **Tables 2** and **4** among lower caste populations have rather simplistically been characterized as the natural consequences of poverty and underdevelopment. Although these rates are partly attributable to the need for low-caste children to supplement their family wages through labor, more insidious and less well documented is the discriminatory and abusive treatment faced by low-caste children who attempt to attend school, at the hands of their teachers and fellow students. Over 50 years since India's constitutional promise of free, compulsory primary education for all children up to the age of 14 – with special care and consideration to be given to promote the educational progress of scheduled castes and tribes – illiteracy still plagues a large percentage of the their population.

SCs and STs are considered the most backward sections of Indian society in terms of educational development **Table 3**. They constitute the statutorily recognized weaker sections of society and form a distinct target group under the existing pattern of planning. The Government of India has assumed a wide-ranging responsibility for the educational upliftment of the disadvantaged groups. This has included free primary education, reservation in certain centers of higher education, and financial assistance in a variety of educational programs, to name a few. All these policies and programs are essentially designed to allow the lower castes to avail of these opportunities and the assumption is that their rapid advancement will bring them at par with the rest of the population.

Indisputably, education holds the key to socioeconomic development; however, the system of education itself is colored by several biases of caste, language, economic gradations, and gender. These perpetuate the inequality that exists in society. The Government of India was aware of the hierarchical nature of Indian society and hence education was considered necessary for social change. Indian society appears to be still categorized as a pyramid with select strata of the population which form the tip of this pyramid, enjoying the benefits of education. Access to higher education is a seemingly fair practice with a universal entrance exam but on closer inspection, the very nature of this examination favors the upper castes of society to whom, the benefits of education have accrued since a long time. Students from vernacular backgrounds are most often if not always expected to answer an entrance examination in English. In a multicultural and multilingual country like India, a universal language as the general medium of instruction has not spread to all the corners of the country. With SCs and STs receiving their primary and secondary education in a medium of vernacular instruction, they are most often at a disadvantage at centers for higher education. Even though the Government of India has now made it an available option for students to answer their examinations in their own vernacular language, the medium of instruction in classrooms remains English and the reference material suggested is in English.

Language is not the only barrier to the access of education; there are also gender disparities that are characteristic of Indian education. Factors for low enrolment of girls include low socioeconomic status of the parents,

who are more interested in their daughter helping with earning an income for the family and dropout rates are generally high in secondary school with hardly a handful being able to avail of higher education opportunities. In the multicultural and multiethnic Indian society, the parameters of gender, caste, class, and region are crucial in determining access to higher education. Again, gender becomes the all-inclusive negative parameter conferring cumulative and competing disadvantages on women. The educational policies and programs are unable to encompass the complex social reality within a single framework and are, therefore, unable to bridge the gap between policy and practice.

The disadvantaged groups do not have the means to keep their children in school beyond the middle stage, and the small minority that manages to do so can only send them to government schools. None can afford private coaching. Despite these handicaps, a sizable number, much larger than is recognized of children from these groups, manage to do well, and some very well, in public exams. But their family means do not even allow them the luxury of even thinking of higher education. Most educational institutions have a certain number of seats set aside as reserved seats for these communities. A certain group of people especially those against the policy of reservations in the country believe that reservation in admissions to institutes of higher education discriminates against merit and will result in further deterioration of quality. Moreover, it is important to note that reservation in higher education as a whole and in professional courses in particular has focused exclusively on caste as the criterion of backwardness and created strong pressures for widening the scope of the OBCs. This has led to the

cornering of the benefits of reservation by the better-off segments, the so-called creamy layer, of these castes.

Summary

As education connects more closely with economics and development, it assigns certain status to individuals. The years of schooling and special training for career growth make some more advantaged than other. Thus equality of educational provisions and access across divisions of class, caste, and race becomes a very important social and educational problem.

Education cannot be thought of in isolation, it must be studied in the socioeconomic and cultural framework of the society that include the communities that have remained handicapped educationally. It remains beneficial for those who have traditionally been at that level for whom education was always available. Contemporary analysis of the Indian education system should look at access, affordability, performance, and utility as the indicators to measure success of planning initiatives. In this regard, it is important to note that while education is assumed to be a great leveler of society, in a way with its policies and frameworks it is in fact clutching the reins of inequality. Access to education seems the privilege of those who are assumed to benefit most from it and in India, the upper castes.

Development is the new catch word of the twenty-first century in the globalizing world and while every country strives to join this bandwagon, little is done to alleviate the situation of the country's less fortunate. High-caste positions have since time immemorial meant high-class

positions in society. Today, efforts are on to better the lives of people belonging to the SCs, STs, and OBCs who form the highest population proportion in India but for any of these endeavors to be a success, one needs the cooperation of the entire nation's people.

Demography, Community, and the Education of Asian American and Pacific Islander Students

R T Teranishi, New York University, New York, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

There are tremendous challenges to addressing the educational needs of the Asian American and Pacific Islander (AAPI) student population. The challenge is not merely that the educational solutions are difficult to come by; rather, the root of the problem stems from the indelible idea that the AAPI population is a model minority – a racial minority population that succeeds despite the odds. Consider the December issue of *US News and World Report*, in 1966, which states bluntly, “At a time when Americans are awash in worry over the plight of racial minorities, one such minority is winning wealth and respect by dint of its own hard work – not from a welfare check.” (Success Story of One Minority Group in the U.S. (1966, December 1966). *U.S. News and World Report*.)

In 1971, *Newsweek* had a feature story that proclaimed that Asians are outwhiting Whites. *Time Magazine* ran an article declaring that Asians are The New Whiz Kids (August 1987). More recently, in May 2006, a *New York Times* column on The Model Students declared that “stellar academic achievement has an Asian face” and that others would be fools not to learn from these perfect students.

The perspectives with regard to the educational success of the AAPI population have led to the idea that they are a population that does not need attention in research and policy. Thus, unlike other minority populations in the US, the AAPI population faces the unusual obstacle of overcoming the stereotype that they are a successful minority and the idea that they are not educationally disadvantaged such as other minority groups. However, an informed discussion of access and equity requires an understanding of the AAPI educational experience within the context of the conditions that are affecting all students. Moreover, an understanding of the AAPI educational experience requires a contextual examination of the population itself. The AAPI educational experience is actually a conglomeration of varied experiences, opportunities, and outcomes driven by a wide distribution of demographic characteristics with regard to national origin, ethnicity, immigration histories, social class, and cultures. In fact, there are more differences between groups than similarities.

While many studies have attempted to examine the AAPI population, most have been comparative by design, measuring the outcomes of AAPIs against those of other

racial groups. These studies are often guided theoretically and conceptually by frameworks that have been applied to the study of race in the context of the black/white binary, which has been found to have several limitations for the study of the AAPI educational experience. In other words, a key to understanding the position of AAPIs within the equity agenda is to first understand that the exclusion and misrepresentation is predicated upon two key conceptual problems in the study of race. First, normative framing – a perspective that is comparative in nature – has historically been focused on the gap between blacks and whites, without much consideration for other racial populations. While there is certainly a place for the use of comparative research, it should not be the only basis for understanding race in America. In fact, scholars have noted that this perspective often leads to a system of deficit thinking – an idea with regard to marginalized groups that Valencia (1997) states is “tantamount to ‘blaming the victim’ . . . [and is] founded on imputation, not documentation” (pg xi). Allen (1999) cites this paradigm as commonly applied to educational research as an often “misguided and counterproductive game of ‘oppression sweepstakes’ ” (pp. 206–207), whereby various groups are pitted against one another in competition for the dubious status of “Year’s Most Oppressed.” Blacks and Latinos are viewed as a problem in comparative research, while AAPIs are viewed as a solution. This leads to the second problem with the conceptualization and positioning of AAPIs in America’s equity agenda, which are the deeply held beliefs and stereotypes that people hold about AAPIs as a model minority.

At present – in the world of higher education research and policy – some of the key assumptions that drive the treatment of AAPIs in higher education state that: (1) the AAPI population is a successful minority group with high achievement and no academic challenges, and (2) there is an Asian invasion in colleges and universities and the AAPI population is overrepresented in the US higher education. These ideas about AAPIs are not just restricted to research and policy. Rather, they can also be found in the public’s perception that AAPIs are a successful model minority in American society – a population that has lived the American dream, overcoming barriers, and succeeding despite their challenges. While some Asian Americans have achieved the American dream – similar to many other immigrants that have arrived in the United States – the lives of the

Figure 1 AAPI population in millions and as a percentage of the total US population, 1980–2020. 1980 to 2003 are actual data; 2010 and 2020 reflect projections. From US Census Bureau, decennial census of population, 1980–2000.

many individuals and communities that comprise Asian Americans cannot and should not be reduced to a single story (Zia, 2001). Thus, while there is tremendous interest in rectifying inequality in the educational opportunities and outcomes of different racial groups in America, the study of AAPIs, ironically, is a major obstacle for understanding the AAPI educational experience.

This article attempts to transcend these conceptual challenges both by systematically examining some basic baseline information concerning AAPI participation and outcomes in US higher education, and discussing the ways in which demographic distinctions of the AAPI population has implications for the educational experiences and outcomes of different AAPI subpopulations. In particular, this article describes the ways in which differences among the population – with regard to ethnicity, immigration histories, and social class – influence differences in post-secondary opportunities and outcomes that exist among the population. This article will demonstrate that a broader, more thoughtful consideration of the subpopulations that contribute to the larger AAPI racial category can lead to better research, policy, and practice.

Higher Education Participation and Attainment

AAPI participation in US higher education can be traced back to late in the nineteenth century. However, as late as 1940, the Asian American population was still considerably less than one percent of the US population (Daniels, 1997). Exceptions of this trend could be found in Hawai'i – which was then a territory and, therefore, excluded from US population figures. In Hawai'i, 58% of the people, in 1940, were of Asian descent (Tamura, 2001). The growth of the AAPI population in mainland US

	Number	10-year percentage change
1980	271 006	–
1990	570 873	110.7%
2000	903 360	58.2%

Figure 2 Total AAPI enrolment in US higher education, 1980–2000. From US Department of Education, IPEDS.

began with the passage of the 1965 Immigration Act, which created many new opportunities for immigrants that were formerly excluded. Between 1960 and 1994, the Asian American population grew from 1 million to nearly 8.8 million people. The sizable growth became more evident, beginning in 1980 when the population reached 3.5 million (see **Figure 1**).

Over the past three decades – from 1970 to the present – AAPIs have been the fastest growing population in the United States. At present, the AAPI population is large and continuing to grow. In 2003, there were over 13 million AAPIs in the United States, representing 4.5% of the total population. In 2020, the population is projected to be nearly 18 million. By 2050, the AAPI population is projected to be nearly 10% of the total US population (not in table).

The presence of AAPIs in US higher education coincides with the growth in the overall population – which also occurred following the 1965 Immigration Act. There were more than a quarter of a million AAPIs enrolled in US higher education in 1980, nearly a half million in 1990, and almost one million in 2000 (see **Figure 2**). These were similar trends to what occurred for the total AAPI population, with the total enrolment of AAPIs in US higher education doubling between 1980 and 1990, and nearly tripling between 1980 and 2000.

While the growth in AAPI participation seems drastic, it is typically overstated and assumed to be greater than

that of other racial minority groups. However, the growth of AAPI total enrolment is actually quite similar to the pace of the growth among African Americans and Latinos. For example – between 1993 and 2003 – Latino total enrolment in US higher education increased by 68.8%, compared to 43.5% for AAPIs, and 42.7% for blacks. In fact, the change in participation among AAPIs is tied mostly to two distinct demographic features. First, the sheer size and growth of the total AAPI population created a larger pool from which AAPI college students could be drawn. Second – during the past three decades – there has been a general shift in opportunity for higher education that has led to greater opportunities to attend college for all minority students in the United States.

While there has been tremendous growth in AAPI participation in US higher education overall, it is important to also consider the distribution of AAPIs in different regions of the country. Colleges and universities are distributed unevenly throughout the United States, with some states and regions having a larger student population than others. The disparate distribution of student populations across different states and regions is often correlated with the disparities in the distribution of the general US populations throughout the country. For example, analysis of population estimates, in 2003, shows that a little over half (51.2%) of the US population was located in just eight states. Twenty states comprised about three-quarters (76.7%) of the US population (See ‘Annual estimates of the population by race alone or in combination and Hispanic or Latino origin for the United States and States’, 1 July 2003. Population Division, US Census Bureau (US Census Bureau, 2003)).

The distribution of the total US population in different states and regions of the country is not necessarily the same as the distribution for individual racial groups. In 2003, AAPIs were more concentrated in fewer states than the general US population, with half of all AAPIs residing in three states (California, New York, and Hawai‘i). Ten states comprised approximately three-quarters (74.4%) of the total AAPI population. The residential patterns of AAPIs are tied – in large part – to patterns of immigration settlement and migration resettlement with concentrated populations of AAPIs in large urban communities such as New York, Los Angeles, Long Beach, San Francisco, Oakland, Honolulu, Houston, and Jersey City (see Teranishi, 2004).

Similar to the residential distribution of AAPIs nationally, the regional distribution of AAPIs in colleges and universities throughout US higher education is also unique. For instance, there is a large concentration of AAPIs in a small number of institutions. In 2000, two-thirds of all AAPI college students nationally were concentrated in 200 institutions out of more than 4200 Title IV institutions in the United States. These 200 institutions represent less than 5% of all Title IV institutions. Three-quarters of all AAPI college students nationally are concentrated in less than 300 institutions in the United States. The distribution of

	Total FTF to any college	Percent of national total	Cumulative percentage
California	323 351	35.8%	35.8%
New York	67 725	7.5%	43.3%
Texas	50 578	5.6%	48.9%
Illinois	43 140	4.8%	53.7%
Hawaii	35 489	3.9%	57.6%
Washington	26 340	2.9%	60.5%
New Jersey	24 041	2.7%	63.2%
Massachusetts	23 718	2.6%	65.8%

Figure 3 AAPI first-time freshmen attending any college by state, 2000. From US Department of Education, IPEDS.

AAPIs across a small number of institutions is nearly always overlooked in research and policy considerations.

AAPI enrolment is also highly concentrated in a small number of states. In 2000, nearly two-thirds of all AAPI college students attended college in eight states (**Figure 3**). Nearly half of all AAPI first-time freshmen nationally attended college in California, New York, and Texas. In California alone, over 300 000 first-time freshmen were enrolled in higher education in 2000 – comprising over one-third of all AAPI students who entered college nationally.

While the largest concentration of the national AAPI student population can be found in the West and North-east, the greatest growth in AAPI college participation occurred in the Midwest and the South between 1990 and 2000 – a rate of 75% and 86%, respectively. These states have historically had a very small AAPI population overall and very few AAPIs enrolled in higher education. However, the Midwest and the South – in recent decades – have experienced an increase in their AAPI population caused by immigration settlement directly to these regions along with migration and resettlement among AAPIs looking for better occupational opportunities and a lower cost of living (see Teranishi, 2004).

In addition to the trends in the overall AAPI college-participation rate and their changing regional representation, it is also important to consider their distribution in different institutional types. US higher education is diverse and highly stratified with colleges that range in type (2-year and 4-year), selectivity (selective and nonselective), and control (public and private). The idea that AAPIs are universally successful is tied to the assumption that they are all selected by the most selective universities in the country. However, when total AAPI enrolment in US higher education is disaggregated by institutional type and control, there is evidence of a wide distribution of AAPI participation.

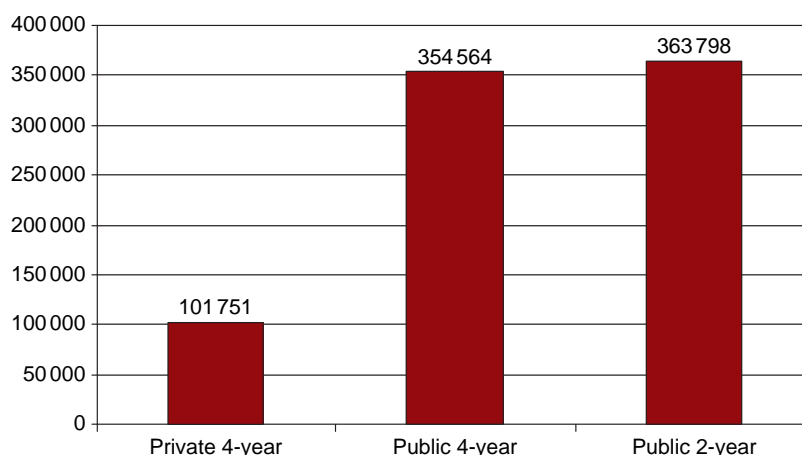

Figure 4 AAPI enrolment in US higher education by institutional type, 2000. Private 4-year does not include private for-profit institutions. From US Department of Education, IPEDS, 2006.

Most surprising in this analysis is the sizeable concentration of AAPIs in community colleges (**Figure 4**). In 2000, there were more AAPIs enrolled in public 2-year colleges (363 798 AAPIs) than in public 4-year colleges (354 564 AAPIs) or private 4-year colleges (101 751 AAPIs). AAPI college participation is rarely discussed in the context of the community college sector, and is, instead, mostly a discussion reserved for looking at the elite colleges, where it is assumed they are all located.

While a large number of AAPI students in higher education can be found in the community college sector, it is also important to recognize that the greatest increase in the number of AAPI college students between 1990 and 2000 also occurred in that sector. Between these time periods, the participation of AAPIs in public 2-year institutions increased by 73.3%, which was greater than their change in enrolment in public 4-year colleges (42.2%) and private 4-year colleges (53.4%).

These data demonstrate that AAPIs have a wide range of participation in US higher education, which varies by demographic region and institutional type. These varied outcomes among the population challenges the notion that AAPIs are all succeeding equally, and experiencing universal educational success. The next section considers more thoroughly the demographic distinctions within the population and the extent to which these differences factor into disparate outcomes within the population. Specifically, this author examines ethnicity, immigration status, social class, and language as predictive factors for educational outcomes.

Ethnicity, Social Class, and Disparities in Opportunities and Outcomes

Understanding the participation of AAPIs in US higher education requires consideration of a larger context of

AAPI demography and community. For the AAPI population, there is a great deal of diversity within the population that is masked by the larger racial category. The 1996/97 Minorities in Higher Education Report (Hune and Chan, 1997) indicated that aggregated data on Asian Americans homogenizes the experiences of Asians and depicts a distorted picture of the educational participation of subgroups within the population. This racial categorization hides the diversity within the population with regard to ethnicity, social class, and immigrant subgroups that encounter different social and institutional experiences. Unfortunately, lack of careful and critical approaches to the study of race in higher education results in misleading generalizations with regard to the population.

The limitations of existing research on AAPIs are not restricted to the examination of within-group distinctions; there is also evidence of confounding of data with other categories. Consider data from the Eighth Annual Status Report for Minorities in Higher Education (2001) which show that 32% of doctorates conferred in the US were to Asians; however, 86% of those degrees were actually conferred to international students from Asia, rather than to Asian Americans. A recent National Science Foundation (NSF) publication reported that, during the same time period, doctoral degrees awarded to Asians who were US citizens accounted for a mere 2% of all doctoral degrees awarded (Thurgood *et al.*, 2006). By reporting these racial categories and including international students, we use inflated numbers that exaggerate the achievement of Asian Americans. Such inflations prompt some scholars to describe Asian Americans as overrepresented in terms of earned doctorates; they are actually underrepresented.

In addition, it is also problematic when studies on race in higher education completely omit Asian Americans from the analysis, or even conveniently include them with the Others category – a practice that is also found

Asian American		Pacific Islander American	
Bangladeshi	Laotian	Carolinian	Papua New Guinean

in the treatment of Native Americans. As a result, very little is known about the Asian American educational experience, including their participation, satisfaction, and outcomes in US higher education. This leads to the conclusion that there needs to be more research that understands the diversity of the AAPI population, including a better understanding of the differences across ethnic groups – with regard to social class, timing of migration to the United States, and population distribution across different states and regions within the United States.

Evaluating basic, baseline information pertaining to the AAPI population can yield important information to consider in educational research and policy. Consider one of the most obvious indications of the diversity among the umbrella racial category Asian American and Pacific Islander – ethnic diversity. The US Census Bureau (2000) included 48 different AAPI categories to make up the AAPI racial population.

Across racial groups, some populations have a greater likelihood of having a tighter distribution of education, income, and wealth compared to other groups. Consistently, the perception of AAPIs is that their educational attainment levels are exceedingly high compared to all other racial groups in the nation. Implicit in this assumption is the idea that both high educational achievement and attainment are universally attainable goals representative of the entire population. This is not only untrue, it is actually quite the opposite of what the trends show; AAPIs have a wider distribution of educational attainment than any other racial group in the United States. Consider that while AAPIs – in the aggregate – have a higher level of education than all other racial groups, a large proportion of Hmongs (59.6%), Cambodians (53.3%), Laotians (49.6%), and Vietnamese (38.1%) adults over the age of 25 do not have a high school diploma. The national averages for certain AAPI ethnic sub-populations are

even more striking when you isolate certain ethnic communities (see **Figure 5**). Consider the Hmong population in St. Paul, Minnesota – the largest of concentration of Hmong in the United States. Among Hmongs in the St. Paul community, nearly two-thirds (65%) of adults only have high school education or less. The implications of low educational attainment among adults have been linked to a lack of college guidance and support for children (McDonough, 1997; Teranishi, 2003) and limitations in the likelihood of upward mobility from one generation to the next.

Low educational attainment among certain communities is consistent with a high level of poverty – which is another class indicator that is seldom associated with the Asian American population. For example, according to the US Bureau of the Census (2000), Southeast Asians (e.g., Laotians, Hmong, Lu-Mien, Cambodians, Vietnamese) experience poverty rates that are 2–4 times greater than the national average. In 2000, 38% of Hmongs, 29% of Cambodians, and 19% of Laotians lived in poverty – compared to the national average of 12%.

For particular AAPI ethnic communities, poverty is especially pronounced. A group that has a particularly high prevalence is Southeast Asians – a population with the highest welfare-dependency rates of any ethnic or racial group in the United States. Southeast Asians constitute nearly 80% of all Asian Americans on welfare. There are similar trends in employment rates among Asian Americans. In a study of Southeast Asian high school seniors in California, 49% of fathers and 75% of mothers of Cambodian students were unemployed (Teranishi, 2004).

Among AAPIs, the challenges associated with low social class are not restricted to Southeast Asians. Consider the native Hawai'ian and Pacific Islander population. In the Wai'anae community in Hawai'i – which is the

largest concentration of native Hawaiians in the United States, 79% of the adults have achieved high school education or less and 32% of families with children are below poverty line – a rate that is three times the national average. The high level of poverty often leads to high levels of dependency on social services, including welfare. This wide distribution in economic capital has implications for the distribution of resources that are available to students as they pursue their educational aspirations.

Other areas for which AAPIs are often not recognized are immigration and language research and policy. For Asian Americans – which are the fast-growing racial group in the nation – much of their growth is fueled by immigration. A high degree of immigration implies that, among AAPIs, there is a larger proportion of the population that is foreign-born. Many of the individuals, families, and communities that represent this sector of the population face challenges associated with language. The likelihood that English is spoken at home in some groups is very low. As a result, students often feel they cannot leave home to attend college because their families need them to translate English. For Hmongs, it was emphasized more so than among Vietnamese because the language is so rare and different than the structures of other languages. For example, a written language does not exist for Hmongs.

Patterns can be found in the rate of AAPI foreign-born residents and the likelihood that the same community will speak English with fluency. The Chinese American community in Brooklyn, New York, is a good case in point. This Chinese American community has a high rate of residents who are foreign-born (77%) along with a high rate of children who speak English less than very well (64%). In Westminster – which is one of the largest Vietnamese American communities outside of Vietnam – 67% of the adults speak English less than very well.

While language is a challenge for most first-generation AAPI immigrants, there are important variations that also warrant consideration; among immigrants from Asia, there is great unevenness in their immigrant experiences. Consider the rate of individuals granted access to the US under employment preferences, which varies widely by country of origin. Following the Vietnam War, immigrants, refugees, and asylum seekers from Southeast Asia – including Vietnamese, Hmong, Cambodians, and Laotians – created a vibrant Southeast Asian population in America that is quite significant today. For those populations that arrived in the US from Laos, Cambodia, and Vietnam, a high rate arrived in the US via refugee status (88%, 52%, and 50%, respectively) between 1990 and 2000 (Office of Immigration Statistics, US Department of Homeland Security, 2005). Conversely, during the same time period, a large share of immigrants from Taiwan (37%), China (36%), and Korea (25%) were much more likely to be admitted under employment preferences. Therefore, it is clear that different sectors of the AAPI

population arrive in the United States with a wide distribution of resources and capital, including educational attainment prior to their arrival, economic capital, and other forms of capital that translate well into the United States opportunity structure.

Conclusion

Research and policy on race need to transcend the stereotype types and assumptions with regard to AAPIs that have been used to characterize their experiences and outcomes in education. To be truly inclusive of the population requires thoughtful consideration of the complexity and uniqueness of the population. Asian Americans are a unique racial group with needs, issues, and challenges that vary within the population. Even beyond the ethnic diversity of the AAPI population, there are also a wide range of indicators and outcomes related to educational attainment and poverty status. These demographic distinctions within the population lead to a wide range of opportunities and outcomes that can be found across subpopulations within the larger racial category. In other words, just as some Asian Americans are at the top of the curve, many struggle at the bottom of the curve. The differences among Asian American groups are often greater than their similarities, and, because of this, Asian American data must be disaggregated to have meaning.

Introduction: Defining Mortality and the Causes of Mortality

Previous research has consistently found extensive and positive associations between education and health. Those with higher levels of education have lower risk of overall mortality, and the gap has increased over time. Defined by the number of deaths in a population, mortality is caused by a number of different factors, including: chronic diseases, HIV/AIDS, suicide, accidental death, infant and childhood conditions, and poor overall health quality.

This article summarizes the literature on education and mortality and assesses the impacts of social and economic stratification on mortality differentials in the United States and internationally. Although findings from various disciplines are included in this entry, this article is couched in a sociological perspective and focuses heavily on the social structural conditions that contribute to the link between education and mortality. Multiple aspects of stratification contributing to the link between education and mortality are discussed, including: race/ethnicity, gender, socioeconomic status, marital status, citizenship, and neighborhood context. The article concludes with a discussion of policy implications.

Chronic Diseases

Historically, infectious diseases were the major cause of mortality around the world. Malaria, the plague, and smallpox killed hundreds of thousands of people internationally. Today, the top four causes of mortality in the United States are degenerative diseases rather than infectious diseases. The major chronic diseases associated with degeneration – the biological deterioration of a body – are heart disease, malignant neoplasm (cancer), cerebrovascular disease (stroke), and chronic lower respiratory disease.

HIV/AIDS

Rates of HIV/AIDS are spreading rapidly around the world, especially in sub-Saharan Africa, Eastern Europe, and Asia. Yet, deaths from HIV/AIDS have slowed in North and South America and Western Europe. Rates continue to increase because the vast majority of people do not know they have the disease or do not acknowledge the infection. Education is directly linked to HIV/AIDS

as the disease is more prevalent among those with lower levels of education.

Suicide

Approximately 1 million people each year commit suicide and as many as 20 times that number attempt suicide but are not successful. Europe, especially Eastern Europe, has the highest rates of suicide; the United States and Canada have average rates; and Mexico is well below the world average. Suicide is caused by depression, hopelessness, and feelings of powerlessness, all of which are increased in individuals with lower educational attainment.

Infant and Childhood Mortality

Although the United States is among the wealthiest countries in the world, it continues to have infant mortality rates greater than any other industrialized nation. While the rates for the United States are extremely high, not all groups experience similar risk of infant mortality. Some communities experience very high infant mortality rates, while others experience much more modest rates. The reasons for these disparities are complex but have generally been thought to reflect the enduring social and economic inequality in the United States. For example, while infant mortality rates in the United States have consistently declined since the 1950s (largely as a result of technological innovation), the gap between whites and African-Americans has remained relatively stable since the early 1970s. Infant mortality rates are highest among those with the lowest levels of education.

Trends

Life expectancy in the United States has increased since the 1980s. Yet, life expectancy increases have been almost exclusively restricted to those with high levels of education. The mortality gap between those with low versus high levels of education in the United States is increasing. In 2000, the life expectancy for a 25-year-old with a high school diploma was 50 years, but for a person of the same age with some college education, the life expectancy was almost 57 years. What is more, the data show that the widening disparities in mortality are not explained by increased race or sex differences in mortality trends.

Socioeconomic differences in rates of mortality over the life course are greatest among those who are middle-aged. These differences are primarily a function of income at the low end of the socioeconomic continuum and education at the high end. In addition, inequality trends are more adverse for older persons than for younger

Table 1 Life expectancy (in years) at age 25, by race, sex, and educational status (1990 and 2000)

	1990	2000	Change
White men	49.6	51.0	1.4 ***
Low education	47.0	47.1	0.1 ***
High education	53.2	55.0	1.8 ***
White women	55.6	55.8	0.2 ***
Low education	54.3	53.4	-0.9 ***

Reproduced from Meara, E.R., Richards, S., and Cutter, D.M. (2008). The gap gets bigger: Changes in mortality and life expectancy, by education, 1981–2000. *Health Affairs* 27, 350–360.

ones. The cumulative effect of education on mortality over the life span means that there is greater disparity in risk of premature mortality between older individuals with divergent levels of education. A comparison of the magnitude of educational mortality differentials in the United States and Europe, where healthcare is more equally distributed, shows that at middle age, the proportionate reductions in mortality for each additional year of schooling are similar. This suggests that healthcare access may not be as important a determinant of mortality as previously thought.

Not only does the effect of education on mortality vary by age, but also by gender. Research finds that educational differentials in mortality have increased for men over the past several years but not for women.

Table 1 displays life expectancy by race, gender, and educational status in the United States. While life expectancy increased from 1990 to 2000 among all groups with a high level of education, it actually decreased over the 10-year period for white and black women with low levels of education. Further, the life expectancy gap between those with low education and those with high education increased for each of the four race–gender groups from 1990 to 2000, indicating that educational attainment is becoming more important in reducing one's risk of mortality.

Figure 1 shows that certain conditions have contributed more to the increased gap in educational disparities in mortality than other conditions. Heart diseases and

Figure 1 Contribution to growth in education-related disparities, ages 25–84 (1990–2000). Authors' calculations were based on data from non-Hispanic blacks and whites in the Multiple Causes of Death (MCD) files linked to census data. COPD, chronic obstructive pulmonary disease. Reproduced from Meara, E. R., Richards, S., and Cutler, D. M. (2008). The gap gets bigger: Changes in mortality and life expectancy, by education, 1981–2000. *Health Affairs* 27, 350–360.

cancers contributed most to the rising mortality disparities between those with low and high educational attainment from 1990–2000. Lung cancer and chronic obstructive pulmonary disease (COPD) largely attributable to smoking, accounted for 21% of the increase in mortality between those with high and low education.

Explanations for the Association between Education and Mortality

Social Structural Conditions

The sociological perspective emphasizes that social structural conditions affect the association between education and mortality. Two important social structural conditions affecting mortality are inequality and stratification and access to healthcare resources.

Inequality and stratification

Inequality refers to disparities in the distribution of income, wealth, social, economic, and political power in society. Stratification is the hierarchical arrangement of social classes within a society. Inequality is created and maintained through social structural forces that privilege certain groups of people and disadvantage others. Increasing social inequality is manifested, in part, by increasing geographic isolation. Community conditions affect individual mortality risk. Residential segregation, for example, reinforces social isolation and economic segregation. People in poor and disadvantaged places have significantly higher mortality rates. Residential segregation and political disenfranchisement are, in part, responsible for elevated infant mortality rates in US cities. Furthermore, decay in US housing stock, undesirable land use, and marginalization of places through withdrawal of municipal services has led to higher rates of homicide, suicide, and deviant behavior, all of which increase mortality risk.

Research demonstrates that the social and economic context of the neighborhood affects mortality risk net of individual characteristics. This pattern is especially salient in highly segregated neighborhoods. For example, net of individual socioeconomic characteristics and neighborhood characteristics are accountable for risk of death experienced by blacks. Further, this risk is not specific to blacks but is shared by anyone who lives in highly segregated black communities. Residential segregation perpetuates racial disparities in poverty, education, and economic opportunities that in turn lead to differences in health outcomes. Residents of economically deprived neighborhoods have higher body mass indices, larger waist circumferences, higher waist–hip ratios, and greater risk of diabetes than their peers in more economically advantaged residential areas. The higher cost of food in segregated neighborhoods leads to consumption of poor-quality food items which affect residents' overall health quality.

Working conditions

Work and economic conditions also directly and indirectly contribute to the link between education and mortality. The likelihood of being employed and the type of work an individual does is influenced by educational level. First, the well educated are more likely to be employed. Lack of education limits employment opportunities. The poorly educated are more likely to work only part time, and are at greatest risk of losing their jobs in times of economic downturn. Employment affects an individual's overall well-being; being unemployed is associated with poor health.

Second, low educational attainment translates into lower expected income. Poorly educated people experience more economic hardship than those with more education. Economic hardship and poverty negatively affect health. Ongoing strain and stress related to not being able to pay the bills, depression, and hopelessness all decrease an individual's resistance to certain diseases and makes them more susceptible to untimely death.

Third, those with lower levels of education work in occupations that put one at greater risk of mortality. Fatal injuries by industry are most represented in occupations entered by individuals with little or no education, including construction, transportation and warehousing, agriculture, forestry, fishing, hunting, and mining. Further, nearly half of all work-related fatalities in the United States involve vehicles. Occupations that require workers to travel include logging, refuse and recyclable material collection, farming and ranching, electric power-line installing, roofing, traveling sales, and truck-driving. Most of these high-risk occupations are entered by those with lower levels of education.

Finally, well-educated people are employed in occupations that allow them greater autonomy and less monotony. Increased independence on the job and nonroutine work increase both psychological functioning and job satisfaction. Work that is characterized by job security, variation in tasks, and inclusion in decision making is more subjectively rewarding, leading to better mental and physical health.

Health lifestyles

There are a number of ways in which a person's health lifestyle can play a role in risk of mortality. Compared to the poorly educated, those with higher levels of education are less likely to engage in lifestyle behaviors that would increase risk of untimely death, including smoking, drinking, and risky behaviors. Further, individuals with higher levels of education are more likely to engage in healthy lifestyle behaviors including exercise and health checkups. There is an interaction between lifestyle and educational level such that behavior posing a threat to good health has less impact among those with higher levels of education.

First, smoking has been linked to chronic diseases that often lead to death, including lung and other cancers,

coronary heart disease, stroke, atherosclerosis, aneurysms, emphysema, and chronic bronchitis. **Table 2** displays the percentage of smokers in the US population by gender and educational status. Statistics show that as one's educational level increases, the likelihood of smoking decreases. Prevalence of smoking is highest for those with a GED diploma and lowest for those with a graduate degree. This pattern holds for both men and women.

Second, those with lower levels of education are more likely to drink heavily, often as a strategy to cope with the stresses of poverty. While excess drinking is less ubiquitous in its health consequences than other unhealthy

behaviors, it is linked to death caused by cirrhosis of the liver, suicide, homicide, and car accidents. Conversely, those with high levels of education are more likely to engage in moderate drinking, which has been linked to positive health outcomes, including lower risk of coronary heart disease, stroke, and hypertension.

Education also affects risk of preventable death. The risk of dying from either a highly preventable or less preventable death decreases as years of education increases. **Figure 2** displays hazard scores representing risk of dying by either a highly preventable or low preventable cause in the United States. Preventable deaths are those wherein death can be prevented by means of medical treatment or other interventions and/or by preventing the incidence of the disease to start with through good hygiene, diet, vaccines, and other lifestyle factors. Among individuals in the United States aged 25–44, those with the fewest years of education have the greatest risk of highly preventable death.

Finally, those with higher levels of education are more likely to engage in healthy lifestyle behaviors, such as exercise and regular health checkups. Physical activity reduces mortality related to cardiovascular disease, atherosclerosis, colon cancer, obesity, high blood pressure, and diabetes. The well educated are also more likely to get preventive healthcare, including annual exams, immunizations, and screenings. This type of preventive healthcare helps detect early signs of illness, reducing the risk of premature mortality.

Table 2 Estimated percentage of persons aged 18 or older who are current smokers^a by Gender and Educational Level (2006)

	Men	Women	Total
0–12 (no diploma)	30.6	23.0	26.7
GED diploma	51.3	40.2	46.0
High school diploma	27.6	20.4	23.8
Some college	26.1	20.0	22.7
Associate degree	25.4	17.8	21.2
Four year degree	10.8	8.4	9.6
Graduate degree	7.3	5.8	6.6

^aPersons who reported smoking at least 100 cigarettes during their lifetime and who, at the time of the interview, reported smoking every day or some days.

Date retrieved from the Centers for Disease Control Morbidity and Mortality Weekly Report Vol. 56. No. 44 (November 9, 2007).

Figure 2 Cox proportional hazard scores predicting death by educational attainment for ages 25–44, US National Longitudinal Mortality Study (1995). Reproduced from Phelan, J. C., Link, B. G., Diez-Roux, A., Kawachi, I., and Levin, B. (2004). 'Fundamental causes' of social inequalities in mortality: A test of the theory. *Journal of Health and Social Behavior* 45, 265–285.

Social Psychological Resources

In addition to social structural conditions and individuals' own health lifestyles, social psychological resources, including a sense of personal control and social supports are linked to improved health and lower risk of mortality, while other social psychological conditions, such as perceived stigma and discrimination may lead to increased risk of mortality.

Sense of control

Education affects the sense of self-control one has over their own life. Perceived powerlessness and lack of control are linked to one's socioeconomic position within society. Those with more years of education are at higher socioeconomic levels and experience a greater sense of control, mastery, and ability to effectively alter their life chances. Education helps one develop self-direction, communication skills, analytical ability, and problem-solving skills. Those with lower levels of education and poor economic circumstances often learn to accept failure and perceive that others have control over their lives. This lack of personal control has deleterious affects on one's health, since those with less perceived control are less knowledgeable about their health, less likely to initiate preventive behaviors, and more likely to experience emotional stress leading to worse immune systems.

Social support

The well educated also have higher levels of social support than the poorly educated. Economic hardship, linked to low levels of education, decrease the number and quality of social support. Social support increases a person's sense of being loved, valued as a person, and being part of a community or social network. Social support decreases mortality through psychological and behavioral mechanisms. Psychological distress increases likelihood of premature death through depression, smoking, drug use, and heavy drinking.

Discrimination

Perceived or actual discrimination may increase one's level of stress, thereby negatively affecting health outcomes. Those with lower levels of education, particularly if they are also non white, experience greater perceived and actual stigma and discrimination by employers and co-workers. Both the economic and non-economic forms of discrimination relate to each other and combine with one's socioeconomic position and other risk factors to affect health. Socioeconomic inequalities in health are produced, in part, by differential exposure to stress and negative life events. Longitudinal survey data reveal that negative lifetime events are positively associated with mortality. Perceived discrimination – both daily exposure and lifetime exposure – is associated with poor mental health, putting one at greater risk of untimely mortality.

Demographic Characteristics Affecting Mortality

Several demographic characteristics interact with social structural conditions, health lifestyles, and social psychological resources to mediate the link between education and mortality. Such characteristics include race/ethnicity, gender, socioeconomic status, marital status, and context of residence.

Race/Ethnicity

Race/ethnicity confounds with education to affect mortality risk in several ways. Of all racial groups in the United States, blacks live the fewest years and spend a high proportion of those years with a chronic health problem. Socioeconomic conditions, not health behaviors, are the primary cause of racial health stratification. Poverty, residential segregation, racism, the lack of adequate social and economic resources, and cultural beliefs about health are some of the contributors of the observed racial differences in mortality risk.

Studies have demonstrated that in the United States, blacks are more likely than whites to die of cancer and heart disease, more likely to get diabetes and asthma, and less likely to seek preventive care. They are 3 times more likely to be hospitalized and 4 times more likely to die as a result of asthma than are white patients.

Early-life socioeconomic conditions, such as parental occupation and family structure, explain part of the race gap in mortality. While black men's higher rates of death are associated with lower socioeconomic standing in early life, these effects operate indirectly through adult socioeconomic achievement processes. Research suggests that education indirectly accounts for the racial gap in black men's mortality since lower levels of education lead to lower family income, wealth, and occupational standing.

Race and ethnicity also affect infant mortality. **Table 3** shows that in general, infant mortality rates are lowest for infants born to Chinese and Japanese mothers and highest for infants born to non-Hispanic black and Puerto Rican mothers. These same patterns hold even when controlling for educational attainment. Infant mortality rates generally decrease with increasing educational levels among all racial groups. Rates are highest for infants born to mothers with only 9–11 years of education and lowest for infants born to mothers with 16 years or more of education.

Gender

Gender also combines with education in several ways to affect risk of mortality. Social structural conditions, health lifestyle, and social psychological resources all play a role in the link between gender, education, and mortality.

One of the most striking recent trends in mortality has been the divergence of male and female death rates.

Table 3 Infant mortality rates^a by race and mother's education at attainment (1999)

	<i>White</i>	<i>Black</i>	<i>American</i>	<i>Asian/Pacific</i>		<i>All races</i>

^bPersons of Hispanic origin may be of any race.

Data retrieved from the Centers for Disease Control. National Vital Statistics Reports Vol. 50 No. 4 (January 30, 2002).

There is evidence that biological differences between the sexes lead to lower female mortality. Various environmental factors also interact with gender to create differential mortality risk for men and women. Relative mortality differentials by educational attainment are greater for men than for women. Differences are more apparent at prime working ages than at older ages, with relative differentials narrowing as age advances. As socioeconomic inequalities have increased in recent years in the United States, these trends have been more adverse for men than women. Alternatively, some countries actually have higher life expectancy for men (i.e., Botswana, Kenya, Zambia, and Zimbabwe). Research suggests that this difference is due to cultural and socioeconomic factors, such as nutritional practices that discriminate against female children, food allocations that favor men, and higher quality medical treatment for men.

Evidence suggests that men are also more likely to engage in dangerous lifestyle behaviors, such as excess drinking, risky driving that may lead to accidents, drug abuse, and poor eating habits. Accidental deaths are among the top five causes of mortality in the United States, Canada, and Mexico. About 50% of all deaths in the United States are attributable to motor vehicles. These victims are disproportionately young males. Those with lower levels of education are most likely to engage in risky behaviors, including substance abuse, dangerous driving, and unhealthy eating. Thus, gender and educational level interact to increase risk of mortality for men with lower levels of education.

Finally, there is a well-documented literature examining men's reluctance to seek out preventive medical treatment. Largely due to their socialization, men are far less likely than women to get regular medical exams or go to the doctor when they are sick, increasing their risk of premature mortality.

Socioeconomic Status

There is a direct link between education and income. Those with greater educational attainment earn more income over their life. Studies show that higher income

provides increased access to healthcare, proper diet, quality housing, consistent employment, and a healthy lifestyle. Individuals with both high income and high education have lower mortality on average than individuals with high education and lower income or those with high income but low education. Both education and income have important independent associations with mortality. This association is not limited to the United States. In Great Britain, mortality differentials according to socioeconomic circumstances increased in tandem with increases in income inequality. Recent research has found that almost 25% of deaths in Great Britain are attributable to unfavorable socioeconomic circumstances.

Marital Status and Family Conditions

Marital status and childhood family conditions also combine with education to affect mortality. Education has a comparable effect on mortality for both married men and women, but the negative effect of being single and having a low education level has increased over time.

Research also suggests that there is a link between spouse's educational level and mortality, particularly for women with higher levels of education. While women with low levels of education are not affected by their husband's educational level, highly educated women have an almost twofold increase in risk of cardiovascular disease when married to less educated husbands.

Early childhood family conditions also impact mortality. Living conditions in the parental home contribute to social class differences in mortality. Parental home characteristics, such as social class, number of siblings, parents' marital status, and employment status, all affect risk of various types of mortality. Research has found, however, that much of the effect of early childhood family conditions is mediated by an individual's educational path.

The Role of Context on Mortality

Research has also been conducted on how context of residence impacts mortality. These studies, largely

conducted under the ecological perspective, have focused on the relationship between community socioeconomic status characteristics and overall mortality rates. In some cases, high mortality in a community may reflect its population composition rather than the characteristics of the place, while in other cases, high mortality risk may reflect the quality of the neighborhood and exposure to accidents, violence, and environmental hazards. Where one lives also affects one's access to quality education and the subsequent life opportunities that come from that education. Context of residence interacts with education to impact mortality in two ways: access to health-care services and environmental hazards and social disorder.

Individuals living in rural areas in the United States have historically had less access to a wide array of health-care services due to lower income, lack of private health insurance, and shortage of healthcare providers. Yet, despite these healthcare disadvantages, rural residents in the United States experience better health, including longer length of life. **Figure 3** presents life expectancy for the typical married white male at the age of 45 who is in good health for three different socioeconomic levels in urban, suburban, and rural areas in the United States. Among those living in both urban and suburban areas, those with high socioeconomic status (higher income and more years of education) have longer life expectancies. However, there

is no significant difference in life expectancy by socioeconomic status among those living in rural areas. This suggests a greater level of health parity among socioeconomic groups in rural areas in the United States.

That same equality is not found in highly segregated urban areas in the United States. Healthcare access for blacks living in residentially segregated urban areas is limited. While geographic access to physicians has continued to improve over the past two decades, blacks disproportionately lack regular sites of care and experience less continuity of healthcare. Physicians are significantly less likely to participate in Medicaid in areas where poor people are nonwhite and those that are racially segregated. Residential segregation also reduces access to physicians and hospitals for blacks and poor people and they must travel much farther on average than white patients. Patients visit hospitals more frequently when the distance traveled is minimized and the rate of use of hospitals declines with distance.

Policy Implications

In their landmark study on mortality, Kitagawa and Hauser (1977) state that, "mortality is presumed to have little relevance to policy because health and longevity are near-universal human values, and governments are expected to spend all that they can to promote the health and longevity

Figure 3 Life expectancy at age 45 by socioeconomic status and urban, suburban, and rural residence in the United States. The controlled characteristics for the life expectancies are: white, married, in good health, and currently retired. Low socioeconomic status men are defined as having less than 9 years of education and a family income of \$14 177 (in 1983 dollars); average socioeconomic status men are defined as having 9–12 years of education and a family income of \$24 567 (in 1983 dollars); and high socioeconomic status men are defined as having some college education and a family income of \$35 416 (in 1983 dollars). Reproduced from Hayward, M. D., Pienta, A. M., and McLaughlin, D. K. (1997). Inequality in men's mortality: The socioeconomic status gradient and geographic context. *Journal of Health and Social Behavior* 38, 313–330.

of their citizens” (p. 381). A public discussion about educational differentials in mortality is important because it points to the possibility of reducing mortality through improved socioeconomic conditions.

Some causes of death are more preventable than others and are therefore more amenable to policy interventions. The Healthy People 2010 initiative aims to entirely eliminate all health disparities in the United States by the end of this decade. Several interventions have been designed to reduce disparities in health and mortality, including the Medicare disproportionate-share hospital program, the State Children’s Health Insurance Program, and Medicaid expansions. Efforts to improve public health and disease prevention have intensified over the past several years, with particular focus on risk factors that are prevalent among those with lower levels of education: smoking, obesity, and under-use of prevention services. The very large socioeconomic differentials in mortality in the United States suggest that the most important next step in mortality reduction in the United States and internationally might be to improve social and economic conditions of disadvantaged groups rather than further advances in medical knowledge.

Educational Opportunity and Latino/Chicano College Choice: New Findings, and Theoretical Perspectives

Introduction

Increasing educational attainment and achievement among Latino students continues to be an important policy concern. Latinos, defined as individuals of Mexican, Central and/or South American descent, make up the largest racial/ethnic minority group in the United States and are one of the fastest growing groups, second only to Asians/Pacific Islanders (National Center for Education Statistics (NCES), 2007). Despite the growth experienced by the Latino population in the United States, accessing equitable educational opportunities and achieving educational success has proven to be a substantial challenge. For example, national data show a 60% high school completion rate among Latino students (Harvey, 2002). When compared to all other youth aged 16–19, Latinos are more likely to drop out from high school (Fry, 2003). These low rates illustrate an educational crisis for the Latino population at all levels of the educational system.

The direct impact of these trends on adult Latinos is clear, given that approximately 41.5% of Latinos aged 25 and over have attained less than a high-school diploma (NCES, 2007). Latinos also lag behind every other student population group in attaining college degrees (Fry, 2003). When Latino students do transition into postsecondary education, they are less likely to enroll in a 4-year institution immediately after graduation and more likely to be concentrated in the community college system (Kurlaender, 2006). These trends are particularly disturbing given recent findings suggesting that in California only 18% of community college Latino students with intentions to complete a program or to transfer into a 4-year institution managed to do so within 6 years (Shulock and Moore, 2007).

Understanding how and with what resources Latinos form and complete postsecondary plans will assist in enhancing their educational opportunities. Indeed, the college-choice decision process that students make impacts both the individual student and, collectively, society as a whole. That is, evidence proposes a more educated workforce provides better economic returns for our nation as well as a multitude of social benefits to the individual (Pascarella and Terenzini, 1991). Research suggests, however, not all individuals have access to the same resources to make college a reality and make an informed college-choice decision (McDonough *et al.*, 2003, 2004). Research highlights Latinos,

as well as other minority groups, experience the college-choice process differently than their white counterparts and that traditional models of college choice are not sufficient to explain their particular processes (Ceja, 2001; Kim, 2004; Perna, 2000; Talavera-Bustillos, 1998). To this end, we examine the theoretical and empirical research on educational opportunity for Latino students. In addition, this article explores how factors such as race, socioeconomic status, college generational status, and gender, influence access to resources and the college-selection decisions Latino students make. Finally, we propose a new model for understanding the college-choice process of Latino students.

Latino Educational Access and Opportunity

Across the educational pipeline, Latinos experience learning opportunities that are far from equitable (Orfield and Lee, 2007). It is well documented that Latinos start school less prepared than their white counterparts, giving way to an achievement gap that has Latinos and other ethnic/racial minorities succeeding at a lower rate than their white peers (Garcia and Gonzalez, 2006; NCES, 2007). Contributing to this is the fact that Latinos are the least likely of all major ethnic/racial groups to enroll in pre-kindergarten (pre-K) programs (NCES, 2007). This is important given research findings showing positive gains in school readiness for students who attend pre-K programs (Barnett *et al.*, 2005); and for Latino children in particular, research has shown substantial improvements in prereading, prewriting, and premath skills among those who attend (Gormley, 2007).

In addition, because almost 25% of all persons living in poverty are Latino (US Census, 2001), they are more likely to be ethnically segregated in neighborhoods with predominantly minority schools (Orfield, 1992). In 2005, an estimated 77% of Latinos attended schools that were predominantly minority, compared to only 12% of white students attending similar types of schools (NCES, 2007). In their work on school resegregation, Orfield and Lee (2007) lay out the relationship between the low socioeconomic conditions of minorities and the types of schools they attend. Orfield and Lee (2007) write:

Poverty has long been one of the central problems facing segregated schools. Segregation tends to be multidimensional. Few highly segregated minority schools have middle class student bodies. Typically students face double segregation by race/ethnicity and by poverty (p. 18).

Since Latinos are concentrated in resource-poor schools with less competitive instruction, they are more likely to have underprepared and fewer credentialed teachers, higher teacher turnover, less access to honors and advanced placement courses, be in classes with large teacher-student ratios, and more likely to enroll in schools that receive fewer per-pupil dollars than nonminority schools (Yosso and Solórzano, 2006). Oakes (1990) argues that in predominantly minority schools, ability grouping is more common. Oakes highlights ability grouping as increasing academic underachievement.

Furthermore, evidence suggests quality college academic preparatory programs are less likely to be found in predominantly minority schools versus majority schools (Solórzano and Tejeda, 1998). In predominantly Latino high schools, for example, curricula tend to focus on remediation rather than academic enrichment. As several scholars document, inadequate academic preparation is a major caveat to attending a postsecondary institution (Cabrera and La Nasa, 2001; McDonough, 2004; Perna, 2005). In particular, Perna (2005) identifies academic preparation as essential "because the groups of students who continue to be underrepresented in higher education are also the groups that [were] the least likely to be academically prepared" (p. 114). Consistent with Orfield's (1992) research, Perna (2005) argues disadvantaged groups are less likely to be academically prepared, attend schools with less-rigorous programs, and are less likely to be placed in challenging classes when available.

Latino academic underpreparation and tracking into non-college preparatory courses effectively steer them into non-competitive and less-selective higher education institutions (Gutiérrez *et al.*, 2000). McDonough (2004) reinforces that the role of counselors within this tracking dynamic is crucial considering, "counseling [is] often tied to the track placement of students. Those students who [are] not in the college track do not receive college information" (p. 10). The importance of receiving college information cannot be understated. For example, focusing on financial aid information, in a national survey study conducted by the Tomás Rivera Policy Institute (TRPI), results indicate 75% of young Latinos (aged 18–24) not currently enrolled in college would have been more likely to attend college if exposed to better financial aid information (TRPI, 2004). Consistent with these findings are those of Santiago and Cunningham (2005), suggesting that Latinos receive less financial aid for college.

These unbalanced educational environments have produced academic outcomes for Latino students that are substantially lower than their white student peers

(Yosso, 2005). Indeed, the most recent report by the NCES (2007) reveals that throughout K-12 (4th, 8th, and 12th grade), the percentage of Latinos performing below basic in reading and math is among the highest in the country. In fact, by the time Latinos complete high school, only 34% would have taken some type of advanced math course compared to the national average of 50% for all students. The report also notes that only 12% of Latinos, compared to 64% of white students, take advanced placement courses and of those who take the exam, only 47% achieve a passing score or three or higher. Furthermore, recent national data from the College Board shows that only 11% of Latinos took the Scholastic Aptitude Test (SAT), a requirement for admission at many 4-year colleges and universities (The College Board, 2007). Consequently, by the time Latinos move through the K-12 educational system, less than half will be academically prepared for college entry (NCES, 2006).

College Choice

College-choice research suggests that most students who plan to apply to college normally rely on high-school counselors for college guidance, with more affluent students experiencing greater access to such school resources (Bemark and Chung, 2005; Blumberg *et al.*, 2004; McDonough, 1997). In addition, students who have college-educated parents are more likely to participate in higher education and develop a college roadmap, conavigated by family who possess the expertise to aid successfully in their college preparation (Gándara, 2002; McDonough *et al.*, 2000). For these students, the home setting becomes a critical source of college information that children can access during the college-choice process (McDonough, 1997). These students are also provided with a large and sophisticated network of resources, strategic academic options, access to costly college test-taking courses, and perhaps equally important, parental testimonies of successful college experiences (Hossler *et al.*, 1999). This privileged wealth of information helps shape students' understanding of their role in higher education, perceiving college to be a natural progression and a rite of passage afforded to them by their home and schooling experiences (Bateman and Hossler, 1996; Yang, 1981).

Efforts to understand how these factors impact students' college choices have led various researchers to develop models that attempt to explain the stages in students' college decision-making process (Chapman, 1981; Litten, 1982; Hossler *et al.*, 1989). The prevailing model among these researchers identifies three general stages of college choice; predisposition, search, and choice. According to Hossler *et al.* (1989), the predisposition phase can begin very early when educational aspirations are first

developed, which can then lead to a potential search stage. Hossler *et al.* (1989) estimate the search stage runs from approximately the 11th grade through the beginning of the 12th grade. Finally, the choice phase, when the student selects which colleges to apply to and a final postsecondary institution to enroll in, typically takes place throughout the senior year (Hossler *et al.*, 1989). These models, as illustrated in **Figure 1**, have been helpful in allowing us to think about the decision to attend college as a “complex, multistage process during which an individual develops aspirations to continue formal education beyond high school, followed later by a decision to attend a specific college, university or institution of advanced vocational training” (Hossler *et al.*, 1989: 234).

The review of the literature suggests a number of important influences on the college-choice process for Latinos. The early stages of the college-choice process are confounded by several of the background characteristics common to many Latinos, including being from a lower income strata, first generation, older, married, and having more dependents. In addition, Latinos are more likely to postpone college enrollment and attend part time, and are less likely to maintain continuous enrollment once in college. In the predisposition phase, parents play a critical role in encouraging high academic performance and higher education through the development of what Gándara (1995) calls a “culture of possibility” (p. 112). This culture is transmitted from parents through stories and modeling of a hard work ethic. In fact, much of the college-choice literature cites parents as the most important reason for Chicanas, the largest subgroup within the Latino population, wanting to pursue a higher education (Ceja, 2001; Talavera-Bustillos, 1998). It is important to note, parental support in this case is emotional or monetary and does not come in the form of college knowledge. In addition to parents, siblings, teachers, counselors, outreach officers, peers, and caring adults, are known to play important roles for Chicanas with regard to their college-choice processes. These roles range from the initial development of aspirations to enrollment at a particular institution.

In the search phase of the college-choice process, access to a college preparatory curriculum, recruitment programs,

and college and financial aid knowledge are instrumental to the advancement of postsecondary plans. As noted earlier, however, Latino students’ access to these types of resources has been difficult, leading many Latino students to make college choices under less-than-ideal educational circumstances. Indeed, Latino college-choice literature indicates that students are attracted to less-selective institutions that are most likely 2-year institutions, public, less costly, have high dropout rates, and are close to home. In addition, financial aid offers seem to encourage attendance at a particular postsecondary institution that is not necessarily the students’ first-choice institution.

Moreover, Latinas (women) seem to be slightly more sensitive than Latinos (men) to financial issues in the selection of a college, opting to gravitate toward financial and need-based scholarship assistance more often. Latinas, who matriculate into 4-year institutions, tend to enroll in universities that are less selective, less research-intensive, and are primarily master’s-granting institutions. Meanwhile, research has found that Latinas who attend community colleges do so because they decided too late that they wanted to pursue a higher education, find it less costly, are not academically prepared, or opt for a 2-year institution as a last resort. Based on their quantitative examination of the Latino college-choice process, McDonough *et al.* (2004) conclude that “gender, in addition to race, is indeed a critical factor mediating the college choice process for Latinos and Latinas and merits further attention” (p. 35).

Toward a Latino College-Choice Model

Given the emphasis on quantitative methodologies to understand college-choice processes, alternate theoretical frameworks have employed qualitative methods and corresponding theoretical frameworks to highlight nuances inherent in this process. Although quantitative methods are helpful in creating a general picture for mainstream students, existing models fail to capture how race, class, and gender mediate the college-choice process for Latino students. As a result, scholars have utilized frameworks, such as social capital, chain migration, and resiliency, among others,

Predisposition	Search	Choice
Decision to attend college	Explore college information	Completes applications and selects a college
Kindergarten-9/10th	11th-beginning of 12th	12th

Figure 1 College-choice model. From Hossler, D. and Gallagher, K. S. (1987). *Studying Student College Choice. A Three Phase Model and the Implications for Policy Makers*. College and University 2(3), 207–221; and Hossler, D., Braxton, J., and Coopersmith, G. (1989). Understanding student college choice. In Smart, J. (ed.) *Higher Education: Handbook of Theory and Research*, vol. 4, pp 231–288. New York, NY: Agathon.

to bring to light the particular college-choice process for Latino students.

Social Capital Theory, Chain Migration, and College Choice

Coleman (1988) maintained that social networks provided the opportunity for the exchange of information. However, the quality of information exchanged was largely based on the functional components of social capital, trust, and norms. High levels of trust between individuals facilitated the exchange of more knowledge, while norms regulated and influenced behavior related to this exchange. Within education, social capital is the relationships between students, families, communities, and teachers available to support and motivate students toward academic success. Further, social capital theory captures the effects of the school, parents, and community on a students' learning environment (Croninger and Lee, 2001).

Social capital has been used on research that includes Latino students to look at the role of institutional agents on high-school students' educational and occupational expectations (Stanton-Salazar and Dornbusch, 1995); to examine the influence of familial and nonfamilial member social capital on the study habits of Mexican-American eighth graders in comparison to Vietnamese youth (Goyette and Conchas, 2002); and has also been used to understand how familial and school staff positively influence (or hinder) postsecondary access for Latinas (González *et al.*, 2003).

Meanwhile, Person and Rosenbaum (2006) used chain migration theory to examine access to college information and the enrollment decisions of Latino students at 14 2-year colleges. They argued "research on immigrant communities can inform the study of college enrollment, as it encourages the researcher to examine enrollment and persistence as part of a continuous process" (p. 52). Person and Rosenbaum (2006) also suggested that the structures that facilitated

migration to a new community were likely to influence an individual's future experiences. Future experiences may include career as well as academic endeavors.

Using social capital theory as a framework for studying college choice brings into focus those relationships that create and established networks and resources that facilitate Latinos through the educational pipeline from initial aspirations on to higher education. In addition, chain migration influences also are emphasized and interpreted within this social capital theoretical framework. Indeed, having the requisite social capital is necessary in order to establish chain migration contacts (Massey, 1998). More clearly, without having established relationships with certain individuals and developed networks with accessible information, those social structures necessary for migration are absent (Tilly and Brown, 1968). According to Person and Rosenbaum (2006), when applying the theoretical concept of chain migration to college choice, students might (1) apply or select colleges where someone they know has preceded them; (2) apply or choose a college along with someone they know; or (3) seek out contacts once at the college. Based on research, using the concept of chain migration and social capital theory, a new framework for understanding Latino and Chicano college choice is proposed (Figure 2).

This revised college-choice model allows us to understand that for Latinos, the decision to attend college cannot be conceptualized as a natural progression that occurs in their educational trajectory. As noted by Yosso and Solórzano (2006), Latinos experience significant challenges in the educational pipeline, with many of them leaking out before the completion of high school. The educational opportunities that Latino students envision for their future, as well as the subsequent choices they make about their postsecondary options, are shaped by their access to educational learning opportunities available at their schools as well as the resources and information

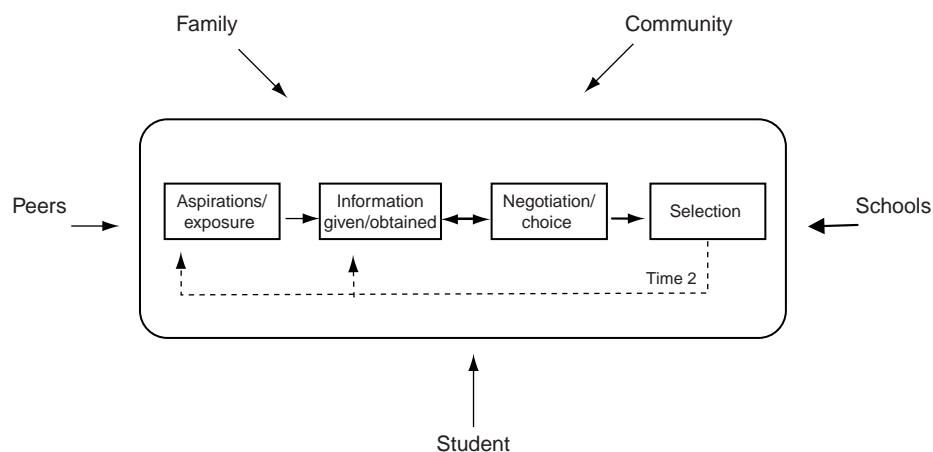

Figure 2 Latino/Chicano college-choice model. Pérez, P. A. (2007). *Social Capital and Chain Migration: The College Choice Process of Chicana and Chicano Community College, Transfer and University Students*. Unpublished Doctoral Dissertation, University of California, Los Angeles.

available to them at home. Latinos, like other ethnic/racial groups, who have parents with little or no college background often face the daunting task of navigating their academic endeavors and college-choice process alone (Ceja, 2006; González *et al.*, 2003). Many of these students are not well informed about accessing higher education and they also lack the instrumental knowledge, mentorship, and social support network necessary to negotiate their academic preparation and college options (e.g., Cooper *et al.*, 1998). In fact, research has shown that ethnic/racial minorities, including Latinos, receive poor and conflicting academic mentorship from institutional agents, such as high-school guidance counselors, resulting in gate-keeping of college resources (Stanton-Salazar, 2004).

This Latino/Chicano college-choice model takes the educational conditions of Latino students into account by placing issues of access to college information and the negotiation of such resources at the center of the college-choice process. These educational conditions are undoubtedly molded by external factors such as the surrounding community and/or school. The model further accounts for community college and transfer students, who may not necessarily follow an immediate or linear progression toward higher education. Should transfer students desire and are able to transfer, this model takes into consideration the second college-decision-making process (see **Figure 2** – time 2). Unlike previous college-choice models, the proposed model highlights student agency and the influence of family, peers, schools, and the community on the Latino/Chicano college-choice process (Pérez, 2007). A conceptual model that better reflects the college-choice decision-making process for Latino students can assist us in enhancing their postsecondary prospects by highlighting critical areas in need of resources. This model emphasizes the need to involve all constituents (e.g., families, peers, and schools) to truly improve equality of postsecondary opportunity for Latino and Chicano students. Finally, this type of model can be helpful in understanding the college-choice experiences of students outside of the United States. For example, the chain migration focus of this model provides an alternate framework for capturing Hamrick's (2007) finding that Pakistani students who enroll in US higher education institutions tend to choose schools that are near relatives or colleges where other Pakistanis are enrolled. Likewise, the applicability of this model can be tested to understand Kaufman's (2008) research on how perceived costs of higher education affects college attendance in Mexico, or how college choices in Portugal are influenced by proximity to home, parents, teachers, and access to college marketing resources (Raposo and Alves, 2007).

Glossary

Gini coefficient – A measure of statistical dispersion most prominently used as a measure of inequality of income distribution or inequality of wealth distribution.

Harmonious society – A political and educational campaign of the Chinese Communist Party to address indications of growing social instability and focused on the coordination of economic and social development, promote social equity and justice, and to strengthen social affairs management and services.

Nationality autonomous regions – The five provincial level areas of the country associated with an ethnic minority and recognized in the constitution as having a number of rights not accorded to other provinces.

Preferential treatment policies – The policies meant to provide advantages to ethnic minorities. In education, it might include financial subsidies for schools, bilingual education, and points added to university entrance-examination scores.

Introduction

Despite China's meteoric rise, little international scholarly attention has focused on its 110 million ethnic minority population who occupy half of China's land mass and 90% of its border regions (Gladney, 1991; Harrell, 2001; Mackerras, 1994, 1995). China's centuries of experience with ethnic intergroup processes and how it navigates its global economic integration in an increasingly multicultural world add up to a Chinese ethnicity on the move, and one with potentially far-reaching international implications. Already, there is an apparent clash of East–West cultural perspectives on the plight of Tibetans in China.

China presents itself as a multiethnic state but promotes cultural assimilation (Heberer, 1989). Educational institutions in ethnic minority regions become civilizing agencies to transmit mainstream Han Chinese cultural capital. The aspiration to become an economic power, and also to restore its status as one of the world's great civilizations – especially following the nineteenth-century humiliations at the hands of the Western powers – drives

national ethnicity. While its economic rise is a promising start for this restoration, China remains highly sensitive about the presentation of its twenty-first-century civilization to the larger global community.

Thus, reconciling ethnic minority cultures within the vision of its national civilization is a major undertaking. China is moving with trepidation toward embracing a Western-style multiculturalism. Yet, it is aware that many of its overseas families – still considered patriotic and Chinese by blood – have become integrated into Western multicultural countries. Unlike the United States with a large population of voluntary migrants, China is a land of indigenous minorities who are not likely to migrate and therefore more akin in this respect to Native Americans (Ogbu, 1978). While several of China's ethnic minority groups sustained their own slave societies into the early twentieth century, these differed in key respects from the slave experience of African Americans. The American government's concern with a Hawaii separatist movement pales in comparison with China's intense focus on its territorial unity – still a major theme in its ethnic minority discourse and foreign policy. For these and other reasons, the Chinese education makes national unity a central focus. With most of its overseas students and future leaders having studied in the United States, China has come to view the United States as a nation that has successfully used education to build a staunchly patriotic nation. (Like the United States in earlier times, China has used the term nationalities to refer to what is now rendered in English as ethnic groups (the term, in Chinese, for nationalities (*minzu*) and ethnic groups is the same), although there has been a growing popularity among Chinese anthropologists (Bilik, 2000) to use the word *zucun* for ethnic group.)

This article argues that China contributes to the global picture of ethnicity by having sustained the longest history of state-sponsored preferential treatment policies in education, and the manner in which it uses education to navigate its current phase of critical pluralism within its emergent global integration.

Ethnic Minority Education Policy

Most – though not all – of China's ethnic minorities occupy western regions of the country which are poorer and more remote than China's prosperous east-coast

urban areas. Many ethnic minority families have only just entered their first generation of literacy and schooling. Moreover, since most ethnic minorities live in concentrated communities called autonomous regions, their educational opportunities are far lower than what would be available to those in China's prosperous cities such as Shanghai, Beijing, and Guangzhou. In fact, China's pace of economic development has exacerbated, rather than alleviated, social inequality. According to the Gini coefficient – which is used to measure the degree of inequality within a country – China's Gini coefficient of 0.47 makes it the most unequal country in Asia following Nepal. Nevertheless, of the 55 officially designated ethnic minorities of China, several groups (i.e., Koreans, Tatars, Daur, Russian, Xibe, Bai, and others) have educational achievement levels near or above the national average. It is also notable that socialist China had much earlier instituted a set of comprehensive preferential treatment policies that are still in effect.

These preferential policies provide subsidies for minority schools, bilingual education, school textbooks in minority languages, curriculum reforms, ethnic minority teachers training, and boarding schools. In higher education, the most notable policies are those that provide preferential access to college and university through both admission quotas and points added to scores on the national entrance examinations, as well as remedial classes during the first year of college and university (Xia *et al.*, 1999).

These policies are widely believed to ensure educational opportunities for economically and educationally underserved ethnic minorities, especially under the increasing impact of marketization. While these policies have been successful in reducing inequalities by raising the numbers of ethnic minorities attending school and university, most ethnic minority groups still have lower rates of access and educational achievement, especially at university level.

The Sociology of Ethnic Minority Education in China

Research on ethnic minority-education underachievement in China has moved ahead in recent years. The focus has been on multiple factors – ranging from language and religion, cultural transmission and family background, migration, and politics (Iredale *et al.*, 2001; Hannum, 2002; Lee, 1986, 2001; Stites, 1999; Lam, 2005; Zhou and Sun, 2004; Mackerras, 1999; Gladney, 1999; Lin, 2005b; Harrell and Ma, 1999; Hansen, 1999; Tsung, 2003; Nam, 1996; Yu, 2009; Cheung, 2003; Chen, 2004). While there are several works that focus on university students, most focus on ethnic identity in provincial or special universities (Lee, 2001; Trueba and Zou, 1994; Clothey, 2003) rather than

ethnic minority access to and achievement at China's top universities (Sautman, 1999). There is also a growing literature on specific groups. For example, in the case of Tibetans, literature has increased in recent years (Nyima, 1997, 2000; Upton, 1999; Bass, 1998, 2008; Zhang *et al.*, 2008; Seeberg, 2006, 2008; Bangsbo, 2008; Wang, 2007; Yi, 2005; Wang and Zhou, 2003). While the literature on ethnic minority achievement in education is multidimensional, most of it is focused on school rather than university access (Chapman *et al.*, 2000).

Among mainland-based Chinese sociologists and anthropologists, the literature has also grown rapidly. For example, Teng Xing established a research institute for ethnic minority education at the Central University of Nationalities and edits its *Journal of Research on Ethnic Minority Education* (*Minzu jiaoyu yanjiu*) (Teng, 2002). More recently, in a special issue of *Chinese Education and Society*, Ma (2007) has examined one of the stickier issues in the sociology of ethnic minority education – bilingual education and sees an increase in support for Chinese as the medium of instruction in ethnic minority schools. While he favors giving ethnic minority parents a choice of either native language or Chinese as medium of instruction, a market economy prods parents to choose the language of the job market, irrespective of the educational benefit. Zhao (2007) has examined the ethnic minority cultural dimension and concludes that minority culture is marginalized at universities. Zhu (2007) explores how minority students in state boarding schools construct ethnic identities and the specific modes used by individual students. Qian (2007) examined how the hidden curriculum creates discontinuities within cultural traditions and ethnic identities. Ba (2007) – a member of the Yugur ethnic minority of Gansu province – studied how schools disseminate both ethnic minority and modern culture, and argues that there is an estrangement and disjuncture between the culture of the classroom and the community – a result of the choice to absorb the national plan of instruction. Finally, Wang (2008) examined how the children of rural migrants from minority regions who try to settle in Beijing experience double discrimination – as migrants and as ethnic minorities – as they strive for urban membership.

Case Studies

Recent case studies have improved understanding of the processes at work in China's minority education. Although the 1990s saw an increase in the amount of useful quantitative data available, it was unable to capture detailed processes at work as minority students construct meanings and identities from state schooling or to explain why minority children have higher dropout rates. The following section contains the case studies of the education of minorities like Tibetans, Uyghurs, Mongols, Naxis,

and Koreans in China. While the themes of these studies are about national integration, ethnic and national identity, and cultural recognition, a common concern in all of these studies is equal opportunity in educational access and achievement.

Zhu (2007) studied the challenge to Chinese education posed by Tibet. Tibetans have had a written language for over 1500 years – one that is in common use across a territory as large as the continental United States. Despite a rich cultural heritage, Tibet has the lowest educational levels of any provincial level entity in China. Doubtless, this has something to do with poverty and remote geographical location. Therefore, schools and classes for Tibetan students were relocated to Chinese cities beginning in 1985 where better school facilities and trained teachers could be used to foster talent to drive Tibet's economic development. In the first year, one-quarter of all primary school graduates were sent to relocated schools in China for 4 years of junior secondary education and 3 years of senior secondary or vocational education. Zhu provides a grounded view of what actually happens in these schools through the eyes of Tibetan students. He also illustrates the contestation over the meaning of Tibetan culture, who defines it, and how students innovate in constructing their identities around that definition. While the school attempted to assign a desired identity in accordance with the state ideologies, the Tibetan students were able to assert a Tibetan identity expressed through the representation of Tibetan culture, as well as influenced by their experiences on and off their school campus.

Chen (2008) examined how Uyghur students in the so-called Xinjiang Classes (Chinese boarding schools located outside of the home province of Xinjiang), respond to the school goal of ethnic integration. Guided by the theoretical framework of social capital analysis, the study's findings suggest that Uyghur students' response to the goal of ethnic integration can be viewed within a series of analytical levels, including the history of the Uyghurs within China, the Xinjiang boarding schools as a formal organization, Uyghur students' social networks, communal norms and sanctions, and Uyghur students' social actions in the Xinjiang Classes. The study finds that the Uyghur students have created bonding social capital within the social practice of their ethnic norms and sanctions. Their social practice draws ethnic boundaries and demonstrates resistance to the school goal of ethnic integration. The students have also created a linking social capital to tap into the resources of peers, as well as staff and teachers, that improves their academic performance and helps them adapt to life in the boarding school. Nonetheless, they lack bridging social capital which connects them with students and teachers of other ethnic groups, thus making the goal of ethnic integration more difficult to achieve. The study explains the Uyghur students' responses as a form of social recapitalization. While

boarding-school life limits the acquisition of social capital from their families and communities in Xinjiang, they develop new forms of social capital among ethnic peers on campus to help facilitate their academic success.

Zhao (2009) examined ethnic minority cultural recognition at universities through a multicase study focused on the Mongol undergraduate students' experiences and perceptions. She examines the institutional obstacles to cultural recognition in higher education – despite the state and university discourses of equal access to learning through preferential admission policies. Zhao reports on three particular institutions: the Inner Mongolia Normal University (governed by a Mongol nationality autonomous region), Beijing Normal University (governed by the State Ministry of Education), and the Central China University of Nationalities (governed by the State Ethnic Affairs Commission). Zhao expresses doubts on the extent to which the universities recognize Mongol culture. She asserts that Mongols are a “decorated culture,” marginalized within the context of university life and few Mongol students speak Mongol language on campus. She also notes the complex layering of identity between *minkaomin* and *minkaoban* students – the former who enter university by taking the examination in their native language and the latter who take it in Chinese. Not unexpectedly, Inner Mongolia Normal University gives more attention to Mongol culture than Beijing Normal University because the former is within the Inner Mongol Autonomous Region. However, even in the Central China University of Nationalities, ethnic culture is marginalized. Zhao acknowledges that preferential admission policies help Mongol students, but concludes that the lack of cultural recognition on the part of universities limits meaningful access to higher education in China for its ethnic minorities, thereby sustaining their patterns of underachievement.

Yu (2009) studied state schooling and Naxi minority-identity construction. She examined Naxi secondary school students' experience, as well as the role played by Naxi intellectuals', as an asset in student-identity resurgence since the 1980s. The changing roles of school, community, and family in the identity construction suggest that Naxi students retain a strong Naxi identity, by inheriting the knowledge, values, and worldview of their ethnic group, while also managing to fit into mainstream culture. Three forces affect identity construction of the Naxi students: the state and the school; Naxi intellectuals; and socialization in the family and community. As an institution of the state, the school conveys national ideology and instills a sense of ethnic unity and an understanding of the culture of the Chinese nation. While the school takes an active role in ethnic identity construction of the Naxi students, Naxi intellectuals – through their research publications – respond to policies and activities so as to revitalize Naxi culture. The Naxi process of identity construction is characterized by a relatively harmonious

and creative engagement with ethnic and national identity. Two factors contributed to this harmonious identity construction. First, since the late 1970s, the identity of ethnic minority groups has been gaining strength and recognition in China, while – at the same time – market forces have been creating assimilationist pressures. The minorities have taken steps to revive the use of their native languages, and to demand that their native cultures are taught in the public schools. Second, the Naxi already have a long historical tradition of integrating well into Han Chinese culture. Their traditional education is heavily influenced by Confucianism and interactions over several hundred years with Han Chinese. The study contributes to an understanding of why Naxi students adapt generally better than many other ethnic minority groups in China to state schooling.

Gao (2008) studied ethnic Koreans in China, a group widely recognized as a model minority primarily for their academic success rates which are above the national average in China. This research examines how Korean elementary-school students construct meaning out of the model minority stereotype in the context of their school and home experience, and how the meaning construction impacts their educational aspirations and strategies in peer networks. Through comparative analysis, Gao notes that, in a variety of cultural contexts, ethnic Koreans survive as a distinct group that participates in the mainstream without being completely assimilated. Koreans in China and the United States are believed to pull themselves up by their cultural predispositions. This research points to the continued need to modify the model minority stereotype that tends to essentialize ethnic Koreans as a homogeneous group with academic attitudes and success. Research results argue that the model minority stereotype may reinforce the cultural deficiency argument about the academic failure of backward minorities, silence the disadvantages suffered by ethnic Koreans, and lead to no active intervention to remedy them.

China's Ethnic Pluralism

Thus, pluralism is as important as harmony in conceptualizing ethnic intergroup processes in China, and has been the source of much cultural vitality throughout China's history. Yet, this pluralism has not been free of ethnic conflict as in imperial times during the Mongol and Manchu Eras when intergroup processes included both harmonious acculturation and conflict-prone impact integration (Dikotter, 1992).

It is helpful to understand the background themes that guide education of ethnic minorities in China (Dreyer, 1976; Fei, 1980). For much of its history, China was a highly pluralistic society in the world and guided by a culturalist tradition that assimilated many groups into

its cultural center. At about the time of the incursions of the Western powers into China in the nineteenth century, this began to change, and, by the twentieth century, China began to adopt the policies of former USSR. This amounted to a more politicized set of themes which led to the establishment of national autonomous regions. There are a number of scholars in China who now suggest that China should draw upon that characteristically culturalist position so as to strengthen national identity among its ethnic minorities (Ma, 2007a, 2007b). In fact, ethnic minority-education policies and practices since the founding of the People's Republic of China have paralleled the changing political climate.

Following the revolution in 1949, the government worked with ethnic minority elites to integrate diverse territories into the national fabric (Dreyer, 1976). Ethnic minority groups were identified and minority languages were recognized and supported. However, political campaigns that stressed class struggle resulted in less generous policies toward cultural vitality of the ethnic minority. The Cultural Revolution wrought havoc on cultural traditions of ethnic minorities. This was followed by a national effort to redress past wrongs, and accompanied by a resurgence of ethnicity. Since 1978, China's economic reforms and its opening to the outside world have greatly increased the interactions between different ethnic communities. This has contributed to a critical pluralism in education in which national patriotism and ethnic minority cultural autonomy have to keep pace with market forces and globalization.

The decision of the Chinese leader Deng Xiaoping in December of 1978 to launch economic reforms and open China to the outside world continues to have major implications for ethnic minority education. In China's new market economy, competition has become part of the national ethos – making preferential policies for minorities less popular among the majority ethnic group. Moreover, as restrictions on population movement are lifted to fuel the labor market for increased economic growth, both ethnic minorities and Han Chinese migrate to urban areas where they increasingly interact and compete. Many Han Chinese also migrate westward to ethnic minority autonomous areas for work and, often, out-compete local ethnic minorities for jobs. This is especially true for jobs in national infrastructure projects linked to the central government's western development project. The same is true for many small-scale businesses that serve the growing population of Han Chinese from other parts of the country.

Within the ethnic minority autonomous regions, inter-ethnic interaction and competition for jobs has increased. The resulting increase in inter-ethnic animosities is viewed as part of the reason for the government's nationwide harmonious society campaign. (While this campaign focuses on ethnic minority regions and minority-Han relations, it is also related to growing urban labor, urban

migration for jobs, rising costs in rural areas, relocation of households due to urban development, and other social problems.)

The underlying theory of ethnic relations in China since the launching of the economic reforms and the opening to the outside world is Fei Xiaotong's *duoyuan yiti geju*, also rendered in English as plurality within the unity of the Chinese nation (Fei, 1986, 1991). This assimilationist theory has floundered in the arena of globalization and market forces. Rather than move China's ethnic minorities toward cultural assimilation, economic globalization and state schooling have also made ethnicity more salient and intensified ethnic identities.

As the reform period unfolded, China's ethnicity entered a period of critical pluralism. This phase of increased interethnic contact, resurgence, and saliency of ethnic identity occurred along with discontinuance of the job-allocation system, market competition for jobs, compulsory mass schooling that stresses a unified national identity, and telecommunications that make it easier for remote ethnic communities to sustain and extend ethnic solidarity. The increasingly critical nature of ethnic pluralism has placed Chinese ethnicity at a crossroad. Ethnic intergroup antagonisms and misunderstandings can foster a nation of plural monoculturalisms in which ethnic groups emphasize their cultural identities above those of the nation and limit their potential to take on a multiple role in national development. The other direction for Chinese ethnicity is toward a harmonious multiculturalism. This would coincide more closely with the state's campaign for a harmonious society. However, the Chinese state has been unwilling to fully embrace multiculturalism. How educational institutions handle the current phase of critical pluralism may determine whether it generates a national society of plural monoculturalism or harmonious multiculturalism (Sen, 2006). If China is to head in the direction of harmonious multiculturalism – in which conflictual tendencies that characterize interethnic relations are viewed as positive opportunities for building increased mutual understanding, then education has a role in transmitting multiculturalism in three ways: first, by making the curriculum of state schools more relevant to the cultural vitality of ethnic communities; second, by stressing multiculturalism and critical thinking skills; and, third, not only by sustaining preferential treatment policies that increase access to higher education but also increasing ethnic minority cultural recognition on campus so as to foster more meaningful access and academic success.

Conclusion

Ethnic diversity in China rivals that of anywhere else in the world and is the source of much of the nation's vitality.

This not only includes diverse cultural traditions and practices, but also the differing social, economic, and political statuses. While the majority Han Chinese culture and Confucian education heritage exert a significant influence on East Asia and beyond, the cultural traditions and practices of China's ethnic minorities are not widely recognized in China's school curriculum. Nevertheless, they are in the family and community through linguistic, religious, and social practices. Religion is central to the lives of most of China's minorities and the Chinese constitution guarantees freedom of religion (Mackerras, 1994, 1995). However, there is a strict separation between schools and religious institutions. All but two of China's 55 officially designated ethnic minority groups have their own languages. Some have more than one, and at least 21 ethnic minority languages are used in schools, either taught as a subject or used as a medium of instruction. Since 90% of China's border regions are occupied by ethnic minorities, schooling is expected to ensure that national identity is strengthened enough to ensure social stability, especially in the case of Tibet and Xinjiang where the government has identified separatist movements. Therefore, educational policies are challenged to strike a balance between local and national interests so that the dual construction of ethnic and national identities can take place simultaneously.

Ethnic Studies and Women's Studies: From the Past to the Present, Providing a Space in the Academy for Scholarship Focused on the Histories and Experiences of Marginalized People

C A Brown

Introduction

Ethnic studies and Women's studies emerged on college campuses as academic disciplines in the late 1960s to the early 1970s (Blumhagen and Johnson, 1978; Karenga, 2002; Labelle and Ward, 1996; Wood, 1979; Yang, 2000). Students, faculty, staff, and community activists played a role in the development of these programs (Blumhagen and Johnson, 1978; Karenga, 2002; Labelle and Ward, 1996; Wood, 1979; Yang, 2000). Through much protest and debate over discrimination and the marginalization of women and people of color, these programs were ultimately approved and institutionalized (Blumhagen and Johnson, 1978; Karenga, 2002; Labelle and Ward, 1996; Wood, 1979; Yang, 2000). These programs are unique in their histories, contributions, and in their interdisciplinary nature. While thousands of universities have implemented programs, departments, and even schools on their campuses, there are still some colleges and universities who have yet to move beyond offering a few classes. However, recent data show that on many college campuses and universities, the initial reasons for the establishment of these disciplines persist in higher education and called for the continued scholarship with a focus on women and people of color.

History

The 1960s was a time of unrest and confrontation, and students (people of color and whites) were at the center of the struggles that ultimately engendered the legitimacy of ethnic studies and women's studies. The struggle against the racist structure and functioning of society began off college campuses. However, students began to see the university as playing a significant role in distributing power. The university was pictured as a microcosm of how society looked and functioned in terms of race, class, and power. It was perceived as racist and unresponsive to women or peoples of color. Students felt as though colleges were committed to the exploitation and oppression of Blacks, other people of color, and the poor, and to their exclusion from the social knowledge, wealth, and power in US society. The decision then was made to take up the struggle against society and the university, which

was seen as society's brain and its intellectual factory which produces leaders and followers as well as its social myths (Karenga, 2002; McEvoy and Miller, 1969; Robinson, *et al.*, 1969; Van Deburg, 1993). This perspective led Black-studies scholars and students to link knowledge and power, campus and community, student learning with student service and activism in and for community, and society and the world.

The social struggles in the 1960s served as both a context and encouragement for the emergence of a student movement which linked itself to these larger struggles for social change both on campus and off campus (Blumhagen and Johnson, 1978; Karenga, 2002; Labelle and Ward, 1996; Wood, 1979; Yang, 2000). There were four basic thrusts in the student movement, each of which aided in creating the context and support for the emergence of Black studies as a discipline. These are (1) the Civil Rights Movement; (2) the Free Speech Movement; (3) the Anti-Vietnam War Movement, and (4) the Black Power Movement (Karenga, 2002). The final thrust of the student movement which led directly to the establishment of Black studies began in 1965 with the emergence of the Black Power Movement.

The Black Power Movement stressed on self-determination, cultural grounding, relevant education, cultural pluralism, and student activism. Within this movement, Black Studies emerged as a movement and a discipline. It began in 1966 at San Francisco State College (SFSC), now San Francisco State University, and was initiated and led by Black students (Edwards, 1970; Karenga, 2002; Orrick, 1969; T'Shaka, 1982). By 1966, the Watts Riots and the Black Power Movement engendered in a more racially self-conscious and assertive activism among Black students at SFSC and on other campuses as they began to respond to this resurgence of national activism. In 1966, the Negro Students Association changed their name to the Black Student Union (BSU), indicating a new identity and direction (Karenga, 2002). That same year, the BSU produced a document demanding the first Department of Black Studies.

To begin working toward their ultimate goal, Black students established a Black arts and cultural series in the Experiment College, which was created in 1966. They also became involved in SFSC's tutorial program for surrounding communities. This and other community-service

activities demonstrated their social commitment to service, which Black Studies advocates placed at the center of the academic and social mission of Black Studies.

There was no resistance to the Experimental College because it was set up with student money, but the demand by the BSU for a legitimate Black Studies Department funded by the college and controlled by Black people brought stiff resistance (Karenga, 2002). By 1968, the situation had escalated to the point where the BSU launched a strike on 6 November around a series of demands connected to the struggle of Black people, including a Black Studies Department, special admissions, financial aid, and decisions on personnel.

In 1967, Black and other minority students at SFSC presented a proposal to the administration. This proposal pushed for more minority students and for institutionalizing a Department of Black Studies. On 8 November 1968, the Black Student Union and Third Liberation Front, a coalition including Black, Chicano, American Indian, and Asian American students, called for a general strike to reclaim their education (Karenga, 2002; LaBelle and Ward, 1996). The main justification for this strike was the historic and systemic exclusion of minorities in higher education, both in admissions and in the curriculum. They felt that the study of American history and society should not merely include minorities but must also derive from the perspective of people from those communities.

Their demands broadened to seek the establishment of a school of ethnic studies that included four minority groups (Blacks, Chicanos, American Indians, and Asian Americans) rather than a separate Black Studies Department. In response to the protest, SFSC decided that it was in the best interest of the institution to establish an ethnic studies program that would offer courses and conduct research from the perspective of minority groups. They argued that those who taught the classes and did the research must be participating members of ethnic minority communities. This criterion was thought to ensure a more authentic view of those communities.

By the fall of 1968, the experiences of SFSC were being duplicated on dozens of campuses throughout the country. That year, ethnic-studies initiatives, programs, centers, and departments at universities and colleges were established around the world. SFSC established the first college of ethnic studies in 1969. While ethnic studies was not expected to last, the growth has continued. In 1983, the University of California, Berkeley approved a doctoral program in ethnic studies.

Much like ethnic studies' parallel with the black power movement, women's studies paralleled the women's movement that occurred in the mid-1960s. The relationship between the two suggests that the principles upon which the movement flourished rest on a strong intellectual base. They felt that the need for knowledge about women and for

women should have a legitimate place within academia. Women's studies was seen as a vehicle for change and expression, as an integral part of the larger context of the feminist movement.

The first women's-studies courses appeared in the late 1960s and early 1970s and the first women's-studies program was founded at San Diego State University in 1970 (Butler *et al.*, 1991). By the end of 1970, the Modern Language Association's commission on the status of women listed 110 college and university courses dealing with women (Crowley, 1999). Moreover, in the early 1970s, journals supporting the idea of women's studies as a separate academic activity appeared.

By the 1990s, more than 2000 accredited colleges and universities offered women's studies as a program of study. Today, women's studies continues to grow as more and more universities and colleges offer majors and minors and new masters and doctorate programs are established.

Women's studies was built by scholars who dedicated themselves to claiming space in the curriculum for women's diverse experiences and societal contributions. They explored gender as one of several important and interdependent social and cultural aspects of identity, including race, class, age, ability, nationality, and sexual orientation. They practiced pedagogies that valued personal growth, reciprocity in relationships, and exchange of knowledge. Their work challenged disciplinary boundaries and critiqued masculine biases embedded in the academy.

Scholarship

Ethnic-studies and women's-studies programs are generally labeled interdisciplinary. Interdisciplinary connotes the idea of multidisciplinary, that is, combining courses from a number of different disciplines into one course of study. Nonetheless, although multiculturalism and feminism were part of a wider seismic shift of social movements, the fact that ethnic studies and women's studies established space either within the disciplines or on their margins was an act of consummate collective political and intellectual will. Scholars in these fields would have to confront research that typically only took into account the perspective and experiences of White men. They were charged with the responsibility of adding other histories, voices, and perspectives to the curriculum to increase the understanding of the human experience to more accurately reflect the diversity of experiences that exist for people.

Justifications for ethnic studies and women's studies moved beyond the allegation that there was need for knowledge about people of color and women to incorporate an additional need for the creation of knowledge by and for them. It was argued that women and people of color could bring new perspectives and values to scholarship

(Blumhagen and Johnson, 1978; Buker, 2003; Burghardt and Colbeck, 2005; Karenga, 2002; Labelle and Ward, 1996; Wood, 1979; Yang, 2000). Although not everyone was convinced that these new perspectives and values were unique to them, as a result of their own subordinate place in the academy as well as society, women and people of color began to pose questions about the prevalent ideas and ways of thinking. While knowledge about women and people of color is important, it is equally important to value the creation of knowledge by them.

Ethnic studies and women's studies have their own set of cohesive and persistent questions that encourage scholars to question the questions (Bartlett, 1990; Wishik, 1986). These scholars persistently question the distribution of power between genders, among ethnic groups, sexualities, and classes. Their questions attempt to recover the contributions of women and people of color in science, society, and the arts. They have worked to challenge and revise canons and standards, and by correcting historical omissions to include the outstanding human contributions rather than merely the most outstanding White male contributions.

Striving for More Autonomy

Despite being in the academy for over 35 years, most ethnic-studies and women's-studies courses cross disciplinary boundaries to foster integrative learning. On many campuses, ethnic and women's studies remain in marginalized positions as programs rather than departments. This can create challenges, as disciplinary departments hold the power associated with intellectual and administrative authority over curricular, hiring, tenure, and promotion decisions. As such, many ethnic-studies and women's-studies programs lack this power and therefore depend on traditional departments to hire and promote faculty trained and willing to do interdisciplinary work. Faculty holding these appointments are required to appease and offer a course that fits in two departments. They also have to rely heavily on their department for resources that impact their professional development.

Furthermore, individual faculty members who are teaching in these programs rather than ethnic-studies and women's-studies departments make scholarly decisions in the context of a patriarchal system. Many worry that power imbalances in colleges and universities favor White males and that much of the curriculum is male centered (Karenga, 2002). Nevertheless, there are increasing numbers of women- and ethnic-studies graduate programs across the country, and more talented interdisciplinary feminist and ethnic-studies scholars will be seeking opportunities to associate with and to teach courses within these disciplines. They are likely to expect

the freedom to work within and beyond departmental boundaries, so retaining them in the academy may depend on the flourishing these programs.

Power Dynamics within the Disciplines

Although ethnic studies and women's studies have similar missions and intent with regard to challenging and adding to previous scholarship, the relationship between these two areas have not been perfect. In both disciplines, there has been critique about the marginalization of the perspective of women in ethnic studies and women of color in women's studies.

Despite differences of sexuality and class, White women had an unrecognized unity which allowed them to be identified as women. Black feminists argued that this collective identity established a sense of White women sharing a reality as women, and of collectively belonging to the cultural traditions which were identified as constituting the realities of women in general (Burghardt and Colbeck, 2005; Crowley, 1999; Hooks, 1982). However, many academic feminists came to realize that their whiteness gave them access to a privilege that was entirely unselfconscious and so unacknowledged and unrecognized (Burghardt and Colbeck, 2005; Crowley, 1999).

This resonated closely with the criticism that women scholars had of their male colleagues. They argued that their maleness gave them access to a privilege that was entirely unselfconscious. For White feminists to concede that differences exist for Black women and women of color, would mean admitting that they had a role in the racist social order (Bhavnani, 1997; Burghardt and Colbeck, 2005). Women's studies was on the whole racially unselfconscious, engendering a critique that women of color were excluded from much of the rhetoric and practices of hegemonic feminism (Bhavnani, 1997; Burghardt and Colbeck, 2005). Their exclusion was compounded not only by the privilege of whiteness but also by the hard-won privilege that White feminists had gained through the development of women's studies (Bhavnani, 1997; Burghardt and Colbeck, 2005). Much in the way that multiculturalism allowed ethnic minorities to participate in the dominant culture provided they had no designs on either the arrangement or the dominant group which initiated it, Black women and women of color could be added-in and be incorporated by the women's studies (Bhavnani, 1997; Burghardt and Colbeck, 2005). Such an accommodation was unsatisfactory because it left the category of feminist itself as singular, universal, unquestioned, and therefore intact (Bhavnani, 1997).

In similar ways, women of color had to make sure their voices and histories were examined and taught in ethnic studies. Given their exclusion from women's studies scholarship, it became even more important for ethnic-studies

programs, their experiences, and histories. Ethnic-studies scholarship, particularly Black-studies scholarship was critiqued for its lack of adequate treatment on women (Karenga, 2002). Black women pushed for space for the teaching and research in Black studies and in women's studies. They challenged male-centered interpretations of African and human reality. Black women scholars produced and pushed for alternative visions (Karenga, 2002). The critique of the exclusion of women of color caused scholars to begin examining how race, class, gender, and sexuality intersect to create different realities and experiences. This inclusion calls for a richer understanding of the diversity that exists within the human experience.

Continued Need for Ethnic and Women's Studies

Recent research (Brown, 2006) that examined two African American studies programs revealed that students' desires to take classes or earn a degree in this field still continue to reflect a number of the reasons that the students fought for the development of such programs. Data were collected at two selective traditionally White institutions. Through document analyses of campuses articles, survey data from 198 student participants, hour-long interviews of 23 students and 11 faculty, Brown (2006) was able to document the contemporary importance of these programs.

The data from this study revealed that racism continues to exist in college campuses and that students take African American studies classes to deconstruct stereotypes and critique racism and learn about the history (which continues to be silenced or marginalized in many K-12 schools). The survey data revealed that the students who take these classes are not just Black; on both campuses over 30% of the students who responded were non-Black and that a large percent (32% at Calvin, 39% at Ford) were White.

The comparative analysis of the data from these two institutions revealed that Black students attending elite, traditionally White institutions have experiences that are similar in some ways and in other ways unique to their institution, personal background, previous education, and racial experiences. Students from both institutions felt that their university's value of the presence of Black students was communicated through a number of policies and practices. Students were particularly concerned with admission policies and practices, something that was of great concern 40 years ago when ethnic studies was developed. Students from the public university explained that the stance against affirmative action, particularly due to their decreased numbers on campus, made them feel devalued. Furthermore, students argued that the absence of affirmative action did not engender a new perspective that they had earned their admission to the institution through merit like other students.

This type of subtle racism has been termed aversive racism. Describing aversive racism Tatum (1997) states that, "Americans have internalized the espoused cultural awareness of fairness and justice for all at the same time that they have been breathing the smog of racial biases and stereotypes pervading popular culture" (p. 118). Students explained that the end of affirmative action did not affirm their admission or presence at Calvin. They still struggled with other's speculations about their inability to do college-level coursework or their level of intelligence. The debate about affirmative action references ideologies that suggests that to treat people equal you must treat them the same. However, despite the reality that Black students at Calvin were held to the same standards in admissions, they did not receive the same treatment as other students.

In addition to admissions, students were greatly affected by their campus culture and their experiences with micro-aggressions (subtle forms of racism) and marginalization. Students on both campuses discussed their need to feel validated. On both campuses, students felt somewhat marginalized either within the curricula, through the privileging of White culture and values, or more overtly through exclusionary practices. In contrast to the negative experiences they had across campus, they explained that they felt valued and validated in African American Studies classes.

Students at both institutions explained that race played a role in their adjustment to college. African American studies served as a safe place to address their issues around race and racism. Students from Calvin explained that African American studies helped them resist racism and cultural oppression. They explained that they were able to have agency in redefining their experiences on campus by seeking out this academic counterspace where their culture, history, and experiences were dominant and valued. For some students, particularly those who came to college from predominantly White high schools, African American studies gave them the opportunity to deconstruct their own stereotypes about Black people. They described these classes as space to shape a positive self-image. Other students who already had positive Black identities explained that they felt validated in African American studies because they could critique and resist racism. Students also expressed a need to know that their experiences with racism were real and that their anger was warranted (Feagin, 2006; Tatum, 1997).

Faculty played a major role in validating and creating validating spaces and experiences for Black students. Faculty on both campuses showed genuine concern for Black students in their adjustment to college and the development of positive racial and intellectual identities. They were described as approachable and caring. They saw their students as capable and provided meaningful feedback. These faculty members were agents who fostered

academic and personal development in and out of the classroom. The effects of their involvement with Black students served as a form of validation. The faculty members also served as transformational role models who through their research and classes modeled a critique and stance against racism while promoting social justice. They also served as transformational mentors, helping students learn to critique and resist racism, while working to disprove negative stereotypes of Blacks. Although it is important for students to find safe spaces where they feel comfortable in college, academic counterspaces are crucial for Black students. These spaces allow students to escape micro-aggressions and marginalization, critique racism, find validation, inclusion, and support. The data from this study reveal the continued relevance of scholarship that challenges the dominant culture and perspective. It reveals a continued need to have spaces for the voices of marginalized people. It also reveals two models, a department and a center, each of which work well for their environment.

Conclusion

Ethnic studies and women's studies brought the issues of marginalized people to the attention of our universities. Although this knowledge has and continues to be challenged every step of the way, ethnic studies and women's studies have accomplished a lot in the past 40 years and continue to have an impact on scholarship that affects the perspectives of students and informs the decisions made in our society at large. Although our society and our universities have made progress with regard to racism and sexism, ethnic-studies and women's-studies programs still have a very important role in the maintenance of marginalized voices through scholarship and courses. These courses and researchers not only impact marginalized groups but students from dominant groups who enrol in them, requiring them to include these voices, histories, and perspectives in their learning and hopefully their understanding of the world.

Gender Equity in Higher Education: Challenges and Celebrations

L Morley, University of Sussex, Falmer, Brighton, UK

© 2010 Elsevier Ltd. All rights reserved.

In higher education, gender is reproduced in processes of knowledge production and distribution, opportunity structures, and social relations that occur on a quotidian basis. Gender is a verb as well as a noun, and we constantly do gender. Drawing on recent empirical studies from three continents (Morley *et al.*, 2006, 2008) and international literature, this article investigates how gender is not a given, but is in continual production.

Gender Challenges and Gains

It would be easy to produce yet another catalog of challenges for gender equity in the academy. There has been extensive exposure of gender and power in higher education. Concerns include gender-insensitive pedagogy (Welch, 2006); sexual harassment (Townsend and Geist, 2000); gendered micropolitics (Morley, 1999); limited opportunities for promotion and professional development (Knights and Richards, 2003; Morley *et al.*, 2006); gendered curricula and subject choices; and the underrepresentation of women in senior academic and administrative positions (Blackmore and Sachs, 2001; Husu, 2000) or in high-status disciplines (Bebbington, 2002) and prestigious institutions (Dyhouse, 2003). Women's relation to knowledge itself has been theorized in terms of the way in which gender structures relations of production and reproduction and is linked to knowledge construction, research opportunities, and dissemination (Mama, 1996; Stanley, 1997; Spivak, 1999). Studies have revealed how liberal and strategic interventions for change such as equality policies (Bagilhole, 2002; Deem *et al.*, 2005) and gender mainstreaming are poorly conceptualized, understood, and implemented (Charlesworth, 2005; Morley, 2007a).

Without wishing to advocate an economy of sameness for women in different national locations, it seems that some gender inequalities are globalized (Morley *et al.*, 2005). For example, there is consistently low representation of women in positions of seniority in a range of countries in divergent cultural and geopolitical contexts (Brooks, 1997; Morley *et al.*, 2006; Singh, 2002). It is now almost a form of common-sense knowledge to berate the patriarchy of higher education and the victimhood of women who dare to enter and remain there. Yet, this binaried power relation does not explain why women are entering the academy in droves! The pleasure/pain juxtaposition has intrigued feminist scholars (Quinn, 2007). Women must be getting something out of their engagement with academia.

Women's academic identities can be precarious. Women are simultaneously constructed as winners and losers – winners because they are gaining access in significant numbers, and losers because of their lack of entitlement to leadership and prestigious disciplines. Women, at whatever stage in their professional careers, are expected to be the good girls of the academy (Evans, 2004). Yet, globally, they are remaining largely underrepresented in senior positions (Singh, 2002). So, what is changing? What are the feminist performance indicators for gender equity? Have there been any successes in the last two decades? Is the academy changing in the context of the concerns about feminization (Quinn, 2003)? (There are beliefs that academic work is rapidly becoming feminized insofar as the dispositions required for scholarship are now heavily perceived as more conducive with socially constructed female behavior, for example, discipline, diligence, perseverance, and commitment to self-improvement (Quinn, 2003). The feminization of learning is becoming an international concern, with increasing anxieties about boys' and men's academic failure and exclusion (Burke, 2007; Epstein *et al.*, 1998).

What exactly do we mean by women's increasing participation in higher education? As the numbers have increased, does this mean that higher education allows more discursive space for gender? Issues of voice, silence, and participation have long been a concern of feminist theorists (Gatenby and Humphries, 1999). Speaking as a woman can mean speaking as a gendered self which is often at odds with the putative ungendered or gender-neutral representations and assumptions of academia (Evans, 2008). However, voice is not just about women speaking, but about the inclusion of gender equality in policy, pedagogy, and planning. There has been a long and painful history of exclusion for women, and this is threatening to reemerge now; some quantitative changes have occurred in audit cultures that privilege measurement. In the UK, gender is a disqualified discourse in higher education policy. Quantitative change seems to imply to policymakers that gender is no longer an issue in a postfeminist era (Morley, 2007b). For example, the former Minister for Higher Education in the UK – John Denham – made a speech about priorities for the next 15 years, and these all relate to innovation and wealth creation, rather than to inclusion and equalities. Gender equality was not mentioned once (Denham, 2008). It is pertinent to ask, at this stage, if the ongoing role of the feminist scholar is to indicate gaps and silences in dominant

discourses and practices. Feminists have had to spend considerable amounts of time on critique. We have had few opportunities to celebrate our successes or indeed to envision a more creative future.

Climate Change and Gender Warming?

One major success is the increased numbers of women entering higher education as students. If we consider that women were barred in the UK until the late nineteenth century (Dyhouse, 1995), this represents quantitative progress. In the UK, in 1995 there were 2.5 times more women in the system than in 1970–71 (Abbott and Wallace, 1997). Participation rates for women in higher education have increased between 1999 and 2005 in all regions of the world, with a global gender parity index (GPI) of 1.05, suggesting that there are now more undergraduate women than men in higher education (UNESCO, 2007: 132). However, the increase in women's participation has been unevenly distributed across national and disciplinary boundaries. Women's participation rates are higher than those of men in North America and Europe, but lower in regions such as East Asia and the Pacific, South and West Asia, and sub-Saharan Africa.

Globally, women students are concentrated in non-science subjects. There is still a sense of what constitutes a gender-appropriate discipline in many high- and low-income countries, with worldwide concern about the underrepresentation of women in the science, technology, engineering, and mathematics (STEM) subjects. Men predominate in subjects related to engineering, manufacturing and construction, and math and computer science (OECD, 2007). In many countries, two-thirds to three-quarters of graduates in the fields of health, welfare, and education are women (UNESCO, 2006). Thus, women continue to be concentrated in subjects associated with low-wage sectors of the economy, in particular health and welfare, humanities, arts, and education.

What do all these facts about women's increased participation or exclusion add up to in terms of how women experience the academy? The author has conducted studies on the micropolitics of academic life and frequently found that the gendered relays of power that cause the most distress and discomfort are the everyday transactions and relations (Morley, 1999; 2006). Blending quantitative facts with interview data helps to reveal both the scale and the lived complexities that structure women's participation in higher education, as students and staff. Focusing on everyday micro-level incidents can provide important information about more macro-focused challenges for gender equality. Dealing with quotidian examples of sexism and discrimination can have a detrimental effect on women's self-confidence and career aspirations (Morley, 1999; Seymour and Hewitt, 1997). The personal is political,

or to use more contemporary vocabulary, the self can become an object of reflexive knowledge (Beck and Beck-Gernsheim, 2002; Hey and Leathwood, 2007).

The metaphor of the chilly climate has been used to symbolize and capture the discomforts and inhospitality of academic cultures for women. Sandler *et al.*'s (1996: 1) study in the USA found some 30 ways in which faculty members often treated women students differently in the classroom. This chilly climate impeded women's full participation in the learning process. It is pertinent to ask today if the temperature is rising, and the ecology, culture, and climate changing for women? There are empirical data that seem to suggest both yes and no. While there are evident structures of inequality, women's agency, as opposed to privilege, is certainly cause for celebration. The following sections will consider data from the author's recent research projects in Africa, Asia, and Europe.

Academic Identities and the Gendering of Ability

It is questionable whether the success of quantitative change this has been accompanied by a qualitative change. Has the nature of the higher education product changed in relation to the changing constituencies of students? A criticism of much of the scholarship on academic women is that it focuses on the experiences and voices of privileged white women in high-income countries (Twombly, 1999). Theorizing links between differently located practices can produce a sense of the patterns and scale of gender challenges. The author draws upon some of her research findings from Morley *et al.* (2006). This study explored gender equity in higher education in low-income countries. It aimed to go behind the statistics and explore women's everyday experiences of higher education in Nigeria, South Africa, Sri Lanka, Tanzania, and Uganda. Identifying key sites of gender-differentiated experiences of the academy was a purpose of the research.

The countries were selected for their varying national policies on gender equity and their commitment to international policies to end discrimination against women. South Africa has generated a range of race and gender equity and transformation policies in higher education. Uganda and Tanzania have specific gender-equity policies. Sri Lanka initiated social welfare policies in the post-independence period. Nigeria has a policy of widening participation in higher education, with emphasis on developing science and technology. A total of 209 interviews were conducted with students, academic staff, and managers. Observation of classrooms and boardrooms was conducted and statistics and policies were analyzed. A noticeable finding was how gender inequalities appear to be fairly globalized. While transnational feminism is

problematic in terms of the diversity of women's oppressions (Mills and Ssewakiryanga, 2002), observations from women in low-income countries can sound remarkably similar to women's voices in the West.

In the study, a strong sense of a hidden curriculum emerged (Margolis, 2001). During the 1970s, the hidden curriculum became one of the powerful concepts in the new (critical) sociology of education. Increasingly, the hidden curriculum is perceived as a vital part of more general curriculum transformation. The overt and the hidden curricula are not mutually exclusive but form a complex mechanism of production and reproduction (Apple, 1980). The hidden curriculum is irrational and contradictory. Negative attitudes to women's academic abilities do not correlate with their actual achievements.

One aspect of the hidden curriculum relates to the conjunction between gender and academic ability and authority. Studies have reported how discrimination against women can involve not taking them seriously and doubting their ability and motivation (Seymour and Hewitt, 1997). Discrimination due to perceived incompetence is based on descriptive gender stereotypes (Rudman and Glick, 2001). Difference is frequently expressed in terms of deficit and located within particular bodies rather than in the "invisible values and assumptions structuring curriculum and pedagogy" (Abu El-Haj, 2003: 411).

In Morley *et al.* (2006), there was widespread reporting of negating women's academic abilities and hostility from male students and staff, as a South African student illustrates:

And I mean the guys ... think we are absolutely useless. I mean we might score high marks you know in courses, but it is just the fact that they think we are stupid. And even our lecturers, I mean, I have a particular lecturer, who just thinks I am an idiot, and I have no reason, I have given him no reason to think that. But I am not interested in proving him wrong and if he wants to think that, then that's great.

Femaleness is repeatedly perceived as irreconcilable with intellectual authority (Shah, 2001). Another South African student reports negativity toward women staff from male students, thus reinforcing the notion that women are perceived as inauthentic academics:

I have also noticed how we've had maybe two or three female lecturers and how the guys in our class just do not listen to them, they do not respect them. And I mean these women are really good, they are brilliant, they know their stuff they worked hard they have their PhDs, but guys laugh at them, ridicule them.

In an observation evocative of Spender's (1982) early work in the UK, and Brooks' (1982) early work in the USA, the Sri Lankan team relate how their classroom observations revealed male students receiving more pedagogical attention:

Towards the end of the lecture when the lecturer was relating real-life examples to the theory he had been teaching, he mentioned a project the female student was involved in and briefly asked her a question related to it but he did not give her any time to answer, smiled and moved on to the next question very swiftly.

The Sri Lankan team also notes how generally male students were invited to comment and question more than females. Consequently, male students became more confident, more assertive, and relaxed than their female counterparts. This gendered interaction did not go unnoticed by students. A Sri Lankan student describes discriminatory behavior from some male lecturers:

There are some who try to put the women down by asking a question and then laughing at us when we can't answer it, or ask something just to put us down.

The gendering of pedagogical interactions poses questions about the full meaning of the concept of women's participation.

A Ugandan student points out that there is a horns effect toward women and a halo effect toward male students, and how this distorts academic assessment:

Male lecturers need to be gender sensitised so that they can avoid their patriarchal tendencies of thinking that male students are better than female students e.g. there was a situation when two students (a female and male) handed in the same piece of work, the lecturer awarded marks to the male student and cancelled the work of the female student on assumption that the female student had cheated. This in my view was not fair.

The notion of men as real academics and women as fakes is also noted by a Sri Lankan student:

[Men] hardly attend class. But get their notes from women. I know of several incidents where the boys have copied the tutorial and given it in and they've got higher marks for the same thing.

Anti-feminism was also widely reported. A Nigerian student describes:

...when you are tagged as a Women's Lib person they see you as way out, deviant person.

It appears that the social penalties are sometimes high for those individuals who set out to interrogate and challenge gender inequalities. They are easily othered, raising questions about whether women participate in higher education on their terms and to follow their own intellectual and political interests.

Women students in Morley *et al.* (2006) were also perceived as impeded by internalized oppression, that is, their interior worlds or psychic narratives that constantly played recordings of inferiority. Women's academic

self-worth was often presented as fragile and unstable. A Ugandan student states:

The problem most girls have is lack of confidence.

A Sri Lankan policymaker in Morley *et al.* (2006) also attributed the low level of women in management to women's reluctance to apply for the posts:

Managerial posts are not held by women in large numbers. In universities, if you take generally speaking how many heads of departments are females ... no not even 20 per cent are held by the females... That is because they don't come forward. That is the reason.

The problem with affective explanations and attributing problems to psychic narratives, such as lack of self-confidence, is that it suggests that women are deficit in and lack the personal attributes needed to succeed. Cognitive, rather than organizational restructuring, is seen as the solution. Problems that are largely collective and social are individuated. It represents the privatization of the public. The power relations that create structures and barriers, and indeed that undermine women's confidence in their abilities, are overlooked. By offering very conventional indicators of professional success, it also marks out women as losers who prefer not to occupy managerial roles.

The gendering of academic ability has been a theme that has emerged in the author's recent study on widening participation in higher education in Ghana and Tanzania (Morley *et al.*, 2008). This study utilizes statistical data, life-history interviews with 200 students and semi-structured interviews with 200 staff in two public and two private universities. It focuses on how gender and socioeconomic status intersect and constrain or facilitate participation in higher education. The data so far suggest that any activity that is perceived as difficult is seen to be inappropriate for women. A Tanzanian female student describes how female students frequently believe that they need to be academically rescued by male students:

You know that for example this question is tough and only boys can tackle it ... and a girl cannot, and we have to look for a boy, who we think can tackle it.

A male Tanzanian student suggests that academic ability is psychosocially constructed:

The problem is always being talked in the newspapers, that the girls they don't have the confidence ... that's all ... they have high capability ... on starting ... the Form Ones and Form Twos they are certain who are very bright, very bright ... but as the days were going on their capability was decreasing and decreasing ... and perishing.

Success criteria for gender equality frequently relate to women's increased participation in male-dominated areas. It is almost as if by working and studying with men, there will be disidentification with the inferior

world of women and a type of positive contagion of male values and behaviors.

Women are constructed as poor choosers when it comes to academic disciplines. Their entry into nontraditional disciplines is seen as a form of empowerment and hence a cause for celebration. In Tanzania especially, where affirmative action interactions have created access or preentry programs for women to enter science, quantitative change is widely acknowledged as success. A Tanzanian professor provides some statistics:

In the year 1994 for example, the female student population was about sixteen percent after this intervention, we are now in the sciences in particular in the Faculty of Science stands now at around thirty to thirty one percent which to me in ten years is quite an achievement. With Engineering that it was formally six percent less than six percent it has now gone to slightly above ten percent.

Women's academic identities are frequently constructed in terms of remediation or absence. A Tanzanian dean of a science faculty discusses women's underrepresentation in high-status disciplines.

When it comes to gender, I think it's the girls who are not well represented particularly in some disciplines. Sciences are less than fifteen percent. When it comes to Physics, Mathematics, Geology there is huge imbalance between the girls and boys ... In Mathematics it could be up to ... you know between eighty and twenty percent. Even in Geology you know twenty percent girls, eighty percent boys.

It is questionable why underrepresentation usually features in relation to certain subject areas, and why men's underrepresentation in female-dominated disciplines is rarely mentioned in policy terms. In Ghana, a female professor comments on gendered patterns of subject choice:

The Education Faculty has the highest proportion of females ... even though we are getting more women than men, they are still moving into those areas that are known as traditional ... The School of Agriculture ... has 143 students but the number admitted females applied which were qualified ... was 22.

The question of what and where women are accessing can also be related to the type of higher education institution (HEI). In Ghana, women comprise 35% of the overall university population (NCTE, 2006a,b), although they make up 41% of the students in private higher education (NCTE, 2006b). In Tanzania, 33% of the overall undergraduate population is female, with women comprising 38% of students in private higher education (MHEST, 2006). If rates of participation for women are higher in lower-status private higher education, this poses questions about core and periphery provision. Socially

disadvantaged groups could be getting diverted into peripheral higher education, thus reinforcing stratification of the sector and social differentiation. In this analysis, widening participation in higher education can be conceptualized as a process of diversion, that is, a re-routing of members of socially disadvantaged groups into lower-status institutions in order to reserve the higher-status universities for the elite (David, 2007). “*Buying* an education becomes a substitute for *getting* an education” (Kenway *et al.*, 1993: 116).

Vaporizing Gender

Policy commitments to gender can evaporate during implementation (Goetz, 1997; Longwe, 1995). In the UK, gender is no longer included in higher education policy. Elsewhere, there are policies that fail to be implemented. In Ghana, an academic relates how gender remains at the level of policy text, with no strategic implementation plans:

They are all making many noises about tertiary education. All they said was they recommended 50–50 and that was it that was it . . . The only one I can think of is with regard to women; it's a little bit more of lip service, if anything.

The implementation gap was discussed by another Ghanaian academic who believed that insufficient resources were allocated to ensure domestication of international policies:

I think Ghana Government has been very proactive as far as international policies of all types are concerned and in the case of education . . . but I must say that the trouble with African states, including Ghana, is that it is one thing saying ‘yes, we’ll do, we will put it into practice’ and another thing actually getting funds to get it really done, putting it into practice . . .

These observations about the implementation gap are evocative of findings from a UK-based study that the author conducted with Rosemary Deem and Anwar Tlili (Deem *et al.*, 2005). The research involved six case studies of HEIs across England, Scotland, and Wales. The project’s aims included exploring staff experiences of equity issues and institutional equity policies. A central finding was that although all six institutions studied had equal opportunity policies in place, not all the policies were comprehensive, completely up to date, or easy to understand. Policies were often communicated to staff via e-mail, which may not reach those with e-mail overload or staff with no computer access at work. Some policies gave the impression of often having been reactively rather than proactively constructed and with an eye to compliance to legislation rather than empowerment of the workforce

and enhancement of their working conditions. Staffs were wary of utilizing grievance procedures for fear of recrimination and professional suicide. The policies were not integrated into strategic management, and there was little action planning or proactivity. The problem of senior- and middle-management inactivity was observed by an academic trade-union representative from one university who felt that for some, it was sufficient simply to note the numbers rather than take any action to rectify underrepresentation:

Now on sex equality last year there was a round of promotions to principal lecturer and, it was noted that I think the proportion of women who applied, as compared to the proportion of women employed, and the proportion of women I think, was one out of six appointees. And the personnel office simply in their report, noted the numbers. But we tried to push them to think about what might they do about it but they were quite content to just note the disparity between the number of women employed in the academic role and the outcome of this round.

Many of the staff that we interviewed frequently noted how policies existed at a textual level – often to meet the requirements of audit and funding bodies – rather than working at the grassroots level of day-to-day work and felt that there was a major implementation gap.

Conclusion

Women’s exclusion from higher education is a historical injustice. Today, women are participating, in increasing numbers, in higher education, in a range of national locations. Yet, women’s academic identities are often forged in otherness, as strangers in opposition to (privileged) men’s belonging and entitlement. This means that gender in higher education is often encoded in a range of formal and informal signs, practices, and networks.

A number of contradictory arguments are emerging. One is that the increasing participation rates for women means that they are in danger of taking over the academy. However, this is unraveling against contexts and cultures that still position them as academically inferior and lacking confidence. Women are simultaneously accused of taking over and not coming forward. Another contradiction is that women are constructed as strategically engaged with higher education, recognizing the impact on their employability and life chances. However, they are choosing the wrong subjects to study, shying away from STEM disciplines that would provide a greater return for their investments. In terms of staff, women are frequently seen as the good girls of the academy (Evans, 2004); yet, they are not getting equally promoted to positions of seniority, or desiring them sufficiently (Singh, 2002).

The contradiction between policy as text and as lived experience is also a noticeable feature of gender architecture. Policy interventions including gender mainstreaming and gender equality suggest that now gender sensitivity and strategic actions should be everywhere – including the curriculum, management, and resourcing of academic life; yet, informants in the author's studies report that they are nowhere!

Feminist scholars and researchers will continue to critique, theorize, and audit power and privilege in higher education, as it is a major site of cultural practice, identity formation, and symbolic control. However, we also need to imagine or re-imagine a different future, asking what type of academy we wish to see. Whereas the UK minister for higher education has a wish list for the next 15 years that includes the expansion of technology, innovation and research-based wealth creation, we wish to invite an international feminist political imaginary to ask what women want, and what would the gender equitable academy of the future look and feel like?

Locating Space and Place in the College Access Debate: New Tools for Mapping and Understanding Educational Inequity and Stratification

B Cantwell and J F Milem, University of Arizona, Tucson, AZ, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Issues critical to college access are closely related to demographic, social, and economic trends. As society changes, so does the social role of higher education. Given the high social and individual returns that accrues from tertiary participation, as well as an interest in social justice, both researchers and policymakers have been focused on broadening participation and exploring ways in which access to higher education can become more equitable. Today, more students from all backgrounds participate in higher education than at previous times. Yet, a greater volume of participants has not resulted in increased equity. College access remains stratified along a number of dimensions including race and ethnicity and socioeconomic status. While evidence suggests that ability is an important factor in access to college, any notion of meritocracy is confronted by the fact that high-income/low-ability students attend college at a higher rate than do low-income/high-ability students.

Continued inequity in college access is particularly disturbing given two social trends. The first is related to demographic changes. While the population is growing older overall, youth populations are becoming significantly more diverse in terms of race and ethnicity, country of origin, first language, and religious and cultural backgrounds. Minority students, or students from nondominant groups, have lower levels of access to higher education, particularly at 4-year colleges and universities. As students from these groups have increased as a proportion of the total population, there have not been commensurate increases in their share of higher education access and attainment at all levels. In other words, access to higher education remains stratified and in many cases this stratification has increased. If this trend continues uninterrupted, larger and larger portions of the population will be excluded from higher education, even if participation increases overall.

The second trend is related to changes in the labor market. As the United States and other developed countries continue to transfer economic production into high-end services and high-tech industries, fewer and fewer jobs will be available to individuals without tertiary education. For individuals and communities with inadequate access to higher education, the effects of this trend could be devastating. Generations may be condemned to unemployment

or underemployment, poverty, and social alienation. The social implications are also troubling. Given the demographic changes underway, the United States and other countries face a shortage of skilled workers that will, in the long run, weaken their global economic competitiveness.

Given these social changes, it is imperative that the inequalities in access to higher education at all levels continue to be addressed through research and policy initiatives. Most often, college access is discussed either implicitly or explicitly using a pipeline metaphor, the idea being that there is a single, streamlined channel through which access to higher education flows. As more students proceed through the pipeline without leaking out, more students will arrive at the end-point of higher education. In this metaphor, colleges and universities are represented as isolated points of entry that stand at the end of a linear path to access. However, colleges and universities are not isolated points of entry but are rather institutions situated as part of a spatially segregated education system in which the structures of opportunity are not the same in all places. That is, the pipeline metaphor does not adequately account for the fact that not all places present clear entrance to a channel that leads to college and university access. Since large portions of many communities are unable to access the pipeline, it is important to reconceptualize college access in a way that allows for a better understating of how many communities are largely excluded.

This article explores how space and place may be related to access to higher education and discusses ways in which to study these issues. The next section reviews some of the most influential ideas in college-access research and discusses how they are related to space and place. The third section introduces a set of technology, data, and methods known as geographical information systems (GIS) that are used in geospatial research. The fourth section uses three examples to show how GIS can be used in college access research. The concluding section presents implications for college-access research.

College Access, Space, and Place

Over time, research on college access has developed into a corpus of knowledge that is sophisticated and nuanced. Distilling this scholarship inevitably obscures its richness; nevertheless, three main factors that contribute to college

access have emerged: (1) finance; (2), college knowledge; and (3) academic preparation.

Finance is one main factor relating to college access. This has to do with the ability to pay for the increasing cost of attending college, the availability of financial aid to subsidize students who cannot afford the cost of higher education, and the opportunity cost of attending college in the form of foregone earnings. During the last few decades, the cost of attending college has increased substantially in real terms. Coupled with increased costs, there has been a shift in the provision of federal financial aid from primarily grants to mostly interest bearing loans and a shift in institutional and state sources from need-based aid to merit scholarships. As a result, the cost of college has become out of reach for low-income students, and the aid available to meet this gap has become less responsive to the needs of low-income students.

A second important factor for college access has to do with possessing information about the importance of higher education, as well as social and cultural knowledge that is useful for gaining admission. Much of the access literature on this topic is informed by Bourdieu's concepts of cultural capital, social capital, and habitus. For the sake of conceptual parsimony, this family of concepts will be referred to here as college knowledge. Simply put, students whose family members and acquaintances have attended college are more likely to know the rules of the game relating to college access and social mobility in general. Many students with this background are prepared to attend college from a young age. Students who do not come from a community where college attendance is the norm are less likely to possess the tacit knowledge that is useful for gaining access to higher education. For these students, the college-admissions process can appear mysterious and overly complicated.

A third factor related to college access has to do with ability and academic preparation. Students who are well prepared for college at the primary and secondary levels of the educational system stand in good stead for both access to and success in the tertiary level of education. In practical terms, this means having a strong primary educational background, having taken a rigorous academic program in secondary school as well as having prepared for and taken college entrance examinations such as the Scholastic Aptitude Test (SAT) and American College Test (ACT). Students who are not adequately prepared for higher education not only have greater difficulty gaining access because of a weaker academic record but also because they are simply less prepared for the admissions process. If these students do enrol in higher education they are more likely to enter higher education at 2-year colleges and less likely to persist to earn baccalaureate degrees.

Research on college access has shown that these factors are interrelated. Students who come from middle and

high income families are likely to have parents or relatives who have attended college and pass on college knowledge, and are also more likely to be well prepared academically. Similarly, students who come from low-income families are likely to attend schools with fewer resources and are less likely to know the college-access rules of the game. Society is stratified in a vertical hierarchy by socioeconomic status and race/ethnicity. As a result, low-income and minority students are often disadvantaged in terms of access to higher education.

Scholars of college access have not fully explored how factors related to college access are distributed horizontally across space. American society has a long history of segregation (both racial and economic) and despite some efforts in the past to redress this, evidence suggests that US society is becoming more racially segregated. This means that people within cities and towns are not evenly dispersed but are rather isolated in highly concentrated communities of people of color and with low incomes. As a result of both vertical stratification and horizontal segregation, individuals face an uneven structure of opportunity depending on where they live. In some communities, or neighborhoods, the pathway (or pipeline) to college access is well known and straightforward. In others, the pathway to access is idiosyncratic and opaque. One way of exploring the differences in place-biased structures of opportunity is by using geospatial data and GIS.

Geographical Information Systems

GIS refer to a set of technologies that include the interface of hardware, software, data, procedures, and networks. GIS are used to store, display and represent, interpret, and analyze geospatial data. In other words, GIS are a group of information systems that store and represent data that are associated with specific places in the real world. GIS are frequently used for research in the natural sciences and are becoming more popular in fields like sociology and education. In the social science, GIS are particularly useful for social-science research that has a spatial dimension such as research that investigates the spatial dispersion of social characteristics and trans-spatial social networks.

It is estimated that 80% of all government policies are informed in some way by geographic data. Spatial data can also inform many of the activities of colleges and universities, which are located in actual social communities and recruit students from real places with notable social characteristics. Potential data sources include national census data, local and regional governmental data, and data already gathered and stored by colleges and universities. All educational data that can be anchored to a place, such as neighborhoods, addresses, and schools (and school service areas) can be use in GIS analysis. Institutional research

and enrolment-management offices at many colleges and universities are already using GIS for a variety of institutional research and marketing purposes.

GIS and Access Research

The value of using GIS for college access research is that they offer the possibility of exploring how social characteristics that are known to be important for access, and actual college-access data, are distributed horizontally across space. This, in turn, allows researchers to produce representations and conduct analyses to help better understand the spatial distribution of college-access opportunity structures. In other words, GIS are a set of tools that can be used to explore how horizontal segregation affects college access in addition to vertical stratification. The remainder of this section is organized as follows: (1) data sources and methods are explained; (2) examples of the sorts of representations and analyses that are possibly using GIS for access research are presented and discussed; and (3) suggestions are given for how GIS can be used to inform research and policy regarding college access.

Data sources and methods

All geospatial data are connected to real places in the world. Thus, in order to provide examples for the use of GIS in college access research, a real and identified place must be used. Tucson, Arizona, the city in which the authors reside, has been selected to demonstrate these ideas. We recognize that colleges and universities are not stand-alone points of entry but rather are parts of a system of education that includes K–12 schools and are situated in real communities in which people live, work, and learn. Hence, community, school, and college access data are used in our analyses. These data come from three sources.

The first data source is the United States Census Bureau. The decennial census gathers aggregated population and socioeconomic data, including race/ethnicity, educational attainment, and income, for all communities in the United States. Census data are aggregated by spatial units called census blocks, which, in urban areas, are roughly the size of a city block. There are limited data available for individual blocks because their small size creates the possibility of identifying individuals. However, data are publicly available for block groups and larger spatial units comprised of several block groups known as census tracts. Additionally, the Census Bureau provides spatial data for the census units so that demographic data can be plotted over space and represented visually.

The second source of data is the state of Arizona's Department of Education, which makes publicly available annual data for all public and charter schools in the state. These data include information on enrolments by race, school performance ratings, graduation rates, and so forth. As school addresses are provided, it is possible to georeference these

data. The third source of data is the University of Arizona Office of Enrolment Management. The Office of Enrolment Management keeps track of information like the number of applications, admissions, and enrolments by school and race/ethnicity.

These data were used to produce seven maps of Tucson, Arizona, that represent social and educational attributes distributed across its space. In producing these maps, census-tract data were layered with school data. Census tracts are areas represented by polygons, while schools are specific places represented by points. Attribute variables used for analysis included population demographics (race/ethnicity, income, and educational attainment) and school data (enrolment, school performance, and college applicants). These variables were categorized using Jenks' natural breaks, which is a technique that allows researchers to set a desired number of categories and then order data within these categories by minimizing within-group sum of squared differences:

$$SSD_{i,j} = \sum_{k=1}^j (A[k] - \text{mean}_{i,j})^2$$

Jenks' natural breaks-classification scheme determines the best arrangement of values into groups according to natural groupings within the data. Five categories were used for all map variables. Categories are represented using color codes and feature sizes. Visual analysis was then used to interpret the maps.

GIS examples

Using seven maps, this section provides some basic examples of how GIS data and analysis can be used for college access research. The first example (**Figures 1, 2, and 3**) shows the pattern of racial segregation in schools and neighborhoods in the city of Tucson. Access to higher education in the United States is stratified by race and ethnicity. Minority students, especially African Americans, Latinos, and Native Americans, are less likely to attend college than their White counterparts. When these students do attend college, they are more likely to attend 2-year community colleges and are less likely to earn a baccalaureate degree. Furthermore, research suggests that attending a racially diverse school can benefit all students but that American communities and schools are becoming more racially segregated.

Figures 1 through 3 show racial segregation by neighborhood using 2000 census-tract data. The lighter-colored areas represent neighborhoods with a lower percentage of White residents, while the darker-colored areas represent neighborhoods with a higher percentage of White residents. Census data are overlaid with school-enrolment data from the 2002/3 school year; the closest period to the census for which these data are publicly available. **Figure 1** shows elementary-school enrolment in the city of Tucson. Each circle represents the location of an elementary school.

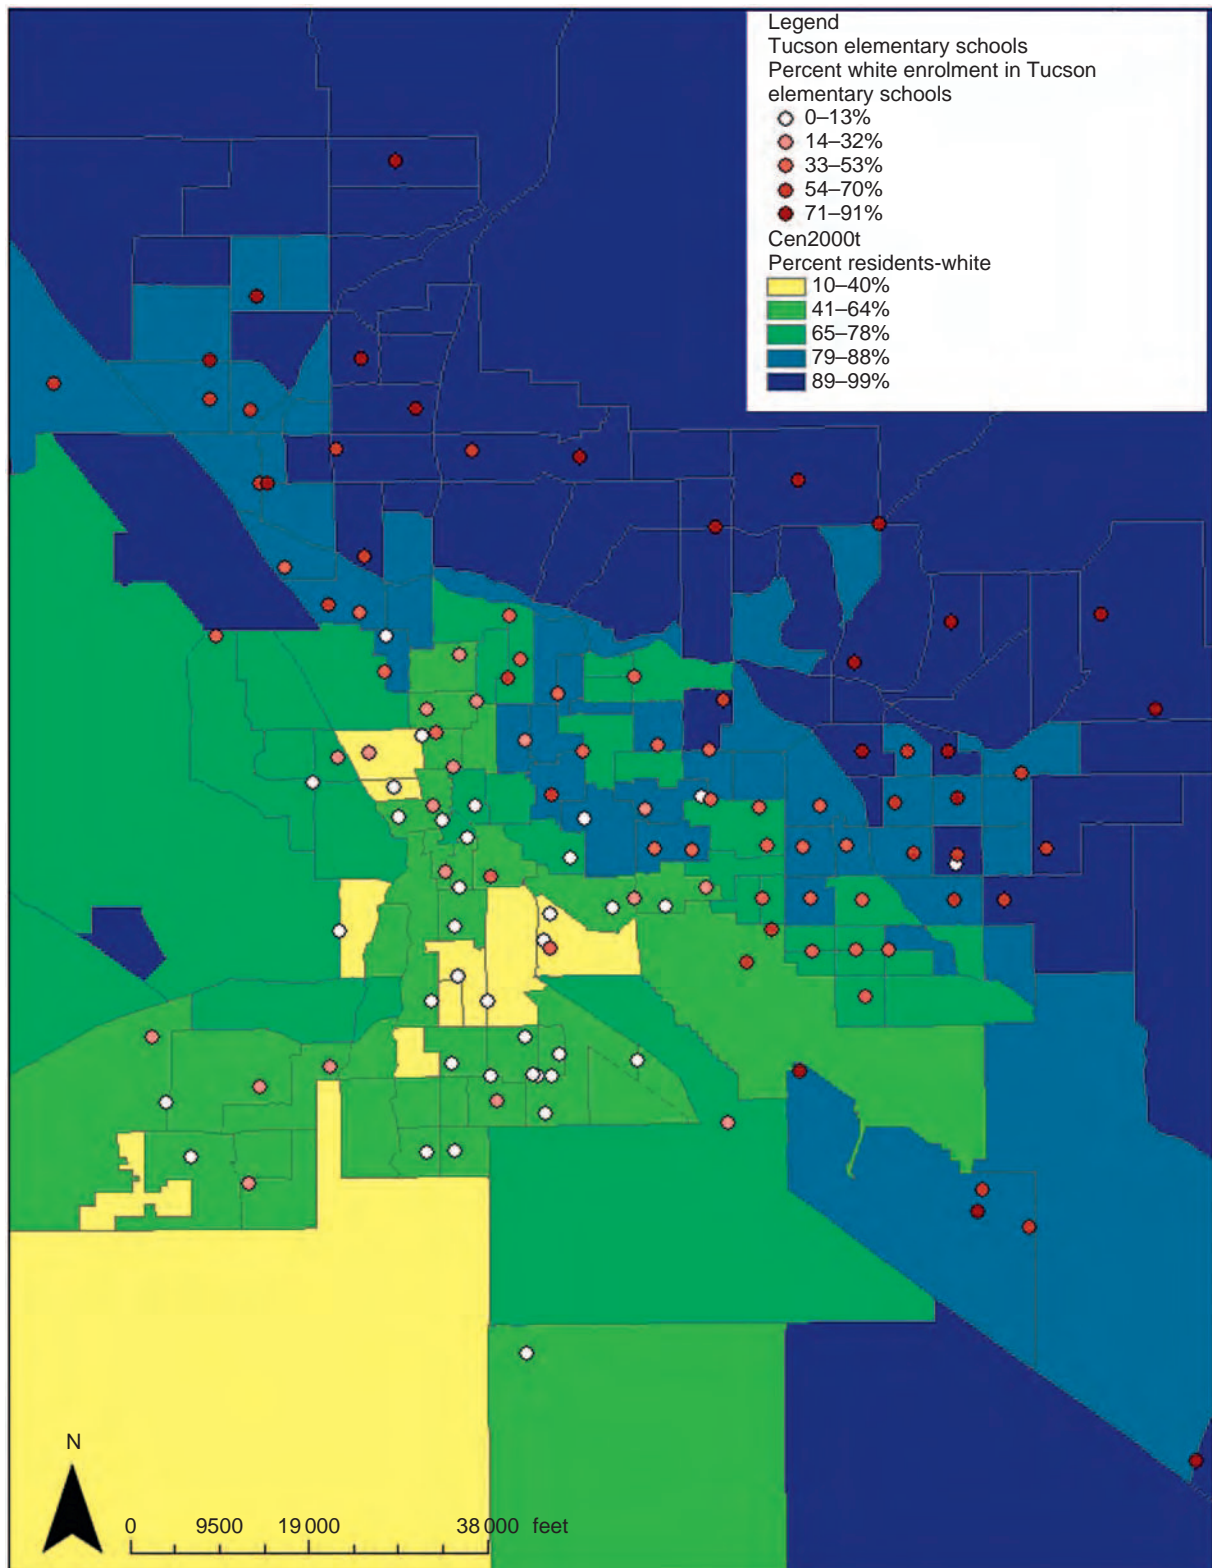

Figure 1 Tucson elementary schools.

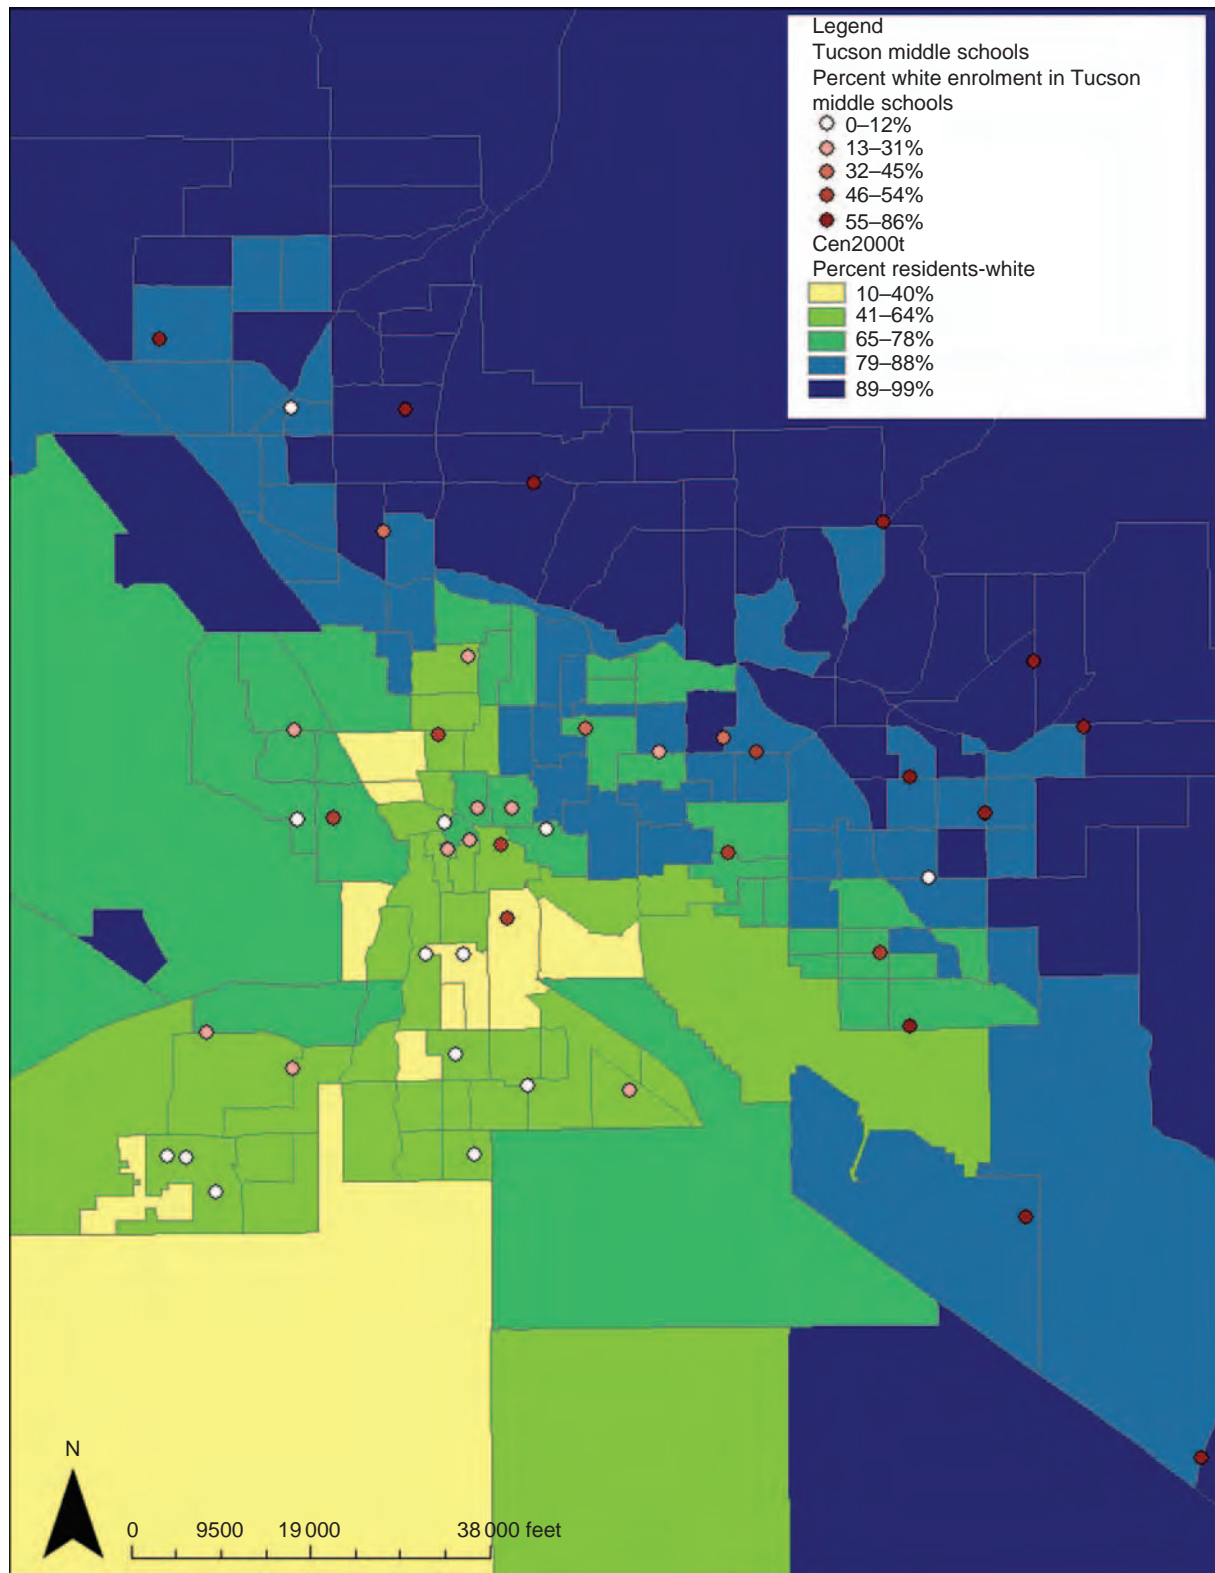

Figure 2 Tucson middle schools.

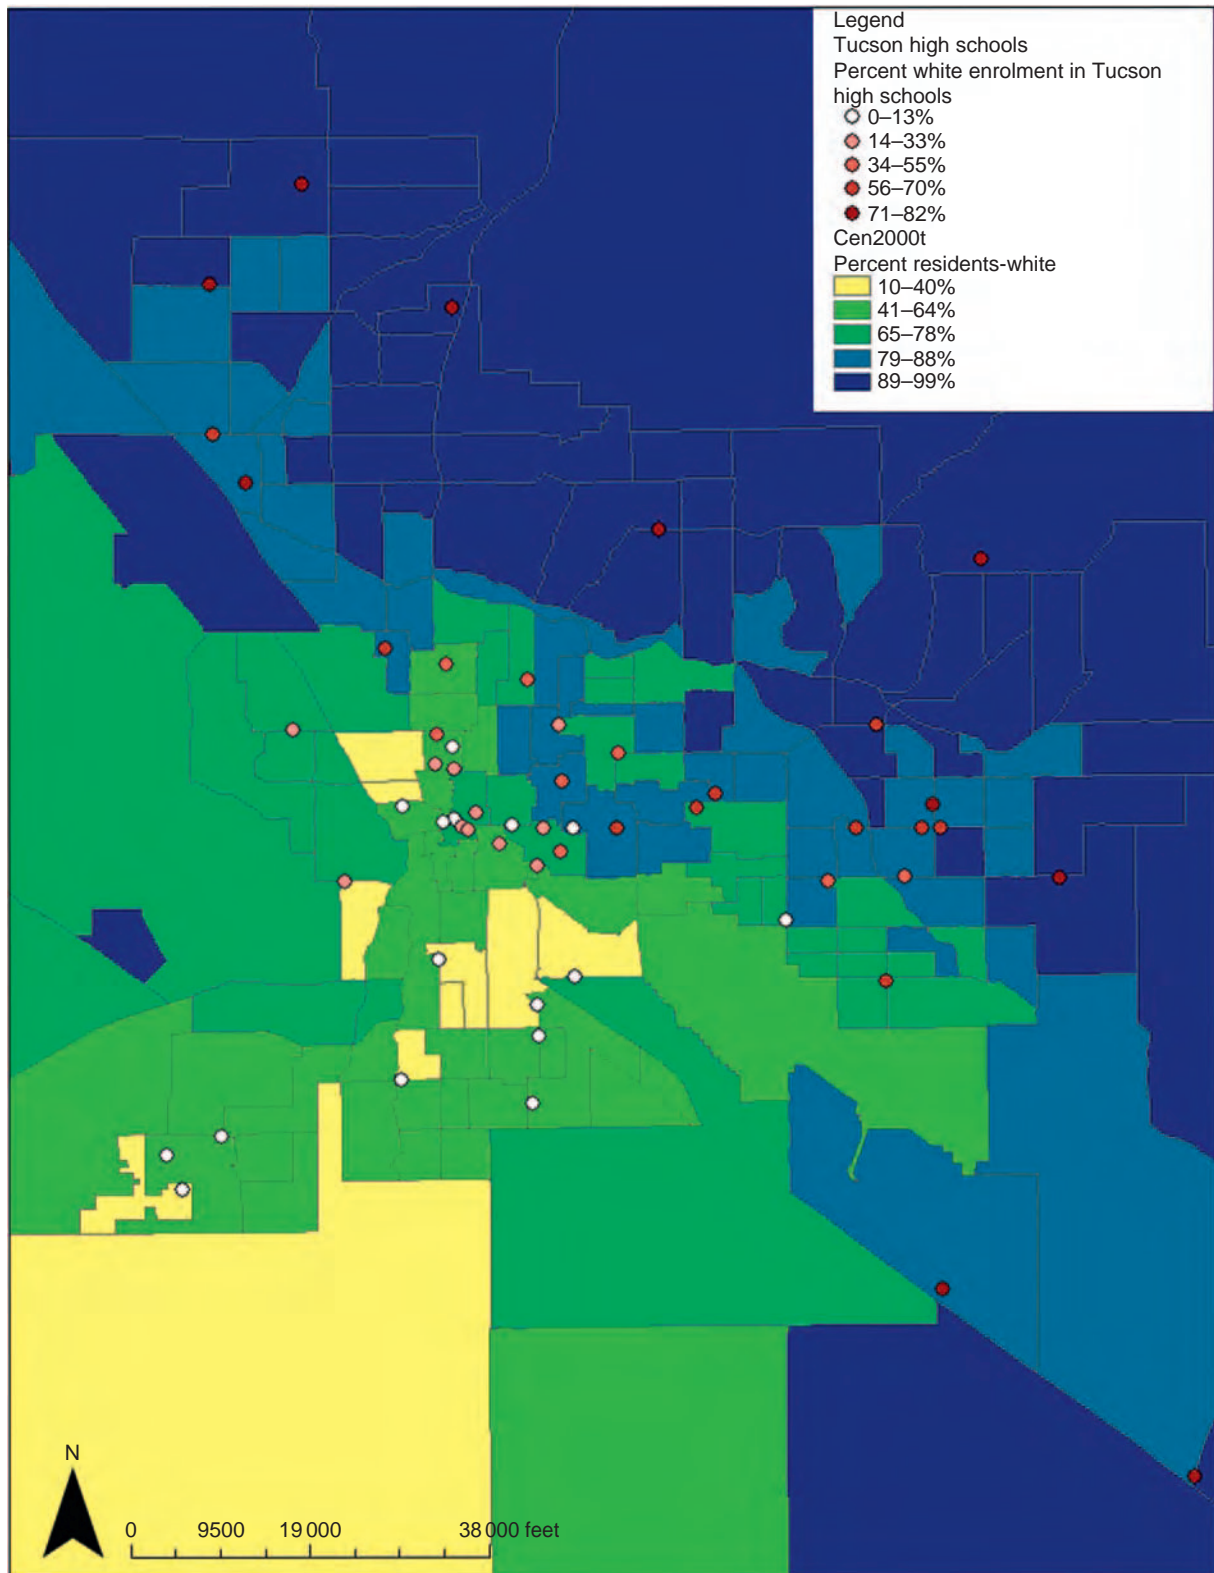

Figure 3 Tucson high schools.

The larger circles represent schools with a larger percentage of White enrollees and the smaller circles represent schools with a smaller percentage of White enrollees. **Figures 2** and **3** represent similar data for Tucson's middle schools and high schools, respectively.

Collectively, **Figures 1, 2, and 3** show that both Tucson's neighborhoods and schools are highly segregated by race. A lower percentage of residents in the south and east of the city are White (primarily Latino) and the cities' northern and eastern neighborhoods are occupied by a higher percentage of White residents. The same is true for schools. These maps show that high White-enrolment schools are located in the north and east while low White-enrolment schools are located in the south and west of the city. In central Tucson, where census tracts tend to be more racially diverse, there are schools with both a high percentage of White enrollees and a low percentage of White enrollees. This trend is most pronounced among elementary schools, which are more numerous and tend to have the smallest school-service areas. This suggests that even within diverse census tracts, communities are segregated by race, which results in segregated schools, especially at the elementary level.

Using the natural-breaks method, features (in this case census tracts and schools) are broken into categories where there are large jumps in values for the variable of interest. For the schools, categories are fairly evenly distributed across the range of the population. Take for example elementary schools, which range from 0% to 91% White enrolment. The natural-break categories for the schools cover about 15–20% points of White enrollees. Natural breaks for the census tracts, however, are clustered at the high end of the range (1%–99%) and the low category covers around 40% points; yet, the high category covers only about 10% points. This suggests that schools may be more segregated than neighborhoods. It also suggests that shifting demographic trends are coupled with increased spatial segregation in the southwest, which is the fastest-growing region of the country. Diverse groups are migrating into the area and their children are attending public schools. Moreover, while undocumented immigrants are unlikely to be captured in the census data, their children are likely to be captured in school-enrolment data. These enrolment data suggest that the overall population is becoming more diverse but that it is also more segregated across space. Thus, school enrolment may be a vanguard to large demographic trends of increased racial and ethnic diversity and increased racial segregation in southwestern cities like Tucson.

The second example shows the relationship between elementary school performance and neighborhood economic and racial composition (**Figures 4** and **5**). Academic preparation is an important factor related to college access and not only refers to individual student's performance but also to the educational resources available to students in their

schools and communities. Schools with more resources, on average, provide better opportunities for college access to their students. In this example, 2003 high school performance ratings, determined by the Arizona Department of Education, are used as a proxy for varying levels of school resources and academic preparation.

Figure 4 is a map of Tucson using 2000 census-tract data that shows median household income and elementary school performance levels. The darker census tracts represent neighborhoods with higher median household income while the lighter tracts show less-affluent areas. The schools represented by darker points represent excelling and highly performing schools and the lighter points represent performing and underperforming schools. The north and east parts of Tucson are more affluent than the central and southern parts of town. As discussed above, the northern parts of Tucson also have a higher percentage of White residents. Visual analysis suggests that there is at least a loose relationship between median household income and school performance. Ten of the 13 excelling schools are located in census tracts that are among the top-three income categories while 13 of the 15 underperforming schools are located in census tracts among the bottom-two income categories. None of the excelling schools are located in census tracts in the lowest-income category and no underperforming schools are located in the census tracts with the highest median incomes.

Figure 5 is a map showing the same school-performance data overlaying census tracts categorized by the percentage of residents who are White. This map shows that while household income is related to school-performance levels, race is an important factor as well. Most of the excelling schools are in census tracts with a high percentage of White residents and most underperforming schools are in census tracts with a lower percentage of White residents. Hence, comparing these two maps (**Figures 4** and **5**) shows that, with some exceptions, there is a strong relationship between the racial composition of the neighborhood and medium household income in that many of the non-White census tracts have a lower median household income. When underperforming schools are located in higher-income neighborhoods, these neighborhoods also tend to have a relatively low proportion of White residents. The three excelling schools in lower-income neighborhoods are in census tracts that are among the top three categories in terms of the percent of residents who are White. There are no excelling schools in census tracts in the bottom-two White resident categories. This means that White residents account for at least 64% of the total population in every census tract that contains an excelling school. These maps (**Figures 4** and **5**) show that families and students who live in low-income neighborhoods and neighborhoods with a significant population of people of color are more likely to attend elementary schools that are marginally performing or underperforming.

Figure 4 Tucson elementary school evaluation.

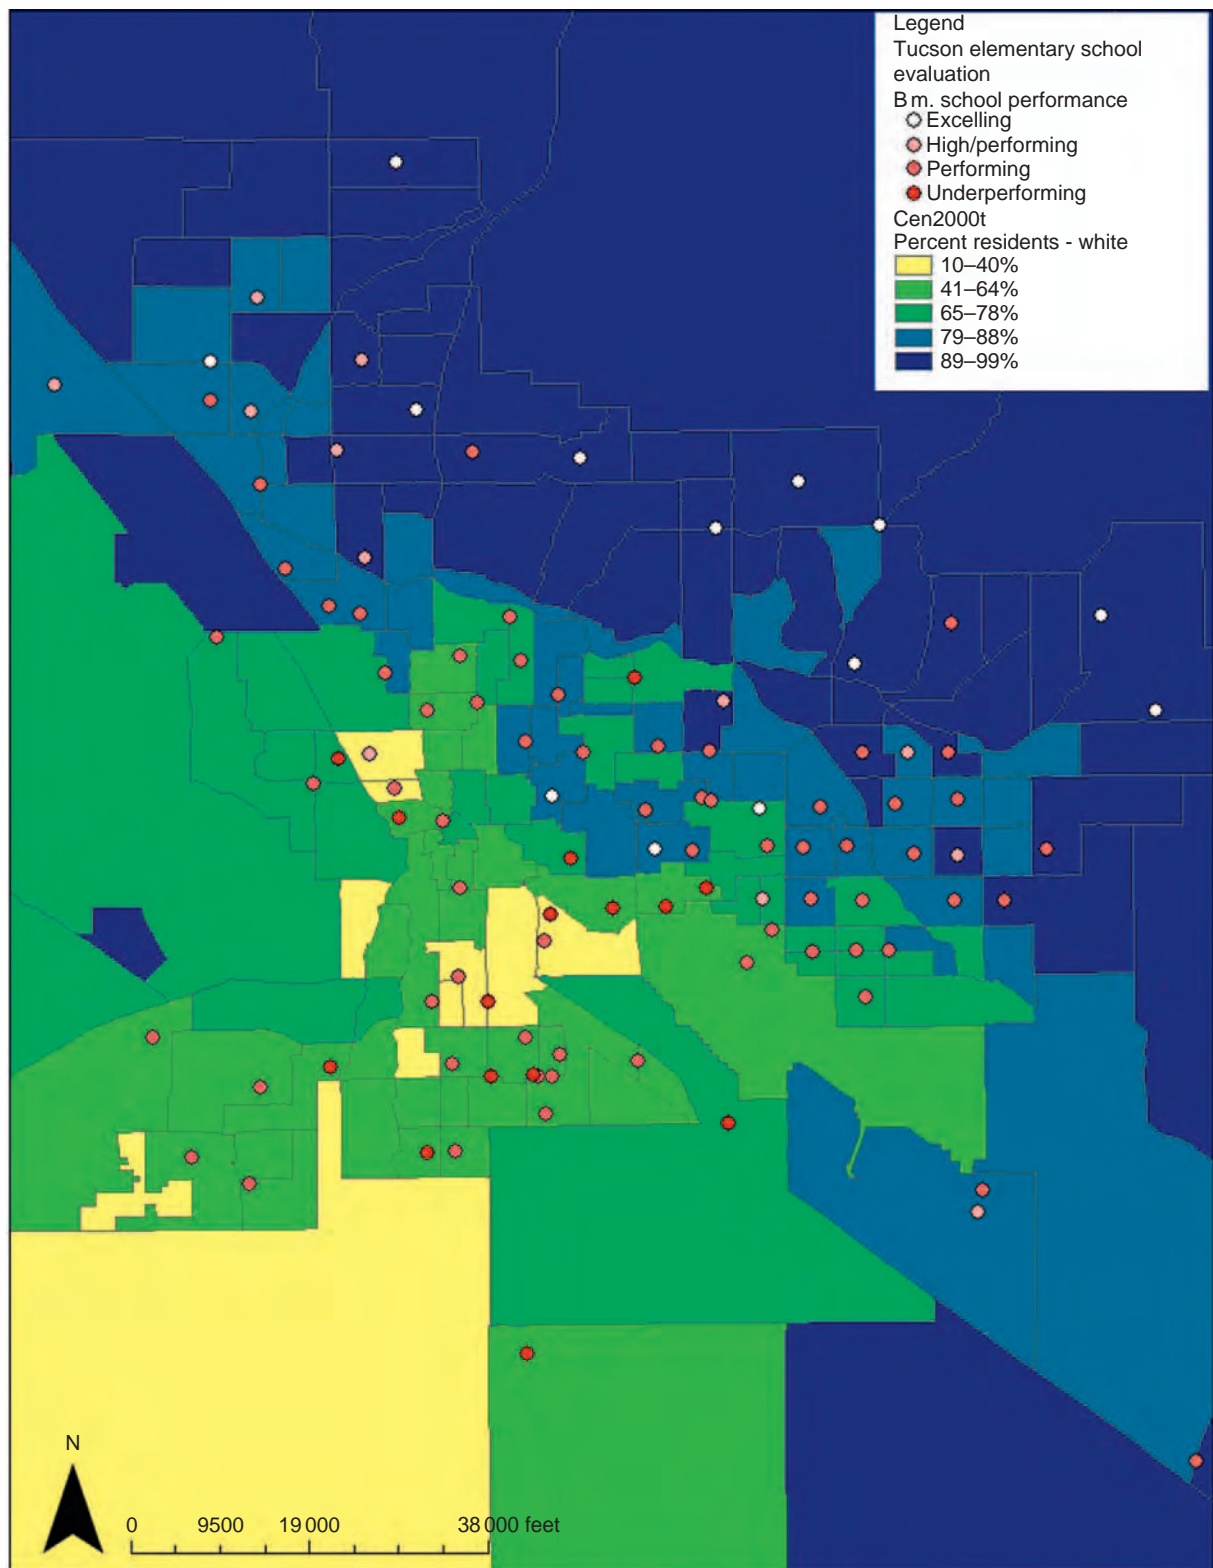

Figure 5 Tucson elementary school evaluation.

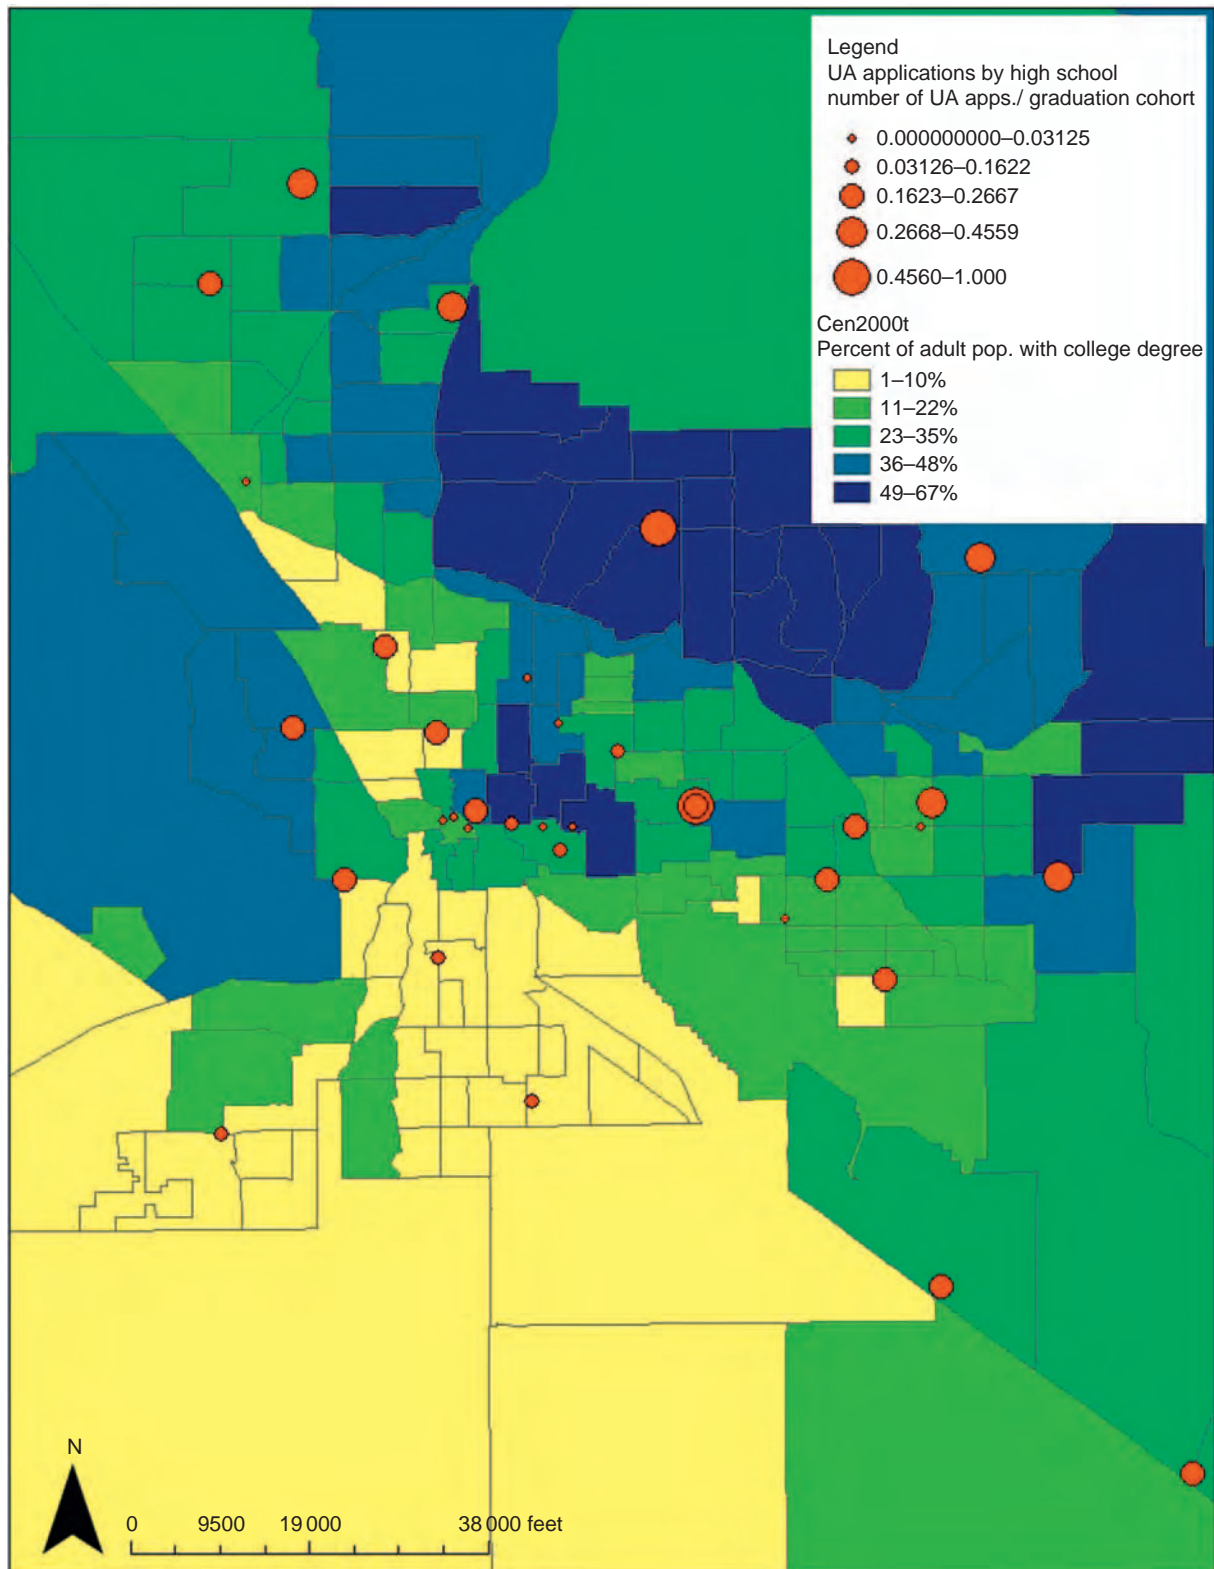

Figure 6 University of Arizona (UA) applications by high school – number of high school applications/graduation cohort.

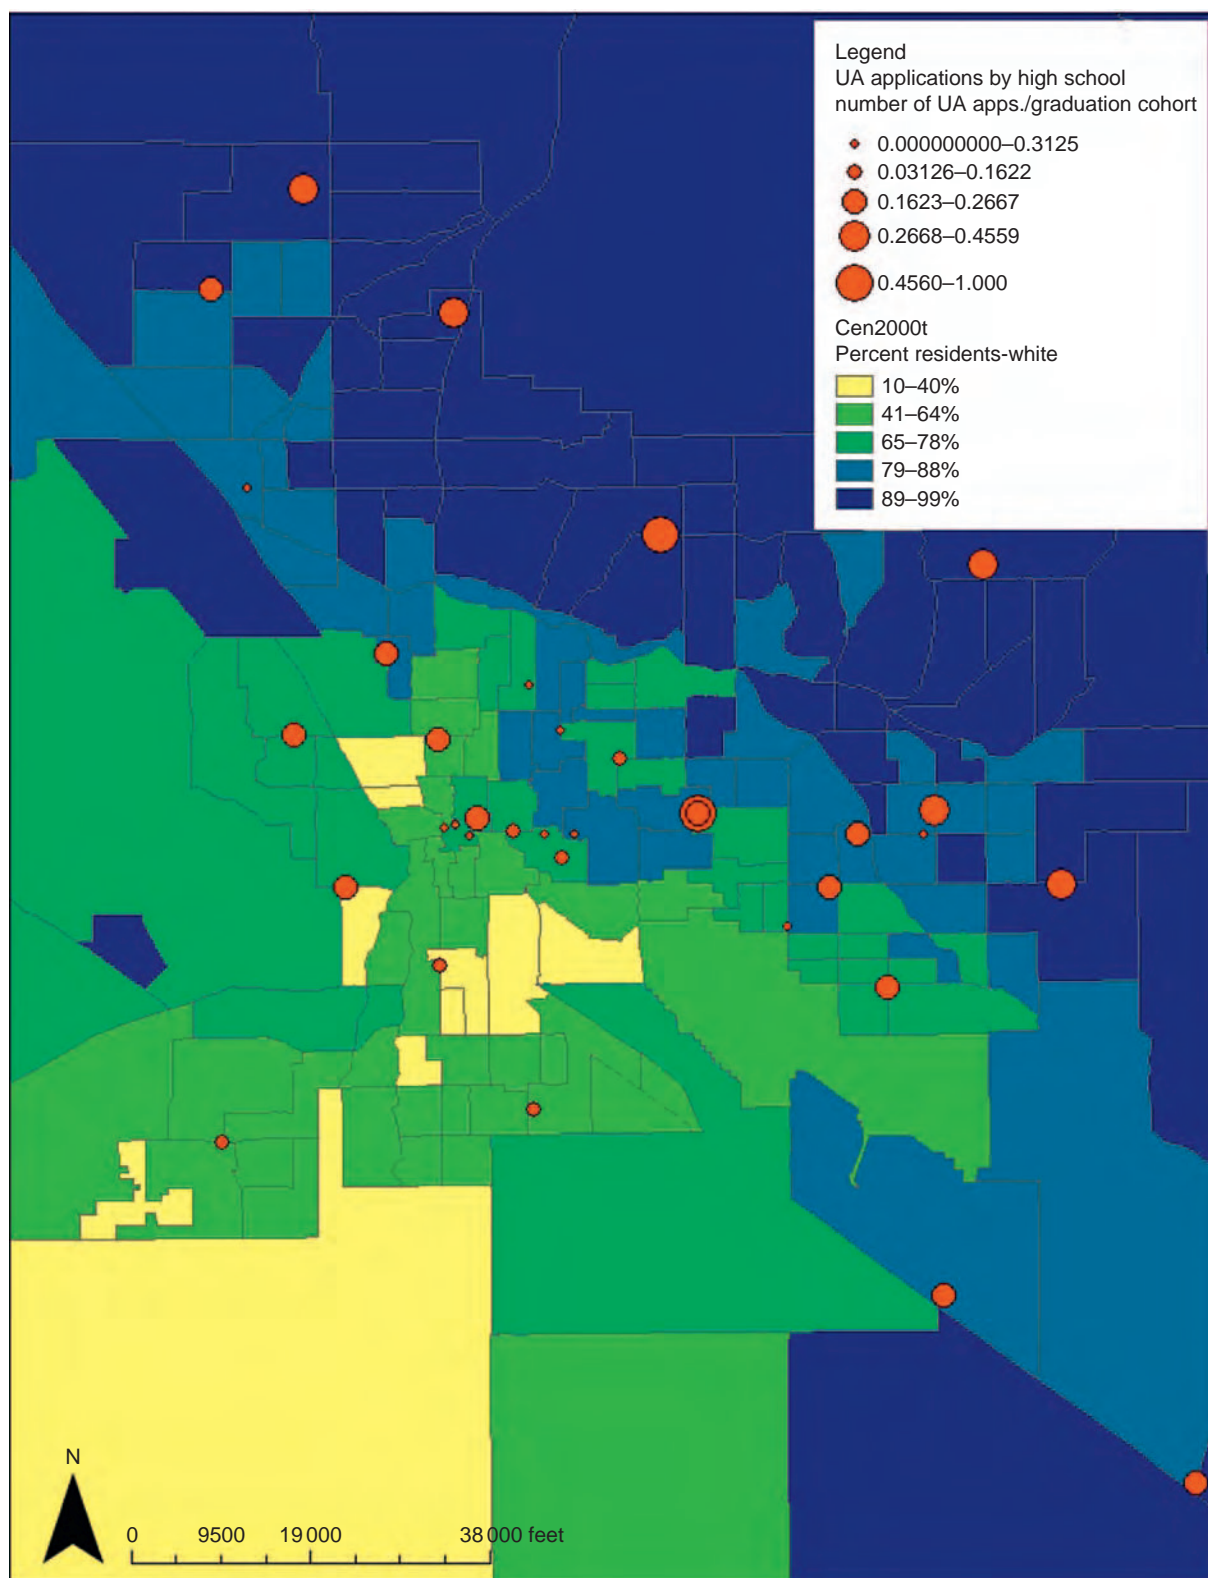

Figure 7 University of Arizona (UA) applications by high school – number of high school applications/graduation cohort.

The third example explores the relationship between neighborhood college knowledge, neighborhood racial/ethnic composition, and college-going practices (Figures 6 and 7). In Figure 6, college knowledge is represented using 2000 US census-tract data on the percentage of residents 25 years and older who have completed at least a baccalaureate degree. Darker census tracts represent neighborhoods that are comprised of a higher percentage of college-educated residents (assumed to have more college knowledge) and lighter census tracts represent neighborhoods that are comprised of a lower percentage of college-educated residents (assumed to have lower college knowledge). College-going practices are estimated by looking at the ratio of applications submitted to the University of Arizona with the size of the graduating cohort at each high school in Tucson for which there were data from the 2006/7 school year. Schools that exhibit high levels of college-going behavior are represented by larger points.

Figure 6 shows that neighborhoods in the northern parts of the city have higher levels of college knowledge and that schools in these neighborhoods exhibit higher levels of college-going behavior. Likewise, neighborhoods in the southern part of the city have lower levels of college knowledge and schools in these neighborhoods exhibit lower levels of college-going behavior. Figure 7 shows that in northern and southern neighborhoods, college knowledge and college-going behaviors tend to be closely associated with the racial composition of the neighborhoods. Census tracts with a high percentage of White residents in these neighborhoods tend to have relatively high levels of college knowledge and college-going behavior while non-White neighborhoods have lower levels of college knowledge and college-going behavior.

These patterns do not hold completely true in the central part of Tucson, which tends to be more diverse in terms of both race/ethnicity and socioeconomic status. This may be because in these more-mixed neighborhoods, college knowledge is more closely associated with the individual household than the community. It may also have to do with the way college-going behaviors are measured. Only applications to the University of Arizona are counted toward college-going behavior. Since census tracts in central Tucson include both higher income and predominantly White neighborhoods as well as lower income and more diverse neighborhoods, and because these different neighborhoods may feed in to the same high schools, the relationship between college knowledge and college-going behaviors in this area of the city is less apparent at the level of data granularity presented here.

Discussion of the three examples

Overall, the three examples and seven maps presented show that Tucson, Arizona is socially segregated along the lines of race/ethnicity and socioeconomic status and that this segregation has created unequal structures of opportunity

for college access. Students in affluent, White neighborhoods with higher levels of college knowledge have access to higher-performing schools and exhibit high levels of college-going behavior than students from less-affluent neighborhoods with a higher proportion of minority residents. Additionally, schools and neighborhoods in Tucson are racially segregated, depriving all students of the cognitive and social benefits of diversity that could lead to higher levels of college access for all. Given demographic and social trends underway, these examples show the importance of exploring place-biased opportunity structures in college-access literature rather than relying on pipeline modes for exploring educational opportunity.

Implications for educational research

Clearly, there are limitations to the analyses that we did in this study. Census-tract data do correspond directly to school-service areas which can provide imprecise representations of the relationships that we depict in this study. However, through the use of more advanced statistical techniques and methods of spatial analyses, it is possible to more accurately and appropriately represent school-service areas which can provide a much more precise picture of the nature of these important relationships.

We think that the use of GIS tools can make several important contributions to the study of college access and other educational phenomena related to important social and economic characteristics. As can be seen in the analyses described in this article, GIS tools can be used to create helpful visual representations that can be used as cognitive maps depicting important and often complex patterns of relationships. In these analyses, we used GIS tools to examine the relationships between segregation, stratification, and educational opportunity in one US city – Tucson, Arizona. Cognitive maps like the ones that we created can be used to further inform important public policy debates and improve educational decision making.

Public Policy and Inequality in Postsecondary Opportunity: Educational Statistics and the Failure of Education Reform

E P St. John, K Williams and K Moronski, University of Michigan, Ann Arbor, MI, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Academic preparation – A high school curriculum that includes the advanced courses in math, science, and English necessary for enrolment in 4-year colleges.

Accountability – A government system of regulation of schools and/or colleges that requires compliance with specific mandates.

Basic Educational Opportunity Grants (BEOGs) – The original name of Pell grants when the program was created by the Education Amendments of 1972.

Campus-based aid – College work study, national direct loans and supplemental educational opportunity grants are awarded to colleges, based on specific criteria. Campuses award aid to students based on financial need. Campus-based programs were created by the Education Amendments of 1972, which reauthorized the Higher Education Act (HEA).

College access – The rate of enrolment in college by a population or subgroup. Usually measured for the traditional age group (18–24) or the percentage of high school graduates going on to college the year after high school.

College success – Students finishing college with majors consistent with their interests. Simple measure in college-completion rates, a measure sometimes used in state accountability systems for higher education, including some budgeting systems.

Cost of attendance – The sum of tuition, books, living costs, and other expenses for attending a college or university.

Educational Opportunity Grant (EOG) – The original federal, generally available need-based grant program, now named supplemental educational opportunity grants.

Education Amendments of 1972 – The reauthorized version of the HEA that created BEOG (now Pell) and reorganized supplemental educational opportunity grants, work study, and national direct loans into the campus-based programs.

Expected family contribution – The estimated amount a family can pay for college, taking into

account parental income, number of siblings in college, savings, and other assets.

Federal loans – The student loan programs administered by the federal government and authorized under Title IV of the HEA.

Financial aid – The grants, scholarships, loans, and work study awarded to college students based on financial need, measures of merit (e.g., high school grades or test scores), and/or special abilities (athletic ability, music talent, etc.).

Financial inequality – The inequality in opportunity attributable to income differences. In an equitable society, education should be equally available to all groups regardless of income or race.

Financial need – The financial need of a student, which equals the cost of college minus expected family contribution.

Great Society – The image of a fair and just America, used by President Lyndon B. Johnson as a rationale for major, new educational and social programs in the 1960s.

Higher Education Act (HEA) – Passed originally in 1965, the HEA all-student-aid programs under Title IV, developing institutions under Title III, and other federal programs under other titles. The act is reauthorized every 4–6 years.

High school (K-12) graduation requirements – The courses required for high school graduation. Historically, the standards for high school graduation were set by local school boards. Since the early 1980s, federal education policy has encouraged states to set graduation requirements.

Merit grants – Aid awards based on student achievement. Example: Georgia Hope.

Middle Income Student Assistance Act of 1978 – A law that reauthorized Title IV of the HEA and removed income limitations on Pell grants.

Need-based grants – Student awards of money that are based on the families' ability to pay for college; for example, Pell grants.

Pell grants – The major federal need-based grant program. A portable form of aid students can take to any institution in which they are accepted. The programs are named after Senator Pell.

Pell maximum – The maximum award for Pell grants in any given year. Pell eligibility is determined by financial need. The Pell maximum is set each year in the federal budget. Since the late 1970s, the actual budgeted Pell maximum has consistently been less than the limit authorized under Title IV of the HEA. Limiting the Pell maximum has become a method Congress uses to control the costs of Pell grants.

Supplemental Educational Opportunity Grants (SEOG) – A federal need-based grant program administered by colleges.

Tuition and fees – The charges colleges and universities collected from students for the education and services provided.

Unmet need – The cost of attendance minus the sum of expected family contribution and financial aid awarded.

Unsubsidized loans – The loans provided by lenders without any federal subsidy. Some programs are federally authorized, such as some family loans, while others are administered by private lenders. Federal subsidies reduce interest rates and insure loans.

Work–loan burden – The amount of cost of attendance after grants and family contributions that a student must cover through work and borrowing. Since some loans are considered need-based aid, the work–loan burden is usually higher than unmet need.

Introduction

For the past quarter century, the federal government has published reports advocating improvements in the nation's high schools. There have also been a plethora of statistical reports emphasizing correlations between high school courses completed and college-enrolment rates. Some have argued that the disparity in preparation explains differences in college-enrolment rates across income and racial/ethnic groups. Not only have publications on the tool box focused on high school math courses completed as a predictor of college completion, but reports by the National Center for Education Statistics (NCES) have argued that all students who take the right courses and who apply for college have the opportunity to enrol. These reports have been used by the National Governors Association to argue that states should raise their standards for high school graduation to a level equaling college preparation, including at least algebra II.

A counter argument advanced by the Advisory Committee of Student Financial Assistance (2002) is that increased funding of federal Pell grants, the primary federal program promoting equal opportunity for college

enrolment, is necessary to reduce inequalities. This counter-interview to the dominant rationale of academic preparation has its origins in an earlier period of public policy, the Great Society programs of President Johnson. The federal role in K–12 and higher education developed as part of the initiatives in the 1960s aimed at reducing inequality in educational opportunity. Interestingly, a few recent reports like that of the Spelling Commission have promoted increases in need-based grant aid along with higher educational standards and increased accountability for higher education.

This article examines changes over time in public policy on college access along with trends in two key indicators related to college access: academic preparation and enrolment rates. Our focus is on how policies relate to changes in college enrolment rates and differentials in these rates. Our approach differs fundamentally from the one used by analysts who identify correlates of college success, like high school math courses, coupled with building rationales for policies that require these correlates. Instead, our focus is on how these policies, based on flawed rationales, actually relate to changes in enrolment and equality in educational opportunity.

Public Policies Promoting College Access

Federal policies promoting equal opportunity in college access began in earnest with the passage of the Higher Education Act of 1965, which funded the first generally available grant and loan programs under Title IV, Educational Opportunity Grants. In 1972, the Pell Grant Program replaced the Educational Opportunity Grant (EOG) program with Basic Educational Opportunity Grants (now called Pell Grants). The grant programs of the 1960s and 1970s were implemented during a period of increasing access attributable to the growing size of the college-age cohort and college expansion to accommodate the baby-boom generation. The rise and decline of Pell Grants took place in a decentralized system of higher education in which states had the primary responsibility for academic preparation through K–12 graduation requirements as well as funding for higher education. As background before reviewing key enrolment trends, we examine trends in Pell grant funding relative to college costs, state policies on high school graduation, and coordination of state funding for grants and tuition.

Federal Pell Grants

Recently, several leading economists have argued that reinvesting in Pell grants provides a means of increasing social justice and promoting economic development, restating an argument that had a substantial influence on the early development of federal grant programs. In the

1960s and early 1970s, in the wake of *Brown versus Board of Education*, the inequality in educational opportunity was used to argue for federal student financial-aid programs. These earlier arguments about inequality were often coupled with arguments about economic development in advocacy of federal grant programs. The Higher Education Act (HEA) of 1965, which initiated the contemporary federal role in student financial aid, was one of Lyndon B. Johnson's Great Society programs aimed at remedying racial inequality. The reauthorization of the HEA in 1972 created Basic Educational Opportunity Grants (BEOGs) (now Pell Grants) as a portable grant program intended to equalize post-secondary educational opportunity and increase enrolment. (For a more complete discussion of the history of federal student aid see St. John (2003).)

Initially, the maximum Pell grant was higher than the costs of attending public 4-year colleges, but there was a half-cost provision in the original legislation which limited the maximum award to half of the total costs of attending. Students attending more expensive private colleges could get the full grant and, in these cases, Pell grants enabled low-income students to choose more expensive colleges. Initially, program eligibility was limited to low-income students, but in 1978 the Middle Income Student Assistance Act extended the eligibility to include middle-income students, removing income caps in favor of using unmet need as the indicator of eligibility. (Unmet need equals the cost of attendance (COA) minus expected family contribution (EFC). Early in the history of the Pell program, grants often met need after EFC, but this is no longer the case. Usually low-income families have substantial unmet need after total grants, causing excess borrowing and work.) By the early 1980s, the cap for the Pell program had also dropped.

Trends in the Pell award maximum compared to the average COA at public 4-year colleges and universities (Figure 1) reveal that college costs increased much faster than the Pell maximum award after 1975. The maximum Pell award actually declined in constant dollar value between the fall terms of 1975 and 1995, while the costs of attending public colleges rose. Although the dollar value of the maximum Pell award rose slightly after 1995, the increase did not keep up with the rising costs of public colleges. Consequently, the gap between the Pell grant maximum and the cost of attending 4-year colleges continued to increase. Other forms of federal aid did not increase, so while many colleges had other forms of federal grants to award low-income students, the total amount of federal aid declined in relation to tuition. (Supplemental Education Opportunity Grants (SEOGs) are awarded to only some public and private colleges as a result of historical grant applications. It is very difficult for a new or growing institution to increase its pool of money through SEOG.)

The gap between the Pell maximum and COA at public colleges and universities, the amount of unmet need for the highest-need students, is filled by a combination of loans, earnings from work, and other types of grants if available. Only a few states have sufficient need-based grant aid to substantially reduce the gap, so low-income students in public colleges and universities often had work/loan burdens in excess of US\$8000 in 2005. The growing cost of attending public 4-year colleges has added to inequality in financial opportunity for low-income students to enrol in 4-year colleges (Fitzgerald, 2004), a fact too often ignored in arguments which posit that improvements in high school curricula and additional academic requirements for graduation will solve the access challenge in the United States.

Figure 1 The Gap between the actual maximum Pell award and university attendance costs.

State Policies on Academic Preparation

The publication of *A Nation at Risk* (US Department of Education, 1983) emphasized improving high school graduation requirements in the United States and advocated other reforms related to standards, curriculum, and assessment. Since then, the US Department of Education has published and republished various papers on the correlation between completion of high school math and college-success indicators, from initial enrolment through college completion. These correlations have been used to advocate for adding requirements for high school graduation, echoing a rationale advanced in *A Nation at Risk*. Not only has there been nearly continuous advocacy for increasing requirements along with raising standards and using high-stakes tests, but many of these policies have been implemented in most states since 1990 (see Table 1). For example, more states now require students to pass exams to graduate from high school (rising from 15 states to 22).

The most visible indicator of change, however, has been in math requirements, a development that appears to have had an influence on math achievement. (This section summarizes a discussion of school reform in St. John (2006), updated by the Promoting Equity in Higher Education Project, part of the University of Michigan's National Center for Institutional Diversity (NCID).) The number of states requiring at least two math courses increased from 11 in 1990 to 28 in 2005. Further, no state required algebra I for high school graduation in 1990, about the time federal reports began to emphasize the correlation between high school math and college success,

but 22 states required this level of math (or higher) for graduation by 2005. In addition, the percentage of students taking the Scholastic Aptitude Test (SAT) and the average scores on the SAT math exam improved over the 15 years, providing a tangible sign of the policy's impact on achievement.

However, while math requirements and achievement rose, high school graduation rates decreased during this period, dropping to about 70%. Further, there is no evidence to support claims that improving graduation requirements is associated with improved enrolment opportunity, a situation that complicates the reality for recurrent arguments about academic preparation. It is necessary to consider the state's role in financing public higher education as background to this aspect of the problem.

State Coordination of Tuition and Need-Based Grants

While states collaborate with local school districts to provide free K–12 education, no such arrangement exists in higher education. As noted in Figure 1, the cost of attendance at public 4-year colleges has grown substantially in recent decades. While the decline in federal Pell grants has eroded access, states continue to have the responsibility for providing equal opportunity for their citizens to receive an education. In theory, raising the minimum standards for high school graduation could improve opportunities for low-income students to enrol in college, but only if adequate need-based student financial aid was available.

Table 1 State policy indicators for selected years, 1990–2005

	1990	1995	2000	2005
<i>Policy-related variables</i>				
State-established content standards in math	7	46	50	50
Requires three or more math courses for graduation	11	12	21	28
Requires one or two math courses for graduation	33	31	24	17
Requires at least algebra I or above	0	2	12	22
High school curriculum is locally controlled	6	7	5	5
Offers an honors diploma	15	17	19	22
Exam required for high school diploma ^a	15 ^b	12	14	19
Percentage of schools participating in AP ^{a,c}	45%	51%	58%	62%
Percentage of students taking SAT ^d	42% ^a	41%	44%	49%
Ninth-grade cohort size (millions)	3.2	3.32	3.79	3.96
<i>Outcomes of interest</i>				
SAT verbal mean	500	504	505	508
SAT math mean	501	506	514	520
SAT combined	1001	1010	1019	1028

^aBased upon numbers reported in 1991.

^bThis number is higher than anticipated but cannot be externally validated.

^cReflects the median percentage for AP and the median dollars per FTE for K–12 expenditures.

^dThese numbers reflect the national figures reported by Educational Testing Service.

^eDollars reported are unadjusted.

From the project on Promoting Equity in Higher Education Project, National Center for Institutional Diversity.

States also provide funding for need-based grants, although the level of state funding per student varies substantially across states, as illustrated in **Figure 2**. Only three states – New York, California, and Indiana – had an average of 20% or more per full-time equivalent enrolment (FTE) funding of grants. (This indicator used the FTE of students in public and private colleges in the numerator and total funding for state grants in the denominator. State funding for grants is not reported with a breakdown by different types of colleges.) These states provide substantial grant aid for students enrolling in private colleges and public colleges. Only 12 other states maintained this ratio at a rate above the national average. Thus, high-need students in the majority of the states have substantial unmet need.

The link between state funding of need-based grants and enrolment rates for college students should not be overlooked. The link is illustrated by the correspondence between grants and the inequality in enrolment across income groups: The years when the Pell maximum was higher than the average cost of attending public 4-year colleges, enrolment rates were nearly equal across racial/ethnic groups. **Figure 3** illustrates that trends in the ratio of state funding for grants and tuition corresponds with the continuation rate (the ratio of high school seniors to college freshmen enrolling in states), a further illustration of the link between funding for need-based grants and enrolment. This correlation between state financing and enrolment rates has received substantially less attention in national policy reports than has the correlation between math courses completed and eventual college completion. This oversight is highly problematic.

Public Policy and Post-Secondary Opportunity

Access to higher education is defined as the rate of enrolment in college. In the 1970s, as noted above, enrolment rates did not increase. Equal opportunity to enrol is defined as equality in access across income and racial/ethnic groups. It is possible to nearly equal opportunity for college enrolment across groups whether access increases or decreases during a specific period of time. At the present time, the extent of equal opportunity depends on whether equally prepared students have the same odds of enrolling in 4-year colleges regardless of their family income. Unfortunately, the work–loan burden after grants for the average low-income student in a 4-year college is excessive, so conditions do not favor equal opportunity for enrolment in 4-year colleges.

With the varied and often competing arguments about the role of public policy in promoting college access, it can be difficult to untangle how policy impacts educational

outcomes related to college access. Instead of arguing about correlations – like the ratio of high school math courses to college enrolment or completion – we compare trends in policy (above) to trends in critical outcomes related to college access. After more than two decades of arguments for making high school tougher, it is important to consider whether improvements in preparation (as evident in gains in test taking and test scores) actually result in increased opportunity or reduction in inequality across groups.

Our analyses focus on three key indicators of access to higher education:

- *Access*. The percentage of 18–24-year-olds who indicated enrolment in college (current or previous) and college continuation rates.
- *Inequality of opportunity*. The differentials in rates of college enrolment for African American and Hispanics compared to Whites.
- *College choice*. The percentage of a racial/ethnic group's FTE enrolment in public 2-year and public 4-year colleges, as ratios to the group's percentage in the population, as indicators of whether different groups choose different types of colleges.

These definitions are interrelated, but it is important to distinguish between these outcomes when equity is being considered. Equal access can be realized in a society that has equal rates of college-prepared students enrolling in 2- and 4-year colleges. However, there can still be unequal opportunity if low-income students who are prepared to enrol in 4-year colleges cannot afford to enrol in 4-year colleges. College choice extends the concept of equal opportunity to consider the range of choices, from open-access colleges through elite private colleges. Ideally, measures of choice would consider preparation; this is not only difficult to do, but there are prior inequalities in the opportunity to prepare for college in almost all US states (St. John, 2006). Therefore, we consider the representation of a group in different types of colleges (i.e., proprietary, public 2-year, public 4-year, and private non-profit colleges) as an indicator of whether equity in colleges choice has been realized. This measure implicitly considers the role of college cost and prior preparation. In a society with equal opportunity to prepare for college and fair and equitable student aid, all groups would have representation in each type of college equaling their representation in the population (nation, state, or locality) being considered.

Trends in College Access

While the college continuation rate – the ratio of high school seniors to college freshman enrolment (**Figure 3**) – has varied little since 1992, the percentage of 18–24-year-olds

Figure 2 Ratio of average state funding per full-time equivalent (FTE) on need-based grants to average public tuition charge (2006). Data from NCES Integrated Postsecondary Education Data System and National Association of State Student Grant & Aid Programs.

Figure 3 National trends in continuation rate and grant/tuition ratio.

Figure 4 College enrolment rates for 18–24-year-old high school graduates. Data from *NCES Digest of Education Statistics 2007*, table 195.

(college-age students) who were currently or previously enrolled actually increased between 1995 and 2005 after having remained relatively flat between 1970 and 1985 (**Figure 4**). If we used this as our only indicator of access, we might conclude that college enrolment rates improved, possibly as a consequence of either improvement in preparation or availability of loans. Certainly this is possible, but we also need to ponder the discrepancy between percentage enrolled and the trend in the college continuation rate.

The fact that college-enrolment rates for freshmen did not increase substantially during a period when the percentage of traditional-age students enrolled did increase appears contradictory. However, it is essential to consider these trends in relation to college cost. The measure of currently and previously enrolled students includes students who have dropped out, while continuation rate is a measure of currently enrolled freshmen. People can have access to college – be able to enrol – and not be able to persist. Persistence can be deterred by academic, social, and financial

factors. The second measure of access – the percent of the population enrolled (used in **Figure 4**) – is a broader measure that includes students who have delayed enrolment and those who drop out. Low-income students are more likely to delay enrolment and to drop out than middle-income students (St. John, 2006), so the second measure captures more of the low-income, traditional college-age population that eventually enrolls.

The college-continuation rate (**Figure 3**) provides a ratio from institutional reports on freshman enrolment compared to school reports on students who graduate. The rate of current/previous enrolment provides a self-reported measure of students enrolled at any time over a 6-year period (**Figure 4**) as reported on the Current Populations Surveys (CPS). (The continuation rate, calculated every 2 years by Tom Mortensen, provides a ratio of the actual number of high school graduates to the actual number of college freshmen. In contrast, the self-reports on CPS (the indicator reported in **Figure 3**) cannot be as easily

verified.) There are two ways to interpret the discrepancy between these two measurements. It is possible that the CPS has consistently overreported enrolment after 1992. It is also possible that many students enrol in proprietary colleges or delay enrolment, as has long been reported. There is reason to expect that the number of students who eventually find a way into some type of college has increased over time, especially given the improvements in preparation noted above.

In combination, these two measures of college access appear to indicate that the rate of enrolment after high school has been relatively static (i.e., continuation rate), but that more students have eventually entered college since the educational reforms were implemented after 1990. Thus, there is mixed evidence of success on access. Educational reforms may be working, but they do not seem to be enabling growth in the traditional pipeline to college. This apparent discrepancy raises an important issue given that the government reports on access extolling the virtues of math preparation use a pipeline rationale which assumes continuous enrolment.

Unequal Opportunity

The CPS self-reports on college enrolment are also important because they provide a measure of equity in enrolment opportunity. In **Figure 5**, we compare the differentials over time in the percentages of Whites, Hispanics, and African Americans who reported enrolling in some form of post-secondary education. Trends in this indicator illustrate persisting inequality since a brief period of relative equality in the 1970s; instead of, for example, nearly equal African

American and White enrolment rates and higher enrolment rates for Hispanics than Whites in 1975.

In 1975, the Pell program was fully implemented and college costs were relatively stable. In addition, the Pell grant maximum had not yet been eroded. There is reason to speculate that relative equality in enrolment at this point was at least partially attributable to Pell grants. A comparison of trends in the Pell gap (**Figure 1**) with trends in the differential in enrolment rates (**Figure 4**) suggests that the growth in inequality since 1975 could be related to the decline in Pell grants coupled with increasing college costs. (As indicated in **Figure 4**, the data on Pell maximums are based on reports on college costs published annually by the College Board.)

All types of student aid increased over the last decade, adjusting for inflation: Pell grants increased by 73%, federal grants (Pell plus other) increased by 83%, and total federal aid (grants plus loans) increased by 77% (College Board, 2007). (This set of percentage rates was provided by the editor and included upon the request of the editor.) Given that all forms of student aid increased at rates similar to Pell and the gap between the Pell maximum and COA increased substantially, student aid did not keep up with tuition. All federal programs have maximum awards. The amounts of aid students could receive simply did not increase as fast as inflation.

The problem with the interpretation of trends is that Pell should have resulted in an increase in enrolment rates, according to arguments by economists, so there are lingering questions about the efficacy of Pell. In actual fact, total federal grant aid did not increase after Pell was implemented because of cuts in other grant programs, but

Figure 5 Difference in college enrolment for African Americans and Hispanics compared to high school graduates. Data from NCES *Digest of Education Statistics 2007*, table 1.

Pell did target aid to financial need. Economists have tended to focus on increases in Pell funding without considering the fact that total federal aid did not increase. With this additional background, it is apparent that targeting financial aid on need-based programs equalized opportunity and that additional funding may have been needed to increase enrolment rates.

Based on the review of access trends above, it may be tempting to argue that improvements in preparation improved enrolment rates better than Pell, but this argument does not solve the problem of unequal enrolment rates. The statistical analysis of the effects of state K–12 policies on preparation by students in the high school class of 2004 indicates that minorities benefited more substantially than majority students from raising standards, probably an artifact of improvements in preparation in high-poverty schools. The inequality in enrolment rates, however, does not suggest a link between improved preparation for minority students and improved enrolment rates. That is, if there were benefits from the new education policies on enrolment, they did not take the form of reducing inequality in enrolment rates. Quite the opposite, inequalities in enrolment opportunity persisted in the 2000s, even after educational reforms were widely implemented and modest gains were recorded in the rates of students taking the SAT and improved SAT math scores.

The persistent and growing inequality in post-secondary opportunity in the 2000s is perplexing because unequal access is often portrayed as a problem of academic preparation (Adelman, 2005; Choy, 2002). The inequality, however, appears to be linked to changes in student aid. In fact, graduation requirements increased during the period, a policy shift that favored minorities because it gave them access to college preparatory courses (Daun-Barnett, 2008; St. John, 2006; St. John and Moronski, 2008). In addition, test scores improved, an indicator that the new education policies worked, resulting in improved test scores. However, in spite of improved preparation and scores, inequality grew: The widespread implementation of the new math policies did not result in reduced inequality in access. Even if improved overall rates of enrolment were attributable to improvements in graduation requirements, a real possibility, this explanation would not hold up as a cause of the differentials, the inequality. To address this question further, we need to dig deeper into the sources of the inequality.

College Choice or Opportunity Denied?

As part of the Projects Promoting Equity in Urban and Higher Education, we have developed a set of indicators of representation: the percentage of FTE students by racial/ethnic group in a sector of higher education compared to that group's percentage of the population. (We generated

these statistics from fall enrolment data in the NCES Integrated Postsecondary Data System (IPEDS) and national statistics on population composition.) This measure has the ratio of the minority group to the college population. To judge the meaning of this, we needed to weight the percent of the group enrolled in a type of institution by that group's representation in the population as a whole. This approach is the best available measure of equal representation in higher education. We present trends in representation of students by group (African American, Hispanic, Asian, and White) for enrolment in public 2-year and public 4-year colleges.

Trends in enrolment composition at public 4-year colleges (**Figure 6**) illustrate a substantial and persistent differential in enrolment across groups. Hispanics and African Americans enrol at rates substantially below their representation in the population, while Whites enrol at a rate nearly equal their percentage of the population and Asian Americans enrol at a substantially higher rate. (The decline in the rate of enrolment of Asian Americans in the sum across groups after 2000 in **Figures 6** and **7** may be attributable to the growth in the percentage of students with unidentified racial/ethnicity.) This inequality is a serious problem in the United States. All groups subsidize public colleges through their taxes. In addition, state education policies have been implemented to improve preparation for all students, a policy that has benefited African Americans and Hispanics more than other groups (Daun-Barnett, 2008; St. John and Moronski, 2008); yet representation by these groups has not grown at a rate we would expect from the improvement in academic preparation. Thus, while there are indicators of growing access to 4-year colleges for some groups, it does not extend to all groups. Hispanics and African Americans clearly do not have equal opportunity to enrol in public 4-year colleges. This is sad and ironic given that the educational reforms implemented in the late 1990s and early 2000s (**Table 1**) were rationalized based on raising the level of preparation for and access to 4-year colleges for all students.

Instead, there has been a shift in enrolment of minorities into 2-year colleges at the same time that Whites have moved out of 2-year colleges (**Figure 7**). In 1992, both Whites and Hispanics were represented in 2-year colleges at a rate equaling their representation in the population, while African Americans were underrepresented. However, during the subsequent 14 years, African Americans increased enrolment in 2-year colleges relative to their proportion of the population. Latino representation in community colleges declined after the 2000 census. When interpreted in combination with other trends, it is apparent that: increased access by African Americans was limited to 2-year colleges, while Latin lost ground in access to both 2-year and 4-year colleges.

If we examine these trends in representation in comparison to patterns of high school reform and test scores,

Figure 6 Ratio of group representation in public 4-year institutions to group representation in the United States. Data from NCES Integrated Postsecondary Education Data System and US Census Bureau.

Figure 7 Ratio of group representation in public 2-year institutions to group representation in the United States. Data from NCES Integrated Postsecondary Education Data System and US Census Bureau.

it is apparent that the reforms have not had their intended consequences for African Americans and Hispanics. While reforms over the past two decades have been rationalized as a means of improving enrolment in and graduation from 4-year colleges, gains in opportunity have largely been denied to the groups in greatest need. If all students had benefited equally from the education reforms – which is not an unreasonable hypothesis since most reforms required improvements in preparation of all students – then inequalities in opportunity for higher education should have been reduced.

The best explanation for the growing inequality in opportunity to enrol in 4-year colleges is the failure of state and federal grants to keep up with college costs. The gap between the Pell maximum and costs at 4-year colleges grew after 2000 (Figure 1), when there was also a slight drop in state funding of need-based grants as a ratio of tuition (Figure 3). With the reduced ability to pay, the subpopulations with the highest percentages of low-income families – Hispanics and, to a somewhat lesser extent, African Americans – were priced out of 4-year colleges. The low representation of Hispanics and African Americans in public 4-year colleges, coupled with their overrepresentation in public 2-year colleges, reflects this outcome.

Conclusions

For more than two decades, correlations between college high school math courses and college outcomes have been used to argue that preparation is the most critical issue in expanding college access. Many of these studies used longitudinal data on the high school class of 1992 to build this argument. An examination of policy trends since 1992 reveals that all states have raised math standards since that time and increased the number of math courses required for high school graduation. In addition, the percentage of students taking the SAT and their average scores improved. Yet, inequality in post-secondary opportunity worsened. Since 2000, a period when this new regime of policies was well established, college continuation rates have decreased slightly, inequality in enrolment rates has increased, and gains in minority enrolment have been constrained to 2-year colleges. These conditions are serious and problematic.

What explains the growing inequality? Certainly improvement of opportunity to prepare for college should remain a high priority for state and federal officials. However, these trends reveal that we cannot rely on education reform alone as the remedy to inequality in opportunity. The growing gap between college costs and Pell grants, coupled with the decline in state funding for need-based grants relative to tuition charges, provides the best explanation for the growing inequality of the early twenty-first century. It is time to face up to the challenge by sustaining

and enhancing efforts to improve high schools while ensuring low-income students who meet the qualifications now being set as standards for high school graduation will have the financial means to pay for college.

Misreporting of statistics on academic preparation and hauling out statistics from studies of the high school class of 1992 no longer make sense. There have been extensive educational reforms since the class of 1992 enrolled in college, along with a very substantial rise in costs. The repetition of the message that deficits in preparation are the cause of inequalities may have been a motivation for raising requirements, but as recent history has shown, raising requirements does not guarantee equal opportunity. Leaving qualified students behind by limiting their opportunities to enrol in public 4-year colleges denies the promises of the new reform rationale. To fulfill this implied promise, it is necessary to ensure financial access for low-income students who take the steps to prepare for college.

Of course, social and cultural factors also influence enrolment behavior. No doubt interventions that encourage parents and children in low-income families to visit campuses and apply for student aid can lead to gains in enrolment rates, provided students are prepared academically and they have adequate student aid. Indeed, a comprehensive approach to improving access to higher education should include encouragement along with high school reform and guarantees of adequate student aid. The focus on academic preparation and financial aid in this article is not intended to overlook the role of encouragement. However, encouragement without the underpinnings of finances and academics could create false hope and cannot ensure equal opportunity.

The Education of Indigenous Students

J W Tippeconnic and S C Faircloth, Pennsylvania State University, University Park, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

The awareness, knowledge, and bond of Indigenous peoples around the globe have increased in recent years. A greater understanding of their education conditions has been facilitated by actions of the United Nations; policy and practice by national and Indigenous governments; the growth of Indigenous schools, institutions, and organizations; and the collective research, teaching, and service of many individuals and organizations. Key leadership in this renewal and reconstruction of education has been provided by Indigenous peoples throughout the world. In keeping with this global movement, this article provides an overview of the historical and current factors that have served to shape the education of Indigenous children and youth. In doing so, we focus on Indigenous education from a global perspective.

According to the United Nations Permanent Forum on Indigenous Issues, (2006) there are more than 370 million Indigenous people residing in approximately 70 countries across the globe. Within this population, there are more than 5000 individual groups, representing approximately 4000 languages (IFAD). The term indigenous is often used synonymously with aboriginal, with different usages preferred in various regions of the world. Indigenous is used most often in international reports such as those published by the United Nations. However, terms such as native, tribal, First Nation, traditional, and Indian are also used to describe Indigenous people. Although these terms are used, there is a growing preference within many Indigenous communities to refer to themselves in a more precise and respectful manner that acknowledges the Indigenous name of the individual tribe or group (e.g., Marker, 2000). For example, in the United States, Indigenous people may refer to themselves as *Diné*, *Comanche*, *Lumbee*, or any of the more than 650 federally and state-recognized tribes across the nation.

In a study of the problem of discrimination against Indigenous populations, a report commissioned by the United Nations, (cited in Secretariat of the Permanent Forum on Indigenous Issues, 2004), Martínez Cobo described Indigenous communities, peoples, and nations as those with

historical continuity with pre-invasion and pre-colonial societies that developed on their territories, consider themselves distinct from other sectors of the societies now prevailing on those territories, or parts of them. They form at present non-dominant sectors of society and are determined to preserve, develop and transmit to

future generations their ancestral territories, and their ethnic identity, as the basis of their continued existence as peoples, in accordance with their own cultural patterns, social institutions and legal system (Introduction).

Indigenous peoples have also been characterized as having a long-term, continuous connection to a specific place, ancestry/lineage, culture, and language. Each of these groups generates and, to some extent, lives by its own unique core of Indigenous knowledge and ways of knowing.

Indigenous Knowledge and Its Relationship to Education

According to the United Nations Educational, Scientific and Cultural Organization (UNESCO), Indigenous knowledge is “culture- and context-specific; non-formal knowledge; orally transmitted, and generally not documented; dynamic and adaptive; holistic in nature; [and] closely related to survival and subsistence for many people worldwide.” Indigenous knowledge has also been described as “the local knowledge that is unique to a given culture or society ... the basis for agriculture, health care, food preparation, education, environmental conservation, and a host of other activities” (Sri Lanka Centre for Indigenous Knowledge, 1996). (For additional information, see the website of *Best Practices on Indigenous Knowledge*.) Transmission of Indigenous knowledge often occurs from generation to generation through use of oral traditions. (Adapted from *Indigenous Knowledge and Sustainable Development*, Sri Lanka Centre for Indigenous Knowledge, University of Sri Jayewardenapura, 1996, pp. vii–viii.)

Indigenous knowledge is important not only for Indigenous people, but the world as a whole. For example, Indigenous knowledge has much to say about the ecosystem and the ways in which communities can ensure the sustainability of natural resources.

Cajete (1994) relates Indigenous knowledge to education by identifying a number of elements of Indigenous education, including the recognition of Indigenous languages as a “sacred expression[s] of breath.” Indigenous education also recognizes that each person and each culture contains the key to one’s well-being and development. In addition, integration and interconnections are universal principles of Indigenous education. The purpose of Indigenous education is to teach a way of life that sustains

both the individual and the community by integrating “human individuality with communal needs” (p. 30).

Although a critical component in the successful education of Indigenous peoples, Indigenous knowledge lacks widespread understanding and use in most Western systems of education. According to Battiste (2008):

colonial and neocolonial [educational] models continue to offer publicly funded schools and their students a fragmented, negative, and distorted picture of Indigenous in history, textbooks, and curricula. These models characterize IK [Indigenous Knowledge] as primitive, backward, or superstitious, causing Indigenous peoples to be viewed as deficient and requiring remedies that destroy Indigenous peoples’ self-esteem and self-confidence. (p. 86)

The inclusion of Indigenous knowledge in national education systems has been a long-standing challenge, made difficult to realize because of the deficit approach mentioned above and because of the complex nature of the task. King and Schielmann (2004), in discussing the recognition and inclusion of Indigenous knowledge, suggest that indigenous communities must support and consent to what knowledge is included in school curricula. They go on to discuss the inclusion of Indigenous knowledge in Western education:

Quality indigenous education offers innovative solutions to the complex issue of incorporating indigenous knowledge, and values indigenous knowledge systems as equal and complementary to Western systems. This includes:

- Respect for, and recognition of ownership of, indigenous communities as holders of indigenous knowledge, and for their specific way of generating and transmitting knowledge.
- Identification and incorporation of relevant local, cultural knowledge with the participation and informed consent of indigenous communities and elders, in particular as regards the selection, transmission and documentation of that knowledge – in planning programmes, the selection of teaching methods, the design of curricula and the production of educational material.
- Inclusion of stories, diaries, textbooks, etc., as well as non verbal education materials produced by indigenous teachers [and]
- The active participation of students and community members who serve to develop a curriculum founded on indigenous people’s cultural identity and history (p. 37).

Indigenous Knowledge and Education from a Historical Perspective

Historically, educational policies and practices have excluded Indigenous knowledge in schools. Battiste (2008)

notes that a common experience among Indigenous peoples is colonization by foreign forces. This has resulted in assimilationist policies which have sought to abolish the use of Indigenous languages, knowledge, and cultures in the education of Indigenous children and youth. Although Indigenous knowledge has always been a guiding force in the lives of Indigenous peoples, historical accounts of Indigenous education routinely describe education as if it began only at the point of contact. In general, colonizers worldwide viewed Indigenous people as individual lacking knowledge, inferior in their ways of thinking, illogical, and intellectually weaker, and set to work to change and improve them. For instance, in Australia, Eckermann (1998) noted “since colonization in 1788 Australia’s history has followed patterns common to most colonial nations. Early contact between colonists and Indigenous groups was marked by conflicting attitudes and perceptions” (The living past section, para. 1).

Formal education in schools has been used as a means of assimilating, acculturating, civilizing, and Christianizing Indigenous people. These goals were carried out by sending Indigenous children to schools where they were prohibited from speaking their native languages or practicing native religions and other cultural manifestations. In many instances, particularly in the United States, Canada, and Australia, these practices were in direct violation of the provisions outlined in treaties between the colonizing governments and Indigenous nations – treaties in which many Indigenous nations ceded land to the governments in exchange for provisions including the education of Indigenous children (National Indian Education Association, n.d.; Eckermann, 1998; Barman, *et al.* 1986). By entering into treaties with Indigenous nations, governments were recognizing the sovereign status of these nations and their right to establish a government-to-government relationship with other nations – a right which has been routinely abrogated.

In effect, politics, power, and control were intertwined with education. Adams (2008) argues that in the United States, “the Protestant ideology, the civilization–savagism paradigm, and the White hunger for Indian land were all mutually reinforcing and hopelessly intertwined as factors influencing the educational campaign to assimilate the Indian” (p. 32). Over time, the Federal Government of the United States supported different religious groups in their efforts to Christianize and civilize Native Americans; established a federal system of schools for Native children; and later provided incentives to public schools to accept and educate these students (Lomawaima and McCarty, 2006; Reyhner and Eder, 2004). Boarding or residential schools were an educational approach used by national governments, not only in the United States, but elsewhere across the globe, and by religious groups to assimilate and change Indigenous peoples. Students, often young students, were taken from their families and communities and placed in boarding schools where they were not

allowed to speak their native languages or practice their cultures and indoctrinated in a course of study that aimed to assimilate them into mainstream society (Adams, 1995; Lomawaima, 1994; Carroll, 2000; Child, 2000; Trafzer *et al.* 2006).

In a discussion on education and culture, the United Nations Permanent Forum on Indigenous Issues provides a snapshot of the historical effects of schooling around the world for Indigenous students. In general, the UN observed:

that millions of children [continue] to be taught in languages they [do] not use or even understand ... the participation of indigenous peoples in designing curricula [is] still limited, and education still [falls] short of eliminating prejudice and discrimination targeted at indigenous peoples. The lack of indigenous education ... continue[s] to set indigenous youth apart from their own cultures. (UN Press Release HR 46/74)

Among the issues identified at the UN Forum were high drop out rates among Indigenous students; the need to integrate Indigenous languages and cultures into school curricula; preservation of human rights of Indigenous peoples; bilingual education; lack of funding; adequate facilities; the need for educational policies to show respect for cultural and linguistic identity; and the critical role of self-determination in improving the status of education among Indigenous students and schools (UN Press Release HR 46/74).

The findings reported above are similar to findings reported in a 1969 study commissioned by the United States' Congress. This study concluded that the education of American Indians and Alaska Natives in public and federal schools was a failure and a national tragedy and a national disgrace (US Senate, 1969: x). The failure of the educational system has "condemned him [American Indian] to a life of poverty and despair" (p. x). In addition to the need for adequate funding, the report recommended "maximum participation and control by Indians in establishing Indian education programs" (US Senate, 1969:106). A change in the national educational policy, including a return to Indian controlled education, was considered necessary to reform the educational system for American Indians and Alaska Natives in the United States. Similar calls soon began to resonate across the world.

Movement Toward Self-Determination

The movement toward increased Indian control and self-determination was in response to the historical policies and practices in the education of Indigenous peoples. Policy changes in the 1970s marked by the growth of tribal self-determination in the United States (Tippeconnic, 2007) and a movement toward Indian control of education

in Canada (Hare, 2007) resulted in increased parental and community involvement, integration of Indigenous knowledge into the curricula, and an increase in the number of Indigenous educators in teaching and leadership positions.

In Australia, self-determination became official policy in 1972, but only recently have concrete steps been taken to bring the policy to life. According to Eckermann (1998),

all states have initiated Aboriginal Education Consultative Groups (AECGs) which, at local, regional and state levels, have been actively advising Departments of Education. Most States have developed Aboriginal education policies in order to address issues related to Aboriginal Studies curricula, providing appropriate environments and teaching strategies to facilitate Aboriginal expectations of Aboriginal decision making within educational institution. (Current trends, para. 1)

In New Zealand, the Māori continue their quest for self-determination in the educational arena as they work to gain educational parity. They seek a system of education that is shaped and guided by Māoris for Māoris (Durie, 1999).

Effects of the Self-Determination Movement on Post-Secondary Education for Indigenous Peoples

An area in which Indigenous peoples have witnessed much growth and success is at the higher education level. In establishing institutions of higher education, Indigenous peoples asserted their right to shape the design and delivery of educational programs across the lifespan. As Jennings (2004) suggests, Indigenous people recognized that the factors that influence educational attainment are not the same for all individuals and communities. For successful education practices to be sustained, they must be desired, shaped, and controlled by local communities (Jennings, 2004).

In the United States, the tribal college movement began in the 1960s with the establishment of the Navajo Community College in 1968. Today, there are approximately 40 tribally controlled colleges and universities across the nation. (See the website of the American Indian Higher Education Consortium for additional information regarding tribally controlled colleges and universities in the United States.) Similar movements have taken shape in Canada and New Zealand. In 2002, the World Indigenous Nations Higher Education Consortium was established to recognize and promote the significance of Indigenous education through a global higher education network. Moreover, in the United States, there are approximately 80 Native-studies programs nationally that stand alone or offer minors in related academic areas. These programs

have experienced a renewed interest and growth in recent years (Tippeconnic and Swisher, 2000).

In addition to working within tribally controlled colleges and universities, Indigenous scholars, many of them working in institutions of higher education, are conducting research using native epistemologies (Cajete, 2008; Smith, 1999). Tribes are also reframing research by establishing protocols that control the conduct of research in their communities (Lomawaima, 2008).

Current Status of Indigenous Education

In spite of the progress Indigenous people have made in regaining self-determination and control of education, for many Indigenous peoples worldwide, education remains a sociocultural, as well as politically contested arena. As Eckermann (1998) writes about Indigenous people in Australia, Indigenous people around the world have been “subjected to systemic bias by being excluded from gaining the skills necessary to participate in and impact . . . mainstream systems, whether these be economic, educational, health or political” skills (The living past, para. 15). It is a fact that Indigenous education remains in a state of crisis across the globe (see **Table 1**).

In Canada, Aboriginal children experience high drop out rates (Australia Government Department of Education, 2007). Less than 50% of Aboriginal students in British Columbia graduate compared to more than 80% of non-aboriginal students. Graduation rates are even lower in many districts. Aboriginal children are also disproportionately represented in special-education programs and services; they perform lower on achievement tests and enter college at rates significantly lower than their peers. Many of these children also tend to experience high rates of mobility as they move on and off reserves. In the classroom, Aboriginal

students are rarely taught by Aboriginal teachers and the curricula and teaching methods often do not reflect Aboriginal needs and values (Council of Ministers of Education, Canada, 2004). Responding to the call for reform in Aboriginal education policies, in 2006, the Canadian government granted First Nations’ people the right to control education for First Nations students living on reserves in British Columbia. This was the first province within Canada to enact such legislation.

In Australia, Indigenous peoples are less likely to receive preschool education than their peers. They also lag behind their peers in literacy and numeracy skills. Access to education is another issue of concern as there is limited access to community-based secondary education for Indigenous students. Indigenous students also experience high drop out rates and school failure. Those who do remain in school are often placed on a vocational track (Australia Government Department of Education, 2007).

In New Zealand, approximately 90% of Māori children attend preschool/early childhood programs; however, they score significantly lower on tests of achievement and drop out of school at rates significantly higher than their peers (Ministry of Education, n.d.a). The situation is similar in Mexico, where fewer Indigenous girls than boys attend school and there is a high rate of illiteracy. To combat these problems, there has been a movement since the 1970s, toward bilingual education and the use of fluent native speakers as teachers. Although Indigenous students have experienced greater levels of success in Indigenous schools as compared to non-Indigenous schools, there are few secondary Indigenous schools in Mexico (Ministry of Education, n.d.b).

In the United States, American Indian and Alaska Native students represent less than 1% of the total school-age population. While the majority (90%) attends public schools, approximately 10% attends schools operated or

Table 1 Selected demographics

<i>Country</i>	<i>Total population</i>	<i>Indigenous population</i>	<i>Indigenous school-age population</i>
Australia	20.9 million	458 500 (2.2%)	135 668 (4% of total)
Canada	33.4 million	976 305 (3.3%)	324 500 (5.6% of total)
Mexico	100 million	10 million (10%)	1.3 million (16.4% do not attend school)
New Zealand	4.14 million	635,000 (15%)	162 685 (21.6% of total)
United States	281.4 million	4.1 million (1.5%)	1.35 million (33% of total) ^a

funded by the Bureau of Indian Education and tribes. American Indian and Alaska Native students represent approximately 650 federally and state-recognized tribes, each with their own unique culture and many with their own languages still being spoken. American Indian and Alaska Native students experience high drop out rates and continue to perform significantly below their non-Native peers on achievement tests in reading and math (e.g., Rampey, *et al.* 2006).

As demonstrated above, Indigenous peoples continue to feel the effects of colonization and its assimilationist ideologies and practices, many of which have been inextricably linked to educational institutions and practices. The challenge for educators working in and with Indigenous schools and communities, as well as those working with Indigenous students displaced, either willingly or unwillingly, from their places of origin, is to develop and implement educational practices that honor and validate Indigenous knowledge and ways of knowing. Such a commitment does not negate the pursuit of high academic standards, but affirms the potential for such standards to coexist, and in many cases, to be cross-fertilized and nurtured by Indigenous languages, cultures, and practices.

Working to Strengthen and Improve Indigenous Education

Kind and Schielmann (2004) identified 16 Indigenous programs from different parts of the world that provide quality education to Indigenous peoples, including efforts in early childhood education; bilingual education; language preservation; training of Indigenous educators; educational reform; and capacity building. As educators work to improve and strengthen education for Indigenous children and youth, they are challenged to:

1. facilitate meaningful parent and community involvement in planning, delivering, and evaluating educational programs and services;
2. promote educational self-determination, the right to determine the purpose, mission, and ultimately the way in which education is designed, delivered, and evaluated;
3. diversify the teacher and administrative ranks to include Indigenous teachers and school leaders;
4. expand and improve early childhood education and care;
5. ensure children and youth have access to education across the life span;
6. provide high-quality education through secondary school such that Indigenous youth will graduate prepared for a full range of post-secondary options; and
7. expand Indigenous efforts in developing and operating tribally or Indigenous-controlled systems of higher education (or institutions of higher education) (Magga, 2005).

Conclusion

Although progress has been made in providing quality education for Indigenous students, many obstacles and challenges remain (King and Schielmann, 2004). According to the United Nations Permanent Forum on Indigenous Issues (n.d.), Indigenous children around the world face a number of challenges including lack of adequate healthcare; relocation to urban areas; suicide; illiteracy; high drop-out rates; lack of culturally appropriate education; poverty; and racial and ethnic discrimination. Lack of participation in higher education programs is also evident among Indigenous people in Canada, Australia, Mexico, and the United States (Australia Government, 2007).

Each of these factors impact Indigenous children's access to high-quality educational programs, which not only equip them to thrive in an increasingly globalized world economy, but also maintain and strengthen their individual and collective ties to their Indigenous languages, cultures, and practices. Language loss, in particular, poses a threat to the continued production of what many have deemed Indigenous knowledges and Native ways of knowing (see e.g., Barnhardt and Kawagley, 2005). Some have argued that loss of language leads to loss of culture. According to McCarty, *et al.* (2006), "when even a single language falls silent, the world loses an irredeemable repository of human knowledge" (p. 29).

The education of Indigenous children and youth is an area in need of continued research and, more importantly, of translation of this research into practice – a practice that recognizes, affirms, and respects the critical role of Indigenous knowledge, culture, and ways of knowing into the teaching and learning process for Indigenous children and youth. Indigenous peoples across the world have always engaged in and valued the praxis of teaching and learning; unfortunately, the Indigenous way of engaging in this praxis has often been overshadowed by the process of colonization and globalization. The key to improving the overall education of Indigenous children and youth is to build upon the strengths they possess – strengths grounded in Indigenous knowledge. In the long run, the strengths of Indigenous knowledge and education (Lomawaima and McCarty, 2006) will persevere and grow as Indigenous peoples seek greater participation and control over the education of their children and young adults.

The Health Advantages of Educational Attainment

Glossary

Social status – The honor or prestige attached to one's position in society (one's social position). The stratification system, which is the system of distributing rewards to the members of society, determines social status. Social status – the position or rank of a person or group within the stratification system – can be determined in two ways. One can earn their social status by their own achievements, which is known as achieved status, or one can be placed in the stratification system by their inherited position, which is called ascribed status. Ascribed statuses include race/ethnicity, age, gender, and nativity.

Socioeconomic status (SES) – A combined measure of an individual or family's economic and social position relative to others, based on income, education, and occupation. When analyzing a family's SES, the mother and father's education and occupation are examined, as well as combined income, versus with an individual, when their own attributes are assessed. In addition, income, occupation, and education have been shown to be strong predictors of a range of physical and mental health problems, such as respiratory viruses, arthritis, coronary disease, and schizophrenia.

Introduction

Over the past several decades, the relationship between (socioeconomic status (SES)) and health has been well documented. In developed countries, such as the United States and United Kingdom, research has shown that individuals with higher levels of SES are less likely to suffer from chronic and acute illness, have healthier life-styles, and are able to prolong life compared to individuals with lower SES. Measures of SES, such as income, education, and occupation, are the indicators most commonly used to assess the mechanisms through which social factors influence morbidity and mortality. Although there is a strong relationship between high levels of SES and health advantages, there has been continuous debate concerning whether different measures of SES have similar buffering effects on health when examined independently. Income

and occupation provide some indication of exposure to unhealthy living and working conditions, as well as the ability to purchase medical and preventive care (Lynch, 2003). However, there is no clear consensus about whether the relationship between health advantages and educational attainment are strong predictors of health compared to income and occupation or how education operates to protect health. Some argue that education mediates the relationship between SES and health because it increases income potential and allows individuals to seek higher-paying occupations. Others claim that educational attainment works independently on health outcomes because the educated are less likely to practice health-risk behaviors and are more informed about new technologies that improve health. However, not much is known whether the advantages of educational attainment are similar for racial/ethnic or other marginalized groups in the United States and abroad. From a social science perspective, this article reviews the current research that has informed the relationship between education and various indicators of morbidity and mortality in the United States. We briefly discuss the direct and three popular mechanisms associated with educational attainment which scholars have identified as advantageous to health over the life course. Using demographic and sociological research that has informed our knowledge about educational attainment and health, we also discuss popular research in the international front which identifies how intergenerational processes are important for understanding how education mediates the relationship between SES and mortality. After reviewing the mechanisms of health advantages, we then comment on whether using levels of schooling as a mechanism for understanding health advantages is useful in global health.

Measuring Educational Attainment and Health Outcomes

The relationship between educational attainment and health advantages has been well documented. Beginning with Kitagawa and Hauser's (1960) study of socioeconomic variations in mortality in the United States, many scholars have since used educational attainment as an important measure of SES. Educational attainment, schooling, or educational status has been the preferred measure of SES for several reasons. First, in most industrial countries, basic levels of schooling are required and although some

individuals drop out before obtaining a high school diploma, most have had exposure to the fundamentals of reading, writing, and arithmetic. For example, a vast majority of citizens in the United States (with the exception of older adults born in the early twentieth century and some marginalized racial/ethnic groups) have had some level of schooling because prohibiting a child from attending primary school is against the law. In terms of measurement, in most developed countries, educational attainment is usually measured by the number of years respondents spent in school which can range from primary (kindergarten, middle, and high school) to secondary schooling (undergraduate, graduate, professional, and technical training). Levels of schooling are regarded as better indicators of SES compared to employment because individuals may or may not have a steady source of income but have had some exposure to school. In addition, one's educational attainment is unaffected by health impairments that may emerge in adulthood (Elo and Preston, 1996) so educational attainment is stable and does not change over time to the extent that income might. For these reasons, scholars contend that education is a good measure of SES when assessing the relationship between schooling and health advantages/disadvantages.

As regards indicators of health, it has been measured in various ways, including self-rated health, mortality, functional health, mental health, cognition, and psychological well-being, to name a few. Depending on the health indicator used, we can assess various states of the body that are physical, mental, or cognitive. For example, scholars contend that self-rated health is a good indicator of health status because it assesses general well-being and is a better predictor of mortality than physician-assessed health. On the other side, some scholars contend that measuring the presence of disease is appropriate for assessing how the body degenerates over time and can become at risk for comorbid conditions over the life course. Moreover, mortality is important for measuring endpoints of life and the antecedents that are implicated in death. Regardless of the health indicator used, the association between educational attainment and health outcomes has shown to be a strong predictor of good health over the life course with the most benefits occurring in later life particularly between the years of 45 and 60 or compromised health because of the lack of educational attainment at earlier years.

The Relationship between Education and Health

The literature focusing on how education operates to protect health relies on two prevailing explanations. The first measures a direct effect of education on health and mortality, whereas the second identifies several mediating mechanisms implicated for explaining the relationship

between knowledge acquisition and health outcomes. Typically in demography, the focus of studies has been to use mortality as the type of health measurement, whereas states of health such as morbidity are more popular in other areas of social science, particularly sociology.

In terms of the direct effect, several studies have provided empirical evidence that levels of schooling and their effects on health are substantial. Majority of studies that examine this association have provided strong evidence for education's protective effects on self-rated health and mortality. In one of the most extensive discussions and tests of the effects of schooling on health, Ross and Wu (1995) found that self-rated health and physical functioning are strongly and positively associated with education, both cross-sectionally and over time. When we follow the trajectory of education's impact on health, longitudinal studies have found that higher levels of schooling are mostly advantages in the earlier years, peak in midlife, and then do not show much of an effect in the later years. However, studies in this area are few, fairly new, and have not differentiated between age and cohort effects. There is one recent study which examined both age and cohort differences on the effect of education on self-rated health. Lynch (2003) found that the probability of reporting fair or poor health increases across age but decreases across birth cohorts, indicating that education's buffering effects on health are more apparent for individuals who were born later than earlier in the twentieth century. More recent research on education and health has also extended to mental health, physical impairments, and physical health outcomes or examines these effects concomitantly. For example, in a study that examined educational differentials in functional and mental health over the life course, Kim (2008) found that among those with less than a high school diploma had higher physical impairment. Moreover, individuals with a high school diploma and higher educational attainment measured by college degrees had more favorable trends in depression which varied by age over the life course.

As regards education's buffering effects on mortality, the inverse relationship between education and mortality has been well established since the famous Kitagawa and Hauser (1973) study which found significant differences in mortality rates across educational categories for both men and women. In one of the more recent studies that substantiated the Kitagawa and Hauser study, Elo and Preston (1996) found that college graduates tend to have lower mortality compared to high school graduates and that people who did not attend high school have higher mortality. They also found that the mortality of those who attended but did not complete college did not differ significantly from that of high school graduates, except for females aged 65–89. Interestingly, they discovered a large educational mortality differential between blacks and whites between the ages of 25 and 64. Most studies that research status variations for education and health find that

education may or may not have the same protective factors for marginalized groups. Further evidence that substantiates the varying relationship between education and mortality by social status contends that blacks are at an increased risk for all the causes of death that are atherosclerosis related (Howard *et al.*, 2000), leading to cardiovascular-related causes of death which are most prevalent in the population, particularly for individuals with less-than-average educational attainment. Other studies that have substantiated this conclusion have provided evidence for self-rated health and mortality. For example, in a study that examined the relationship between race, SES, and self-rated health, Farmer and Ferraro (2005) found that over time, the health of blacks declined faster than whites. For blacks and whites of average age and education, their health is similar; however, the process operates at higher levels of education – for every year past the average level of education (normally 13 years) Blacks experienced a health deficit that increased with age. Popular conclusions about the differential benefits of education between blacks and whites are not well explained or understood. It is assumed that the decreased ability of racial minorities at any given level of education to translate educational resources into good health includes the influence of racial discrimination on access to healthcare and the lack of accumulation of social capital over the life course. However, these conclusions are yet to be empirically challenged.

In the sociological and social science literatures, the important mediating mechanisms that are believed to drive the relationship between educational attainment and health are economic, social, psychological, and behavioral. The relationship between education and economics is strong because in the United States, the more education that is acquired allows of higher-paying jobs, more prestigious occupations, and the means to purchase the necessary goods to support a comfortable or privileged lifestyle. If we look solely at the advantages of having a steady income and its impact on health, it improves health through the ability not only to support ones self financially, but also to purchase health-enhancing goods – such as health-care services and nutritious food – live in cleaner environments, and reduce stress. Also in the United States, the more schooling a person acquires allows of higher-paying positions that offer better health insurance and other employee benefits. Health insurance coverage is basically fee for service, where a significant proportion of Americans use employee-sponsored healthcare to pay for health insurance. For those without employee-sponsored healthcare and meet the requirements necessary for subsidized care from the state or government, programs such as Medicare and Medicaid pay for doctor visits and hospitalization. However, individuals who rely on these two programs are more likely to be poor, elderly, reside in lower SES neighborhoods, or are concentrated in urban areas that do not provide similar quality of care compared

to hospitals and clinics in more affluent areas. Moreover, a significant proportion of individuals residing in low-SES areas can be considered the working poor, that is, they work full or part time but their employers do not offer health coverage or other benefits. Moreover, their salaries are too high to qualify for subsidized medical coverage by the state or government. Typically, the demographics of this population are low income, having less than a high school degree, being members of marginalized racial/ethnic groups, and being residentially segregated. Education's impact on health is significant because the well educated are less likely to be unemployed, more likely to work full time, have higher incomes, and experience less economic hardship, which are all protectors against adverse health outcomes (Sewell and Hauser, 1975).

Education's impact on health also has a social psychological component. Education is beneficial to health because it allows of an individual to develop a sense of personal control, social support, and coping mechanisms needed to minimize stress. Education develops one's sense of self-efficacy because it allows individuals to gather and interpret the necessary information to control events and situations in life. Lack of personal control affects health through physiological mechanisms because experiences of uncontrollability are associated with suppression of the immune system (Rodin and Timko, 1992). The body's immune system is designed to defend the body against foreign or dangerous substances that invade it and when individuals are bombarded with untoward stress, it suppresses the immune system, thus increasing the susceptibility to disease. Since psychological stress has proved to be associated with the breakdown of physiological systems which protect the individual against disease, the regulation of stress is imperative for overall good health. Research has shown that people with different levels of schooling have various coping resources and strategies and social support to avoid the deleterious effects of stress. For example, Ross and Wu (1995) found that individuals with higher levels of education were more likely to report having supportive relationships, less likely to practice adverse health behaviors, and had greater life satisfaction. Berkman and Glass (2000) found that social networks reduce not only physiological stress responses but also health-damaging behaviors and encourage health-promotion behavior. Education provides individuals with resources needed to make life easier which in turn reduces stress and operates to protect health. The better educated have a higher sense of control, and better life conditions allow them to adopt preventive lifestyles against diseases in cases where lifestyle is uncovered as important for health (Mirowsky and Ross, 2005b).

Educational attainment has a direct effect on health not only through income potential and psychological mechanisms but also through knowledge about behaviors that promote healthy lifestyles (Backlund and Keller, 1995),

and having access to information about technological advancements in health innovations. Adverse health behaviors account for nearly 10% of the variance in SES differences in morbidity and mortality; therefore, it is important to examine how lifestyle mediated through levels of schooling is associated with health outcomes. The most common health behaviors examined in the literature are smoking of tobacco and substance abuse, such as excessive drinking of alcohol. The relationship between adverse behaviors, education, and health contends that individuals with lower levels of education are more likely to practice these behaviors because of cultural influences on the acceptability of smoking, stress, community norms, and parental/peer influences. In a study that examined how area-level characteristics could affect smoking by serving as a source of stress to local residents, Tseng *et al.* (2001) found increased odds of smoking for black women with low, average education. Moreover, smoking has a significant impact on health because it compromises the operation of physiological systems that operate to protect the body against disease. Research has shown that the direct links to poor health practices, such as smoking, can increase the risk of coronary heart disease, stroke, atherosclerosis, aneurysms; lung and other cancers, including that in esophagus, pancreas, bladder, larynx, and cervix; emphysema, bronchitis, pneumonia, and other respiratory infections; as well as liver disease and burns (Ross and Wu, 1995). Public service announcements and programs to educate the community have been employed to reduce smoking behavior and resulting deaths from tobacco use. Research has shown that individuals with more years of schooling tend to have access to information which chronicles negative risk factors associated with adverse health behaviors, particularly from the health consequences associated with smoking tobacco. Majority of programs that operate to educate individuals about the negative consequences of smoking have made the most considerable impact on young adults. Recent evidence has suggested that college graduates have made gains in improving important health-related behaviors, such as smoking cessation.

The health consequences associated with heavy drinking are similar to those of smoking. Alcohol use and other drugs are major risk factors in the prevalence of acquired immune-deficiency syndrome (AIDS), violent crimes, child abuse and neglect, and unemployment (Hawkins *et al.*, 1992). Not only is excessive drinking detrimental to health at older ages, but also it interferes with educational trajectories if started in early years. Alcohol consumption's effect on educational attainment has been studied primarily at the K-12 level showing the negative consequences for life chances and well-being. Research has shown that alcohol abuse is most detrimental to health in adolescence and early adulthood since these are the major years of physiological, cognitive, and physical growth. Furthermore, drinking in early life is positively associated with alcohol

abuse over the life course. A recent report from a 25-year longitudinal study of inner-city youth found educational level and school dropout rates to be a predictor of later alcohol consumption (Crum *et al.*, 1998). The concluding consensus concerning alcohol use and education is that the effects are cyclical. Excessive drinking influences dropping out of school, which in turn leads to low self-esteem, which encourages more alcohol use and other behavioral problems at older ages. In addition, reduced educational achievement increases stressors such as financial or employment problems which in turn elevate alcohol use as a coping mechanism.

More educated people are better informed about health-related innovations (National Science Board, 2000). Several studies have documented that educational attainment substantially increases the propensity to seek care from medical specialists, even after controlling for health status, and in countries with national health insurance systems. For example, in a study that examined the association between education gradients, health-related innovation, and all-cause mortality, Gleid and Lleras-Muney (2008) found that the education gradient was steepest for those diseases that have seen the most health-related innovation. The effect was most substantial for mortality conditional on cancer diagnosis for both men and women. In another study, Lleras-Muney and Lichtenberg (2002) show that education is positively correlated with the use of new drugs recently approved by the Food and Drug Administration. The ability to access drugs to prolong life and continue taking medication is imperative when trying to treat or manage health conditions. Goldman and Smith (2005) found that among individuals with diabetes and those infected with human immunodeficiency virus (HIV), the best-educated patients were more likely to adhere to new complex treatment regimens.

Research has shown that the various mechanisms in which education operates to influence health are direct and/or mediated through social mechanisms. In the United States and developed countries, where SES stratification shapes life outcomes, educational attainment is important not only for economic advancement, conditioning social psychological impacts on health, and knowledge about the negative effects of adverse behaviors, but also for improving access to health innovations responsible for promoting health and well-being. Although literature has proved that levels of schooling are directly linked to good health, whether this association is strong for various health outcomes in various social contexts outside of the United States, especially in underdeveloped countries, remains understudied.

International Focus

An important question to ask is whether educational attainment can be an effective measure of SES when

examining the underlying causes of health stratification in the global community. Researchers have found health inequalities within every country studied and these inequalities vary considerably from country to country (Feinstein, 1993). Although different countries have stratification systems based on various criteria, such as skin color, income, occupation, and gender, can we use education as an appropriate tool for measuring change or stability in health status? Not all countries use educational attainment as a reliable indicator of SES because their stratification systems are different from those of the United States. For example, an overwhelming majority of studies that examine the root causes of inequalities in health in the United Kingdom and most European countries have found a link between occupational status and health outcomes with individuals on the lower end of the occupational hierarchy exhibiting worse health compared to the more privileged. In countries such as Brazil and South Africa under apartheid that base their stratification systems on subjective measures such as skin color, individuals who bear the racial marker, particularly with darker skin tones on average, have worse health outcomes compared to the rest of the population. Moreover, gender stratification exists around the world but have different meanings, depending on the severity and history of gender subjugation within a respective country or region. Of the few studies that have found a strong association between educational stratification and the health gradient over the past 30 years, intergenerational processes seem to be the most popular when assessing how SES impacts on health. Researchers have found that mothers' education plays a major role in reducing child and infant mortality. A considerable body of research suggests that maternal education is the single most important factor in explaining differentials in child health outcomes more important than paternal education, health service availability, and SES measured by income and occupation. The educational level of the mother is closely linked to both her own and her household's socioeconomic conditions as well as to other complex factors relating to her self-esteem, coping ability, and competence in mobilizing resources for herself and offspring (Bicego and Boerma, 1993). In the past 40 years, child mortality has declined with maternal literacy for Costa Rica, Mexico, and Bangladesh. Research has provided strong evidence that regardless of social context, educational attainment of mothers matters most for children's health and well-being.

Conclusion

Education is the most influential investment a country can make because it improves skills, wages, economic well-being, contraception, living conditions, health of children and adults, and life expectancy (Summers, 1992). At this

particular point in time, the direct and mediating mechanisms conditioned by educational attainment that impact on states of health and well-being speak volumes about how lived opportunities are important at all stages of life. What has been missing in the discourse on educational attainment and health is a clear consensus on whether for some status groups, particularly highly educated blacks in America or marginalized groups in underdeveloped countries, the degree to which schooling translates into positive returns to protect health over the life course. Moreover, besides intergenerational advantages, how does education operate to protect health for adult women in various social contexts or countries around the world? More life course studies of the returns of education on physical and mental health outcomes in the United States and abroad are needed to adequately assess the various mechanisms involved in promoting population health. An important task is to be critical of the meaning of measures of schooling since its interpretation can vary depending on social context. Further, future research should pay attention to how social context, mainly where people live, conditions educational opportunities which are important for health. More recent studies have found that place characteristics, such as noise, quality of neighborhoods, residential segregation, and other risk factors, are important for understanding segments of population health. As a global community, we should focus on ways to reduce educational inequality and create policy that aims to equalize educational opportunities since they are integral to good health over the life course.

To Go or Not to Go: Access and Barriers to Ethnic Minority Participation in Higher Education within the United Kingdom

P Brug and T L Oliver, St. Mary's University College, Twickenham, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

A-level – An A-level, short for advanced level, is a General Certificate of Education usually taken during further education. It is a noncompulsory qualification taken by students in England, Wales, and Northern Ireland (the equivalent to the final two years at high school in the United States).

BSc – Bachelor of science.

Oxbridge – Pertaining to a historically and traditionally elite university, most often with reference to students or graduates of Oxford and Cambridge University.

Post-1992 universities – The term has more recently been used to describe any of the former polytechnics, central institutions, or colleges of higher education that were given university status by the government in 1992 or subsequently.

UK degree classifications – 1st: equivalent to an A grade in the United States; 2i: equivalent to a B grade in the United States; 2ii: equivalent to a C grade in the United States; and 3rd: equivalent to a D grade in the United States.

Widening participation – The concept of encouraging and allowing the underrepresented to partake in higher education.

The 2008 US election, which saw Barack Obama elected as President of the United States, led to many discussions in the United Kingdom about the possibility of a black or Asian Prime Minister. Trevor Philips, head of the Equality and Human Rights Commission, noted that while President Obama's win was impressive, he was unsure that had Obama lived in the United Kingdom, he could have managed to become head of government. Noting in particular the roadblocks within the Labour Party, which has traditionally been more in line with the Democratic Party in the United States, Mr. Philips said he would be surprised, "if even somebody as brilliant as him (Obama) would have been able to break through the institutional stranglehold on power within the Labour Party" (Alice Thomson and Rachel Sylvester, *Times*, 8 November 2008). Politics in the United Kingdom has often been viewed analogously as a machine, not only involving race and

ethnicity but also class and gender; a machine thought to be fueled by an elite group of Oxbridge graduates. Access to these prestigious universities is often thought to be restrictive and highly selective, with the vast majority of these institutions' diversity coming from international students, who contribute more to the (financial) bottom line of these institutions. However, diversity as the result of permanent immigrant and ethnic groups already within the United Kingdom is not so well represented among all groups at Oxbridge and other top universities in the United Kingdom.

The United Kingdom has witnessed a steady increase in the number of people attending University to obtain a (first) degree qualification (i.e., bachelor's degree). In the West (e.g., United States, United Kingdom, and the Netherlands), this can be attributed, in part, to the extension of mandatory schooling until the age of 16, as well as to the decline in the manufacturing sector (see Billington *et al.*, 1998). In the years between 1994 and 2006, first-year enrolment in the United Kingdom increased by over 50%. While the number of students attending university in the United Kingdom (approximately one in three) is less than in the United States (approximately one in two), the growing trend in the United Kingdom is reflective of growing efforts to increase higher educational opportunity to more students. This includes students from underrepresented ethnic groups as well as those from lower-income and working-class families. To some extent, the growing rates of university entry are in line with trends following the 1980s that saw a sharp decline in manufacturing in the United Kingdom. Widening participation schemes that looked to increase access to higher education focused on more than traditional minority ethnic groups, which are the focus of this article.

It has been noted in previous research (see Barn, 2001) that children from ethnic minority groups that attend university tend to come from families that place a high value on education. This is evident from observing the breakdown of incoming first-year students. It indicates that while whites represent just over 92% of the United Kingdom population, they only represent about 76% of the UK student population in higher education, while black African and Asian Indian students are overrepresented in these figures. This may speak well of diversity in the United Kingdom, however it needs to be interpreted with caution. Minority students with lower qualifications are more likely to be unemployed than their white counterparts, which may

serve as a catalyst for continued education. In addition, the figures may represent regional factors. The majority of ethnic minorities in the United Kingdom live in and around London (over 60%); this is reflected in the fact that Greater London has an ethnic minority population of about 30%, far above the 7.9% overall representation. It is likely that students within this region have higher rates of educational attainment because of the economic situation (e.g., need for skilled labor) and the possible cultural emphasis on education that is part of the regional divisions in the United Kingdom. As such, the data may not depict an overrepresentation of certain ethnic groups, but an underrepresentation of the white population.

Further to the above-mentioned issues, in the period from 1994 to 2006, the increase in student numbers varied across the main ethnic groups. Although all groups saw increased numbers, the representation within higher education remained relatively unchanged for most groups; (see Table 2) dramatic increases were only seen for black Africans and to a lesser extent Asian Indians. The significance of these statistics is not clear, so any interpretation needs careful consideration. The increase number of Black African students could be the result of an increase in the overall numbers of Black Africans in the United Kingdom. In addition, the number of students entering university is not always representative of the number of students obtaining qualifications (e.g., BA or BSc) and the classification of those qualifications (e.g., 1st or 2ii).

Data indicate that degree attainment and classification vary considerably by ethnic group. Ethnic minorities are more likely to enter university with qualifications other than advanced levels (A-levels) and go on to have lower rates of obtaining higher degree classifications. In addition, many of the black ethnic minority population are more likely to be enrolled in post-1992 universities, considered to be less prestigious than traditional universities (e.g., University of Cambridge and St. Andrews University). This is not the case for Asian Indians and Chinese, who are well represented at the latter type of institutions. It is also more likely that black populations will enter higher education as mature students, which itself brings up concerns such as being employed while studying and supporting a family. The data further reflect that black Caribbean males are under-enrolled as are Bangladeshi females. These factors draw attention to the fact that while minority representation in higher education is relatively strong, in relation to their representation in the general population, their success (e.g., degree classification) does not mirror this pattern.

These facts reflect a clear need for ethnic groups to be discussed individually, as groups such as the Asian Indians differ in success, as compared to the black Caribbean group. Given these factors, this article does not attempt to cover all aspects on ethnic representation in higher

education, but instead focuses on highlighting general areas of concern. This may explain the previously mentioned disparities and offer some guidance for both practical consideration and further research.

Addressing the issue of diversity on university campuses in the United Kingdom requires, at least, a threefold approach. The first issue is qualifications and the restrictions that are created at the primary- and secondary-school level that make access to university difficult for certain sectors of the United Kingdom population. The second area relates to the support and encouragement from parents and peers. Here, the concern focuses on different levels of attainment for various ethnic groups. The third area of concern is the campus climate – how do particular groups make the transition to university life? This leads to concerns over retention rates and the level of academic and social support available to students. The following sections look at these areas and attempt to present a better idea of the reality of diversity on the university campus and possible ways of addressing key concerns.

Primary and Secondary Education

The reality of higher education is that it is part of a continuous educational system, requiring prior education in order to gain entry to institutions of higher learning. In the United Kingdom, this is most often achieved by studying at A-levels. While not all university students in the United Kingdom have studied A-levels, it is the best route to higher education. However, in recent years, there has been concern about the relative increase in the number of students getting top marks (e.g., four A grade A-levels), whereby universities have had to reject highly qualified students. To this extent, some universities (e.g., Imperial College, University of Oxford) have discussed the idea of separate exams for potential students or higher entry requirements (e.g., from A to A*). However, the reality for many of Britain's ethnic minorities is that they often do not achieve minimal standards. Therefore, an increase in entry requirements will further disadvantage those who are struggling to meet the current requirements. In 2000, while Asian Indians had some of the best A-level and GCSE results, other Asian groups, particular the Pakistani and Bangladeshi groups, did not perform as well. The results were similar to the latter for black Africans and Caribbeans.

The complexity of this divergence in academic progress based on ethnicity demonstrates why the various ethnic groups need to be studied independently. Discussing them as an autonomous homogenous entity does not give an accurate reflection of the different groups. Therefore, it should be noted that the following discussion focuses on issues surrounding the under performance of

many of the ethnic minority students and the research into the causes of the disparities keeping in mind that individual group differences may exist. The concern regarding underperformance often involves two key factors: relative socioeconomic depravity and institutional dynamics within the system.

Social Depravity

Underperformance among ethnic minority students is often seen to reflect a cycle of poverty, whereby children are born into poor families, live in socially deprived areas, go to poorer-quality schools, tend not to go to university, and get low-paying jobs, and so the cycle regenerates itself.

The discussion of social depravity with regard to education comes across at some level as ironic. Research has suggested that education, particularly higher education, is linked with improved future earnings. In many ways, the early notions of widening participation in the United Kingdom can be viewed as attempts to replace apprenticeships with higher education (e.g., Kettley, 2007), thereby creating the opportunity for higher earning potential among students from less-fortunate families, who would have been more likely to have taken up apprenticeships. For the most part, students themselves see (higher) education as a means of securing an improved financial status (e.g., Patiniotis and Holdsworth, 2005).

In the United Kingdom, like other places (e.g., the United States), there is often a strong correlation between ethnicity (and race) and poverty. Statistics show that white students are less likely (25%) to come from low-income households compared to minority ethnic group members (*c.* 45%). However, individual variation exists among the various minority ethnic groups. The high rates of poverty for the Pakistani/Bangladeshi group may in some part be a result of the fact that this group also has the largest household size (average 4.5 people) compared to other groups: Indian (3.3 people) and white and black households (2.3 people). Larger household sizes are often a reflection of multiple generations living in a single household. At the opposite end, black Caribbean families had the highest rate of single-parent families, another factor often associated with poverty.

The irony of the poverty–education connection is that while education is seen as a vehicle for improved financial circumstances and opportunity, educational outcomes are very much tied to the current economic situation. Reports and investigations into the poverty–education connection continue to show that a family's socioeconomic status influences members' educational participation. For instance, young people from middle-class families are more likely to remain in education longer and pursue higher education than their peers from skilled or unskilled families (e.g., Gayle *et al.*, 2002). This has important

implications for policymakers and society, as this suggests that individuals' social class can hinder them from developing their academic ability.

The British government is attempting to make university education more accessible to the lower classes, as evident in the suggestion by Egerton and Halsey's (1993) that it is now a requirement for many institutes to accommodate more students from the lower classes. Some scholars have argued this can reduce the credibility of university education and may be symbolic of the divide between the more historic traditional universities and the post-1992 universities. However, the concern over poverty is not limited to a notion of the poverty cycle but also that poverty has direct bearing on the institutional dynamics of the educational system. These dynamics include: (1) the quality of education students receive, (2) the conditions of schools, and (3) other dynamics, such as discrimination.

Institutional Dynamics

Recent discussion in the UK news media has highlighted concerns over the quality of teachers in poor areas, particularly in the inner city. Teachers were said to possess lower qualifications and have fewer years of experience. There appears to be a consensus in the literature with regard to the impact poverty has on students' educational experience. Students who attend schools that reflect the economic deficiency of the area have lower results than students in advantaged areas. These same students also appear to have lower results than similarly deprived children who are able to attend more privileged schools (Yu and Taylor, 1997). Furthermore, deprived students often have a less positive attitude toward education and schooling (Horgan, 2007). In addition, teacher expectations of students in deprived schools are often thought to be lower, whereby students are often not encouraged or meant to feel positive about their potential. This relates to another concern regarding institutional discrimination.

The research clearly shows there is a pattern within the educational system, either by coincidence or somehow created by the design of education (in the West): minority ethnic students often feel discriminated against, more so than their majority student counterparts. Whether this discrimination is real or grounded in misunderstanding, the impact it has on the students is often detrimental. A common outcome is academic disengagement which can have a negative impact on student performance. The other concern with regard to institutional discrimination is that minority students, particularly black male students, are more likely to be excluded from school. Several studies have shown this high rate of exclusion may in some part be due to overreactions by educators based on negative stereotypes of black males (see Barn, 2001).

Culture of Higher Education: Influence of Family and Friends

Common knowledge has often assumed that university graduates produce university graduates. This logic not only fits in with the idea of the poverty cycle but also underlies the influence of parents as role models. Within families where neither of the parents entered higher education, the lack of so-called role models could make it less likely that children in these homes would themselves go to study at university. Clearly, the influence of parents is quite strong if at least one of the parents has a university degree (e.g., Gayle *et al.*, 2002). Many of the UK's minority ethnic population come from households where neither parent went to university. In some cases, this is a result of the parent's native country, where education was either restrictive or poor in quality (Louie, 2005). As a result, many of these parents migrated to the United Kingdom in part to provide their children with better educational opportunity. As parents play an important role in their children's educational potential and the likelihood that they will remain in the education system longer (Urdan *et al.*, 2007), the importance placed on education by minority ethnic parents may go a long way to influence their children's choices. Even though ethnic minority students at times can be frustrated by the level of pressure put on them by their parents; they nonetheless come to appreciate it (see Louie, 2005).

The role of parent is also important in giving students information with regard to what to consider when it comes to figuring out what to do, applying for university, and considering funding support. Students whose parents do not have higher degree qualifications may choose not to seek out their parents for input, because they perceive them to be less knowledgeable about this matter. This can then place a greater reliance on the schools (and sixth form colleges) to inform students about the cost and benefits of higher education. The expectation that schools will fill this gap may be a bit presumptuous and misconceived as students are likely to identify more with their parents' situation (Trusty, 1991). In addition, concern could also be raised that better schools where families with higher education levels attend are more likely to provide better information about the benefits of further education.

Despite the role of parents, adolescents are also influenced by peers. Whether as a result of peer conformity or simple social comparison, friends can have a strong impact on the educational attainment of a student. This concern is often discussed with reference to potential detrimental impacts. For example, when it comes to black Caribbean students, particularly males, there has been discussion about the belief this cohort either directly or indirectly discourages one another from serious participation within the educational system – the idea being

education is a 'white thing.' However, this is not solely a black issue; negative peer influence can be found in various settings (e.g., urban and rural) and among various populations (e.g., white and Asian; Louie, 2005). It is not possible for this article to offer extensive coverage of this complex issue. However, what is worth highlighting is that the support and encouragements, by peers, to attend university may vary for some populations within Britain's ethnic communities. This is likely to become an issue if there is also no proper and sufficient information and encouragement come from within the schools (e.g., teachers) and/or from home (e.g., parents).

There is also the concern that peers can have the potential to undermine the influence of parents; nevertheless, it has been noted that while teens are spending more time with their peers, who tend to have more influence on an adolescent's day-to-day behavior, they are more likely to take on values, like the importance of education, from their parents (Noller *et al.*, 2001). Furthermore, it should not be assumed that peer influence is always negative (e.g., drinking or smoking); research has shown that peers can help improve student performance by setting challenges, such that an individual works harder to perform as well as their close friends (Azmitia and Cooper, 2001). In some cases, this may be reflected in the fact that students who go to university are more likely to have close friends who are also going to university.

The key concern here is that students from disadvantaged backgrounds may not have equal access to information about university studies or are not given enough opportunity to carefully consider university as an option. In the United Kingdom, there are growing attempts at opening up opportunity, primarily through widening participation schemes. These schemes often involve visits to campus by students or visits to schools by university representatives. These are noble schemes but their impact is yet unclear. It is likely any serious impact, in the most-needed areas/schools, will only occur if a more sustained and comprehensive approach is undertaken, as opposed to a few sporadic interventions. However, getting into university is half the battle, once there, students should want to remain and feel a part of the academic community. Therefore, attention has to be paid to the campus climate.

Campus Climate

The issue of diversity in higher education is complex. Figures may reflect an increase in the number of minority applicants, as well as an increase in the number of first-year students from minority ethnic backgrounds (particularly black African and Caribbean). However, lower retention rates and mediocre results among certain groups highlight the fact that entry into higher education is not where the

concern and attention should end. While Asian Indian students, for example, do well at university, black and some of the other Asian students, in general, tend to perform average or worse, with few able to obtain higher honor degrees (i.e., 1st). While some of this may relate to the previous sections (quality of secondary education) other aspects may be a result of campus life.

For many ethnic minority students the demographics of the university may be in sharp contrast to the demographics of their previous school and the neighborhoods where they grew up. This is an additional adjustment that these students have to cope with, as part of the normal transition to university. Furthermore, many students from ethnic minority as well as low-income families are choosing to live at home during higher education. This is in large part a way to reduce the cost of higher education. It is also likely that for some ethnic minority students it is a way parents seek to protect their children from the perceived darker side of university life (i.e., partying and sexual relations). The concern here is that students who live at home may not make use of the full support services on campus (e.g., library and tutors). In addition, these students may have less social contact with their cohort and less peer support. This can make the experience of higher education particularly isolating. Even if the students develop close friendships at university, they may not provide an upward social comparison. This type of comparison is thought to offer positive academic support and inspiration, thereby improving academic performance.

Students may also differ in their ability to take part in extracurricular activities, such as sports, student clubs, and student events (e.g., dances and trips). The inability to fully embrace university life may make it more likely that a student feels disconnected and thereby easier to leave, even if not for academic reasons. University student satisfaction among ethnic minority students does not appear to have been studied extensively, but is an area that deserves some consideration with regard to retention. Student satisfaction in many ways may be linked to academic performance in that it offers students a positive attitude about the institution and makes them more inclined to seek support, as opposed to feeling further frustrated by the university and what it has to offer.

Conclusion

It should be the case that if a university accepts a student, they should be in a position to support that student, so they have an equal chance of graduating, as any other student. However, some students may not be supported by higher educational institutions in a manner which best serves them. This article has dealt with some factors that impede the matriculation of large numbers of ethnic

minorities in the United Kingdom. However, what is presented here is a snapshot of a large and more complex situation that deserves more comprehensive attention. Still article should help to highlight and bring to the forefront some areas for consideration, if greater equity is to be established in higher education and increased academic performance.

In this race-income dynamics, one of the key factors will often be the family. While parents may have a strong desire that their children go to college, the attainment of that goal will require more than just desire. While the debate and the struggle to create true equality in primary and secondary education continue, often it will be the level of parental support and involvement which has a real impact on a child's progression through the educational system and the performance outcomes. This is not to put the blame on parents or shift responsibility away from the educational system, but to emphasize the significance of parents in helping breakthrough in the cycle and open up opportunity even if the financial resources are lacking. Neither does this resolve the complexity or eliminate the stress for many families with regard to funding higher education.

The challenges of primary and secondary school education are also vast. While this article has discussed several areas to be addressed (institutional dynamics), these factors need to be teased out and addressed in combination with other factors. They are also factors that are part of the political discourse, which not only complicates matters but also makes a timely solution unlikely. However, because of the connection between lower-level education and higher education, this point cannot be emphasized too much.

One of the first cautions noted in this article was the fact that while the focus would be on minority ethnic students as a whole, the diversity of these group warrants more individual focus on each group, even those deemed to be the model minority. Attempts should be made to assess what lessons can be learned from the individual groups, especially the groups that are having greater success. Another issue in that has not been discussed but that warrants mention is the fact that some researchers would argue that academic performance is tied to intelligence and that some minority ethnic students are going to perform better than others based on their race. However, the merit of this argument fails to be met when considering the Southeast Asian groups. For example, Asian Indians tend to have great success in school and at university, while the results for Bangladeshi students are very different. Therefore, there have to be other reasons that help explain disparity in academic outcomes for ethnic minority students in the United Kingdom. It is vital to look across the various groups and try and assess the differing success and failure in order to see what can be learned and possibly shared.

Universal Secondary Education and the Two-Tiered School System in the English-Speaking Caribbean

P Anderson and J Devonish, University of the West Indies, Kingston, Jamaica

© 2010 Elsevier Ltd. All rights reserved.

Overview

The education system of the English-speaking Caribbean bears both the imprint of its colonial origin, as well as the struggle to reverse this heritage of inequality. This continuing struggle has infused efforts across the Caribbean region to reshape educational provisions to ensure greater access and development for the mass of persons who had been disenfranchised through slavery. This section looks specifically at the system of secondary education – examining its structure and performance during the first decade of the current century. The Commonwealth Caribbean Region is generally defined to include the islands in and along the Caribbean Sea, as well as some of the countries located on the adjoining continental mass bordering the Caribbean Sea, which were originally part of the British overseas possessions. The focus is on three of the 17 territories which constitute the English-speaking Caribbean region. These are Barbados, Trinidad and Tobago, and Jamaica.

The three countries which are discussed here share a common history of exploitation, as the system of plantation agriculture was implemented by European powers using forced labor from Africa. However, the trajectories which were followed by their education systems varied significantly as a result of several factors. These included the size of the country and its economic resources, the size and composition of the planter class under slavery, and their relative needs for locally delivered schooling, given the pattern of sending children back to the metropole for their education. In the first period following emancipation (1834–1944), critical factors which fostered the expansion of primary schooling for the majority black population included the role of the missionary churches in providing instruction, as well as the impact of indigenous resistance and protest movements in modifying the outlook of the Planter class with regard to the dampening effects of socialization through education. The Negro Education Act – which was passed in 1834 – committed State support on a phased basis for the development of education for the masses, following the abolition of slavery in these territories. Accordingly – between the efforts of the state and the church – a broad-based system of primary education was established throughout the Caribbean. This system combined two types of dualism: that between the planter class and the dispossessed, and between the church and the State.

World War II ushered in a period in which many of the English-speaking Caribbean territories countries moved to self-government and subsequently achieved political independence, and in this vast restructuring of the society, education played a central role. Far-reaching changes were implemented with the objective of fostering national commitment and identity, removing the separate and highly unequal system of provision for secondary education, and increasing access for the less privileged. As noted by Miller, between the 1850s and the 1950s, secondary education in the region was limited to less than 3% of the school-age population, and depended on the ability to pay.

The 30 years from the 1950s through to the 1970s witnessed huge investments in education. However, the extent of this expansion again varied with the size of the country, its economic resources, and its philosophy with regard to the role of education in nation-building. Nearly 60 years later, Barbados – which is the smallest of these island-nations – holds the distinction of having almost universal secondary education. In 2007, Barbados had a Human Development Index which ranked first among developing countries, and was 31st globally. Trinidad and Tobago – which was a late participant in the system of plantation sugar production under slavery – has the benefit of rich petroleum resources, and was able to expand its education system rapidly during the period 1956–81. In addition, this twin-island state was governed by a single party for 30 years, with a major commitment to decolonization in the society and explicitly, through transforming education. Jamaica – which is the largest of the countries under review – had an extensive plantation system during the period of slavery, and faced the challenge of trying to build a secondary education system on the basis of an inadequate and unequal primary schooling foundation.

In reviewing this period of educational expansion in the Caribbean, Errol Miller observed:

Nationalist politicians gloried in the social transformation of educational opportunities. Each claimed to have offered greater opportunities to the middle and lower classes by building more schools and altering the rules that governed access to the most coveted segments of the school system. The result of this competition between political parties

was a remarkable continuity in educational policies from one government to the next. Each tried to outdo the other by offering more. (Miller, 1992: 37)

From the 1980s, these Caribbean countries had to come to terms with the economic recession which was engendered by the Organization of the Petroleum Exporting Countries (OPEC)-oil-price increases of the early 1970s, and all entered some form of structural adjustment program. Although Trinidad and Tobago had benefited from the influx of petro-dollars – and had used this to invest heavily in educational expansion – there were general cutbacks in the 1980s. The end of the century also saw an increasing concern with issues of educational quality in all of these countries – as evidenced both in low or unsatisfactory student performance in several sectors, and imbalances in resource distribution.

Common to all of these territories is the continuing reliance on external examinations to establish levels of competency at the end of the secondary cycle. This approach to assessment was derived from the integration of colonial education with that in the metropole, as it was essential for the children of the planter class to be able to access tertiary education in Europe, if they had not been schooled there. Success in external examinations continues to play a similar role for the brown and black majority in the Caribbean, and serves as the most important mechanism of credentialing – both for absorption into the upper tiers of local labor markets as well as for being the gateway to tertiary education. From as early as 1863 – led by Trinidad and Tobago – the Caribbean had started to participate in the overseas school-leaving examinations which were designed and administered by the Examination Syndicate of Cambridge University (the Senior Cambridge Exams). This was followed by the Oxford and Cambridge Higher School Examinations around 1917. Once these examinations were opened up to participation by students in private and denominational secondary schools, they provided the foundation for the entire system of accreditation for secondary school students.

Since 1979, these external examinations have been replaced by regional examinations which rely on meeting standards that are both internationally comparable, but also incorporate material that is of greater regional relevance. The regional examining body is known as the Caribbean Examination Council (CXC), which was established – in 1972 – as a fully managed Caribbean entity with the mandate to replace the overseas examinations with local secondary school examinations in the 16 participating territories. The expected performance level at the end of grade 11 is for students to obtain a minimum of five passes on the Caribbean Secondary Education Certificate (CSEC) in subjects that include English Language and, preferably, mathematics. The performance of students in these examinations, therefore,

establishes the overall success level of each territory. It also distinguishes the higher-performing schools in each country. Since these schools are in general the elite grammar schools – whose establishment predates the major expansion of government secondary schools in the postwar period – the external examinations continue to document and legitimate their continuing higher status.

In several Caribbean countries, the expansion of secondary education has been achieved in stages through the addition of years to the secondary cycle. These extra years of instruction may have been tacked on to junior secondary schools which started with only grades 7–9 forms. Alternatively, they may have been added to the All-Age Schools which were in essence an extended primary school that terminated at age 15, or at the equivalent of the ninth grade. While these additional forms represented a logical solution to the need to expand secondary education, they were being grafted on to a structure which was generally much weaker than the comparable secondary schools – whether public or private. The New Secondary schools – as they were labeled – therefore, represented a lower tier in the education system – and in some countries – they did not register their students for the external examinations. The move to upgrade the secondary system, which occurred in the 1990s, was consequently directed at offering a common curriculum in these schools, and to ensure these students could, in principle, appear for the external examinations. This was an essential step if all secondary students were to be positioned to access tertiary-level training.

As long as secondary education remained in short supply – or as long as there were perceived disparities in the quality of education in each tier of the secondary system – a mechanism was required for allocating students to each tier. This was achieved through the operation of the Common Entrance Examination (CEE) – which students appeared for at the end of the primary school period, or before they progressed to the seventh grade. The Common Entrance Examination has been described as a cruel mechanism which exacted harsh emotional costs on its participants and their parents. Nonetheless, despite its recognized limitations, this examination remains in operation in most Caribbean territories. The main exception is in Jamaica – which replaced the CEE with a Grade Six Achievement Test. This exam serves to distribute students to different secondary schools based on a combination of factors, including performance, preference, and location.

The assessment made by the World Bank, in 1993, with regard to access, quality, and efficiency in the Caribbean region still holds relevance. This report noted sharp differences existed between the secondary schools which served those who passed the CEE, and the junior secondary and all-age primary schools which are the destination for those who do not take – or who do not pass – this selection exam. The authors noted that, in many respects,

the large overall secondary enrolment ratios masked what, in most countries, were largely elitist educational systems.

Although the Caribbean territories embarked on their educational systems with the same gender biases which characterized the colonial societies of the eighteenth and nineteenth century, it is important to note that – by the end of the period under review – there were no restrictions against women in the school system, and girls – at present – outnumbered boys in many institutions. The underrepresentation of boys, and their relative underachievement, now became questions of increasing concern.

As the first decade of the twenty-first century draws to a close, issues of educational reform remain at the centre of education policy in the English-speaking Caribbean. The debates which are engendered still revolve around questions of social inequalities, that are not yet fully divorced from racial inheritance.

Barbados

Barbados is the most easterly of the Caribbean islands, occupying a land area of 166 mi² (approximately 432 km²). The census of 2000 recorded a population of 250 010 persons – which reflected an annual growth rate of 0.11% over the intercensal period 1990–2000. Early fertility declines in Barbados – as well as high levels of emigration – have resulted in declining proportions of persons younger than 15 years. This stood at 23% in 2000. The small size of the country, the fairly flat terrain, the early efforts to control population growth, and relatively high income levels have all facilitated the country's efforts to make education widely available.

This tiny island is distinguished by the fact that, when it achieved political independence in 1966, it had an unbroken history of 339 years as a British colony. During this time, the island was exploited for sugar and rum production. Its subsequent economic development since independence has expanded to include tourism, information services, and light manufacturing.

During the period of plantation slavery in Barbados, there was some limited instruction for the enslaved Africans, and this was mainly with the objective of being able to read the Bible. At this point, public education was established primarily for the poorer whites and the free coloreds who could not afford to send their children to England for schooling, or to hire private governesses. Following emancipation in 1834, public education was established for the general population, and, by 1846, Barbados was reported to have primary enrolment levels comparable to the highest in Western Europe. The subsequent development of the primary school system – and its effectiveness – are evident from the findings of a 1982 survey on reading achievement conducted by the Ministry of Education in the primary schools which showed that approximately 85% of

children were functionally literate by the end of the primary cycle.

While mass primary education was achieved by the beginning of the twentieth century, it was not until after the end of World War II that any attempt was made to reform the hierarchical structure which allocated primary education to the masses and secondary education to the elite. In describing educational policy in Barbados prior to this period, Layne observed it was a highly reactionary force that provided the white planter-merchant class and its allies with the skills needed to perpetuate their hegemony over the rest of the population, and to perpetuate the values upon which that hegemony rested.

After gaining full internal self-government in 1954, and adult suffrage in 1959, several reforms were introduced. Among the most important was the establishment of modern secondary schools as a more relevant counterpart to the traditional grammar schools – which were the bedrock of the colonial period – as well as the introduction of a CEE to provide a competitive mechanism for entry to the government grammar schools. Access to secondary education, therefore, no longer depended on the ability to pay. While it increased access to secondary education, the system which evolved was essentially based on two tiers with pronounced inequalities. The two types of secondary schools had different school-leaving ages, and differed markedly in resources and access to trained teachers.

Following 1966 when Barbados attained Independence, education policy shifted radically toward meeting the needs of modernization of the country – with an explicit focus on moving the society from an elitist to an egalitarian society. By 1979–80, the budget for the Ministry of Education accounted for 20% of the government's total capital and recurrent budget. There was a large expansion in secondary school places in order to meet the demand in densely populated areas. However, the country also fell victim to the economic crisis of the 1980s, and was forced to embark on a structural adjustment program. This program was designed jointly by the International Monetary Fund (IMF), the World Bank, and the Inter-American Bank – taking effect in 1990–92. Although expansion continued at a slower pace over this period as a result of the economic contraction, there was, nonetheless, a steady series of reforms which sought to increase access, improve teacher-training, and diversify the secondary curriculum.

In Barbados, basic education is legally defined to include education for children in the age range between 5 and 16 years, and thus it includes secondary education. The Modern Education Act, in 1981, also made education to age 16 compulsory. By the mid-1990s, Barbados could boast of having excellent coverage at the secondary level – with this being estimated at 95% of the age group from 11 to 16 years. At the secondary level there were 33 secondary

schools, and 23 of these were government-run. The most recent data from the 2000 Census shows that, among persons aged 15 or older, nearly four-fifths (79.4%) had achieved at least a secondary education, with 20% of this age-group reporting tertiary training.

This outstanding educational achievement was made possible both because of the country's universal access to primary schooling, and because of the decline in the school-age population, resulting from the earlier fertility declines of the 1960s. Nonetheless, as in all this region, the secondary school system displays lines of fracture based on the academic level of the students who are allocated to different schools through the mechanism of the CEE. The traditional elite schools – which are referred to as the older secondary schools or the government grammar schools – continue to receive the students who perform best on this qualifying entry exam, thus contributing to their continued superior performance on the exit exams (the CXC). The newer secondary schools receive those with significantly lower CEE scores. These differences in student aptitude are reinforced by differences in budgetary allocation, and in the proportion of trained teachers in individual schools within each secondary tier. The government of Barbados has recognized the distortions that result from the operation of the CEE, and has declared its intention to replace the CEE with a new system of transfer from primary to secondary schools, and to implement a common curriculum during the first 3 years of secondary education. However, these reforms are yet to be implemented.

Trinidad and Tobago

The twin-island state of Trinidad and Tobago lies off the north-east coast of South America and comprises the island of Trinidad – which covers 5130 km² (about 1980 mi²) – and Tobago – which is approximately 300 km² in area. Although both islands were seized by the Spanish toward the end of the fifteenth century, Trinidad remained under Spanish control until it was captured by the British in 1797. In contrast, Tobago was the subject of considerable rivalry among European nations, being finally settled by the British in 1802. The history of this period records that the Spanish did little to develop the island during the first three centuries of occupation, once they confirmed there was no gold to be extracted. However, close to the end of their period of occupation, they actively encouraged the large-scale immigration of French planters and their slaves from the neighboring French Islands. Accordingly, Trinidad and Tobago became distinguished by a mixture of European cultures. These were to be later reflected in the education system, and the respective influence of the Church in the provision of education.

The opening of the island to French settlers, in 1783, and the subsequent conquest by the British led to the plantation cultivation of sugar cane with slave labor, along the lines which were characteristic of the other colonies at this period. Following the abolition of slavery in 1834, the continuation of this relatively new plantation system depended on having access to other supplies of unfree labor. This was achieved through the indenture system, which – from 1845 – brought contract workers mainly from India and a few other countries. The large numbers of indentured workers, therefore, added a further dimension to the cultural complexity of this island state, as the Indian immigrants adhered to their Hindu and Muslim religions. After 6 years of the inflow of indentured workers, the Indian population was 5.8% of the entire population. However, by 1891, this community accounted for more than one-third (35.1%) of the total population, which was estimated at 200 000 persons. The most recent census, in 2001, enumerated a population of 1 114 700 persons – with 40% being of East Indian descent and 37.5% of African origin.

In explaining the limited development of local schools during the eighteenth and nineteenth centuries, historians have placed emphasis on the late development of the plantation system in Trinidad, and the small size of the settler class – which was itself internally divided between the French and the British, in addition to the Spanish descendants. In countries such as Barbados or Jamaica – where the plantation system flourished – local schools were usually established for the children of the poorer settlers, or for the free colored population. These often originated through a bequest from a wealthy planter or merchant. The abolition of slavery provided the first major opportunity for the development of schools for the masses, and – as was the case in other former British colonies – this was facilitated by the Negro Education Grant between 1835 and 1845. In the period immediately following emancipation, these schools were established by the churches, and these included the Roman Catholic Church – the stronghold of the French and Spanish settlers – and the Church of England. In addition, schools were founded by the Mico Charity, which was a nondenominational, but Protestant, organization, and which received the bulk of the funding from the Negro Education Grant.

The colonial government's concern to firmly establish the British culture in the island led to considerable unease with regard to the dominance of the church schools, as they continued to teach in their own language. Accordingly, from the nineteenth century, there were tensions between the church and the state in regard to the delivery of education, and this continued through to the twentieth century – with a significant influence on the secondary school system. Following 1868, the system of church-run schools was further elaborated by the work of the Canadian Presbyterian Mission – which concentrated its efforts on

converting the Indian population through a wide network of elementary schools. While it has been argued all of the elementary schools in this period served the traditional function of seeking to maintain a subservient laboring class, the government schools had the additional challenge of trying to integrate this diverse society on the basis of English culture.

At the secondary level, a handful of schools were established between 1836 and 1869 to meet the needs of the white upper class. Such schools were modeled on the public school system of Britain, charged fees, and were not linked with the primary school system. Among the black and colored population, it was only those young men of exceptional intellect who gained access to these prestigious institutions through scholarships. Even when the government established its own secondary school in 1859, this institution – then known as the Queen's Collegiate School and later renamed Queens Royal College – was conceived as meeting the need for superior education for white boys. It was not until after World War II that there was any major expansion or liberalization of secondary school provisions.

The war had been preceded by widespread economic depression and a series of labor uprisings throughout the Caribbean, emphasizing the need for social change. In the case of Trinidad and Tobago, the Butler Riots of 1937 served to force concessions from the ruling classes, and these included recognition of the importance of increasing access to education. Achievements of the postwar period also included the gaining of universal adult suffrage, and the establishment of a ministerial system of government.

The postwar period itself brought about a greater liberalization of ideas concerning the role of education in social development, and this was translated into a major expansion in the provision of primary school places in Trinidad and Tobago. By 1956, it was estimated the coverage of the elementary school population was in the vicinity of 95%. This provided the basis for the radical increase in the number of secondary school places which began from the period of the War. The continuing expansion of the school system – and its re-organization – were part of the lasting contributions of the 30-year administration of the People's National Movement, which commenced in 1956. This was largely due to the overriding influence of its leader Dr. Eric Williams – a fierce nationalist.

This period of Trinidad's education history was associated both with large-scale expansion of secondary education, and the continuing attempt to reduce the role and the voice of the denominational schools in educational provision. Starting from a base of only three governmental secondary schools in 1957, the government expanded their stock to 21 by 1967. This total compared with 23 denominational schools in that year. Although this period was characterized by a process of renegotiation between

church and state in regard to their spheres of influence, an agreement was reached, in 1960, in regard to the incorporation of the private schools into the public secondary system. This became known as the Concordat. Further efforts to curtail the power of the denominational sector were encapsulated in the Education Act of 1966, which brought the church-run schools under the inspection of the Ministry of Education. In addition, the government claimed the right to control the admission policy of these church schools.

The opposition of the government to the denominational sector was based on the strongly articulated view of Dr. Williams that it was the government's responsibility to build a nationalist education system which could provide social integration in this ethnically diverse country, and so to establish a foundation for economic development. The 1973–74 increase in oil prices catapulted Trinidad and Tobago into a position of wealth, and thus provided the government with the resources to advance its ambitious program of education reform.

Other significant changes – which accompanied the expansion of the governmental secondary school system – were the removal of tuition fees and the location of new schools in rural areas which had been previously underserved. The postindependence period – commencing in 1962 – saw the restructuring of the secondary system into two cycles. This comprised a junior secondary school (for children in the age range: 11–14 years) and a senior secondary school (for children in the age range: 15–18 years). It was estimated that, by 1986, nearly 80% of the eligible age-cohort had access to secondary education. In addition – in tandem with the country's decision to embark on a program of heavy industry – technical training became integrated into the secondary school curricula, instead of being concentrated in the technical secondary schools. By 2001, the United Nations Educational, Scientific and Cultural Organization (UNESCO) estimates showed a gross enrolment rate of 71% for the secondary school-age population, with the out-of-school population being estimated at 26%.

The incorporation of larger numbers of students into the public secondary school system was reflected in increasing failure rates, based on the external examinations. Some of these problems were traced to inadequacies at the primary level, as it was argued many students were moving on to the secondary level without having mastered basic literacy skills. Nonetheless, there has been steady improvement at both the primary and the secondary level. Statistics collated by the World Bank showed that, in 2001, among primary school students who were tested at the end of the sixth grade on the Secondary School Assessment Examination, 63% obtained passing grades in English Language and 68% obtained passes in mathematics. This examination was the equivalent of the CEE in other territories. On the CSEC exams which

assessed performance at the end of the secondary cycle, 68% of secondary students obtained passes in English while 44% passed mathematics. Concerns with improving the quality of education, therefore, continue to dominate recent approaches to education in Trinidad and Tobago.

Jamaica

Situated in the Northwest of the Caribbean, the island of Jamaica comprises one of the Greater Antilles – and covers a land area of 4243.6 mi² or 10 989.7 km². The population which was enumerated in the 2001 census comprised 2 607 600 persons – representing an intercensal increase of 0.88% annually.

Having been originally captured by the Spanish in 1494, Jamaica remained a Spanish colony until 1655 when it was seized by the British. Both the Spanish and the English colonial powers exploited the country through the cultivation of sugar cane with forced labor from Africa until 1834 – when slavery was abolished. Although Jamaica's economy, like Barbados, was dominated by sugar cane production, the island differed significantly both in size and in terrain. The mountainous nature of the country limited the land available for plantation production, and once emancipation was achieved, many of the former slaves moved up to the hills where they engaged in peasant farming. These dispersed patterns of settlement were to present challenges in the effort to incorporate the population within the ambit of a basic education system.

As in other Caribbean countries, the education system derived its origin and structure from the plural structure of the society, and educational policies came to reflect the struggles of the dispossessed to assert their rights to social advancement. The strong missionary presence in Jamaica meant these groups led the way in providing primary education for the masses. This set the basis for the dual system of church and state control of primary schools which has continued into the present century. The development of secondary education was also stimulated by the work of various denominations – with the first high school being established by the Roman Catholics in 1850. These early secondary schools were designed as grammar schools along the British model, and catered for the rising middle classes – since the children of the wealthiest classes were already receiving their education in Britain.

An important outcome of the 1938 Disturbances and the ensuing shift in political power to the black population was a re-examination of the education system. As documented by Errol Miller, two separate systems of education had developed during colonial times; these were the preparatory school/high school system and the elementary/teachers' college system. The first catered to the ruling elites and some segments of the middle

classes – particularly those living in urban centers – while the second catered mainly to the lower strata and members of the middle strata in rural areas. Although far-reaching recommendations were advanced in the Kandel report of 1943 for the reorganization and integration of the entire education system, the removal of barriers to secondary school access remained a goal for most of the remaining century. This ongoing process of educational reform which started in the postwar period has been largely directed toward addressing the intractable problem of separate and unequal provisions for different social classes.

Change was facilitated by the attainment of adult suffrage and the achievement of self-government in 1944. This set the stage for the introduction of two critical policy initiatives. The first was the 1957 Reform in education which introduced a CEE to select students for the secondary schools. This was the first major reform in secondary education since the grant-in-aid system was introduced in 1920, and it doubled the number of students who could receive free tuition. The second was the 1966 New Deal in Education as a result of a UNESCO-led planning mission. This program promoted the development of junior secondary schools for the 12–15 age group by providing schooling at the grades 7–9 level. This was conceived as the first cycle of secondary education. Both of these initiatives were accompanied by a large expansion in the number of schools, and so served to ensure greater access by a wider cross-section of the society.

The country achieved independence in 1962, and the main adjustment to the secondary school system over the 1970s was the addition of two additional years of schooling – so the junior secondary schools became upgraded to new secondary schools. However, the terminal school-leaving examination for the New Secondary schools (the locally administered Jamaica Secondary School Certificate) was not the same as for the high schools which relied on external examinations. Since passing in the external examinations was required for university admission, the new secondary schools did not constitute a route to higher education. In this two-tier structure of secondary education, a link was provided by the Grade 9 Achievement Test which acted as a conduit through which a handful of students could transfer to the traditional high schools, and so participate in the elite system which provided the main foundation for tertiary education.

Although the recession and the budgetary restrictions of the 1980s and 1990s curbed educational expenditure, the government instituted a far-reaching policy initiative, the World-Bank funded Reform of Secondary Education (ROSE) program (1993–2000). This program incorporated the recommendations of the 1983 UNESCO mission, and sought to ensure that a common curriculum would be delivered within the secondary grades of all institutions.

Under the ROSE program, several new secondary schools were upgraded to the level of secondary high schools and comprehensive schools. For the first time also, the All-Age schools were brought into this ambit. This meant those students who remained in the All-Age schools after the age of 11 years could participate in the same curriculum as those in the secondary schools. This was expected to be a transition stage until the All-Age schools were phased out. By offering only grades 1–6 schooling, they would be converted into primary schools. Over this period, the new secondary schools were reclassified as comprehensive high schools, and, by 2001, all were further reclassified as secondary high schools – being currently known as the upgraded high schools. The outcome of these efforts to expand the secondary school system was reflected in the findings of the 2001 census, which showed that among the population aged 15 and older, 69.4% had attained at least some secondary schooling. Data from UNESCO point to a gross enrolment rate of 86% for the secondary school-age population in 2001, while the out-of-school population was estimated at 18%.

In order to assess the extent to which the country has been able to meet the challenge of integrating secondary education, it is useful to compare the two types of secondary school in regard to their participation in the CSEC examinations and their relative success. Data collated by the National Council on Education showed that, in 2005, the cohort eligible to take the CSEC examination for English Language stood at 12 393 students in the 54 traditional high schools. The number who actually took the examination was 10 751 and, of these, 8336 or 78% passed with Grades 1, 2, or 3. In contrast, among the 80 upgraded high schools, the matching cohort stood at 19 930 students and, of these, only 6477 students were enrolled for the exam. This represented less than one-third of the group. The number who passed the English exam totaled 2515 students, or only 39% of those who enrolled. In summary, the students in the traditional high schools (the upper tier) were at least 2.5 times more likely than those in the upgraded high schools (the lower tier) to be entered for this critical exam, and they were twice as likely to pass. It is apparent, therefore, that – despite efforts at reform – there are marked differences in the experiences of children in each tier of the secondary school system. The conclusion of Derek Gordon appears to still hold true – namely the structure has largely remained a class-based dual-track system.

Summary

The secondary school system in the Caribbean is still engaged in the struggle to transform itself from being a mechanism of colonial patterns of social distribution to being a pathway toward equitable access, equality of opportunity, and justice. The situation which faces each Caribbean island differs as these challenges are shaped by history and culture, and constrained by economic resources. Equally important is the philosophy that guides this important set of institutional choices, and which will determine the future development and social stability of the Region.

Women of Color in Science, Technology, Engineering and Mathematics (STEM): Refining the Concepts, Reframing the Issues

C B Leggon, Georgia Institute of Technology, Atlanta, GA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The fields of science, technology, engineering, and mathematics (STEM) are the drivers of economies worldwide. In such global knowledge economies, it is imperative that nations develop, enhance, and utilize human resources effectively and efficiently. The greater the diversity of backgrounds of scientists and engineers, the greater the variety of perspectives brought to bear on the science and engineering enterprise; this results in more creativity and ingenuity that enhances both science and engineering (Bassett-Jones, 2005; Malcom *et al.*, 2004). Several commissioned reports express concern that the relatively homogeneous science and engineering workforces in the US, puts at risk its competitive edge in the global knowledge economy.

Recognizing the link between science/engineering/technology and domestic development, many nations have incorporated increasing women's participation in these fields as an integral part of their domestic policy strategy. Why is it that despite policies and programs to increase women's participation in STEM, data from the United States (US) and the Organization for Economic Co-Operation and Development (OECD) indicate that in STEM fields, women remain unevenly distributed in both research and decision-making positions? This is counterproductive to maximizing economic development because there is a positive correlation between the diversity of perspectives among scientists and engineers, and the quality of science and engineering – and consequently, economic development. For example, lagging growth in sub-Saharan Africa, North Africa, and the Middle East has been attributed to gender inequality (Katseli, 2007).

Scientists and engineers affect the direction of science and engineering fields insofar as they determine the:

- problems selected for study;
- framing and formulation of research problems;
- populations/groups that should be studied – and how they should be studied;
- methods used to collect and analyze data; and
- ways in which results are reported and disseminated.

In addition, scientists function as gatekeepers who control certification of both scientists and the institutions that train them, including

- the curricula for institutions of higher education that train scientists and engineers and

- who will be recruited, educated, trained, and mentored for science careers in science and engineering and how this will be done.

Although the extent varies from one country to another, gatekeepers limit who and which categories of persons enter and advance in a career. Even though small groups of individuals might benefit from arbitrarily (and artificially) limiting participation in science and engineering, research indicates that the most productive societies have permeable boundaries between categories of people. Diversifying the science and engineering workforces brings a greater variety of perspectives to science and engineering which, in turn, can have beneficial results. Examples of these beneficial results include:

- assessing differential impacts of the products of science and technology on various segments of the US population
- increasing the potential for reducing health disparities between racial and ethnic groups
- increasing the extent to which more of the population benefits from science and technology.

In the US, discourses on diversifying the science and engineering labor forces are problematic in two major aspects: defining terms and conceptualizing issues. Language enables not only the expression of ideas and abstract concepts, but also puts limits on the forms those ideas and conceptualizations can take (Whorf *et al.*, 1998). It is problematic when a word and/or concept used to describe a phenomenon takes on a meaning of its own that differs from the phenomenon to which it refers – as is the case for research, policy, and programs concerning women's participation in science and engineering careers. This is best illustrated by the way in which under participation in the US science and engineering labor forces tends to be conceptualized in terms of two groups: women and racial/ethnic minorities. Not only does this dichotomous conceptualization imply that the categories are mutually exclusive, it also masks significant gender differences within racial and ethnic groups as well as significant racial/ethnic differences within gender groups – both impede the ability to target policy, programs, and practices designed to promote and enhance participation in science and engineering careers. This article argues that there is a need to both reframe the issues and refine the concepts concerning women's under participation in science and

engineering. Just as critical as it is to systematically disentangle concepts, it is also imperative to disaggregate data.

Data, Documentation and Indicators of Women's Participation in Science

The UNESCO Institute for Statistics (UIS) estimates that women comprise slightly more than 25% of the world's researchers (UIS, 2006). Women are under-represented in science worldwide, although this under-representation varies by region and within region by nation. For example, women comprise 15% of researchers in Asia overall, ranging from a high of 50% in Central Asia to a low of 12% in South Asia; the low percentage for South Asia is due to the fact that in India women comprise only 10% of the researchers. Women comprise 85% of all researchers in Myanmar, almost half of all researchers in Latin America, 42% in Europe, and 35.2% of researchers in China. The extent of women's under-representation in science is difficult to measure because of limited comparable cross-national data and statistics (UIS, 2006). Moreover, despite having a large number of researchers, Australia, China, and Mexico lack data on women's participation in science and engineering.

Women in both the US and European Union (EU) tend to be more highly represented in the humanities, biological and social sciences, and less well represented in engineering, mathematics, and physics. Despite similarities between the US and EU in terms of women's participation and uneven distribution in science and engineering fields, the EU is ahead of the US in developing indicators for tracking trends in women's participation in science and engineering careers. Austria, Germany, and the Netherlands have low percentages of female scientists and little data on them; countries formerly under communist rule have good statistical documentation of their high proportions of women scientists (UNESCO, 2007).

Increases in the numbers of women graduates in science and engineering fields have not been reflected in concomitant increases in the proportions of women in academic posts in these fields in the US, EU, and Canada. Unlike in the US, the EU has made issues concerning women in academic careers in science and engineering a top priority; consequently, the EU has a centralized mechanism to collect data, create, and disseminate indicators of women's participation in SET. Assessing women's participation in science and engineering careers requires collecting and analyzing longitudinal data. Without data that track careers of the same women over time (rather than the careers of different women at different points in time), it is impossible to accurately assess trends and identify factors that enhance career success as well as those that impede such success.

Refining the Concepts

Field Concepts: STEM and SET

Much of the research on under-representation in the science and engineering workforces in the US uses the acronym STEM to refer to science, technology, engineering and mathematics as if they were one homogeneous entity; similarly, researchers in Europe use the acronym SET to refer to the science, engineering and technology workforce. Both acronyms obscure important distinctions between the sciences and engineering/technology in terms of the structure of both the knowledge base and careers in these fields. Similarly, these aggregations obscure significant distinctions among fields within both categories (sciences and engineering).

Demographic Concepts: Race, Ethnicity, and Gender

By 2005, one in every three US residents was part of a group other than single-race non-Hispanic white. The two largest minority groups in the US are African Americans and Hispanics. The US Census Bureau uses the term Hispanic to refer to people "who identify their origin on the census form as Mexican, Puerto Rican, Cuban, Central or South American, or some other Hispanic origin" (US Census Bureau P20-353). Hispanics comprised the fastest growing portion of the population, growing by 3.3% between 2004 and 2005. Numbering 42.7 million, Hispanics are the largest minority group in the US. It is somewhat ironic that the racial and ethnic groups that comprise the fastest growing segments of the US population are the same groups that are under participating in science, technology, and engineering fields. Despite the growth among Hispanics and African Americans, the US science and engineering workforces remain overwhelmingly composed of non-Hispanic European American males (BEST, 2006; Leggon and Pearson, 2006).

Traditionally in the US, the science and engineering talent pool consisted largely of white non-Hispanic males; however, as this group's interest in the sciences and engineering declined over the last two decades, concern arose over increasing the participation in this talent pool of other groups. In the past, the US remedied any shortages in the science and engineering talent pool by importing talent from abroad rather than developing it among indigenous racial/ethnic groups that are under participating in science and engineering. Increasingly, this remedy is no longer viable for the US for many reasons. First, the EU and other nations are increasingly competing successfully for this talent. Second, the nations from which much of this imported talent came are becoming attractive enough in terms of infrastructure and jobs for them to return. Third, after 11 September 2001, heightened security

concerns have limited certain jobs in science and engineering fields to US citizens.

In theory, it is assumed that women from racial/ethnic minority groups – African Americans, Mexican Americans, Puerto Ricans, Native Americans/Native Pacific Islanders – are included in the categories of both women and racial/ethnic minorities; in practice, these women are frequently treated as marginal or invisible in both categories in terms of research, policy, and programs. There is a parallel situation in Europe: research on women in science, engineering and technical careers seldom discusses African-Caribbean women's under representation in science and engineering employment, nor how race and ethnic differences among women affect their experiences in those work forces. It is important to note that race and ethnicity are defined differently in different nations. Regardless of how race and ethnicity may be defined by a given nation, it would be useful to track women's participation in science, engineering and technical careers by disaggregating data by immigration status. For example, in the US, the category Black sometimes includes individuals born outside of the US; this gives a misleading picture insofar as it makes the extent of African Americans' participation in the science and engineering workforces seem greater than it actually is.

Disaggregating the category women into two groups – women and women of color is also problematic, primarily because women of color is an umbrella category that includes women from disparate race/ethnic groups – African American, Hispanic, Native American/Native Pacific Islander; this umbrella category obscures significant socio-historical and cultural differences among these women. Similarly, Hispanic is an umbrella category that obscures significant socio-historical and cultural differences among women who are Mexican American, Puerto Rican, Cuban, and from Central America, South America, and Spain.

Since 1992 in the US, there has been an increase each year in the numbers of bachelor's degrees in the natural sciences awarded to women who are US citizens or permanent residents. However, disaggregating the data reveals that the percentages of bachelor's degrees in the natural sciences to non-Hispanic white women declined from 79% to 70%, while the percentages awarded to non-Hispanic African American women and Hispanic women increased from 6% to 8% and from 5% to 6%, respectively (CPST 2004, table 2–74). Regardless of race and ethnicity, women are severely under-represented among tenured faculty at research universities. In terms of tenure, the gender gap has remained fairly constant over the past 30 years. Furthermore, among academics with doctorates in science and engineering fields, only 25% of women have been awarded tenure as compared to 50% of the men (Trower and Chait, 2002).

Race/ethnic data must be disaggregated by gender because how one experiences race and ethnicity is

mediated by gender. Similarly, gender data must be disaggregated by race and ethnicity because how one experiences gender is affected by race and ethnicity. Among African Americans and Hispanics, males as well as females are under-represented among tenured faculty at US research universities. Among both African Americans and Hispanics there are gender differences in the field distributions of PhDs and representation on academic science and engineering faculties. During the 1990s among both African Americans and Hispanics, women were responsible for the increases in the numbers of science and engineering doctorates earned by their respective race/ethnic group, but males still held more faculty positions and a greater number were tenured than females in their race/ethnic group. It is also significant that women of color – African American, Mexican American, and Puerto Rican – are less likely than either non-Hispanic white women or men of any racial or ethnic group to be awarded tenure. Masking crucial intra-gender and intra-racial distinctions results in policy, programs, and practices that are at best ineffective and at worst counterproductive for diversifying the science and engineering workforces.

Reframing the Issues

In the US, research on under participation in science and engineering fields has been framed in terms of two groups – women and racial/ethnic minorities. This dichotomous categorization is problematic because it implies that women are non-Hispanic and white, while racial/ethnic minorities are male. Even more problematic, this dichotomy suggests that women and race/ethnic minorities are mutually exclusive groups. Whether women of color are included in the category of women or a given racial or ethnic group, significant differences are obscured. Although women of color share characteristics with both men in their respective racial/ethnic group and women in different racial/ethnic groups, it is crucially important to systematically identify differences between women of color on the one hand, and men of color and non-Hispanic white women, on the other hand. The effects of the intersection of gender, race, and ethnicity are not additive – that is merely summative. Rather these effects are synergistic and bidirectional: that is, gender impacts how race and ethnicity are experienced; and race and ethnicity impact how gender is experienced.

In the US, analyses of participation in science and engineering tend to focus on quantitative indicators, such as numbers of degrees earned and labor force participation rates. This focus is problematic because numbers provide no information on the qualitative aspects of this participation. For example, focusing on the numbers of advanced degrees earned in science, engineering and technology does not adequately address the issue of the quality of the

institutions from which those degrees were earned. In the US some institutions that were formerly degree mills (and not accredited) now award the greatest numbers of degrees to indigenous racial/ethnic minorities – African Americans, Mexican Americans, and Native Americans. The absence of information on the quality of degrees earned makes it easier to make unwarranted inferences that differences in workforce participation among degree earners are due to deficiencies in individuals rather than differences in the quality of the institutions from which they were awarded their degrees. Although advanced degrees are entry credentials to the science and engineering workforces, much of the research on gender differences in participation in the science and engineering workforces stops with the award of the PhD or tertiary degree.

Qualitative indicators of women's participation in the sciences and engineering are just as important as quantitative indicators. In other words, equally important as the numbers of women in careers in science and engineering is the quality of those women's career experiences. Indicators of the qualitative aspects of women's participation in science and engineering include rank, honors, and prestige. Although women in China comprise more than one-third (35%) of all scientific researchers and 34% of those in technical service, they comprise only 4.6% of chief scientists, and receive only 12% of the top three government awards in science and technology. In 2000, female academicians comprised only 6% of the total membership in the Chinese Academy of Science. Data from Canada also reveal significant gender differences in the quality of participation in the sciences and engineering. In 2003, 88% of male academic staff either had tenure (70%) or held tenure track positions (18%); by contrast, only 40% of female academic staff was tenured and 25% were in tenure track positions (CCWESTT, 2006). Women had been appointed to 21% of the Canada Research Chair Positions as of 2006.

In the US, there is an inverse correlation between the number/percentage of women faculty and the quality of an institution of higher education: the higher the rank of an institution, the fewer the number of women faculty; moreover, this applies across fields. Regardless of the quality rating of a college or university, there is an inverse correlation between academic rank and the number of women: the higher the rank, the fewer women in that rank. Women in both the US and EU were more likely than males to have short-term contracts and/or to be on soft money. In the Glass Ceiling Index, an innovative indicator that compares women's and men's chances of reaching top academic positions, the higher the score, the greater the barrier to women's advancement. According to this index, the greatest barriers were in Malta, and the fewest barriers were in Romania and Turkey.

Another aspect of the quality of women's participation in science and engineering careers is the extent to which

they are in decision-making positions and can influence research agendas. One indicator of this is participation is the portion of scientific boards comprised by women. The 2000 Survey on Leadership in China conducted by the Association for Science and technology found that women comprise 15% of director generals, and 28.6% of directors. Women comprise 40% of science board members in Finland, and more than 30% in the UK and Denmark. In the US, women comprise 25% of the 24-member National Science Board. In Argentina, there are no female deans in private universities (UNESCO, 2007).

Finally, research on women's participation in science and engineering fields should conceptualize such participation in terms of careers, and progress over time. This would enhance the identification of factors that enhance as well as impede women's career at each stage. For example, in 2004 the Athena Project, a consortium of UK research funding organizations, universities, and government science departments, conducted a survey that found that although women had a slightly higher success rate than did men in applying for their first lectureship post, women were significantly under-represented both at senior levels and in older age groups. The UIS, Eurostat, and the OECD have developed a method of tracking aspects of the careers of doctorate degree holders across nations, such as the time it takes to secure employment and salaries.

Summary and Conclusions

Through focusing on women of color in science and engineering, this article points out the criticality of refining concepts and reframing issues concerning under participation in science and engineering. Refining concepts and reframing issues should be data driven and in turn should inform data collection. Data on participation in science and engineering careers must be longitudinal and disaggregated by race, ethnicity, and gender to help identify issues, track trends, and monitor the effectiveness of interventions.

It is useful to situate the modern-day concept of educational diversity in its historical, social, political, and legal contexts. The modern version of the term educational diversity is derived from the United States Supreme Court's usages in the Michigan law school affirmative action case – *Grutter v. Bollinger* in 2003 – in which the Court held that a state university has a compelling interest in seeking to derive the educational benefits that flow from a diverse student body and may pursue that interest through a narrowly tailored system and in a time-limited manner. Social scientists have identified institutional and student diversity, particularly racial and ethnic diversity, which is associated with a range of positive educational outcomes for the students, their institutions, and society. Research linking educational diversity to these outcomes ranges from experimental studies that involve different combinations of students who are instructed to interact on problem-solving tasks to large national studies of undergraduate and graduate/professional students that examine attitudes, cross-racial interaction, course taking, and academic performance during and after graduation.

The study of educational diversity within the law school setting is of particular interest because of legal case history as well as the nature of the academic experience and training for this highly accomplished set of students. Law students arrive at law school with a set of personal characteristics, family background, academic and interpersonal experiences, attitudes, and expectations about their future in law school and their careers. Depending on many

student-level, institution-level, and curricular factors, the composition and experiences of law students may frame their law school educational experiences, including how they interact with their professors and their peers, analyze cases, engage in activities while in law school, choose courses, select internships and interview opportunities, and apply their legal knowledge after graduation.

Legal Background of Educational Diversity

Thrusts to improve the political, economic, and social conditions of African Americans did not begin with the modern era of affirmative action programs. Indeed, the beginning point for a full discussion of America's relationship with its oppressed peoples of African descent would have to recount the justifications, deprivations, and continued effects of a legacy of slavery. But that is beyond the scope of this article. Affirmative action effectively began with the Emancipation Proclamation of 1 January 1863, which freed the slaves. Proponents of abolishing slavery and of uplifting former slaves recognized the need to protect the former slaves' new freedom and to remediate some of the past injustices they had suffered. Therefore, they pushed for antisubjugation provisions, political protection measures, and remedial measures. Some of these provisions were added as amendments to the Constitution of the United States:

1. The Thirteenth Amendment adopted in 1865 prohibited slavery and provides, in part, that “[n]either slavery nor involuntary servitude, except as a punishment for crime . . . shall exist within the United States, or any place subject to their jurisdiction.”
2. The Fourteenth Amendment adopted in 1868 made persons born or naturalized in the United States citizens and provides, in part, that “All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside.” To prohibit the defeated slave states from formally re-subjugating the newly freed slaves, the Fourteenth Amendment also provided that no state could deny “the equal protection of the laws”: “No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any state deprive any person of life, liberty or property without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws.”
3. The Fifteenth Amendment adopted in 1870 gave the newly freed slaves, declared by the Fourteenth Amendment to be citizens, the right to vote, and provides that: “The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color or previous condition of servitude.”

These constitutional measures empowered Congress to enact programs to protect the former slaves and to improve their political, economic, and social conditions. As the Civil War drew to a close, the US government created the Freedmen’s Bureau in 1865 (ended in 1871) to provide assistance (e.g., educational services, land, and other aid) to the newly freed slaves, but not to white refugees or others. The government promised to sell or lease to farmers parcels of unoccupied land and land that had been confiscated by the Union during the war; it also promised the loan of a federal government mule to plow that land (40 acres and a mule). Some African Americans took advantage of these programs and either bought or leased parcels of land. During reconstruction, however, President Andrew Johnson vetoed a bill to enlarge the powers and activities of the Freedmen’s Bureau, and he reversed many of the policies of the Bureau. Much of the promised land, which had been leased to African American farmers, was taken away and returned to Confederate loyalists. As the promise of significant, sustained aid and land was soon breached, for most African Americans, the promise of 40 acres and a mule was never kept.

After the Civil War legislation, and the aborting of much of the Reconstruction steps to protect and uplift the former slaves, a bleak era of Jim Crow descended upon the nation. Segregation and discrimination pervaded America. In 1896, the US Supreme Court’s decision in *Plessy v. Ferguson* in 1896, sanctioned discrimination against

blacks under the separate-but-equal rubric. Another half a century of struggle ensued. The issue of black subordination and exclusion would not go away. So again it reached the Supreme Court. This time, at last, the Court recognized, in its *Brown v. Board of Education* decision in 1954 that black citizens had a right not to be excluded from educational opportunities the states offered to whites, repudiating the separate-but-equal doctrine of *Plessy v. Ferguson*.

After *Brown*, institutions realized that they needed to take additional steps to make educational opportunities realistically available to blacks. Affirmative action provisions also included women and selected other minority groups who had been historically victimized and who were under-represented at elite educational institutions. Many institutions adopted various forms of affirmative action that considered the race and ethnicity of applicants. One prime reason for the need to consider race in an attempt to assure access for minorities and to attain diversity within educational institutions is the disparate performance by blacks and some other minorities on standardized tests as compared with white test takers. The reasons may derive from contemporaneous effects of historic racism, continued educational discrimination, and pervasive economic disadvantages.

A quarter-century after *Brown*, the Supreme Court’s *Bakke* decision in 1978 held that race could be a plus factor in university admission decisions. The Supreme Court, in *Grutter v. Bollinger*, again affirmed that race may be a plus factor in admission decisions. Yet, debate continues about consideration of race in university admissions. The issue of color, thus, remains controversial in the United States.

Grutter held that the Constitution permits educational institutions to make a narrowly tailored use of race in admission decisions to further a state’s compelling interest in attaining a diverse student body. The case sanctions the use of race as a factor that universities may consider as they seek the “educational benefits that flow from a diverse student body.” Justice O’Connor’s opinion for the Court in *Grutter* recognized specifically that an educational institution, in this case a law school, may, in good faith, define its institutional mission so as to derive the benefits of educational diversity because diversity “promotes learning outcomes,” “better prepares students for an increasingly diverse workforce and society,” and helps in “cultivating a set of leaders with legitimacy in the eyes of the citizenry.” Justice Scalia, one of the dissenting judges, set forth issues that subsequent suits may challenge including “whether . . . any educational benefits flow from racial diversity” or “the bona fides of the institution’s expressed commitment to the educational benefits of diversity.” Pointedly he says, “Other lawsuits may focus on whether, in the particular setting at issue, any educational benefits flow from racial diversity.”

After *Grutter*, therefore, major research tasks remain, including deriving a more articulated and analytical

conceptualization and operationalization of educational diversity, empirically examining whether race/ethnicity contributes to that diversity, and if it does, explicating how any contribution of race is manifested during an educational experience. A clearer understanding of these issues is essential to explain how considering an applicant's race/ethnicity supports permissible educational objectives that an institution may pursue consistently with constitutional limitations. It would not be permissible to consider race for the purposes of enrolling minorities to achieve a certain racial balance, correcting for societal discrimination, training professionals to serve underserved communities, or creating minority role models for minorities to emulate.

Diversity as a concept has been used in contemporary discussions of higher education since the mid-twentieth century. In 1950, *Sweatt v. Painter* held that segregated education provided at makeshift black law schools was not substantially equal to education available at the University of Texas School of Law, in part, because of a lack of diversity among the students enrolled in the all-black law school. The court made similar statements in 1951 about the important value of diversity in the case that ordered the end to state-sanctioned segregation of the law school at the University of North Carolina in *McKissick v. Carmichael*. Diversity has been linked to deeper historical antecedents and earlier judicial references, including Justice Powell's citation in the 1978 case of *Regents of University of California v. Bakke* to Harvard College's use of diversity for admission purposes dating back 30 years.

Social Science Research on Diversity

Our examination of previous research on race, education, and the value of diversity leads us to conclude that most of that research can be characterized as examining foundational questions or secondary questions. Foundational questions ask whether racial diversity is essential to educational diversity or what role race plays as an aspect of educational diversity in fostering educational goals. Secondary questions assume – implicitly or explicitly – that racial diversity is a given, that racial diversity is an independent goal, or that racial diversity equates to educational diversity. Having made one or more of these assumptions, researchers can analyze various secondary questions, such as, whether diversity affects educational outcomes or in what ways educational diversity affords benefits to institutions, individuals, or society.

Substantial and valuable social science research has addressed law, diversity, and race. More particularly, some examinations of diversity have assumed that racial or ethnic diversity (or some other aspect of diversity) is a given. From that starting point, researchers have made broadly theoretical examinations of diversity. Other works have assumed

either that racial diversity is the end to be sought or that achieving racial diversity assures some measure of educational diversity. From that vantage point, researchers have examined one or more educational diversity constructs, such as interactions with cross-race peers, choice of social justice-oriented courses, or ability to solve complex cognitive problems. Based largely on the assumption that racial diversity creates educational diversity or that the goal is to assure racial diversity, scholars have explored aspects of diversity from empirical perspectives, through theoretical discussion, as well as by offering speculative legal and doctrinal viewpoints. Other works have assumed the existence of diversity (based wholly or in part on having achieved some degree of racial diversity) and then examined the impact of diversity in one or more educational domains (e.g., the effects of a particular undergraduate course on students' educational experiences and interactions with peers both inside and outside the classroom), as well as the perceived benefits of diversity based on opinion surveys of faculty members in higher educational institutions and law schools. Still other research has examined how assumed educational diversity influences student learning, educationally related outcomes in educational domains, and preparedness for future interactions in a democratic society, again largely on the premise that racial and ethnic diversity equals educational diversity. Research has also focused on ways to foster diversity at an institutional level with attention to racial and ethnic diversity; recognizing structural diversity or achieving a particular percentage of minority representation is not a sufficient condition for influencing students' attitudes and orientation toward racial equity. Studies have examined the educational domain of minority graduates' achievement in rendering special service to society. Other research has focused on general attitudes and opinions about ethnic diversity as an aspect of academic life or in the nation, with some polls addressing attitudes toward several diversity constructs such as sociopolitical attitudes on equal opportunity, affirmative action policies, or symbolic racism. Finally, researchers have conducted empirical analyses of the extent to which minorities would be excluded from selective educational institutions and graduate/professional schools and law schools if racial diversity were not used as a consideration in making admission decisions.

To study diversity and race more fully, researchers might first examine whether students' race/ethnicity or other definable personal attribute (e.g., gender, family background, socioeconomic status, geographic origin, or political orientation) is associated with educational diversity. Such a study would identify educational diversity construct areas in which diversity might be relevant, such as:

- Diversity of student background, including a person's race/ethnicity, gender, age, sexual orientation,

highest level of education, religion, spirituality, political orientation, current debt levels, and other descriptors of a person's current state.

- Diversity of family background, including demographic and social family factors, such as family structure (one/two parent), family size, family socioeconomic status during the growing up years, culture, language spoken at home, customs, and traditions that may influence students' perceptions and interpretations of curricular material.
- Diversity of experience, including positive and negative life experiences, which each student brings to the classroom and the campus. These experiences might include exposure to customs, cultures, and perspectives as well as experiences of prejudice and disadvantage that might influence a student's perspective on the social order.
- Diversity of attitudes, including differences in values, beliefs, sociopolitical attitudes, and conceptions of the world and one's self. Students who hold different beliefs about what is important, worthy, beautiful, and good in life may be more likely than a group whose values are homogeneous to show flexibility in thought, have the ability take others' perspectives, and discover for themselves the depth and interminability of the disputes in which human beings find themselves entangled.
- Diversity of educational expectations, including predispositions that students bring to the educational setting, such as curricular interpretations, classroom interactions, and how learning will occur. These predispositions derive from prior classroom experience (e.g., from one's undergraduate experience) and are manifested in, for example, class participation rates, the way assignments and class projects are prepared and presented, and the extent to which students engage in study groups, class project groups, and other group-oriented academic behaviors. These predispositions may also be reflected in student expectations and plans to engage in specific law school academic activities both inside and outside of the classroom. For example, students may be differentially likely to choose certain courses related to social justice, participate in political groups as a means of advancing issues of social justice, engage in specific volunteer public service activities, or orient toward certain curricular activities.
- Diversity of career goals and aspirations including differences in reasons for pursuing higher education and variability in student expectations for their own professional careers beyond law school to different foci that students bring to issues under study. It explores the extent to which students foresee that their education will be beneficial to themselves or to their communities after they leave the formal educational setting.

Second, researchers might consider the multilevel influence, if any, that race plays as an aspect of educational diversity in educational domains, such as:

- The individual domain emphasizing enrichment of each individual student's educational experiences during law school by deepening his/her personal understanding about ideas through exposure to many different perspectives (with other students and faculty members) and by making educational encounters richer, livelier, and more interesting.
- The institutional domain emphasizing the presence of diverse groups and the opportunities for intergroup interaction within the educational settings, widening the scope of perspectives expressed in the classroom, in the hallways, and on campus. This perspective focuses on an increased range of discussions, activities, programs, and interests represented within institutions and on formal and informal institutional changes that may be fostered by these phenomena.
- The social domain emphasizing that the creation of opportunities for students to interact with others of different backgrounds, races, and cultures within the educational institution, where they are enrolled will, in turn, increase and enhance their ability to interact positively and effectively in a diverse and global society.

Recent Research Examining Educational Diversity in the Law School Setting

Much of the extant research examining how student body diversity contributes to educational outcomes has focused on college student samples. The undergraduate setting allows the study of a broad cross section of students and institutions and captures student experience of social interaction, attitudinal development, and academic growth during the formative years.

Law students reflect an academically successful subgroup, who have completed a very deliberate set of steps by the time they have matriculated at one of the 196 American Bar Association (ABA)-approved law schools (in 2007). Members of this select group of students have:

1. chosen to pursue a law-related career;
2. completed all of the necessary academic and preparatory behaviors and research during their undergraduate and in many cases, post-undergraduate years, to apply for law school admission;
3. been admitted to law school;
4. matriculated at a specific law school;
5. embarked on a very structured set of common courses during their first year and internship experiences thereafter; and
6. have chosen educational activities that would prepare themselves to enter the workforce and contribute meaningfully nationally and globally, in areas such as government, private practice, education, business, and public service.

The Educational Diversity Project (EDP) is a longitudinal, multiple method study of law students, assessing a broad set of experiential and psychological characteristics to understand (1) the individual differences that incoming students have upon entry to law school and how these differences do or do not relate to race/ethnicity (and other personal characteristics); and (2) how individual differences identified during the first weeks of law school may frame a student's legal training, interaction with classmates with diverse viewpoints different from their own, and personal decisions about how they will use their legal training in employment after graduation. The study also examines the extent to which student variability would be attenuated if there were no racial diversity. Thus, the EDP examined the research questions: Does race/ethnicity (and other personal factors) relate to educational diversity, as defined by individual differences in student background and history, attitudes, academic experiences, and career aspirations? Does a student's racial/ethnic diversity provide a context for learning, interacting, and changing future expectations during law school?

Over 8000 incoming law students were assessed at 64 American Bar Association (ABA)-approved law schools during the first weeks of law school. Students self-reported about six different diversity domains: demographic background, family background, past experiences, perspectives and attitudes, educational expectations, and career aspirations. Supplementing these data on the institutional characteristics of the students' degree-awarding undergraduate institution and their enrolling law school, we examined associations between race and individual differences in a multilevel context. Incoming law student data were supplemented with a wide range of ancillary, archival information, including the Law School Admission Test (LSAT) registration information (e.g., race, gender, LSAT scores, counts of the number of times they took the Law School Admission Council (LSAC), law school application outcomes, such as where did students apply and where were they accepted, rejected, or waitlisted?), and first-year law school averages. A second assessment was administered prior to graduation, which tapped school experiences, attitudes, and professional aspirations.

To capture more nuanced views of the law school experience (from the student perspective) and how, if at all, student body diversity affected student learning, a subset of law students participated in focus groups during each year of law school. Each year the general themes for the focus groups varied. Students in the first year were asked about their learning experience, the diversity of the incoming class, and how race and gender were treated in analyses of specific legal cases. In the second year, they were asked about their activities, support sources (financial, emotional, and intellectual), mentoring, relationships with faculty, course choices, and perspectives on student diversity. In their last year, they were asked about

support sources during law school (financial, emotional, and intellectual), mentoring, relationships with faculty, future plans, and perspectives on student diversity.

Controlling for law school attributes of the schools where students were enrolled, the first major finding was that substantial variation exists in each of the six diversity domains as a function of race/ethnicity. Differences due to race/ethnicity were obtained in most areas of student background (e.g., one's family structure, parental educational and occupational achievement, racial socialization while growing up, religion, neighborhood while growing up, academic behaviors during college, and presence of a mentor), as well as in reported discrimination history (everyday discrimination, chronic discrimination, and perceived future discrimination in professional settings), race-related attitudes (e.g., domestic federal spending, negative attitudes toward immigrants, entitlements for all American citizens, symbolic racism, race relations, work ethic, gay/lesbian rights, affirmative action, current levels of discrimination toward minorities, low-income groups and religious groups, and value of educational diversity), and academic expectations (expectations about classmates, learning style, intentions to join student groups, personality, reasons for attending law school, desired future employment settings, desired job attributes, expected area of law, and anticipated eminence in law).

Not all variables under study showed variability as a function of race/ethnicity, including political orientation, sexual orientation, high school type, intent to work during law school, personal attributes relative to classmates (e.g., academic ability, writing ability, agreeableness, conscientiousness, emotional intelligence, and honesty/integrity), or attitudes about the military or certain social issues (e.g., rehabilitation for drug offenses, abortion, general fairness of the college process, and perceived discrimination against religious groups). Race/ethnicity also did not strongly predict certain academic behaviors as an undergraduate (e.g., whether or not students missed classes due to work and family responsibilities, met with faculty outside of class, participated in a student organization or in student government, or worked on assignments in advance of deadlines). Finally, in general, views about what might occur during law school did not differ as a function of student race/ethnicity (e.g., expected likelihood of learning about courtroom procedures, conflict resolution, and legal problem solving).

Longitudinal findings from the baseline assessment during the first weeks of law school to graduation showed that a law school with high racial diversity (i.e., having a high minority student representation vs. a low minority student representation; institutional domain) was related to reduced prejudice and increased exposure to diverse ideas (individual domain), and these effects were mediated by more frequent interpersonal contact with diverse peers (social domain).

Focus group findings confirmed several prior findings from undergraduate student samples that minority law students experienced alienation, lack of support, and everyday discrimination during all years of law school, especially students at institutions in which student racial diversity was low. Reported classroom experiences differed considerably as a function of race/ethnicity, and there was an oft-noted classroom-level tension between a professor's desire to adhere to strict legal analysis versus the consideration of a case's sociocultural context. For example, despite law schools' fairly uniform first-year curriculum, focus group participants identified strong differences in the extent to which issues around race/ethnicity were introduced into the discussion of certain legal cases, and these differences varied by professor and by the representation of minorities in the class. As a result of these observations, a national interview study is underway with a random sample of law professors probing whether and, if so, how they present case law and course materials related to race/ethnicity. The faculty interviews also inquire about the extent to which student racial diversity in their classrooms (vs. other forms of student diversity) impacts how they conduct their courses, about the extent to which difficult dialogs involving racially sensitive topics take place in the classroom, and about their viewpoints of student and faculty racial diversity in legal education.

The EDP's longitudinal and multiple method design has helped capture the law student's entire educational context, rather than taking a snapshot of a moment in time. We were able to assess their self-reported background, attitudes, and expectations when starting school; their undergraduate education's attributes; their law school's attributes; their concerns, opportunities, and academic performance during school; and their perceptions about their learning experiences upon completing school. Archival data and reports from professors about their pedagogy and interactions with students add nuance to the student trajectories under empirical study.

Conclusions

The legal state of educational diversity relies on the accumulation of empirical evidence across a range of educational settings (K-12, undergraduate, and graduate/professional schools) to identify educational benefits resulting from the exchange of ideas permitted in the context of a diverse student body. Research has clearly shown that diversity of background, family, positive and negative life experiences, attitudes, academic expectations, and aspirations vary as a function of race/ethnicity. That is, diversity of history and thought is associated with student racial diversity and is a lens for future educational interactions and learning. The increasing body of evidence about the effects of these sources of variability on

learning outcomes, interactions with peers of different backgrounds, exchange of ideas related and unrelated to course material, and preparation for active and meaningful participation in a global and diverse workforce will benefit from research that captures multilevel features of the student *in situ*. Such research should focus on students within their institution, as affected by their personal characteristics, family, experiences, attitudes, course choices, curricular and extracurricular experiences, peers, professors, and aspirations for the future.

Educational Reform

F Lopez-Segrera, Technical University of Catalonia, Barcelona, Spain

© 2010 Elsevier Ltd. All rights reserved.

Educational reform is a transformation plan and movement, which tries to bring about a systematic change in educational theory and practice in the level of basic or higher education (HE) in a given community and society.

Educational reform has been pursued for a variety of specific reasons, but generally most reforms aim at redressing some social problems – poverty, gender, race, or class-based inequities – or eliminating perceived ineffectiveness and lack of quality and pertinence, and inadequate management of funds.

It is not only true that the current changes and reforms of HE systems cannot be reduced to the impact of globalization, but it is also true that globalization – in its neo-liberal dimension, a concept that combines a market ideology with specific practices drawn from the world of business – has had a profound influence on educational systems during the last two decades of the past century and the start of the twenty-first century.

Our concise analysis has the following objectives:

1. refer to the impact of globalization at the world level over the last 20 years;
2. highlight the fact that certain levels of social equity are necessary in order to attain ongoing lifelong education as well as successful educational reform;
3. analyze the quantitative and qualitative impact of globalization on HE at the world level; and
4. formulate several proposals that would not only mitigate the negative impact of globalization on the education sector, but would also produce the necessary transformation of the main trends.

Among the latest trends, we can include the permanent updating of professionals and educational content; introduction of electronic networks for learning; translation and adaptation of the main scientific contributions; modification of institutional management; *ad hoc* public policies; and mutual enhancement of different educational models (public–private) and between different educational institutions – formal, informal, and distance. In the documentation of the World Conference on Higher Education (1998), convened by the United Nations Educational, Scientific and Cultural Organization (UNESCO) and its follow-up meetings, a series of valuable suggestions were adopted for confronting these global and regional challenges and problems.

It is important to identify the main trends in HE – quantitative expansion; growth of privatization; institutional diversification; public spending restriction; and

brain drain (UNESCO, 1995, 1998) – to solve the basic problems – reduction of public spending; changes in government policies; bureaucracy; rigid structures; and relationship to enterprise and production – and the challenges facing them. In the documentation of the World Conference on Higher Education (1998), convened by UNESCO, a series of valuable suggestions were introduced for confronting these challenges and problems.

The impact of globalization on the higher education institutions (HEIs) in Latin America and the Caribbean (LAC) is shown in the dialectics between three contradictory key themes: the public versus the private university (or administration vs. market), autonomy versus regulation, and production of knowledge versus mere teaching universities. Conversely, in the different perceptions of education and globalization, some attribute the changes to a different origin, minimizing the theory of great effects (Brunner), while others consider globalization to be the independent variable of the main changes (Gonzalez Casanova, Tunnermann, Didriksson, Lopez Segrera, Tedesco, Filmus, Broveto, Dias Sobrinho, and Boron).

Other key elements related to the globalization impact are the modifications that the TIC generates in the context and the debate concerning the possibilities of radically transforming our higher educational systems along UNESCO's guidelines, as well as following the guidelines of different reports from international organizations (e.g., UNESCO and World Bank (WB)), or from the national commissions of developed countries (Attali, Dearing, Boyer, and Bricall) or less-developed countries (ANUIES, Mexico). These reports, as well as the work of the principal Latin-American, European (Burton Clark, John S. Daniel, and Guy Neave), and North American experts (Altbach), despite diversity in scope, seem to suggest as guidelines permanent lifelong education for all; distance education; and institutionalization of the networks.

Our main hypothesis is that a dialectical synthesis is on its way, but many consider that market forces will have the final victory due to the exponential growth of private HE. The WB is evolving in its position and now asserts that investment in HE is important to development. On the other side, the state – as well as HE leaders – is convinced of the necessity of evaluation, and more diversified sources of financing.

In our opinion, globalization is a new qualitative phenomenon that arises from three interdependent processes that coincide simultaneously, and which have their

own internal logic: the crisis and downfall of socialism itself, neoliberalism, and the accelerated development of TIC.

Globalization is having a major impact on education in five principal areas (Carnoy, 1999: 15–17):

1. In the organization of work and types of work that people generate, which demands a higher level of education in the labor force and permanent ongoing training through *ad hoc* courses.
2. The governments of the developing countries are under increasing pressure to invest more in all levels of education, in order to create a better-equipped labor force, capable of using sophisticated techniques for production, which is the only way to compete in a more-globalized world market.
3. The quality and level of the educational system are growing at the international level. Curricula are becoming more complex and education, especially HE, should train students to handle new technology in several languages. On the other hand, there is an increasing tendency to exact accountability regarding the management of resources and results achieved, with regard to predefined objectives.
4. The virtualization of education is developing at an incredible pace, seeking to expand education, at a lower cost, through distance education. Education on Internet will become the predominant means of education, particularly HE.
5. Globalized information networks indicate the transformation of world culture. Those excluded from this world order fight against the values of this world culture, which possesses overwhelming market forces – as can be seen in the protests held in Davos, Seattle, Prague, and all those places where the *maîtres du monde* meet, the leaders responsible for the neoliberal policies and their consequences. They themselves admit that it is necessary to mitigate these policies, due to their disastrous consequences on the prosperity of the North and the adversity that has prevailed in less-developed countries.

Brunner states that it is not strange that the principal problem or weakness of the thesis of great effects lies in attributing the immediate cause of a variety of consequences to globalization, in the field of education or education policies – as a background context; consequences that without a doubt have very different origins. To be in the background is not necessarily to cause something. For instance, “the decentralization of education could be due to many causes and follow different national tendencies in different societies” (Brunner, 2001: 3).

Although this text by Brunner restores the multicausal theory, it tends to breakdown a specific model into causes and consequences of different origins, when in our opinion the independent variable that explains diminishing investment in education is closely tied to the triumph of

financial capitalism in its speculative form – neoliberal globalization.

The neoliberal model for universities has the following connotations: the university negotiates with the state, enterprises, and fathers of families who are able to pay for their children’s education. They all demand excellence in the field of knowledge and learning, which would be marketable, and try not to overreach the demand with surplus offers that would lower salaries and jobs. This new neoliberal university has a humanitarian policy whereby public or private foundations offer scholarships or credits to the poorer students who are not able to afford studies. “If the concept of the neo-liberal university puts emphasis on the public as well as on the private domain, the concept of university capitalism emphasizes the transformation of the university’s activities into merchandise” (Gonzalez Casanova, 2001: 102). They are conceived as market terms and this leads to the creation of corporate universities, to meet the necessities of the corporations, such as the case of the pioneer (in 1950), General Motors.

UNESCO proposes lifelong education for all for the recuperation (or inauguration) of democracy in education. This proposal – if put into practice – is incompatible with the neoliberal project.

It is not only true that the HE systems have progressed from simple and homogenous systems to ones that are more complex and diverse in the last decade, but it is also true that as a result of the deregulation of the 1980s policies have been drawn up for quality control, through institutional evaluation. It is clear that these are recently introduced policies that do not make a substantial difference with regard to the transformation of the HEIs. Nevertheless, they constitute an important change and a prerequisite for attaining real quality change. The mere market orientation of many private universities on the one hand, and the traditional concept of corporate autonomy on the other, seem to be some of the main obstacles impeding this quality change. The appropriation by the university of corporate logic is the perversion of autonomy. The university ceases to be an institution of and for society, and becomes an institution of and for members of the university community.

From the 1990s, even though a new conceptual framework was adopted, we cannot claim that these policies have essentially modified HE at the world level. What prevails is tension between the positive and negative aspects of the market and the state, respectively.

The analysis and systematic study of HE, and its irruption as an autonomous discipline, have hardly seen four decades. This interest in HE policies, associated with its emergence as a discipline, constitutes a study field that arose at the time of the disappearance of the classic university of elites when HE was mass extended at the beginning of the 1960s, showing a remarkable quantitative increment in enrolment. (Neave, 2001: 15).

The enrolment projections of UNESCO provide a worldly increase from 65 million students in 1991 to 79 million in the year 2000, 97 million in 2015 and 100 million in 2025. In 2004, we already had 134 million students enrolled in HE. This means a challenge for the countries of the South in relation with pertinence in an increasingly globalized world, in which competition will be more sophisticated in the knowledge market and where the young people of the poor countries have 17 times less chances of continuing a HE than those of the developed countries (GUNI, 2006).

The World Declaration on Higher Education in the 21st Century: Vision and Action (Paris, 1998), as a result of the World Conference summoned by UNESCO, states that there exists an unprecedented demand for a greater diversification of HE, and also an increasing degree of awareness of its vital importance for economic and socio-cultural development. The guidelines of this Declaration and the documents resulting from this Conference imply a solid change of paradigm, concerning the recommendations of HE policies (UNESCO, 1998; Segrera, 2001: 189).

In the WB report – *Higher Education: The Lessons of Experience* (1994) – it is stated: “there exists evidence that the investments in higher education have lower social rates than those made in primary and secondary education”, hereby these “will continue to be priorities for the Bank’s loans” (World Bank, 1994: 84–85). However, in a later report – *Higher Education in Developing Countries: Peril and Promise* (2000) – made by a task force of the WB and UNESCO, we observe that the WB in this document has changed its traditional position substantially. In chapter 2 of this report, it is stated: “the task force supports that great investments should continue to be done in primary and secondary education, but believes that the traditional arguments of economic character are based in a limited comprehension of the contributions of higher education institutions” (World Bank, 2000: 39).

The HE systems, according to the UNESCO/WB report – *Higher Education in Developing Countries: Peril and Promise* – should have the following characteristics or desired features (World Bank, 2000: 50–53):

1. Stratified structure.
2. Stable and long-range financing.
3. Competitiveness.
4. Flexibility.
5. Clear objectives and results.
6. Autonomy in front of political manipulations.
7. Narrow and well-defined links with the other levels of the general education system.
8. A legal system as a base for innovations and achievements.
9. An adequate information and database systems.

Concerning the reports developed by national commissions, we should mention the proposal of ANUIES in

Mexico, which, starting with the recommendations of the UNESCO World Conference of Higher Education (1998) comprises 14 programs grouped in three levels.

The *University 2000 Report* of Spain, known as the Bricall Report, since the ex-rector of Barcelona’s University, Joseph Bricall, coordinated it, came out with a request from the Conference of Rectors of Spanish Universities (CRUE), that a work group make some recommendations to improve HE in Spain. The report submits the constitution of a new social pact between the university, society, and state.

In the United States a report sponsored by the Carnegie Foundation and worked out by a commission directed by Ernest L. Boyer, president of the Foundation, – in the same way as the other commissions – carried out a critical diagnosis of HE in that country. A very severe criticism is made of the undergraduate system and it states as an objective the reinvention of the degree in universities of research. “The University of Research should facilitate the inquiries in the libraries, computers and study, expecting that the more advanced students and the proper professors and researchers body be the fellows and guides of the student. The University of Research gives to each student an integral educative experience, in which the whole of it is more profound and more comprehensive than what can be measured by won credits”.

This report shows – the ones that come from international agencies as well as those of independent national commissions – the priority that is given to HE at the world level in a knowledge society. Its key role in the training of human capital and its strategic dimension to modernize and give competitiveness to national economies are recognized. It stresses its value in citizenship training and in the acquisition of new identity values in the framework of the globalization process. It insists on the need for greater linkages with the social environment and there are formulated viable recommendations of specific transformations through a HE of quality (Segrera and Maldonado, 2002).

In ‘*Creando universidades innovadoras. Estrategias organizacionales para la transformación*’ (2000), Burton R. Clark defines the innovative universities, comparing them with European case studies – Warwick University, England; Strathclyde, Scotland; Twente, Holland; Chalmers, Sweden; and Joensuu, Finland. These institutes have changed from merely forming professionals, to becoming modern institutions with important development in scientific and technological research and technology, having a practical and innovative attitude. The essence of these transformation strategies, according to this author, is comprised of five common elements in the case studies:

1. strengthening of a central focus;
2. widening the periphery of extended development, going beyond the limits of the university’s boundaries

- to unite with external groups and organizations, via a transdisciplinary definition of problems;
3. diversification of financial sources;
 4. converting teaching staff and departments into dynamic innovative units; and
 5. creating a innovative work culture that adopts and promotes change.

In the following paragraphs, we summarize the main hypothesis of Boaventura Sousa Santos concerning university reform. According to him, the financial crisis in universities is related to their institutional crisis. Public universities have lost priority in states' public policies. This is due, above all, to the general decrease in the priority of social policies (e.g., education, health, and social security), caused by a model of economic development known as neoliberalism or neoliberal globalization. This model has spread around the world since the 1980s. In public universities, the imposition of this model meant that existing institutional weaknesses – of which there were many – were not used to create a pedagogical, political program of university reform. Instead, the problems were judged insurmountable and used to justify opening up universities – a public good – to commercial exploitation. Likewise, these weaknesses were used to explain the recapitalization and restructuring of public universities in favor of an emerging university market, where human resource transfers sometimes involved a rudimentary type of accumulation by private universities to the detriment of the public sector (Sousa Santos in GUNI, 2008).

Another contradiction also emerged in this area: the rigidity of university education and the changeability of the qualifications required by the market. The university became a service that one could access as a consumer, by paying for it. Thus, a citizen's right to education was drastically diminished. The number of free university education systems dropped and most grants were replaced by loans. As a result, students were transformed from citizens to consumers. The other main factor in the neoliberal project for universities is the transnationalization of university services.

As mentioned above, this neoliberal project is linked to a reduction in public funding. However, other factors are equally significant, such as a general deregulation of commercial exchanges; the defense, or even imposition, of the commercial solution by multilateral financial agents; and the high concentration of the potential benefits of new information and communication technologies in the North.

Public universities – and the education system as a whole – have always been linked to the project of nation-building. This project is now in crisis due to the progress of neoliberalism.

The only effective, liberating way to face neoliberal globalization, according to Boaventura de Sousa Santos,

is to challenge it with an alternative, counter-hegemonic globalization. National public university reforms should reflect a project of nation-building. This project has to be focused on political preferences that mark the integration of the country into contexts of knowledge production and transfer that are increasingly transnationalized and polarized between contradictory transnationalization processes: neoliberal globalization and counter-hegemonic globalization. Nation-building should be the result of an extensive political and social contract, specified in several sectorial contracts. One of these is the educational contract, which includes the idea of universities as a public good. The main aim of the reform is to respond to social demands for the radical democratization of universities. This should end the exclusion of social groups and their access to knowledge.

Counter-hegemonic globalization of universities as a public good is therefore a demanding political project. To attain credibility, it must squash two deeply rooted, conflicting, preconceived ideas: (1) that universities can only be reformed by university staff, and (2) that universities never reform themselves. The main protagonists are public universities themselves, that is, they are the ones interested in alternative globalization. The second protagonist capable of responding to these challenges is the nation-state. Finally, the third protagonist of the reforms proposed in this article are citizens, organized either individually or collectively, as social groups, unions, social movements, nongovernmental organizations and their networks, and progressive local governments. Reforms should be based on the assumption that in the twenty-first century a university only exists when three factors are present: graduate and postgraduate courses, research, and extension activities. If any of these factors is missing, there will be HE but no university (Sousa Santos, GUNI, 2008).

Universities must overcome a three-fold crisis, which they have been facing since the 1990s: a crisis of hegemony (it no longer has a monopoly on research), a crisis of legitimacy (it is perceived as an institution that is inaccessible to underprivileged people), and an *institutional crisis* (due to the difficulties it has in maintaining its independence in the face of pressure from market demands and the view of universities as companies). Therefore, reform should be undertaken, in accordance with a viable national project that considers education to be a public good and trains its graduates to work on sustainable development and equity (Sousa Santos, GUNI, 2008).

The principles and objectives that Didriksson proposes for the new education policy, which would become a new education pact, are consonant with the paradigms that UNESCO proposes for the twenty-first century. They are:

1. educating should be a task shared by both government and society;
2. education should have the maximum public priority;

Figure 1 Diagnosis of higher education in Latin America and the Caribbean according to enrolment rates. Sixty percent of the enrolment of higher education in Latin America and the Caribbean (LAC) is concentrated in three countries: Brazil, Mexico, and Argentina. LAC had 13 991 517 students enrolled in universities in 2003, but in contrast, it still has 37 million illiterates. From IESALC/Informe de la ES 2000–05.

3. learning is the new teaching paradigm for change and innovation;
4. education is a key factor for poverty reduction;
5. quality is intrinsic to the processes, results, and social value of knowledge;
6. education should be pertinent and respond to criteria of equality and equity;
7. basic education needs to elevate the achievement average;
8. the role of HE needs to be redefined;
9. teaching staff need to be professionals;
10. formation for work should provide new abilities, capacities, and work competence;
11. HE needs to be urgently redefined, rationalized, and diversified; and
12. the objective should be to generalize the social capacity to create a knowledge society.

It is necessary to introduce new reforms in education (basic and well as higher levels) along UNESCO's guidelines, the Delors Report, Boaventura de Sousa recommendations, and Edgar Morin's ideas.

In conclusion, in spite of the advances made, we have still not been able to create a new university model where the production of knowledge predominates and not just the transmission and management of it. We are witnessing a crisis at the university, not only in its financial evaluation and curricula management but also in the concept of the university itself, which we should adjust to the circumstances, reflecting a growing identity crisis and basic suppositions. Some consider that this socialization deficit is linked to the social and teaching capacity crises of our traditional institutions such as the family and the school. The challenge consists of creating a new university in this climate of uncertainty, avoiding the victory of anomie and pessimism.

Figure 2 Regional average (28.5%) of higher education enrolment in LAC. Data from Series 2000–2004/UNESCO Follow Up Report 2006 1.

Emergence of For-profit Higher Education

X Li, University of California, Los Angeles (UCLA), Los Angeles, CA, USA

Growth of For-Profit Higher Education

For-profit higher education in the United States remains with a relatively small sector, when compared its traditional counterparts, public and private nonprofit colleges and universities. The total education industry is estimated at about \$826.6 billion in 2003. Higher education expenditures were generally estimated at about \$315.4 billion in 2003 for an enrolment of about 17.4 million students (US Department of Education, 2005). The corporate education and training market comprises another \$75 billion and is expected to grow more rapidly than any other segment. The overall scale of the degree-granting, for-profit post-secondary institutions currently remains a small sector. The four degree-granting institutions most cited – the University of Phoenix, DeVry Inc., Strayer Education Inc., and ITT Technical Institute – together account for more than 100,000 students and over \$1 billion (Breneman *et al.*, 2006). Thus, the overall scale of the degree-granting for-profit post-secondary institutions is currently quite modest.

Conversely, for-profit higher education is often considered an emerging phenomenon. This is particularly true if we look at its rapid and tremendous growth in the past 10 years. For example, the for-profit degree-granting enrolment increased by more than 200% between as compared to 1995 and 2006 public institutions 20% for and –20% for private nonprofit institutions (Table 1). In the 2005–06 academic year, the number of for-profit degree-granting institutions is twice the number in 1995–96 (from 345 to 936), while the numbers for public and private nonprofit institutions have remained almost unchanged (US Department of Education, 2008).

Furthermore, if nondegree-granting institutions are included, there are currently more for-profit post-secondary institutions than public and private nonprofit post-secondary institutions. The 2006–07 census of institutions by the National Center for Education Statistics documents 2679 for-profit institutions, 1848 private nonprofit institutions, and 2009 public nonprofit institutions (Table 2).

According to the literature, for-profit higher education is an understudied area even though this sector has received much attention in recent years, due in part to a rapid development, in ways that traditional higher education has not. This article examines the recent growth of for-profit higher education, focusing on degree-granting higher education institutions in the United States. It explores the driving forces for such a rapid growth.

Throughout the article, different voices for the development of for-profit institutions are listed and compared. Their similarities to and differences from traditional (public and private nonprofit) colleges and universities are also presented. The article concludes with a discussion of potential directions and developments for this sector.

For the purpose of this article, the theory of academic capitalism is utilized to examine influential current processes of for-profit higher education in a global context. Slaughter and Rhoades (2004) describe how higher education is linked through networks to the new economy. They move beyond the conception of students as consumers and conceive colleges and universities as marketers that compete intensely at different levels. The theory of academic capitalism explicitly encompasses processes such as commercialization and marketization, and goes beyond these in several aspects. Most importantly, it conceptualizes changes to the system as a general shift from a public good knowledge/learning regime to an academic capitalist knowledge/learning one. Whereas the former was characterized by valuing knowledge as a public good to which the citizenry can lay claim, the latter regime values knowledge privatization and profit taking in which institutions, inventor faculty, and corporations have claims that come before those of the public. This concept of knowledge economy is well observed in all aspects of for-profit higher education sector.

Driving Forces for the Growth of For-Profit Higher Education

Several reasons and forces have been identified as contributing in part to the growth of for-profit higher education in the United States. Among such forces, permeation of globalization, technology advancement, decreased federal and state funding, market factors, as well as for-profit institutions' unique methods of catering to the special needs of adult learners are widely accepted.

Globalization and Commercialization Serve as a Broader Context

One major force for change in higher education is the globalization of economic, sociocultural, political, and technological factors, along with the increasing interdependence of nations. When the promotion of a free market constitutes the core of globalization theories and practices, efficiency is believed to be the key to success both at

Table 1 Numbers of degree-granting institutions and enrollment by level and control (1995–96 vs. 2005–06 academic years)

	<i>Public</i>		<i>Private-non-profit</i>		<i>For-profit</i>	
	<i>Two year</i>	<i>Four year</i>	<i>Two year</i>	<i>Four year</i>	<i>Two year</i>	<i>Four year</i>
Number of institutions						
1995–96	1047	608	187	1,519	228	117
2005–06	1053	640	113	1,534	528	408
Enrollment						
1995–96	5 314 463	5 806 036	75 375	2 867 181	173 489	130 976
2005–06	6 184 229	6 837 605	43 522	3 411 170	260 304	750 645

the institutional and individual levels. As Altbach and co-workers claim, “the correct path to improvement and prosperity is that of deregulation, decentralization, privatization, information technology (IT)” (Altbach *et al.*, 2005: 1).

Public good or private good

With the rapid growth of the for-profit sector, the controversy concerning the legitimacy of for-profit colleges growing is also in academic, governing, and accreditation agencies. They are criticized for lack of qualified faculty, predominant use of distance-teaching and learning approaches, lack of library resources, and so on. However, the core of the controversy has to do with the nature of the for-profit institutions’ motive – profit—which leads to the ongoing debate whether higher education is a public good or a private good, a relationship that has been cause for great concern.

Higher education – public institutions in particular – was traditionally and mainly sponsored by federal and state funding. Therefore, one of its major missions was to provide public service or public good to society. Higher education as a public good was dedicated to the idea that US universities must be more responsive to the changing needs of American society and the development of human beings. That is why wordings, such as commitment,

engaged, service, and partners with their communities are often seen in mission statements of colleges and universities.

However, with the growing commercialization of higher education, driven in part by globalization, the values of the marketplace have entered the campus. One of the main factors is the change in society’s attitude toward higher education, which is now seen as a private good benefiting those who study or do research. Slaughter and Leslie (1997) suggest that the nonprofit university research enterprise has already moved significantly in the direction of commercial production at the expense of public good.

According to Slaughter and Rhoades (2004), as colleges and universities become more entrepreneurial in a postindustrial economy, knowledge is less seen as a public good and more as a commodity to be capitalized on in profit-oriented activities. By emphasizing the role of the market when defining academic capitalism, they describe and analyze the aggressive engagement of US higher education institutions in the knowledge-based economy and the efforts of colleges and universities to develop, market, and sell research products, educational services, and consumer goods in the private marketplace.

From this perspective, it seems reasonable that the consumers should pay for this service as they would for any other. The provision of knowledge becomes just another commercial transaction. The main provider of public funds, the state, is increasingly unwilling or unable to provide the resources needed for an expanding higher education sector. Universities and other post-secondary institutions are expected to generate more of their funding themselves. They have to think more like businesses and less like educational institutions (Slaughter and Rhoades, 2004).

In this environment, the privatization of public universities is unavoidable as they are selling knowledge products, partnering with corporations and increasing student fees. The proliferation of private academic institutions of all types, especially in the for-profit sector, is another byproduct of commercialization (Altbach, 2001). Education companies, some of which call themselves

universities, sell skills and training, awarding degrees or certificates to their customers (students).

The Institute for Higher Education Policy (IHEP), in examining the value of higher education, explicitly made the case for viewing personal and public, economic and social benefits as a whole (IHEP, 1998). They point out that public dialog has predominantly moved away from an appreciation of the multiple societal and personal benefits of education. The focus now, according to IHEP, is personal economic benefit.

In these changed circumstances, it is not surprising for the World Trade Organization (WTO) and its related General Agreement on Trade and Services (GATS) to propose that knowledge products are freely traded in the international marketplace. Many of these developments link academic institutions and systems globally. The use of English as the lingua franca for scientific communication and for teaching, especially when combined with the Internet, makes communication easier and quicker. The advent of multinational higher education institutions makes it possible to spread new curricular and other innovations quickly and to meet the immediate needs of students.

Conversely, while much of the concern over the growth of for-profit education points to its leading to private-good, it has also been argued that the expansion of non-profit education in the post-war period and the concurrent implementation in those institutions of public policies on affirmative action and gender equity have contributed significantly to increased access, diversity, and efficiency in higher education (Hurtado and Navia, 1997).

Funding Cut for Public Universities

During the mid-1990s, public educational institutions in many states faced increasing criticism and tough state legislatures as well as tighter-than-ever federal and state funding. State legislatures, increasingly sought to hold public colleges to higher standards by implementing accountability regulations that tied at least some funding to the performance of the institution (Burke *et al.*, 2000).

Many states increased the reporting requirements for their public colleges as a step to encourage greater efficiency and accountability. Influential analysts foresee a radically changing and much more competitive higher education landscape in which the traditional, established institutions are threatened by burgeoning educational providers and new forms of educational technologies. Thus, Frank Newman, the past president of the Education Commission of the States, in an article subtitled 'The end of the *status quo* and the rise of the market in higher education' argues that "competition is forcing a hard reexamination of the purpose and effectiveness of every activity – from how well and often faculty interact with students, to whether expenditures on student life actually create a learning community, to the issue of costs and wise use of resources"

(Newman, 2001: 9). As institutions seek to make up for declining federal and state funding, public colleges and universities are increasingly becoming privatized (Zusman, 2005).

On the other hand, it has been argued with regard to costs, that the different institutional norms of the for-profit institutions may enable these providers to reduce costs and achieve greater efficiencies than their peers in the nonprofit sector. The costs of higher education at public and private institutions and the increased burden on individual students are creating enormous pressure on the nonprofit institutions in the United States and around the world (Ehrenberg, 2000). This in turn suggests an increasing competitive leverage for the for-profit sector if those institutions are able to utilize capital investments and lower wage scales to maintain lower overall operating costs. According to the National Sciences for Education Statistics (NSES, 2008), at public institutions in 2004–05, the average total expenditure per full-time-equivalent student was \$23 353. At private not-for-profit institutions, the total expenditure per full-time-equivalent student rose by 14% between 1996–97 and 2004–05, after adjustment for inflation. In 2004–05, the total expenditure per full-time-equivalent student at private not-for-profit institutions was \$38 472. The expenditure per student at for-profit institutions was \$11 205 in 2004–05, which is significantly lower.

In contrast to the reduction in public state funding, growing interest in education by ventures and corporations has contributed to the growth in for-profit higher education. For the high rates of return based on the human capital theories proposed by Becker (1964, 1993), these investors provide crucial financing for new companies as they see high potential for rapid growth here. For similar reasons, these firms are more interested in investing in post-secondary education, including for-profit and technical schools, rather than K-12 (Breneman *et al.*, 2006).

Technology Development Makes Distance Learning Possible and Easy

It was widely believed that campus-based universities and colleges were an important, if not the only, transition platform for youth from high school to join the workforce and job market. The introduction and increasing use of technology has greatly expanded access to higher education and fundamentally changed the models of education. In particular, technology has changed education from teacher centered to learner centric, making education far more relevant to the needs of individuals. Technology has freed education from being time- and place-bound, as it allows for anytime, anyplace learning, which is particularly flexible and attractive to working adults. Moreover, it enables lifelong learning in the true sense.

As Green (1999) argued, information technology increases access to higher education and the growing numbers of adults engaging in lifelong learning are fostering an evolutionary event in American higher education: “Technology brings new, rich resources to the learning of content; creates new contexts for interaction between and among instructors and students; and can fundamentally change the way students and institutions approach assessment and certification” (p. 14). It is fair to say that emerging technologies are changing the way of teaching and learning in both nonprofit and for-profit sectors; however, they provide more opportunities to for-profit education and training organizations not only because they fit working adults better, but also because corporations who operate for-profit institutions respond to modern technologies faster.

The Internet, for example, is used as the preferred primary technology to improve instruction, increase access, and raise productivity in higher education. A great number of universities, public and private alike, offer some extension or degree credit courses over the Internet. However, number of these types of courses remain relatively small, while for for-profit institutions, University of Phoenix for instance, using the Internet to reach geographically dispersed students has become one of the major means of instruction in their curriculum.

For-Profit Institutions Meet the Demand for More Skillful Labor Forces

Among the reasons believed to be responsible for the growth of for-profit higher education, their clear and narrow focus on professional training as well as customer-first and convenience-centered services are commonly accepted.

A global job market emerges as markets become more globalized. More and more corporations tend to recruit the skilled workers needed for these markets, and there is a growing demand for accessible and career-oriented adult education at the post-secondary level to fill this need. The increase of the general demand for the training, skills, and credentials offered in higher education, the needs of adult learners, and the rising tuition at traditional colleges and universities have stimulated the emergence of for-profit higher education in the United States as a viable sector of post-secondary education (Breneman *et al.*, 2006).

According to Levine (2001), the demographic composition of college students in the United States has changed. Traditionally, full-time 18- to 24-year-old residential students comprise the majority of the student population. However, this is no longer the case. In fact, only 16% of college students today fit this traditional profile. As a growing trend, over 60% of students are attending school part time and working part time. About 45% of college students are 24 years of age or older

(Levine, 1997). This explains clearly why much of the growth in enrolment in the last two decades has occurred among older, nontraditional students.

This growing trend provides great opportunities for for-profit institutions, and for them the key to success is their ability to accommodate the special needs of nontraditional adult students, who need the right credentials to obtain good employment as their primary goal. Recognizing that they can not receive a degree from a reputable university, adult learners enroll in for-profit institutions, which focus on convenience and shorter period of study time. They prefer courses in the evening and on weekends. Most importantly, easier access and lower cost of attendance than afforded by the traditional private universities and colleges in their region matter to most for them.

Levine (1997) found in a study of undergraduate attitudes and experiences that older, part-time, and working students, especially those with families and children, want a different type of relationship with their college – a relationship that is more like those they have with their bank, supermarket, or gas company. They want their colleges to be convenient, accessible, high quality for low cost, open during the evenings and on weekends, and having helpful staff, sufficient parking, and no waiting in long lines, and so on. Many students in the study preferred distance education so that they could study at home or in the office. They viewed higher education as one of many routine daily activities. They valued convenience, expected high-quality service, and were cautious about cost. In brief, for-profit institutions focus on students as customers and provide services for them that minimize the amount of bureaucratic control through which a student very likely has to pass in a traditional public or private nonprofit college or university.

The success of these institutions also depends on their market-oriented programs, such as international business, business administration, criminal justice, information technology, and health. Instead of helping students become well-rounded persons by giving them a liberal education, as these institutions promise in their mission statements, the promise students that they can complete the program in a shorter period of time, and get a better job. According to Ruch, (2001), the US for-profits sector pays more attention to placement rates, which help with their advertisement and recruitment. For example, they range from 96% at De Vry to 76% at Strayer. Similarly, the return on educational investment (ROEI) is higher than for the average BA: 28% as compared to 18.7%.

Coexistence of Distinctions and Similarities

When people talk about for-profit institutions, they are more likely to do so by making comparisons to their

nonprofit counterparts. Along with the debate over higher education being public good or private good, the essential difference between private nonprofits (e.g., Harvard University) and private for-profits (e.g., University of Phoenix) is that for-profit institutions provide education to make profit, while nonprofit colleges and universities charge tuitions to provide education. This fundamental difference in mission makes a great difference in areas such as admissions (required tested scores and comprehensive evaluation when entering nonprofit institutions vs. 'come on in' welcoming at for-profit), instruction and curriculum (walled-classroom liberal education vs. market-oriented e-learning courses), governance (more corporation management style at for-profit), services (more customer-first services at for-profit), and so on.

The source of their revenues has constituted a fundamental distinction between nonprofit and for-profit organizations. Traditionally, the public nonprofit sector received significant direct funding from the federal and state governments. Private nonprofits received large endowments and benefited from tax treatment. On the opposite end of the spectrum, for-profits relied solely on tuition income and tax benefits that their affiliating corporations received from the government. Consequently, different sources of funds determine their specialization, with public nonprofit institutions dominating the highly subsidized 2-year sector, private nonprofit institutions dominating 4-year degree-granting institutions, and for-profit institutions dominating the 2-year certification and training institutions (Pusser, 2005).

Although great differences between for-profit and nonprofit sectors can be observed, researches on institutional forms, using the theory of institutional isomorphism (DiMaggio and Powell, 1983) suggest that there is a convergence of nonprofit and for-profit institutions because of the increasing adoption of commercial behavior in nonprofit higher education institutions. In the mean time, for-profit institutions intend to be like nonprofit by means of one or another for the purpose of advertisement, recruitment, or accreditation.

Similar sources of revenue are attempted by both nonprofit and for-profit higher education institutions. In response to the reduction of state funding, a great number of public and private nonprofit institutions have initiated innovative efforts to offer programs and degrees without direct state subsidies. They charge tuition at a similar, if not the same, level, as the for-profit institutions. We see a rapid growth of affiliated enterprises, continuing education programs, industry-university partnerships, and the creation of for-profit subsidiaries of nonprofit institutions (Pusser, 2005). As both nonprofit and for-profit face the lack of public funding, the share of revenue coming from tuition charges and commercialized service activities has risen for them all.

Conversely, in the past 35 years, due to the passage of the 1972 Higher Education Act, students in for-profit

institutions are becoming increasingly eligible to apply for federal financial aid, a service previously available only to the nonprofit sector. They also benefit significantly from tax subsidies in which some or all of their tuition is paid by their employers, who in turn receive tax deductions for those payments. Students can often fund their tuition payments through federal subsidies, including financial aid programs such as the Pell grant program, subsidized student loans, and tax credits.

Conclusion

The for-profits have proven successful in competing with the nonprofits. In a gradually globalized market, which demands more skillful workers, the needs of adult learners and the rising tuition at traditional colleges and universities have stimulated the emergence of for-profit higher education. Increased availability of investment capital, excellent job-placement records, freedom from traditional curricula, lower costs through increased productivity, economies of scale, and state-of-the-art technology are cited as key assets of the for-profits. Taken together, these factors are seen as enabling the for-profit degree-granting institutions to capture market share from the nonprofits, and their perceptions are in accordance with those expressed by investment industry analysts and for-profit providers (Ortmann, 1998). The for-profit sector has successfully managed to become an active, viable, and financially successful part of the post-secondary education landscape.

However, for-profit providers currently represent a tiny fraction of the total degree granting activity in American higher education. The various layers of regulation requirements for accreditation in different regions of the United States also create significant barriers for for-profit higher education. By and large, it is believed that for-profit institutions are not a significant competitive threat to most of traditional higher education, despite views to the contrary expressed by some observers (Breneman *et al.*, 2006). For-profit colleges and universities have so far remained on the periphery of higher education. It is less than likely that for-profits will be able to supply a product that can match the peer effects and signaling value of elite nonprofit higher education institutions.

As Bowen (1986) wisely puts, "The future of higher education is on the whole not predictable . . . [it is] inscrutable" (p. 8). It is even more so when higher education has undergone so many dramatic shifts the twenty-first century. As the United States, as well as in any other parts of the world, is undergoing the severest economic recession probably since the Great Depression, it is reasonable to foresee the continuing and, more likely, dramatic cut of public and government funding in higher education, which will very likely affect the development of the nonprofit sector, both public and private universities. However, this can be a very difficult time for the for-profit

Figure 1

sector as well, given that many corporations have closed down, the credit market may affect student loan programs, and high unemployment ratios indicate a shrinking labor force. Thus, it is safe to say that, in the long run, the for-profit sector will continue to grow, as many of its major driving forces discussed in this article are growing, such as permeation of globalization, technology advancement, continued shrinkage of federal and state funding, and for-profit institutions' unique catering to special needs of adult learners.

Engaged Education: Experiential Learning, Intensive Field Experiences, and Social Change

T R Rone, Morgan State University, Baltimore, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Engaged education – A pedagogical tool, which promotes and fosters active, invested relationships between learners, educational institutions, and communities.

Experiential education – A philosophy of education, which emphasizes direct, active learning experiences.

Field experience – Similar to field trip in referring to a learning outside of the classroom. Distinguished from trip by a focus on extended, regularly occurring firsthand experiences. May be undertaken individually or as a group.

Field trip – Learning opportunities outside the classroom, generally as a group and limited in duration to a few hours.

Intensive field experience – Firsthand learning opportunities, which take place outside of the classroom.

Introduction

The concepts of engaged education, experiential learning, intensive field experiences, and social change are distinct, yet have the potential to be inextricably linked. In this article, it is understood that the four are indeed linked if one approaches the process of education as one leading, directly or indirectly to education as an active learning process and a product of relationship building. The article presents a discussion that: (1) describes engaged education; (2) defines and discusses the interrelatedness of this article's guiding concepts – experiential learning, intensive field experiences, and social change—as relevant to engaged education; (3) discusses the uniqueness of intensive field experiences as an effective pedagogical strategy; (4) illuminates the aims, components, and strategies of experiential education, and specifically, intensive field experiences, through a discussion of examples suitable for use in undergraduate and graduate social science courses; (5) describes a model for working with economic, transportation, housing, and social justice issues characteristic of urban areas through institutional strategies and resources that facilitate capacity building for community building and empowerment in local

communities; (6) outlines successful strategies for implementing intensive field experiences as an example of experiential learning; and (7) closes with a summary and overview. In an era when complex social issues of inequality, poverty, and injustice continue to markedly inform experiences of education, health, justice, housing and environmental protection, the construct of an engaged university, indeed, a globally engaged university, is increasingly becoming a norm rather than an anomaly.

The term engagement used in a more traditional sense denotes a betrothal, military battle, employment, or run of a performance. Since the 1960s, the term engagement is frequently used in educational contexts to describe learner engagement, student engagement, classroom engagement, school engagement, civic engagement, and political engagement. The concept of globalization has inspired the notion of global engagement. The concept of relationship is central to the meaning of the term engagement in more traditional and educational contexts. For example, in university settings, engagement marks the relationship between students as learners and faculty as teachers, between universities and communities, and between individuals and communities or society as a whole. These are not intended as diametrically opposed categories, but as attempts to highlight existing roles in universities and communities. The overall emphasis of this article is on the potential significance of strategies for dismantling the traditional barrier that exists between classrooms and communities. Engaged education addresses critical long-standing issues related to the extent to which universities and communities perceive their roles and responsibilities as unrelated. In contrast, engaged education calls for partnership, for merging resources and assets, as by the overlapping circles on the right side of **Figure 1**.

The concept of engagement, as embedded in the learning process, has been integral to human survival for centuries. The complete absence of engagement in learning carries substantial costs to human populations and society, as knowledge necessary for survival would fail to be successfully communicated. Broadly defined, engaged education can be characterized as a relationship between participants who in the roles of students, teachers, universities, and communities, are active co-participants in the instructional process. Engaged education refers to relationships characterized by learning via seeing, doing, and experiencing first hand, within and between what is generally perceived as a distant polar relationship between universities and

Figure 1 Universities and local communities: from disengagement to engagement.

communities. Since the 1980s, the measurement of the persistence of academic decline in middle and high school, and significant disparities in educational achievement and attainment between historically marginalized populations and majority populations, have contributed to increased attention on engagement, generally specified as learner, student, or classroom engagement in kindergarten through 12 grade education in the United States. However, studies of learner engagement have not been limited to the United States. Studies from Australia, Canada, Asia, and Europe exemplify the challenges of creating effective and civically responsible learning contexts, globally.

In the United States, precursors to today's attention to engaged education and its linkages to social change can be traced to institutional commitments beginning with the founding of American universities, whether dedicated to training ministers or land-grant colleges with public service missions. Since the 1800s, engaged education movements have been led most consistently by institutions with missions committed to social justice and equality, notably Historically Black Colleges and Universities (HBCU), Tribal Colleges and Universities Programs (TCUP), and Hispanic Serving Institutions (HIS). Increasingly, since the 1950s, universities in the private sector are becoming more socially conscious and creating linkages to local, regional, national, and international communities that engage, empower, and educate inside and outside of university settings. Several factors have contributed to substantial changes and revisioning of institutional commitment and strategic plans, including the surge of civil rights and social movements of the 1950s and 1960s. These changes include (1) postmodernist, multivocal, and dialogic approaches to interpretation and representation; (2) a marked demographic shift resulting in increased training of members of communities, from white elites to ethnic white and racial minorities, whose previous roles were limited to serving almost exclusively as the subject of study; and (3) technological advances have afforded global accessibility to information which has heightened awareness and institutional civic commitments and responsibility.

The term engagement has been used to frame discussions of civic, social, and political engagement, often in the context of debates about the role of higher education in society, or about the need for higher education to contribute to the development of university students as

productive citizens who, after graduation, contribute to society in more engaged, active, and productive ways. In this article, engaged education is understood as a process and a product. Engaged education is a process through which the method of instruction fosters conditions, which position and prompt learners to take on more active roles in education as listeners, seers, thinkers, and doers. The concept of engaged education is understood as a product of the interface between experiential education, intensive field experiences, and social change. Community transformation resulting from the process of engaged education is a product that takes many forms. Engaged education refers to the tangible changes communities are able to implement as a result of participating in the process of engaged education. As a product, engaged education includes the increased vision and visibility given to social issues of injustice, inequality, and human struggle. Also, engaged education, as a product, refers to the documents, papers, and video projects produced from engaged education.

Since the 1980s, interest in and commitment to the importance of engagement in the learning process is reflected in the development of major national surveys, journals, and changes in the criteria of university classifications. National efforts include the Center for Information & Research on Civic Learning and Engagement (CIRCLE), the National Center for Public Policy and Higher Education's *Measuring up 2000: A State-By-State Report Card on Higher Education* (2000), and national surveys such as the High School Survey of Student Engagement (HSSSE), the Survey of Entering Student Engagement (SENSE), the National Survey of Student Engagement (NSSE), and the Community College Survey of Student Engagement (CCSSE). These surveys consist of instruments, which measure a broad range of factors associated with engagement in and out of the classroom. Newsletters and journals include the *Community Works Journal*, *The Generator*, *Journal of Higher Education Outreach and Engagement*, *Journal for Civic Commitment*, *Metropolitan Universities*, *Michigan Journal of Community Service Learning*, *Journal of Experiential Education*, *National Service-Learning and Civic Engagement Research E-Newsletter*, *Partnership Matters*, *Partnerships: A Journal of Service-Learning and Civic Engagement*, *PRAGmatics: A Journal of Community Based Research*, and *Service Learning Advances*.

Since the 1990s, universities in major US cities, including Chicago, Detroit, and Philadelphia, have become actively involved with meshing undergraduate learning, outreach, and civic engagement. National and international initiatives for engaged education at the university level include Campus Compact and the Community-Campus Partnerships for Health (CCPH), as well as funding from private foundations, including Pew Charitable Trusts and the Kellogg Foundation, and federal agencies, including the US Department of Housing and Urban Development, the Department of Education, the Department of Justice, and the National Science Foundation. In 2005, the increase

in American universities' attention to community engagement prompted the Carnegie Foundation for the Advancement of Teaching to announce community engagement as a new elective classification available through a voluntary application process. The classification includes three categories: (1) Curricular Engagement, (2) Outreach & Partnerships, and (3) Curricular Engagement and Outreach & Partnerships.

The purpose, role, and responsibility of the university have been a point of rigorous philosophical and epistemological debate at various, even most times throughout the history of institutions of higher education. Further, in industrialized and postindustrialized nations, major social problems have resulted from historical legacies of social inequality, unequal access to rights, privileges and resources, as well as domination and oppression, and these are widely acknowledged. The university, as an institution, has been the target of criticisms about its ideological and social distance from the communities that often serve as the subject of study, and which are often located in close geographic proximity to the university. In some cases, universities and local communities may be in conflict over resources such as territory. More often, criticisms stem from hostile and contentious relationships resulting from histories of exploitation under the guise of research without reciprocal return of knowledge to the communities studied. Within a select group of universities, especially in urban US regions, there has been a concerted philosophical and strategic commitment to social change through a broader construct of the engaged university in local, regional, and global communities. A parallel movement to address issues of social justice and inequality has been initiated through social entrepreneurship efforts, in some cases, resulting in a blending of the two interrelated approaches.

Engaged education, as exemplified through experiential education and specifically illustrated through intensive field experiences, helps to create and foster linkages between colleges and universities and local, regional, national, and international communities. Engaged education has the potential to build extendable, capacity-building knowledge and sustainable relationships that contribute to social change. Optimally, engaged education, as a pedagogical tool, has a direct, sustainable reciprocal exchange. However, not all engaged education has a direct, reciprocal exchange with a specific community. In these cases, the impact of the learning experience can still have such a significant impact that it shapes how students directly and indirectly engage in the world community.

Key Concepts

Experiential education is a philosophy of education, which proposes the application of educator-guided strategies

intended to encourage learners' direct, active experience as a conduit to increased knowledge, awareness, and skill development. Experiential education is often used interchangeably with experiential learning, which focuses on the individual learning process through direct experience. Related examples of experiential education include active learning, outdoor education, theory practice learning (TPL), service learning, cooperative learning, cultural journalism projects, exchange programs, collaborative learning, adventure education, and field trips. Experiential education has been examined as a viable option for improving outcomes across the curriculum in the sciences, social sciences, and professions of law, medicine, business, public health and social welfares; as well as for community development. Experiential education is also related to the concepts of problem-based learning, place-based education, critical pedagogy, and community-based participatory research (CBPR).

Theoretical and conceptual origins of experiential education are often attributed to John Dewey, David A. Kolb's and Roger Fry, and Kurt Hahn. Dewey (1938) proposed a philosophy of education grounded in a Principle of Continuity, experience occurs along a continuum, and a principle of interaction, where the internal and objective aspects of experience inform a situation of learning. Kolb and Fry (1975) posited a four-point learning cycle, with learning beginning at any of its four points: concrete experience, observation and reflection, forming abstract concepts, and testing in new situations. Experiential education theory is also informed by the contributions of Paulo Freire, Jean Piaget, Maria Montessori, and Rudolf Steiner. Central to pedagogical strategies, which advance experiential education, is the importance of developing a sense of building knowledge through layers or stages of experiences culminating with firsthand experience. These strategies contribute to learning experiences that enhance educational outcomes for students, faculty, and communities. For example, course readings and lectures can inform each other as a foundational layer of knowledge. Film screenings, audio recordings, online resources, and class visits from related experts provide another layer of exposure to course material. Course assignments requiring students to research central concepts create learning opportunities for students to begin to synthesize course material and develop expert knowledge on their own. All of these stages or layers of activities are, to a certain degree active, engaged firsthand learning experiences. Firsthand learning experiences in which students encounter and synthesize readings, lectures, films, audio recordings, or web content, still lack the firsthand experience resulting from spending time in places that are the sites of study and meeting people who are the subjects of study, yet whose experiences are generally filtered through more traditional processes and products of scholarship which privileges the researcher's role and voice. **Figure 2** illustrates stages

Figure 2 Layering of instructional tools and engaged education.

of experiential knowledge flowing from instruction through intensive field experiences as a process that, when partnered with local communities, results in engaged education.

Intensive Field Experiences

Broadly defined, intensive field experiences are firsthand learning opportunities, which take place in sites outside of the classroom. The term ‘field experience’ is related to the term ‘field trip’. Despite the proven success of the field trip in Kindergarten through corporate settings, field trips are still commonly associated with passive learning at the elementary school level. Contrary to popular belief, field trips have the potential to provide rich, intensive, and transformational experiences along the learning continuum of the life cycle.

Both concepts, field trip and field experience, call for a learning experience in a designated site outside of more traditional classroom instruction. The duration of time, as defined by the length of time and frequency, distinguishes the concepts of field experience from field trip. Field experience is broader than field trip and affords for extended, regularly occurring firsthand experiences with sites and communities. Field trips present an opportunity for field experiences, though at a minimum, less intensive field trips are less likely to result in the relationships that lead to sustainable, capacity-building social change. However, all field experiences are not field trips. Field trips are generally group or class excursions, while field experiences may be undertaken individually with guidance from instructors. However, both field experiences and field trips are examples of experiential education.

In the social and environmental sciences, specifically in disciplines, such as anthropology, sociology, education, environmental studies, and political science, field experiences are often used to introduce students to firsthand knowledge beyond textbooks and lectures. Field experiences may be useful in helping students develop skills as ethnographers, in participant observation, and collecting data through interviews. In turn, these skills can be used to help local communities with critical knowledge and resources. In the social sciences, field experiences have the capacity to illuminate lived experiences of social inequality

and blocked access. There are two defining, yet interrelated dimensions of field experiences: duration and depth of experience. Duration of time is a defining aspect of the field experience. Short-term field trips are a few hours to a full day, in duration. The intensive field experience may be characterized by student participation in an activity that recurs repeatedly over an extended period of time, or an immersion experience over an extended period of time. For example, some undergraduate and graduate courses in anthropology, education, psychology, or sociology may require students to incorporate weekly participation in a community setting into instruction in the context of examining a particular social issue or problem. The immersion field experience may take place over the course of a few days, a week, month, or semester. The types of activities and contexts of interaction in field sites determine the depth of experience. While the goal of any field experience should be to increase student engagement, the intensive field experience is distinguished by in-depth experiences over an extended period of time. Short-term immersion intensive field experiences may last a few days in length.

The intensive field experience is an especially appropriate vehicle for civic engagement and social change because it affords an opportunity for sustained partnership between universities and communities, provides a context for firsthand learning about complex social issues, and is supported by a defined pedagogical strategy. The successful implementation of intensive field experiences directed toward social change efforts requires instruction that provides information in layers or stages associated with experiential education pedagogies. The intensive field experience is a suitable strategy for simultaneously fostering student learning about social change and creating social change because it facilitates learning through firsthand experience in community settings.

Social change and cultural change are endemic to human societies and the passage of time. Rapid social change is especially the case in technologically intensive and highly stratified societies. Conceptual orientations of social change may frame change as resulting from shifts in population, technology, or environment. Other conceptualizations of social change may frame change as resulting from the impact of economic, social, and political forces.

Multiple conceptualizations of social change may serve to stimulate insight and understanding in industrialized and postindustrialized nations. Because societies are constantly changing, movements of social change, whether large or small, are simultaneously influenced by and emergent as history, conflicts, environmental events, and shifts in power and resources. Over time, this history becomes increasingly distant from students who currently fill university classrooms. It is for these reasons that engaged education is an especially effective pedagogical tool for undergraduate and graduate instructions. Engaged education, as illustrated through experiential learning and intensive field experiences, offers several potential advantages.

For over a century, the university has been criticized for its intellectual distance from the struggles and challenges of everyday life. Faculty and the academy have been criticized for exploiting communities for the good of professional advancement, without reciprocal investment in the communities, which serve to generate knowledge. Engaged education is intricately linked to experiential education, intensive field experiences, and social change in four fundamental ways. Firstly, engaged education can help strengthen and empower local communities by actively using underutilized resources, assets, and knowledge for the benefit of social change. Secondly, engaged education helps to break down barriers and form relationships between institutions, who have often been perceived as hoarding knowledge and resources, and local communities. Thirdly, engaged education affords real world, problem-based learning experiences which have the potential to yield sustainable solutions. Lastly, intensive field experiences, as a conduit of engaged education, extend learning beyond the classroom and enable a deeper sense of connection between course readings and lectures and people's everyday lived experiences, which may often be rife with injustice, unequal access, and inadequate resources. Ultimately, engaged education results in a multilevel reciprocal synergy of linkages across domains, between schools and communities.

The Intensive Field Experience

The intensive field experience has two primary aims. First, the intensive field experience calls for a collaborative partnership between universities and communities, which helps to elevate knowledge and awareness of social issues, as well as to foster intellectual and civic engagement through firsthand problem-solving, solution-seeking strategies. Second, the experience extends traditional pedagogical methods, which focus on lectures and discussion of course readings beyond the physical boundaries of the classroom to contexts that support learning outside of the traditional classroom. In best-case scenarios, universities have established comprehensive centralized offices, which actively partner faculty and students with community partners

to support student placement to meet the needs of the community. However, many faculty members incorporate engaged education pedagogical strategies into instruction without the support of formal university partnerships.

There are short- and long-term intensive field experiences. Short-term experiences include one-time experiences and immersion experiences. One-time experiences are characterized by participation in events that may last in duration from a few hours to 1 day. Examples include museum visits, real-estate tours which examine property value disparities as mapped upon the racial and class stratification of place and space, or historic preservation walking tours of neighborhoods, which can be examined through a critical lens of power and narrative to determine whose story, is being told, and whose story is being erased. While these experiences may be short in duration, they have the potential to spark immediate tremendously transformational experiences for students. For example, extending classroom instruction on the economic, social, and political inequality to museum exhibits on the history of lynching in the US, or Confederate currency, can be instrumental in the learning process of aiding the understanding of the political economy, history, and social organization of race in the United States. For many students who have grown up in suburban areas, even the journey of getting to and from sites utilizing public transportation is a transformative experience; and it helps students to better understand the struggles faced by marginalized people whose movement and access to housing, employment, schooling, child care, and health care is restricted by urban transport patterns in metropolitan terrains which often leaves some populations afforded greater access than others.

Short-term intensive field experiences are learning experiences that are part of a specialized, planned event, and journeys that may take students considerable distance from the home university; so much so that either a single trip or regular, recurring travel would be logistically improbable or impossible. Field experiences of this type may take place over the course of 3–7 days. In the United States, the legacy of racial inequality and oppression is integral to understanding American history, public policy and law, as well as persistent racial disparities in education, health, and wealth. Rone (2007) describes an intensive immersion field trip to sites of protest and resistance in the American South, which were pivotal in serving as a catalyst for the US Civil Rights legislation of the 1960s that dismantled legal barriers to voting rights, as well as fair housing, education and health care access, education access. The critical pedagogical strategy of layering information was achieved by course readings, including works by James Baldwin and Aldon Morris, and films, *Bridge to Freedom*, 1965, Episode 6 of the Public Broadcasting Service's (PBS) *Eyes on the Prize* series (1987), and *4 Little Girls* (Lee, 1997). Course lectures, readings, local speakers, and films help prepare students for an intensive weekend

field experience to the Birmingham Civil Rights Institute, Sixteenth Street Baptist Church, Kelly Ingram Park in Birmingham; Montgomery; and Selma for the fortieth anniversary commemorative march of Bloody Sunday, a historic event which led to the 6 August 1965 passage of one of the most significant acts of legislation to result from the US Civil Rights Movement. Similarly, a short-term intensive field experience to the Gullah Sea Island region of the southeastern coastal US was central to courses in linguistic anthropology, African-American studies, and religion. Again, course readings and films prepared students, for intensive field experience, which helped to give students who were enrolled in the course, a firsthand knowledge about the challenges of cultural preservation in the Gullah region, and created relationships with local Gullah leaders' social movement to educate the general public and influence national preservation legislation. Intensive field experiences, both short and long in duration, are appropriate for cultural and historical preservation efforts where students are involved in conducting research, and increasing public awareness and taking potential policy decisions about preservation.

Long-term intensive field experiences recur at regular intervals over the time period of a semester or quarter. Students may work individually or in pairs at different sites. Or, depending on the site, smaller seminar-type classes, with an enrollment of less than 15 students, may work with one community in one site. The latter option presents expanded opportunities for creating a synergy between multiple issues at the same site, as well as for more closer instructor guidance. For classes in institutions where students may face transportation barriers getting to local sites, it may be easier to arrange transportation for groups of students if all students are traveling to the same site at the same time. Long-term intensive field experiences are especially appropriate for experiential learning in local communities which are in close proximity to universities. Ongoing, regularly occurring activities, such as schools and community programs or organizations, are ideal because they afford for relationship and knowledge building over time. Examples of activities include tutoring programs with elementary schools and community centers for literacy development programs, mentoring assistance with after-school and Saturday school youth development programs, or providing support by assisting social studies or science teachers to prepare students for specific research projects. Projects may also involve research and include data collection, analysis, and report writing on topics such as housing regulations for populations displaced by gentrification practices, identification of neighborhood resources to support public school students' academic success, and the membership needs of a neighborhood food coop. Semester or quarter-long intensive field experiences are especially suitable for affecting social change for core social issues such as education, housing, health, and justice.

Curriculum Development Planning and Logistics

The successful implementation of intensive field experiences requires additional time and effort for planning and incorporating stages of learning into the course curriculum, as well as the careful arrangement and orchestration of logistics to include clearances, access, admission, transportation, and, where necessary, lodging and meals. Most importantly, reflection and monitoring must be part of the ongoing process for individuals in university and community roles. In **Table 1**, the tasks associated with intensive field experiences are categorized into curriculum development and logistics for three temporal stages: prefield experience, field experience, and postfield experience. These stages are especially relevant for immersion intensive field experiences which require participants to travel an extensive distance for a period of a few days, in contrast to recurring field experiences in local communities.

Despite the ideological shift in the role of and involvement of universities in communities as partners beyond the walls of the university, for the most part, public policy and faculty still largely define research agendas. Exceptions to this include reverse research days in which community organizations are given an opportunity to present proposals for research ideas to faculty research teams. Other examples include research institutes, such as the Institute for Urban Research at Morgan State University, located in the metropolitan area of Baltimore, Maryland, USA (Rone, 2008). This institute sees its mission in addition to focusing on urban issues, as defined in part by a commitment to servicing the needs of the local community through research and intervention. In this capacity, its research staff members are able to partner with local community organizations and address complex social issues, including environmental justice, education, transportation, housing inequality, and inequalities in the juvenile justice system through integrated research methods, such as interviews, surveys, and geographical information surveys (GIS).

Summary

The university has increasingly shifted its focus on knowledge for the sake of knowledge to knowledge for the sake of the common good. Engaged education through intensive field experiences has the potential to focus on educating students who are critically engaged, productive citizens of the broader community. Engaged education, which affords firsthand experience, allows students to observe and actively work in partnership with local communities to identify and propose solutions to problems associated with inequality and the common good. These collaborations reduce barriers, socialize advocacy and

Table 1 Intensive field experiences: Curriculum development and logistics

<i>Phase</i>	<i>Tasks list</i>
Pre-field experience	<p><i>Curriculum</i></p> <ul style="list-style-type: none"> ● Incorporate related readings, films, and Internet resources into syllabus as student preparation for field experience ● Obtain and prepare for distribution as necessary any instructional materials that originate from site of study ● Develop course assignments which will help students prepare for field experience and develop student expertise in specific areas ● Incorporate relevant guest speakers into course planning ● Have in-class discussion(s) to prepare students for trip (e.g., what to expect, what to wear, local cultural and respect preferences) ● For intensive field experiences requiring long distance travel, have students prepare entries for a compendium about the trip's main focal points <p><i>Logistics</i></p> <ul style="list-style-type: none"> ● Contact site and investigate options for transportation, accommodations, meals, activities, ticket purchases, admission fees ● Create a trip information log (contact person, telephone number, fax number, email, confirmation number, fee due dates) ● Make all arrangements and follow up with vendors ● Create, distribute, and collect trip release forms (and be aware of university requirements regarding parental signatories) ● For local trips with students driving their own cars, get directions to distribute to students ● Prepare a trip information sheet for students ● Administer any baseline or pre-test instruments
Field experience	<p><i>Curriculum</i></p> <ul style="list-style-type: none"> ● For ongoing field experiences, encourage participants to maintain handwritten or electronic field notes ● Make and distribute copies of the compendium to students to read and share ● During the journey of getting to the site and during the field experience, identify relevant points that extend class instruction ● Incorporate time for reflection and dialog <p><i>Logistics</i></p> <ul style="list-style-type: none"> ● Plan for possible delays due to unforeseen circumstances in scheduling departure time for an early arrival ● Bring food and water, directions, camera, first-aid kit, change for parking meters/lots, and copies of all trip confirmations and correspondence ● Make sure all students have a contact cell number and prepare a list of all student cell numbers ● Review local cultural preferences, behaviors, and norms with students ● Leave list of contact names and emergency contact information for all trip participants with departmental office
Post-field experience/ follow-up	<p><i>Curriculum</i></p> <ul style="list-style-type: none"> ● Use an in-class free-write exercise assignment to stimulate and frame discussion about the field experience ● Provide time and space for a reflective, honest, and critical dialog between university and community partners to reflect on the progress, review community and student impact, identify needs, shortfalls, and future directions ● Require students to complete a major post-experience assignment which affords students an opportunity to synthesize course material and firsthand learning experiences from the field experience ● Follow-up on any promised deliverables to participants at field site <p><i>Logistics</i></p> <ul style="list-style-type: none"> ● Ask students to complete a post-field experience evaluation form ● Send notes and/or if appropriate small gifts of appreciation ● Follow-up with transportation, and other vendors ● Administer any post-test instruments

agency, and promote civic participation. Engaged education through experiential education and intense field experiences simultaneously fosters student learning and social change in sustainable capacity-building ways. As global inequality along with globalization increase, the demand for institutions to respond and to produce well-educated, productive graduates will increase. Engaged

education as a pathway to social change, as exemplified through intensive field experience, has many potential benefits, including benefiting local, regional, national and international communities; enhancing student learning of course information and application of abstract concepts to real-world concepts; increasing instructor effectiveness; equipping local communities with capacity-building

knowledge and resources to create sustainable change; and functioning as a critical agent of restorative justice initiatives which transform contentious community relationships into healthy, viable productive relationships.

Higher Education and Social Change in Mexico

A Mungaray, G Estrella, P Moctezuma, and M Ramírez-Urquidy, Universidad Autónoma de Baja California, Tijuana, Mexico

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Economic development – Economic growth and improvement of social welfare indicators: education, health, housing, income, poverty rate, inequality.

Economic growth – Growth in the per-capita GDP which is the ratio GDP over population.

Entrepreneurship – The concept in the most general way refers to enterprise creation, although it is frequently associated to innovation and ideas that pull the enterprise start ups, where the individual acumen, talent, and human capital play an important role.

Flexible educational practices – Off-class and off-campus learning practices based on learning-by-doing, experiential learning and situated cognition such as service learning, internships projects in enterprises, and community-based programs promoting the students abilities in the workplace.

Gross domestic product (GDP) – Value of the product and services produced in a region over a period.

Innovation – New way of doing something or 'new stuff that is made useful.' It may refer to incremental and emergent or radical and revolutionary changes in thinking, products, processes, or organizations.

Productivity – Ratio output–inputs, such as the partial indexes with respect labor and capital inputs, as well as, the total factor productivity index, which measures the ratio between output and weighted inputs.

Research and Development (R&D) – According to the OECD, it is creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture, and society, and the use of this stock of knowledge to devise new applications.

Social change – Transformation of demographic, economic, and organization patterns.

Traditional educational practices – In-class teaching methods relying on professor lectures and board (chalk-talk), active learning practices in seminar form, and role playing and simulation in control environment, including the use of technologies.

Value added – Difference between value of the product and services produced at market prices and the cost factors and materials for production.

Introduction

A structural change has occurred in Mexico since the middle of the 1980s, following the implementation of pro-market policies such as trade and capital flow liberalization, privatization, and deregulation. In order to manage this new scenario after decades of economic protectionism, the connection between higher education institutions (HEIs) and diverse social and business sectors has intensified during the past two decades, guided by the argument that higher education (HE) and increased knowledge are necessary conditions to succeed in the new economic structure. These linkages between HE and society, particularly enterprise and industry, have traditionally focused on the mutual benefits derived from high-quality research activities that address the needs of the business sector. However, this justification for linking HEIs to industry has neglected the labor-market perspective, which has the potential to be a great opportunity to connect the developing of professional human capital suited to social and business needs.

Linking the professional training processes of students enrolled in HE with community and industrial needs continues to be one of the great challenges facing the Mexican HE system (Mungaray, 1992). Currently, the non-linking is particularly pronounced in segments of the industrial structure such as micro and small enterprises, whose dynamics have also been impacted by the emergence of more competitive markets, given the liberal trade tendencies. The traditional disregard of HEI–community linkages that are based on training students in real contexts and enterprises, combined with the stagnation of certain sectors of the economy, has led to a mismatch between society's structures and needs and HEIs in Mexico. This disconnect, in turn, limits the connection of social- and business-management-related disciplines to economic development, and the enhancement of business education for social change.

A revitalized conception of the linkage between HEIs and society, which promotes the labor-market perspective and entrepreneurship, would produce a new supply of

trained social actors to support Mexican innovation and promote the growth of businesses by encouraging graduates to look for innovative ways to utilize their education within a renovated entrepreneurial environment. This perspective requires a change in the Mexican assumption that students will participate in labor markets as public or private sector employees to a more entrepreneurial lens where we expect students to become proprietors of businesses. A reorganization of Mexican HEIs, which considers the incorporation of complementary, flexible educational practices that coexist with traditional practices, accompanied by a permanent quality evaluation process, would help to build stronger and more profitable linkages between institutions and both community and the industry sectors.

Economy and Labor Market for HEI Graduates

The economic and political development in Mexico since the 1940s has brought a wide transformation in society. The great economic growth during those years, together with welfare improvement, stimulated a social mobility process, cultural progress, and political stability. Those who were able to advance during these years because of education or business opportunities became the main actors producing the constant changes in Mexican society through the rest of the century.

The outstanding economic dynamics during the period was achieved in parallel with some social and economic inequalities. The industrial structure was characterized by unequal growth and level of prosperity in its different branches, and even great disparities among the different types of activity within a branch. This process generated the coexistence of modern and backward productive sectors.

Fast demographic growth and the industrial and urban concentration in the principal cities stimulated the demand for qualified professionals to fulfill the requirements of modern industrial sectors of the economy. In the middle of the 1970s, the student population spread among distinct fields, negatively impacting upon the quality of service of HEIs due to improvised institutional management and unbalanced student concurrency (Moctezuma, 2003).

The idea of industrial development at the beginning of the 1980s included policies to protect national corporations from international competition, major stimulus for technology imports, and an excess of regulations. These policies inhibited the links between academic centers and industrial development, the national spread of the learning ability to encourage private investment in research and development leading to technological innovations inside the enterprises, and the organization of HE as an important support for national entrepreneurship (Pallán, 1995). Consequently, the economy lost the capacity to generate

an entrepreneurial base and professional employment at the pace required by the alumni from HEIs.

The liberal economic and trade policies were aimed at transforming the different sectors of the economy by generating an environment of competition that would stimulate productivity and quality in order to be competitive. The development of Southeast Asian countries influenced this vision by demonstrating the possibility of building competitive, dynamic employment and growth through this path (Hobday, 2003). However, the business dispersion in the different economic sectors in Mexico limited the scope of these general policies of economic promotion, which have failed to provide differentiated incentives to different firms and industrial sectors.

From the perspective of the labor market, the underemployment of professionals and the consistent underestimation of schooling years has created the scenario to put HE, particularly the public system, at the center of a social discussion questioning its pertinence given its functions. Because of the structure of the Mexican HE system, which responded to the 1917 Mexican Constitution's promises of political stabilization, economic development, and social change, policymakers have insisted on the need for HEIs to respond to government development initiatives; provide the business sector with professionals and qualified technicians; and fulfill societal expectations, which consider university degrees indicative of social mobility (Lorey, 1993).

Demographic Structure and Employment Trends

Mexico is one of the most populated countries in the world, although the current demographic dynamics are substantially lower as compared to the 1960s and 1970s. During the decade between 1995 and 2005, the population in absolute values has gone from about 91 million to more than 103 million people, with a falling annual average rate of change of 1.7% and 1.2% in the period 1995–2000 and 2000–2005, respectively (**Table 1**). Nevertheless, the particular dynamics of some regions recall old patterns of demographic concentration in selected cities and poles, their vitality fundamentally associated with a particular economic vocation. Thus, some of the regions with above-average population growth are associated with the expansion of manufacturing and maquiladora industry derived from either their outward orientation or their vicinity to dynamic markets such as populated regions in central Mexico or the northern states bordering the United States. This is the case of some traditional industrial poles such as Nuevo Leon, whose growth rate increased even more than that in the first half of the decade, and the states of Mexico and Puebla, which had declining growth rates that were, nonetheless, above average. More recently,

INEGI. XII Censo General de Población y Vivienda 2000.

INEGI. I Conteo de Población y Vivienda 1995.

emergent industrial areas are included in this group, such as Baja California and Queretaro, which have the highest population expansions, although the former had a declining rate. The counterparts to regions with demographic expansion are those consolidating or emerging as service economies, perippled fundamentally by tourism activities. This is the case of the regions with highest expansion, Quintana Roo and Baja California Sur, and others with lower rates, though higher than average, such as Chiapas and Colima.

The population-expanding regions constitute two-fifth of the Mexican states, which are concentrated areas and are increasing their share in the demography. The other regions are either in a steady state or are declining in terms of their share of total population, including traditionally highly crowded regions such as Mexico City and

the states of Veracruz, Jalisco, Guanajuato, and Michoacán, among others.

The regional demographic dynamics illustrated above is reflected in employment patterns by sector, broadly classified into primary, secondary, and tertiary activities, which mainly include agriculture and mining in the first group; all kinds of manufacturing activities in the second group; and commerce and all types of services in the tertiary group.

If the analysis goes back to the 1970s, the figures then show an economy dedicated mostly to the primary activities, in which about 40% of the labor force was employed (Table 2). The period from 1970 through 1990 experienced a drastic change in the employment structure by sector, fundamentally favoring the tertiary and the secondary sectors, whose rate of increase was 4.9% and 4%,

Table 2 Employment by sector 1970–2005

Source: Average Annual Growth (AAG) in percentage. From INEGI, Censos Generales de Población y Vivienda, 1970, 1990 and 2000. INEGI, Encuesta Nacional de Ocupación y Empleo for 2005 data.

respectively, far higher than the primary sector, which experienced no growth. With this, the latter sector was transformed from the greatest employer into the smallest one (22.6%) and the shares of total employment of the secondary and tertiary sectors increased from 23% and 32% to 27% and 46%, respectively. These figures are associated with urbanization trends and the rise of populated cities acting as attracting poles even before 1970, as well as the abandonment of rural areas whose population migrated to either larger Mexican cities or the United States.

The period 1990–2000 was characterized by high growth in secondary and tertiary, and low growth in primary employment, with rates reaching up to 6.7%, 10.4%, and 0.7%, respectively. This caused a share increment of the latter as compared to the former, which experienced a slight reduction. The 2005 figures confirm the earlier pattern where primary and secondary sector shares stabilize to 15% and 26%, respectively, whereas the tertiary employment share jumped to almost 58%.

The demographic trends and data on employment by sector complement each other. The particular expansion of tertiary activities, the stability of secondary sector participation, and the decline of primary activities are associated regionally with those areas expanding in population and becoming concentrated. These facts illustrate the profound economic transformations of Mexico resulting from the increasingly outward orientation of the economy and its social impact on the employment structure at all levels. The effects of the North America Free Trade Agreement (NAFTA) since 1994 are reflected by the significant growth in both the secondary and tertiary sectors in the 2000 data, although the latter also expanded its share of employment, given its extraordinary dynamics. The transformation in the Mexican economy is to be expected when regions partake in deep transformation processes. This idea is explained by Fajnzylber's (1983) comments that as the industrial structure is modernized and expands with international dynamics, the employment in primary activities tends to decline and that of industry tends to expand. With growing industrial employment, commercial and service activities accelerate, and the

employment associated with these sectors is higher and the consumption more dynamic because of the growth of distribution channels.

Industrial Structure, Employment, and Productivity Trends

The industrial sector in Mexico is officially divided into four main groups according to the number of employees and economic activity: micro, small, medium, and large enterprises (**Table 3**). The last census figures indicate that in 2003 there were 2.9 million enterprises in the country operating in manufacturing, commerce, and services, which employed more than 14 million workers (**Table 4**). During the 15-year period between 1988 and 2003, enterprise and job creation have steadily declined. In terms of enterprises, the growth rates fell from 4.46% in 1988–1993 to 1.92% in 1993–1998, and to only 0.57% in the 1998–2003 census periods, whereas in terms of job creation, these figures exhibited a decline in growth rate of 2.92%, 2.20%, and 1.46%, respectively. It seems that the overall dynamics of the economy and the strengthening of the economic opening impacted upon the performance of both indicators during the different periods: the period 1988–1993 had relative economic expansion; 1993–1998 experienced recession, implementation of trade reforms, and the start of NAFTA; and 1998–2003 was characterized by recovery, the consolidation of trade liberalization, and intensified market competition.

Three main trends in enterprise and jobs in this context have become well known. The first refers to the large

participation and growth in total enterprises and jobs in the group of micro-enterprises. These enterprises have a stable share of total enterprises, fluctuating around 95%, and an increasing share of employment, from 41% in 1998 and 44% in 2003; both indicators growing at 2.33% and 2.39% on an annual average, respectively, overtaken only large enterprises. The second trend is the extraordinary performance of enterprise start-ups and job creation by large enterprises, where both variables grew 2.88% and 2.58%, respectively, during 1998–2003, well above the overall figures. Although the share in total enterprises remained stable during the period analyzed (0.3%), the jobs provided by this segment of large firms increased substantially from 25% and 21% in 1988 and 1993, respectively, to 28% in 2003, transforming this group of enterprises, which are mainly foreign, into the second largest job provider. The third trend is the relatively poor dynamics of small and medium enterprises in terms of firms and employment, whose rate of growth are below average (**Table 4**). After reducing its share of total businesses from 3.8% to 3.0% in the decade from 1988 to 1998, and recovering to 3.7% in 2003, the small enterprise segment nonetheless reduced its share of jobs from 14% in 1998 to 12% in 2003. During this period, the medium enterprise segment remained invariant in terms of participation in the overall industrial structure with a figure around 1%, but suffered a drastic decline in job creation, which reduced participation from 20% in 1998 to 15%. Hence, the segment of small and medium enterprises, which are primarily domestic, have seen their importance as job providers fall from 34% in 1998 to 27% in 2003.

The performance in terms of value-added generation has favored the large enterprise segment since it has increased unevenly during the period at 2.12% on average, increasing its share in total value added from 51% in 1988 to 56% in 2003. The reduction in the participation by other groups is variable; the micro-enterprise group exhibits the most pronounced changes from 15% in 1998 and 24% in 1993 and 1998, to 15% in 2003. The small and medium enterprises exhibited less drastic fluctuations, yet their share reduced to 10% (from 11% in 1998) and 20% (down from 23% in 1998), respectively, by 2003. With this, the productivity performance as measured by the value added per enterprise and per worker has reduced, on average, to 0.47% and 0.35%, respectively, for all enterprise sizes during the period of analysis (1988–2003; **Table 4**). It is noted that the medium and large groups of businesses, large enterprises in particular, reverted to this negative trend in productivity indicators by experiencing increments during 1998–2003, which may suggest a recovery from the 1994 crisis and adaptation to more competitive markets after NAFTA. The micro and small enterprises appear to have struggled in terms of value-added generation and productivity under these circumstances, since they exhibit either great negative changes

(micro-enterprises), or practically no growth (small enterprises), and the highest productivity losses.

The classification of industry by enterprise size during 1988–2003 illustrates the great disparities in terms of dynamics and potential among the enterprises. There is a huge concentration of income in medium and large enterprises, where no more than 1.4% of enterprises generate up to three-quarters of the value added and a disproportionate share of entrepreneurial activity, since millions of smaller enterprise owners and self-employed, who comprise more than 98% of the total enterprises, generate the remaining share. Hence, the data exhibit the importance of designing policies to support smaller enterprises in overcoming their constraints, and which consider the importance of linking small enterprises with larger enterprises as suppliers in building productive chains to optimize their great potential (Humphrey and Schmitz, 2002), and help large enterprises to take advantage of their flexibility.

In this context, a realistic educational policy would contribute by generating research and encouraged learning about smaller enterprises through suitable academic programs designed to support their competitive ability, as well as promote entrepreneurial training (Mungaray, 2002). This requires classification of businesses in government policies and promotion activities organized by development agencies. As Sylos (1993) has shown, industrial reorganization programs have limitations that are different from those of enterprises: while large enterprises encounter more challenges because of their size, small enterprise constraints are associated with the availability of qualified workers.

The Challenge of HEIs and Community Linkages in the Twenty-First Century

Linking HEIs and society has been considered a strategy for development. Consequently, education, science, and technology policies must collaborate closely with all the economic sectors: industrial, commercial, and service (Mungaray, 2002). It is apparent that the current educational and industrial policies work without coordination, on the one hand, and lack association with priority problems related to development, on the other. In the first case, the efforts of public HEIs seem to be disassociated from those of the government, because the organizations created to promote those linkages have been distant from scientific and technological development centers. In the second case, the concept of linkage has been mainly constructed on the premise of supporting large firms and their requirements to compete in international markets. Hence, the linkages between HEIs and government agencies, despite having different purposes, are oriented to serve the needs of larger

enterprises because of their great contribution to value added productivity and higher-paying jobs.

The scientific personnel in Mexico are considered excellent; they constitute a small community. Policies about researchers have been oriented to basically find differential mechanisms to solve their remuneration problem, to restore scientific equipment in order to avoid the brain drain from established groups, and increase the student population in scientific areas (Sarukhán and De la Fuente, 1993), and, more recently, to foster regional development activities (Rubio, 2006). The importance and capacity of these important research groups associated with the few large companies have fundamentally oriented the linkage practices to university research institutes. For instance, since the middle of the 1990s, in two of the largest Mexican public universities about 27% of the agreement or contracted linkages to enterprise have been research activities where the principal partners are large corporations such as Condumex, Resistol, Negromex, Celanese Mexicana, Bimbo, Bacardi, or Syntex, among others (Casas and Luna, 1994). The importance of research and development activities derived from modern science by large national and international corporations has also fostered private education institutions and public research centers to link research activities with large Mexican firms since the increased trade liberalization. These illustrate how linkages have been constructed among the government, large firms, and the most important HEIs of the country. In all the cases, it is obvious that the most important initiatives came from educational authorities, the Ministry of Public Education (SEP), and the National Council on Science and Technology (CONACYT), which supported many research projects that constituted an essential base for large companies (Foro Científico y Tecnológico, 2007; Conacyt-Foro Científico & Tecnológico, 2008; OECD, 2008).

During the 1990s, the university–industry linkages were beneficial because of the agreements and contracts to directly perform high-quality research, including more regional participation, similar to the practices of other countries, where important educational and industrial leaders have achieved a convergence of interests and are now working together (Shutter and Van Alsté, 1998). It is always the case that resources are scarce and the needs are numerous, so priority allocation supported the linkage between highly prestigious research groups and large enterprises.

Discussions of the need to reconceptualize academic linkages in Mexico go back to the mid-1980s when the International Conference of Higher Education Consultants of 1986 was dedicated to evaluating the mechanisms by which HEIs support, or could support, economic development in their regional or local dimensions. The conclusions emphasized the need for HEIs to develop flexible mechanisms that would allow them to better achieve

an academic environment, and most importantly, orient research and professional training to the technological support of small enterprises (Watson and McGinn, 1987). This emphasizes of the importance of education to industrial policy, because supporting local productive systems induces industrial activity to spread in the locality. Another academic event promoting changes in Mexican academic linkages was the Perspective 2000 Forum attended by Mexican and French researchers, where the latter group emphasized the industrial structure of Mexico, showing the predominance of micro and small enterprises with traditional processes, and on the contrary, the practice of HEIs in the country having linkages with large firms. The French experience in alternative education practices, promoting the involvement of students in real contexts, where the enterprises constitute a great attractions, was relevant to the Mexican context because it allows students to become familiar with labor environments even while studying (Rubio, 1994) and because it is possible to expect students to influence their community through the socially relevant work they do (Mungaray *et al.*, 2007).

It seems clear from the perspective of industrial development of a country, which has an important though small modernised sector, that the strategy of linkages should not only be multipolar and relevant to support modernization and the competitiveness of medium and large enterprises, but also be oriented toward the entrepreneurial learning of micro and small enterprises, which offer great potential for industrial and social development because of their contribution in the industrial structure and employment, and flexibility when linked with larger enterprises. Thus, coordination between education and industrial policies was important when NAFTA started and remains one of the main challenges in reinforcing linkages between university–business–society, not only through research associated with the larger enterprises, but also by defining institutionally a linkage pattern between university and the smaller enterprises through technical assistance, productive collaboration, and the promotion of networks with larger enterprises, as practiced in developed and rapidly growing countries.

The idea of reevaluating HE to transform it to be more practical and relevant for students and pertinent for society is presented in the conclusions of the Round Table about Education and Work in the Second Educational Research International Conference. This implies that besides research and continued education, students' education through internships in small, medium, and large enterprises is also very important for better training. In fact, it is acquiring priority, given the dominant trends of the industrial structure discussed above, and the need of the productive sectors to participate responsibly in the academic sectors in the instruction of future professional employees and businessmen (Estrella and Ponce, 2006). This requires

a reevaluation of the traditional concept of excellence regarding labor criteria and students' participation, as well as the reconsideration of the relevance of practice and social context in learning, which will infuse a social sense into the professional formation (Wenger, 1998).

Thinking the Future

At the beginning of this century, educational institutions confronted the challenge of incorporating research as one of their substantive functions; currently, they confront the challenge of linking research and academic activities with economic and social development as a legitimating factor of their existence. Success in confronting this challenge can be achieved by implementing regular evaluation of study plans and programs, faculty training, and the orientation of basic and applied research toward the country's development needs.

Because academic and administrative organization of disciplines and subjects in Mexico is extremely rigid, the pressures imposed by economic and social change are motivating an intense updating of study plans and programs toward content and study methods (Mungaray and Cuamea, 1992). This evidences a social tendency to get away from traditional academic reforms and instead consider the way new actors in the shaping of professionals learn and participate. Consequently, academic reforms suitable to the requirements of the productive sector have been important, including joint guardianship stays, professional practice through learning by research, and reforms oriented to mitigate the over-specialization of some disciplines. These elements evidence intentions toward an education linked with the needs of local and regional productive sectors (Mungaray and Moctezuma, 1997; Corona, 2005).

A new academic structure is slowly emerging, organized around the development of different professionals, sustained by academic flexibility, and the institutional mobility referred to in international parameters. This is a consequence of accreditation trends observed at an international level and the linkage of the educational process with the regional productive needs, illustrating that organizational innovation in education processes can be achieved from any academic-administrative organization model (Rubio, 2006). This flexible and socially linked academic organization also requires a basic formative level and a level of co-responsible internships or training in enterprises. When considering these levels, disciplinary and professional training help to achieve quality, coverage, and expansion of the services, which help to strengthen linkages between university and jobs. Collaboration is essential in the challenging issue of orienting HEIs to serve society, and must be part of a national and regional agreement concerted with government,

enterprises, and community, inspired by the fundamental idea of linking students to the social context, the prevailing industrial structure and to entrepreneurship, to transform them into real agents of change and development.

The Changing Role of the State in Higher Education

K Gürüz, Retired Professor, Middle East Technical University, Ankara, Turkey

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The university is one of the oldest institutions in the world. It precedes the nation-state, but the creation of the modern university and national higher education systems are generally attributed to the nation-state. Thus, rather than speaking of the changing role of the state in higher education over time, one must speak of the changing role of a higher external authority as well as of what that authority was in various periods of history.

Furthermore, the role of the external higher authority must be described relative to the other major groups of actors/stakeholders that are involved in higher education governance. The latter were identified by Burton Clark in the early 1980s as the state bureaucracy, the academic oligarchy, and the market. For the purpose of this work, the term higher external authority will be used instead of the term state bureaucracy. In what follows, the term market is expanded to include the term society so that all other stakeholders are included in the analysis. With these caveats, **Figure 1** shows a modified version the triangle of coordination proposed by Burton Clark to compare national higher education systems, which are used below as an analytical framework to describe the changing roles of the major groups of actors over time.

The Medieval University

Bologna University, recognized as the first university in the world, traces its origins to 1088, when the jurist Irnerius started teaching Roman law in Bologna for a fee. One can thus argue that initially the university was a demand-driven institution structured by market forces.

As this new institution spread throughout western Europe, the need was felt for the shelter of a higher external authority for several reasons: protection against the outside (townsmen, local authorities, etc.), a source of direct and indirect funding, and a source of legitimacy. For example, the *authentica habita* of the Emperor Frederick I in 1158 provided imperial protection to students and teachers, exempted them from local jurisdiction, and guaranteed their free movement in Europe.

The first seven universities, Bologna, Paris (f. 1160), Oxford (f. 1167), Cambridge (f. 1209), Montpellier (f. 1220), Padua (f. 1222), and Orleans (f. 1235) had come into being spontaneously. These universities, in time, acquired a prestige such that they could grant teaching licenses that

were respected throughout Christendom. Toulouse was the first university to be founded by a papal charter in 1229. Medieval Spanish universities, on the other hand, were founded by royal charters; they derived their authority from the king, rather than the pope. The papal bull of 1233, which stipulated that anyone admitted to be a teacher in Toulouse had the right to teach everywhere without further examinations (*ius ubique docendi*), in time, transformed this privilege into the single most important defining characteristic of the university and made it the symbol of its institutional autonomy. Authorizing universities to grant teaching licenses that would be valid throughout Christendom without further examinations subsequently became the basis for founding charters by popes, emperors, and kings. By the year 1292, even the two oldest universities, Bologna and Paris, had felt the need to seek similar bulls from Pope Nicholas IV. Many of the later medieval universities were founded by papal charters that gave them the title of *studium generale*, and authorized them to award degrees.

The medieval university thus evolved out of the interaction between the Catholic Church, the external higher authority, and the guild(s) of teachers and/or students, that is, the academia, or the academic oligarchy in **Figure 1**. Philip Altbach has defined the medieval university as an international institution, supervised by the international authority of the Catholic Church that used a common language, Latin, to provide training to students from many countries by internationally recruited teachers who used an international knowledge base comprising books translated from Arabic and Greek.

Students from different regions were organized under nations, which then only had a geographic connotation indicating birthplaces. Nations played significant roles in the administration of many of the medieval universities, most notably in Paris and Bologna. As it is rather difficult to distinguish between teachers and students in a typical medieval university, both groups are treated under academic oligarchy in the discussion ahead.

The Catholic Church was gradually replaced as the external higher authority by the temporal authorities as represented by the emperor, king, prince, or local government. Throughout the Middle Ages, the external higher authority, be it spiritual or temporal, acted as a source of legitimacy, standard-setter, and a protector. The various charters, bulls, and edicts it issued served as a licensing, accreditation, and quality assurance mechanism. Its role as a provider of financial resources became more important

Figure 1 The triangle of coordination. The rise of market forces: lay governance and entrepreneurial university. The models indicated in the parentheses on the apexes are the author's interpretation. The original form of the triangle of coordination appeared in Clark (1983, p. 143). Its modified forms have been used by Kogan and Marton (2000) and Gürüz (2008).

as the influence of the Church waned, and the temporal authority became predominant.

The university emerged as an autonomous body corporate with the power to award degrees. By the year 1500, it had diffused to all parts of Europe, except Russia and the Balkans.

Seeking privileges from and protection by a higher authority came at a price. While all of these papal and royal charters addressed issues such as meals and lodging for students and teachers, libraries, and rights and responsibilities of teachers and students regarding matters of discipline, they also included requirements by the higher authority that pertained to academic matters, such as admission and graduation requirements, length of studies, and in some cases, even syllabi, course contents, and books that were allowed. Such charters protected the university as an institution against interference by local administrations and ecclesiastical authorities, and laid the foundations of university governance and autonomy.

From the governance point of view, the medieval university was configured on the academic oligarchy—higher external authority axis, with small roles for market and society. The rector, who was elected by peers from their own ranks, was *primus inter pares* with ceremonial, rather than executive, powers at the head of the institution. Exceptions were some universities where bodies made up of interested citizens had been put in charge by local governments in Italy and princes in Germany.

1500–1800: The Effects of the Protestant Reformation

The Protestant Reformation had three lasting effects on higher education governance:

- Universities in Protestant Europe started teaching in vernacular languages. They were soon linked with the emerging nation-states, eventually becoming absorbed within state bureaucracies. This led to the emergence of the continental European model of university governance.
- Both the Protestants and the Catholics saw opportunities in education to spread their faith. The Protestants, who viewed the university as a Catholic institution, founded new types of educational institutions of their own that became the cradles of many of today's universities and nonuniversity institutions in central and northern Europe. To counter the Reformation, the Catholics, led by the Jesuits, Franciscans, and Dominicans started opening new universities not only in Europe, but also throughout the world. The first university outside of Europe, Santo Domingo (f. 1538) in today's Dominican Republic, and the first university along the Asia-Pacific Rim, Santo Tomas (f. 1611) in the Philippines were founded by the Dominicans. Spanish colonizers, supported by the Catholic Church and the Spanish King founded universities in many parts of Latin America, where clergy and the administrators of colonial administrations were trained.
- The Calvinist Academy in Geneva (f. 1559) had a lay governing board in accordance with the Calvinist creed. This served as the prototype first for the governance of the Protestant universities in Holland and Scotland and Trinity College in Dublin (f. 1592), and later, for the American colleges of the colonial era. The dissenting academies, though short-lived, with lay governing boards and much closer ties to the community, rather than Oxford or Cambridge, influenced the structures and the governance systems of both the civic universities in England and American universities. From these historical roots, the Anglo-Saxon model emerged as a different approach to university governance, which was predicated upon the presence of lay members in the highest governing bodies of institutions.

By the end of the eighteenth century, the central state was emerging as the higher external authority, and the Church was no longer a significant actor in governance. In Russia, too, the University of St. Petersburg, which was part of the Akademia Nauk (f. 1725), and Moscow University (f. 1755) were creations of the czar.

The role of the state evolved differently in the two models of governance. In the continental European model, the state took on a regulatory role that involved issuing rules and regulations pertaining to nearly every aspect of university activities, including the appointment of professors, academic and administrative structures, curricula, graduation requirements, salaries of staff, and matters related to expenditures and budgets. On the other hand, the role of the state in the Anglo-Saxon

system evolved as steering from a distance through intermediary bodies and governing boards dominated by lay members rather than being regulatory.

1800–1950: The Emergence of the Modern University

The Université de France (f. 1806–1808), sometimes called the Napoleonic University, and Berlin University (f. 1810) were both placed directly under ministries of education. With the office of the Grand Maître at the head of the university, Université de France was, in fact, a national system of education rather than a university. Its basic features, such as the division of the country into educational zones called academies, with the rector of each *académie* acting as the chancellor of all educational institutions, including universities in that zone, exist even today in France.

Berlin University was established to revive academic life in Germany in the aftermath of the devastation inflicted by Napoleon. Initial preparations for its foundation had been carried out by von Humboldt. When it was finally established, it incorporated few of Humboldt's ideas. The kaiser appointed full professors, and the minister made the appointments at the associate professor level. Nevertheless, the principle of the unity of teaching and research advocated by von Humboldt had a lasting effect that shaped the modern university.

The ministry of education was established in Prussia in 1817. Similar ministries were founded all over continental Europe, and these soon took over both the financing and the administration of higher education. The process of secularization of higher education was essentially completed in the nineteenth century. Even church-affiliated private universities increasingly relied on the state for their finances, with only vestigial influence of religion left in their governance and curricula. In the Netherlands, for example, the law enacted in 1876 provided for public financing for all institutions, including private ones. These were the beginnings of today's government-dependent private universities.

Higher education in continental Europe came to be viewed as a purely public service to be financed exclusively from the public purse. In return, the state assumed full control of the administration of institutions by appointing a civil servant as the head of administration, such as the *kanzler* in Germany, who was not subordinate to the rector.

In this period, teachers were transformed from being members of the universitas, the guild, a collegial community of scholars, into civil servants. Higher education institutions became the main sources of manpower for the emerging bureaucracies of the nation-states. The examinations used in selecting public servants, such as the *staatsexamen* in Germany, affected curricula and assigned

to the state the role of a standard-setter. The period 1860–1930 especially saw the transformation, professionalization, expansion, and diversification of higher education itself, as also its role in nation-building and an agent for social change and mobility.

The continental European model of governance thus took shape along the state bureaucracy–academic oligarchy axis of the triangle of coordination. The state played two major roles as the major provider of funding and the regulator of processes. University autonomy naturally depended on a delicate balance between the state bureaucracy and the academia.

The evolution of the Anglo-Saxon system, especially its American variant, from the nineteenth century on, introduced the society and the market as a third group of actors in governance in addition to the state and academia. Lay members represented the former in institutional governing boards and intermediary bodies. This meant that autonomy was defined across the whole of the triangle of coordination rather than just along one of its sides.

The state at both the central and the local levels remained as a major source of funding throughout the Anglo-Saxon world, too.

The role of the state, both in the provision of part of the funds and in setting standards, however, was exercised indirectly through intermediary bodies, institutional governing boards, and external organizations. This has continued to date as a characteristic feature of university governance in the Anglo-Saxon countries.

By the second half of the nineteenth century, Germany had emerged as the academic center of the world. It was in Germany that research became an integral function of universities, and the academic profession took shape through the introduction of the research-based doctoral degree and procedures and requirements for progressing through academic ranks. It was also in Germany, where the various vocational and technical institutions of higher education that had been founded earlier were elevated to an equal status with universities, such as the *technische hochschulen* that hosted so many great scientists and served as a model for many countries.

The German research university had a profound influence on the modern American university, both in academic structure and governance. Between 1815 and 1914, there was an extraordinary migration of about 10 000 American students to Germany. As students returned from Germany and took up positions in universities, the idea of the unity of teaching and research and the German research university model permeated American higher education, effectively diminishing British influences.

In 1862, the Morrill Land Grant Act had been passed, which provided public land and federal funds for educational institutions that offered programs in liberal, agricultural, and mechanical arts. The Hatch Act of 1887 provided funds to the experimental research stations in

these institutions and set forth requirements for granting them university status. In this manner, the public state universities were born. The role of the state as a provider of funds was affirmed in American higher education, too. From then on, American higher education evolved as a market-responsive, diverse mixture of public and private institutions.

By the beginning of the twentieth century, American universities had transferred and adapted the German research university model to build the largest higher education system in the world. The German influence did not end there. The first list of accredited institutions was prepared by the American Association of Universities (AAU) in 1914, when Berlin University made it clear that it would accept students to its doctoral programs only from those institutions that were recognized as universities by the AAU. Regional accreditation boards were established by universities and colleges and their number increased rapidly. This was the beginning of institutional accreditation in the American system. State legislatures had earlier recognized the awarding of the license to practice a particular profession as the prerogative of the professional associations. This eventually led to discipline-specific, or specialized accreditation. The G I Bill of Rights of 1944 stipulated that to be eligible for financial support under that federal law, veterans had to enroll in accredited institutions of higher education. This provided another instrument for the state to steer higher education in the United States from a distance. Later federal legislation authorized the US Department of Education to supervise regional accreditation bodies, and state higher education boards to approve new programs in public institutions. Thus, another role of the state in the American system is meta-accreditation, that is, to recognize accreditors at the federal level, and a form of licensing at the state level. At the federal level, the state shares this role with the Council for Higher Education Accreditation, a private, nongovernmental national coordinating body for national, regional, and specialized accreditation.

Except for Oxford and Cambridge, the British variant of the Anglo-Saxon system differs only slightly from the American version in terms of the role of state in governance. In both cases, university heads are appointed and have strong executive powers. While governing boards of American universities in general comprise only lay members, those in British universities have internal as well as external members, with the latter category always constituting the majority. Board members are in general appointed by state governors in American public universities. Those in British universities are stipulated in their founding charters. Compared to the tightly regulated continental European institutions, British universities are considered as government-dependent private institutions.

Such charters authorize British universities to award degrees autonomously. The need to have a quality assurance

system for nonuniversity institutions was recognized early in the nineteenth century. The model for this was provided by Oxford and Cambridge universities, which gave examinations and awarded degrees, while instruction was carried out in their constituent colleges. Durham (f. 1832) and London (f. 1836) universities were founded as federal universities to function in a similar manner for the various institutions in their regions. Furthermore, professional bodies, rather than the state, have traditionally played significant roles in shaping curricula and degree requirements in regulated professions in a manner similar to specialized accreditation in the United States.

The period 1800–1950 was also a period when universities, nonuniversity higher education institutions, and the various institutional models spread to eastern and southeastern Europe, the Middle East, Africa, the Far East, Latin America, and the Oceania. The universities founded in eastern and southeastern Europe paralleled the foundation of the new nation-states in the region, and all were typically continental European in structure. Elsewhere, universities founded by colonial administrations and missionary groups in Australia, New Zealand, India, Hong Kong, Thailand, Vietnam, China, Singapore, Indonesia, South Africa, Latin America, North Africa, and the Middle East were modeled after institutions in the home country.

A point pertinent to the role of the state in higher education is that outside of Europe and North America, universities and other institutions of higher education were introduced by foreigners. Japan and Turkey were the two exceptions that willingly transplanted such uniquely Western institutions into their societies. The modern Japanese higher education system came into being with the foundation of the Tokyo University in 1887 as part of the Meiji reforms, and developed under both continental European and American influences. A university-like institution took more than half a century before it was firmly founded in 1901, which was replaced by İstanbul University in 1933 by the Republic of Turkey.

1950–1980: Massification of Higher Education

For centuries, access to higher education was a privilege for certain societal groups: first the clergy, then the children of the aristocracy, landed gentry, urban merchants, and industrialists. Enrolment ratios were barely above 1% by the turn of the twentieth century even in Europe and North America. Owing arguably to its particular features, higher education in the United States was massified – gross enrollment ratio above 15% in Martin Trow's classification – by the 1930s. This was achieved in Western Europe about 40 years later.

Following World War II, and especially from the 1970s on, demand for higher education took off worldwide as most jobs in the emerging global knowledge economy required tertiary-level qualifications. Global higher education enrolment, which was about 6 million in 1950, increased to 28 million in 1970, 68 million in 1990, and 88 million in 1997. The increase in the enrolment in developing countries was even more dramatic: from about 2 million in 1950, to 7 million in 1970, and 43 million in 1997, which accounted for more than half the global total in that year. According to 2006 the United Nations Educational, Scientific and Cultural Organization (UNESCO) statistics, the historic threshold of 100 million was passed in 2002. Global enrolment in 2004 was 132 million with 8.5 million academic staff, and the average gross enrolment ratio was 24%. This means that higher education in the world, taken as a whole, is now massified. China, with an enrolment of over 20 million students has recently taken over the United States as the largest national higher education system in the world. China and India currently account for about 25% of the global enrolment. Increasing enrolments in higher education is now an established global trend, and global enrolment is projected to double by 2025.

Peter Scott estimates that of the 1854 universities founded between 1200 and 1985, three-quarters were established since 1900, and 1101 were founded between 1950 and 1985. New types of tertiary-level institutions were founded in order to meet the demand from students with increasingly diverse backgrounds, motives, and career prospects in a cost-effective manner. These were generally more vocationally oriented and of shorter duration, such as the community colleges in the United States, the polytechnics in the United Kingdom, the *Fachhochschulen* in Germany, and the *Instituts Universitaires des Technologie* (IUTs) in France. Distance education institutions were founded in many countries, which were modeled after the British Open University (f. 1969). Thus, national higher education systems came into being, in which different types of higher education institutions with stratified missions and diversified structures coexisted. Private institutions, fully independent or government-dependent, are now parts of national systems in many countries; according to estimates by UNESCO, about a third of the students worldwide are currently enrolled in private institutions.

Scott's figures clearly show that the modern university is indeed a creation of the nation-state; this is even more so in the case of national systems of higher education. This led to increased regulation by ministries, and centralization of decision-making in many countries, as reflected in laws enacted by parliaments from the late 1960s on to the early 1980s in France, the Netherlands, Ireland, Germany, Austria, Sweden, and Spain. Guy Neave refers to this process of enacting legislation as a means of enforcing practice and implementing policy as the juridification of

higher education in Europe, whereby nearly all aspects of higher education, ranging from admission and access, curricular content, and internal governance to expenditures, were indeed regulated in detail.

1980 to the Present: Transformation to the Evaluative State and Higher Education as a Global Enterprise

Starting in the mid-1980s, patterns of higher education governance started to change radically. The main drivers of this transformation were the following:

- The changing view of higher education from a purely public service to be financed from the public purse to a semi-public service, the costs of which should be borne by all those who benefit from its outputs.
- A financial crisis resulting from increasing demand coupled with increasing costs.
- The political discourse on what the role of state in general should be in an advanced participant democracy.

Two developments in the 1980s, one in the United Kingdom and the other in the United States, had profound influences on higher education policy formulation throughout the world. The report issued by the Committee of Vice-Chancellors and Principals, known as the Jarrat Report, concluded that in order to be responsive to the needs of the market, managerial techniques had to be used in university governance, and that performance of universities had to be evaluated both qualitatively and quantitatively.

In 1980, the US Congress passed the Bayh–Dole Act, which allowed universities to patent and commercialize the results of federally funded research conducted within the university. Not only was a new source of income created for the universities, but also the ties with corporations grew stronger, and the university came to be viewed as a place that supplies commercially valuable initiatives. Perhaps as importantly, the traditional view of the products and outputs of the activities of the university as public goods began to change.

To the Jarrat Report and the Bayh–Dole Act must be added the literature that emerged, which portrayed higher education as a semi-public good with a private and a social return, rather than a purely public good.

The basic elements of the ensuing changes worldwide included the changing role of the state; new funding arrangements coupled with resource diversification, and increased managerialism in the administration of institutions. Neave refers to these changes as the transformation from the regulatory to the evaluative state. This transformation was accompanied by the introduction of the market as the supreme regulating principle of higher education.

The regulatory state prescribes the processes by which institutions function to produce outputs through an array of detailed legal instruments including laws, line-item budgets, guidelines, and rules. The evaluative state, on the other hand, sets forth institutional missions, qualitative and quantitative input, output targets, and confines itself to evaluating achievements while allowing institutions to determine their own ways of achieving those missions and targets. Among the major changes were lump-sum budgets, resource diversification through the introduction of or increase in tuition fees and provision of incentives for income generation, increased institutional powers, including professorial appointments, and discretion in financial matters.

There was little change in the United States when compared to the changes in continental Europe, Australia, and Japan. In the United Kingdom, too, the basic structure of governance remained essentially unchanged. Elsewhere, governance and funding mechanisms were radically restructured. These changes are collectively referred to as the rise of market forces in higher education, and can be depicted in Clark's triangle of coordination as a move from the state bureaucracy–academic oligarchy axis towards the

market–society apex as shown in **Figure 1**. This move manifests itself in the following ways:

- Resource diversification, with increased tuition fees, and a move from collegial structures to an entrepreneurial institutional culture.
- Spread of lay governance and strengthened institutional leadership.
- Emergence of new providers of higher education services and the blurring of the demarcation line between public and private institutions.

Tables 1 and **2**, adapted from the Organization for Economic Cooperation and Development (OECD) statistics, show the expenditure per student in higher education and the share of parents in those expenditures in the period 1990–2004 in OECD member and partner countries. There are wide cross-country variations in both indicators. In general, both the amount of money spent per student and the share of parents in expenditure have increased significantly. Tuition fees, though still controversial in many countries, are now established features of higher education governance even in continental Europe, except in Greece, the Czech Republic, and Scandinavia.

From OECD (1995–2007). *Education at a Glance*.

So are private institutions of all types, including for-profit providers, especially in countries along the Asia-Pacific Rim, Latin America, and Eastern Europe, where, in some cases they account for over half the national enrollment. All of these changes show that the role of the state as a provider of funds is diminishing, and in countries like Chile, Japan, Korea, and Indonesia private sources now account for most of the funding.

The accompanying changes in governance structures worldwide include a transfer of power to the university head and other university administrators and a loss of authority and decision-making power on the part of traditional participatory and collegial bodies. Although election of university heads continues in a number of countries, the trend seems to be moving towards appointment, often by a board with a majority of lay members. Sweden, Austria, Denmark, Norway, some of the Länder in Germany, such as Lower Saxony, and most recently Japan are countries where radical legislative changes have been introduced in that direction. In those countries where lay governance already existed, as in the United Kingdom, Australia, Sweden, and Holland, it has been strengthened.

Clark himself refers to these changes as the emergence of a new model of institutional behavior, which he calls the entrepreneurial university. As depicted in **Figure 1**, the new governance structures can also be characterized as a move away from the traditional collegial/bureaucratic continental

European model of governance to the entrepreneurial university model epitomized by American institutions.

A radical restructuring of traditional accountability structures and mechanisms accompanied these changes. From the mid-1980s on, starting in Europe, agencies and bodies with various mandates were established at the national and regional levels, which were charged with evaluating the performance of higher education institutions. Presently, there are over 100 such agencies in some 50 countries. Quality assurance and accreditation agencies and evaluation and assessment schemes are now established features of higher education governance worldwide. However, other than in the United States, and for part of the research funding in the United Kingdom, the outcomes of these practices are not yet directly tied to funding from public sources.

In summary, the emergence of national quality assessment agencies and the switch from line-item to lump-sum budgets, accompanied by strengthened role of the university head and the increased discretionary powers of the central institutional administration are basic features that characterize the transformation from the regulatory to the evaluative state.

The rise of market forces and the transformation of the role of state from regulatory to evaluative were no doubt accompanied and enhanced by the increased pace of globalization driven by rapid technological and political changes in the late 1980s and the early 1990s, and this is an ongoing process. Many view globalization as the biggest challenge faced by higher education in its history. Currently, the global higher education agenda is shaped by the following interdependent and mutually reinforcing phenomena: (1) accelerating demand, (2) demographic shift and nontraditional students, (3) the rise of market forces, (4) impact of technology, (5) new providers and increased competition, and (6) internationalization as a response to globalization.

The geographical scale of the competition for students, faculty members, and funds is now global. Competitors no longer comprise similar institutions, but include, in addition to traditional institutions, a whole array of new providers, most of which are for-profit and international, and use advanced technologies for delivery. The number of foreign students, which was 110 000 in 1950, is now over 2.7 million. Many different forms of cross-border delivery of higher education services are now available. In short, higher education is increasingly becoming a global enterprise.

The American university is emerging as the new referential model, and English is becoming the new *lingua franca*. Europe is countering this by the Bologna Process, which some regard as a more subtle and effective means of accomplishing change than legislation to make European institutions more competitive in the global higher education area/market by becoming more like American

institutions. The United States, supported by Australia, New Zealand, and Japan, much to the dismay of the global academic community, is pushing for educational services to be included in the presently stalled the General Agreement on Trade in Services (GATS) negotiations. Multilateral organizations such as UNESCO and OECD are responding by issuing codes of good practice in the cross-border provision of higher education.

Concluding Remarks: Toward a Global System with Universal Enrolment?

The new paradigms of higher education are meritocracy and entrepreneurialism rather than democracy and egalitarianism. At the national level, these changes are reflected in the form of new and more sophisticated control mechanisms. From the mid-1980s on, one-to-one control by the state and routine reporting and evaluations have been replaced by various types of quality assurance schemes, essentially adapted from the world of business. Many of the powers previously exercised by various ministries have been devolved to institutions themselves and external quality assurance agencies.

The role of the state in this increasingly global environment is becoming more complex. The international competitiveness imperative must also be recognized among the main drivers of this new approach to higher education governance, along with the transformation from the regulatory to the evaluative state and the rise of market forces globally.

According to UNESCO, a national gross enrolment ratio of 40–50% is needed for a country to be an active participant in the global knowledge economy and reap its benefits. Most Western countries have now achieved universal enrollment in higher education (gross enrolment ratio above 50%), with countries like Korea, Finland, United States, Sweden, Norway, New Zealand, and Australia now providing higher education to nearly the full age cohort. Many developing countries, on the other hand, are far from that stage, including China (19%) and India (11%), where enrolments have almost doubled in the past decade. Despite recent impressive growth rates, situation in many countries, especially in sub-Saharan Africa, remain bleak with dismal enrolment ratios of less than 5%.

Achieving universal enrolment levels worldwide is desirable for benefiting from globalization in an equitable manner. This requires more than the doubling of the current global average enrollment ratio, with the vast portion of the increase in student numbers occurring in China, India, and elsewhere in the developing world. States in the most developed countries may be required to assume additional, complex, and presently undefined roles in order to achieve a global higher education system

with universal enrolment, an international complementary role, as it were.

It appears that a fourth apex needs to be added to Clark's triangle of coordination that represents the increasingly complex international dimension of higher education.

The Role of the State in School Reform: Responding to Increasing Ethnic Diversity in Britain*

P Ratcliffe, University of Warwick, Coventry, UK

© 2010 Elsevier Ltd. All rights reserved.

Education, especially in the early years of schooling, is universally acknowledged as crucial to future life chances. Arguably, this is even more the case for children from migrant communities whose command of the locally spoken language may be poor. This article focuses on the ways in which the British government has sought to address these challenges. A focus on the period since World War II (WWII) is appropriate since, unlike many other major Western countries such as the United States, large-scale immigration (at least in the modern era) has been largely confined to the last half century. Immigration up to the late 1980s was dominated by those from the New Commonwealth and Pakistan – NCWP (Layton-Henry, 1992) and most of today's settled minority communities can be traced back to these migrant cohorts. For this reason, the article focuses principally on changes in the educational system during this period. Over the next two decades, however, the influx of migrants was much more highly differentiated, with significant numbers of refugees and asylum-seekers and, since the expansion of the European Union (EU) post-2004, large numbers of workers from Eastern European accession countries. In the concluding section of the article, we therefore reflect on the implications of these new arrivals for the school system.

The dominant theme of the article is that most central government policies have been triggered by immediate political considerations and as a result have tended to adopt an overly narrow, doctrinal approach rather than taking a broader, historical perspective. This has invariably led to short-term, and short cut, solutions to long-term, deeply entrenched problems.

The Impact of Post-War Migration

In the wake of WWII, Britain witnessed a significant rise in immigration levels (Layton-Henry, 1992; Solomos, 2003). Much of this was in response to the needs of the economy which was desperately short of labor. As a consequence of the country's colonial exploits there was, it has been argued, a ready source waiting to be tapped (Castles and Kosack, 1973). However, following the first wave of

immigration in the late-1940s represented symbolically by the docking of the S.S. *Empire Windrush* in 1948 (Phillips and Phillips, 1998), the then British government consciously steered away from recruiting colonial labor. It turned instead to eastern and southern Europe, on the grounds that these workers were more likely to be white (Carter *et al.*, 1987). Skin color therefore counted for more in the government's calculations than the fact that workers from colonized countries were much more likely to speak English and had grown up in countries heavily influenced by British colonial regimes. When it, therefore, attempted to argue that the decision was taken on grounds of culture this argument had a somewhat hollow ring to it.

This source of labor did not satisfy the voracious appetite of the post-war economy, however, and the government therefore reluctantly turned to the Caribbean and the Indian subcontinent. The impact on the education system was immediate, provoking furious debates about how it could cope with the significant influx of children who not only often had a poor command of English but were from a very different cultural background, and were non-white. The latter is important, given a considerable degree of hostility on the part of the host community towards the new arrivals, a hostility that broke out into open conflict during serious race riots in the late-1950s (Rowe, 1998; Solomos, 2003; Ratcliffe, 2004). According to the government, the solution lay in a policy of assimilation.

From Assimilation to Multiculturalism

There had been little public debate about the implications for the education system of a multiethnic school population prior to the substantial influx of migrants from the disparate societies that constituted the New Commonwealth. Now, a range of issues were raised.

The first of these was language. Many children from the Indian subcontinent did not have English as a first language. Those from the Anglophone Caribbean were seen as presenting a somewhat different problem. Many of these children spoke various forms of *patois*. Viewed through an assimilationist lens, this was most commonly regarded as an unacceptable form of English. More significantly in many ways, though, was the fact that many teachers saw its use as undermining their authority and/or evidence that black children (especially males) had

* Adapted from Ratcliffe, P. (2004). Race, ethnicity and the educational system. In *Race, Ethnicity and Difference: Imagining an Inclusive Society*, pp. 73–88. Maidenhead: McGraw-Hill/Open University Press. With permission from McGraw-Hill.

a chip on their shoulder. The accusation, as Carby (1982) suggests, is that it was being used as a mode of resistance to the disciplinary code of the institution. In other words, the children stood accused of (consciously) opting for a form of English that was incomprehensible to their teachers. It was also, of course, a potent symbol of cultural difference, and therefore implicitly a threat to the goal of assimilation.

This is also interesting in that it reflects a common theme in the characterization of black as distinct from South Asian students. Whereas the latter were, and (with the possible exception of some Muslims) still are, usually viewed as conscientious and respectful, African-Caribbeans (especially males) have been characterized as more likely to be both confrontational and to lack the necessary application to their studies. Here, there are likely to be parallels with the US educational scene, especially with regard to comparisons between urban blacks and other, more overtly aspirant and upwardly mobile, minority groups.

The second issue links directly to the migration process and the settlement patterns which accompanied it. The majority of early migrants (irrespective of ethnicity) moved into inner urban areas. This meant in effect that residential segregation was accompanied by (ethnically) segregated schooling, although precise ethnic mix and segregation level might vary significantly from area to area.

As far as the government and key educationalists were concerned both represented major problems for the system. Rather than recognizing the potential for a richer teaching environment it was seen as undermining the dominant policy paradigm: the assimilation of migrant groups. Significantly, however, high numbers in particular schools of those whose first language was not English were seen as threatening the performance of local (white) students. It could therefore be argued that the main driver of state reforms at this point was as much to defend the interests of white pupils as it was to improve the performance levels of migrants.

Extra resources were directed toward the teaching of English and a local authority with a sizable New Commonwealth population could recruit additional teachers (part-funded directly by central government). As in the United States, bussing was seen as the solution to the imbalance in the ethnic composition of school populations (Carby, 1982). As in the United States also, the latter was both extremely unpopular (perhaps especially amongst the white population) and its application rather patchy. Bussing across the city also led to objections from migrants about the disruption to their children's teaching day and many white parents were unhappy for their children to study alongside (artificially) inflated numbers of African-Caribbean and South Asian pupils. To some, influenced by stories of disruptive pupils and underachievement on the part of some migrants, there were genuine fears that their children's education would be adversely affected. To rather more, however, their stance

was laced with hostility toward the other, based on a racist world view.

It was clear by the mid-1960s that the policy of assimilation was not working (Troyna and Carrington, 1990; Mason, 2000). There was understandable resistance on the part of migrant communities to the pressure to conform to an implicitly mono-cultural model imposed by the central government (Parekh, 2000). Coinciding with the rethink of immigration policy geared to the limiting of numbers was the idea that integration did not necessarily mean assimilation. The power balance at central government level had shifted to the Left with the Labour government of Harold Wilson replacing the former Conservative administration. Key parliamentarians, such as Roy Jenkins, felt that a more liberal policy of promoting cultural diversity in an atmosphere of mutual tolerance was far preferable to attempting to coerce migrants into shedding core elements of their ethnic and cultural heritage.

The upshot of this was that cultural pluralism became the watchword in theoretical terms, the idea being that migrants would have equal access to the polity and equal citizenship rights (including, of course, education). As far as the school system was concerned this meant the introduction of multicultural education (MCE).

MCE was seen as a solution to a problem referred to earlier, namely underachievement. The latter will be seen later to have taken a highly particularistic form during this period in the sense of being both racialized and gendered, that is, being applied to black, and not South Asian children, and to young males rather than females. There were also clearly identifiable links with the Race and IQ and Bell Curve debates flourishing in the United States (Jenson, 1969; Herrnstein and Murray 1994) and replicated in the United Kingdom by Eysenck (1971). Poor performance was also blamed on pathological familial forms (such as the absent male parent), evidence of a victim blaming model based on a narrow ethnocentrism (Lawrence, 1982).

Promoting Change: MCE and Anti-Racist Education (ARE)

The idea behind MCE was that if pupils of different heritages understood more about each other's ethnic, religious and cultural backgrounds this would bring two benefits. It would result in a healthier and more productive learning environment and would bring more long-term benefits to the society as a whole. Compared with what had preceded it, this was an extremely laudable attempt to democratize the school system. It suffered from some major defects, however. By identifying culture and cultural traditions as the key barriers to the integration of minority pupils and their performance potential, the approach failed to appreciate the broader social and political significance of race and racism. In other words,

it failed to recognize the bigger picture: that an imbalance of power stemming from a white hegemony did much more to limit the potential life chances of minorities than did the latter's cultural diversity.

It could also be viewed as the easy option. It is, after all, much easier to incorporate cultural diversity into teaching than to undertake a radical overhaul of the curriculum and to rethink core aspects of school culture. In practice, the authorities that made serious attempts to embrace the new reforms endorsed variants of a policy characterized by Troyna and Ball (1985) as the "three Ss – Saris, Samosas and Steel Bands." This banality of the approach is well illustrated by the following statement from the Select Committee on Race Relations, 1968–69 and quoted by Carby:

.....much can.....be done.....to create better understanding.....of the national and cultural background of immigrants..... (thus leading the Committee to recommend that).....specific teaching about the countries from which the immigrants in a particular town come. Here material direct from those countries can be displayed in the classroom by immigrant children. Children in primary schools in Hackney or Brixton [London], for example, could be taught West Indian songs, or children in Wolverhampton are taught Indian art, jewellery and costumes. This would help bring the immigrant children into the life of the school. (Carby, 1982: 194)

Although its adherents were for the most part well meaning, in practice, it did little more than essentialize cultural difference and generate crude caricatures of Asian or West Indian culture. Radical-left critiques often saw it as essentially an exercise in social control (Carby, 1982), an attempt to lure minority children into acquiescing in their own exploitation by appearing to respond to their interests and needs. Others (on the political Right) attacked the policy from a quite different perspective, suggesting that it represented unwarranted special treatment for minorities and an unwarranted waste of public funds. In the latter respect they were presented with ample ammunition. There was much anecdotal evidence of teachers being sent on fact-finding trips to the (former) colonies to observe cultural differences for themselves. For the critics, such profligacy merely compounded concerns about the extra expense incurred by changes to curricula.

On the positive side, MCE did at least constitute an official systemic response to the increasingly diverse school population. It made a conscious commitment to respecting the belief systems of faiths other than Christianity. It also helped to bring about a greater sense of relevance to classroom discussions about geography, history, arts, music, and the media. The problem, as with the Black Studies movement in the United States, is that new teaching material was essentially tacked onto existing curricula. It therefore tended to appear as supplementary, rather than

integral, to the existing syllabus. Crucially, it was often viewed as of more relevance to (or even only of relevance to) the migrant than to the indigenous child.

The main problem, though, was that it did not address, at least directly, the main issue for schools. It assumed that racism was simply a question of ignorance: that with a concerted attempt to educate young citizens about the nature and value of cultural diversity, it would wither away. It therefore conveniently ignored the fact that racism was far too deeply embedded in common sense knowledge for this approach to bear fruit. Racism is about power relations outside the specific context of the school and the educational system. However, its effects are also in evidence within schools, with instances of insensitive, ethnocentric, and even racist behavior on the part of teachers and other staff (Mason, 2000: 71; Ratcliffe, 2004). This, combined with the ongoing debate about underachievement on the part of minority children, provided the rationale for the introduction of anti-racist education (ARE).

A further problem with MCE was that it was never adopted universally in British schools. Authorities representing the white highlands were loathe to accept that they had a problem in their area (by which they meant children from minority ethnic groups). The argument that all children need to be prepared for entry into a multicultural adult society was rarely seen as persuasive, nor was the point that areas are not hermetically sealed (as white) in perpetuity. Its application was even patchy elsewhere. Given this, and in the absence of a strong lead from government, it was never likely that ARE would gain universal approval. After all it would, if properly applied, entail a radical form of intervention into the culture and ethos of the school (as well as the curriculum).

Few authorities took a robust approach to ARE. Those which did were prone to attack from neoliberal politicians. One such authority was Brent, in north-west London. Brent became the symbol of an extremist form of intervention in schools. Cross *et al.* (1991) provide a dispassionate account of the authority's wide-ranging review of curriculum and school management. Rather than 'doing good by stealth,' Troyna's characterization of the normative process of educational system evolution, Brent undertook a root-and-branch reappraisal of the education delivered to local children. They disposed of the remnants of MCE, a process symbolized most prominently by the suspension of a universally popular head-teacher, Maureen McGoldrick, and set up what was effectively a local inspectorate to oversee the installation of teachers who were committed to ARE. The degree of radicalism, and the fact that even many South Asian and African-Caribbean parents were extremely concerned by the apparent administrative chaos, left the authority vulnerable to attack even from the mainstream (and relatively pro-ARE) media. Most notable here was a program in the long-running flagship

documentary series, *Panorama*, from the BBC in 1986. Entitled *Brent Education rules OK*, this presented a savage indictment of a school system allegedly captured, and subverted, by a small clique of left-wing ideologists determined to impose their will irrespective of opposition from the ‘voices of reason’ (including Mrs. McGoldrick and other proponents of MCE).

Some local authorities claimed allegiance to the idea of ARE, and undertook a more limited review of pedagogic practice and management style (Troyna and Carrington, 1990). Others did little more than relabel and repackage existing MCE policies. This led many commentators to argue that although very different in theory, MCE and ARE tended to differ little in practice (Carby, 1982).

A further near-fatal blow to ARE came with a tragedy in Burnage High School in south Manchester in northern England. Here, an Asian pupil was murdered in the playground by a white fellow student (Macdonald *et al.*, 1986; Troyna and Hatcher, 1992). This provoked a wave of horror, given that this was a racist murder in a school that promoted its ARE policy assiduously. As this was seen as a national test case, both the miscreant and the school’s policy were effectively on trial. The public inquiry set up to look into the broader implications of the incident deemed that the latter was also, to a large extent, culpable. MacDonald *et al.* (1989) argued that poor, dispossessed white pupils who were already devalued within the normative ethos of the school were inadvertently made to feel even more worthless by the ARE approach. Though not providing the immediate catalyst, the resulting anger was regarded to have contributed in large part to the murder. It therefore shone a spotlight on ARE and deterred other schools that might have been considering going down this route.

The Development of a National Curriculum

The election in 1979 of the Conservative government led by Margaret Thatcher also had a significant impact on the national policy context within which schools operated. Thatcher had no sympathy for the attempts to rectify the problems faced by migrant pupils, and therefore the problems faced in Brent and Burnage simply played into her hands. She and her Cabinet colleagues set about transforming the school system into one which was based around a national curriculum of core subjects such as English, math, and science. According to Troyna and Carrington (1990), the first half of the 1980s was characterized by a government preparing the ideological terrain for a radical reconstruction of the educational landscape. Left-inspired initiatives such as ARE were attacked and ridiculed and local authority education departments in major towns and cities were vulnerable to attack if

they invested in them. Although the core curriculum introduced in the Education Reform Act 1988 was to leave some space for soft subjects designed to prepare youngsters more generally for their lives after school, the bulk of a pupil’s time would be devoted to what many educationalists saw as overly academic pursuits. The government also demanded a return to traditional (i.e., more formal) teaching methods, mocking the trendy methods introduced in the 1960s.

The fear, justified as it turned out, was that many working-class pupils would feel even more alienated from school life. Levels of truancy soared and those who attended often exhibited disenchantment to the point where they were excluded from school, either on a temporary or permanent basis. This effectively left a large number of young people with no formal education.

Schools were encouraged to secede from local authority control and run their own budgets. This policy, heralded (by central government) as promising an increase in local choice and self-determination, was actually a way of undermining and disempowering local authorities. It was effectively an exercise in centralization masquerading as empowerment (Ratcliffe, 2004). Although schools could decide through their boards of governors to institute, say, forms of MCE/ARE, this was always extremely unlikely, given resource implications and the ethnic makeup of most boards (Troyna and Carrington, 1990).

Recapping Core Issues: Ethnic Differentials in Schooling

Policies such as MCE and ARE were introduced as part of a conscious effort to generate a more inclusive educational system and, as an important byproduct, to address some key ethnic differentials in experience and outcome. We now summarize the major issues under three headings: underachievement and differential performance, suspensions and exclusions, and rationing. The issue of ethnic segregation and how this might be tackled dominates current debates and will be treated as a major topic in its own right (in the next section of the article).

Underachievement and Differential Performance

The thorny issue of differential outcomes remains at the top of the public policy agenda, featuring in a recent government report (Department for Communities and Local Government, 2007) and a major national study based on a sophisticated multivariate analysis of all available quantitative data on the subject (Strand, 2008). In the context of the current article, however, it is important to recognize that the debate has a long history stretching back at least half a century. Significantly, in 1979, the then

Labour government sponsored an inquiry chaired by Anthony (Lord) Rampton. This was tasked to investigate the roots of educational underachievement, the premise being the long-held fact that young males of African-Caribbean origin performed consistently worse than those from other minorities. This had become so much a part of common-sense knowledge that it had been incorporated in the syllabi of prospective teachers, and in the process becoming a self-fulfilling prophecy. Teachers had literally been trained to observe the problem, not question it (a point of great contemporary significance (see Strand, 2008)).

Rampton endorsed the orthodox view, but argued that institutional racism was a serious problem to be addressed. This had angered the incoming Thatcher administration, which sought to argue that racial/ethnic (and even class) differentials were no longer a significant issue. Unfortunately for them, however, the race issue would not go away. Serious outbreaks of urban violence in 1980 and 1981 were deemed race riots by politicians, media, and academia alike (Phillips and Phillips, 1998; Rowe, 1998; Solomos, 2003; Ratcliffe, 2004).

Rampton stepped down as Chair, allegedly because of disagreements with the government, and the agenda was subsequently taken up by Lord Swann (Troyna and Carrington, 1990). His Commission endorsed the position on institutional racism taken by Rampton, but failed to say how schools might address the problem (apart for a number of comments on the curriculum (Mason, 2000: 73). Worse than this, it individualized what was effectively a collective problem, by endorsing the use of racism awareness training (RAT). On the basis of the rotten apple theory of racism, offending teachers would be taken out of the classroom and subjected to retraining. This is, of course, much easier to do than to address a collective institutional failure.

On the positive side, Swann championed the cause of targeted recruitment drives so as to increase the number of teachers from the minority communities. Extra resources would be devoted to this end. It also focused in some depth on the value of creating an atmosphere which emphasizes the value of cultural diversity.

Like Rampton before him, the Swann Report (1985) reiterated the facts of underachievement. As Troyna (1988) rightly points out, however, the analysis was deeply flawed. The crude label Asian was used to represent a large number of culturally and ethnically distinct migrant groups and, as if to compound the error, birthplace was used as the basis for classification. The lack of a serious analysis of the influence of social class factors also made it difficult to say how much differential educational performance could be explained by class rather than ethnicity (or, for that matter, some other factor such as gender or school attended). As Mirza (1992) points out, global data on those of African-Caribbean background

conceals marked gender differences with young females performing consistently better than their male counterparts (as they continue to do).

In fact, class background has a major influence on performance, both directly and indirectly. The middle-class child (irrespective of ethnicity) is likely to benefit both from a relatively privileged socialization and a more generously funded school outside an inner urban area. This largely explains why those defined (in conventional census terms) as Indian tend to leave school with better results than their poorer Pakistani and Bangladeshi neighbors, irrespective of gender.

The real dangers in the erroneous analysis from Swann, however, lay in its impact on those policies which sought to redress such ethnic differentials: MCE and ARE. As Troyna (1988) argues, the results seemed to justify the arguments championed by proponents of cultural deficit theory. If Asians not only performed better than black pupils, but sometimes (even) outperformed whites, then surely this casts doubt on the need for ARE (as racism would presumably also impact upon Asians)? In addition, if those from different cultural and ethnic backgrounds achieved such different results, is it wise to treat all cultures as equally conducive to educational advancement (as MCE does)?

If we look at the contemporary data on school-leaving qualifications it is clear that despite some narrowing of ethnic differentials, some major deficits remain. The lowest-performing group is made up of children of Gypsy, Traveller, and Roma origin (DCLG, 2007), explaining the formation of a number of voluntary and charitable bodies seeking to improve their lot in this respect. Working-class pupils (especially boys) of Bangladeshi and Pakistani origin continue to perform badly, but so do those of black- or African-Caribbean heritage and whites. As in the United States, some (middle class) minority groups outperform whites of a similar background.

The picture is therefore extremely complicated, but in terms of debates about performance the focus of attention is shifting somewhat toward socioeconomic class and gender. In terms of the latter, there is increasing research and comment about the often problematic relationship between ethnic/class identity, masculinity, and the educational process. In particular the suggestion is that, among some groups of boys at least, it is simply not cool to do well at school. Controversy has raged over the suggestion that black street styles stemming from phenomena, such as Gangsta Rap and Yardie culture, have not only impacted on attitudes to formal education on the part of black male youth but have also had a knock-on effect on their white peers. In other words, black subcultural forms are now often being blamed for white (working-class male) underachievement! To the extent that sections of South Asian youth are also adopting black street styles which leads to intergenerational conflict within these

communities. The effect of this is to disturb existing ethnic stereotypes that associate Asian culture with commitment to education and status enhancement via a conventional aspirational orientation.

Suspensions and Exclusions

One of the major effects of alienation brought about by poor leadership within schools and insensitive policies in the face of a polyethnic student body has been a rise in school suspensions and, more especially, exclusions. All the available evidence suggests that males of African-Caribbean origin have long been far more likely to be permanently excluded than any other group (Bourne *et al.*, 1994; Gillborn and Gipps, 1996). But there is evidence that this is ultimately the outcome of a series of rather more insidious exclusionary processes. Teacher-training folklore, as was noted earlier, has embraced the notion that these children are to be expected to underperform. This expectation (rather than evidence) has often resulted in allocation to inappropriately low streams in key subjects (Commission for Racial Equality, 1988). Role ascription, that is, applying assumed group characteristics to individuals, then often associates poor performance with resistance to the aims of the institution (the children having chips on their shoulders – c.f. earlier). Ostensibly similar behavior on the part of white, South Asian, or (say) Chinese students is much less likely to be interpreted in the same way or regarded as justifying a similar punishment (Ratcliffe, 1999).

Rationing

In Britain, the legal minimum school-leaving age is 16 (though the current government has indicated its intention to raise this to 18). Prior to leaving full-time schooling most students sit a number of General Certificate of Secondary Education (GCSE) examinations. Although formal unseen examinations are still common, much of the assessment is undertaken through written work that is not examined under such strict supervision. Crucially, teachers decide the appropriate number of subjects for which a student is registered (a potential site, therefore, for discriminatory behavior). The passing at (top) grades A*–C of five or more subjects has become the gold standard for assessing achievement at the statutory minimum school-leaving age. Schools are then ranked in league tables on the basis of the proportion of students who achieve this standard.

The importance to individual schools of obtaining a high rank in terms of their popularity and hence future financial viability means that they value their high achievers and regard so-called problem students (the less academically talented as well as the disaffected) as a threat. The impact of this is that the temptation to suspend and exclude such students has become more likely. Many prominent educationalists have contested use of the

GCSE 5 A*–C economy as a core performance indicator, principally on the grounds that it does not convey any sense of value added. In other words, it is simply not valid to use this statistic to compare the performance of poorly funded and staffed urban schools with suburban schools that can recruit a more privileged student body. Gillborn and Youdell (2000) point to a rather more sinister unintended consequence, however. As implied earlier, those students who are seen by teachers as destined to let the school down (by failing to reach the standard) may receive less attention than those considered potential achievers. Even worse, there is now effectively an incentive to exclude those considered disruptive, especially if they are likely to impinge on the performance of others. This explains why the authors refer to the rationing of education. Once again, it appears that it is male students of African-Caribbean origin who suffer disproportionately.

Alternative Educational Futures: Separatism or Diversity?

Although we have largely focused in this paper on state policies to redress underachievement, this is not intended to suggest that migrants have been passive victims of an exclusionary educational system. To counteract the latter's effects many local minority communities have developed neighborhood support strategies (usually with a rather broader educational remit than available in mainstream provision). The Saturday school movement pioneered by African-Caribbean communities around the country was already in evidence even in the 1960s (Rex and Tomlinson, 1979). Mosques, temples, and community centers have served a vital parallel function in the case of South Asians.

These developments were almost universally welcomed as a highly positive form of community self-help. The fact that they were examples of ethnically segregated schooling was not seen as a problem because this would simply supplement integrated state schooling. There has been an increasing demand over the last few years largely, though not exclusively, from Muslims for separate schooling. This is justified on religious, cultural, and pedagogic grounds. As Islam relates to a whole way of life, it is not possible to separate the public from the private domain. It is also argued that the state school system is incompatible with Islam in a number of respects, not least in the area of gender relations. More recently arguments have often focused on the obvious fact that many of Britain's schools seem to be failing their children, generating a new cohort of underachievers. Increasing pressure from the Muslim Association in Bradford led in 2000 to the establishment of Britain's first Muslim state secondary school (Wainwright, 2000). (In fact, there have long been private Islamic schools in parts of the country where these communities are

concentrated. More recently, some of these have sought state support, exploiting the apparent popularity of faith schools in government circles.)

The more general question of whether this should be seen as setting a broader precedent presented government with an extremely tricky dilemma. There have been Church of England, Roman Catholic, and even Jewish state schools in Britain for many years. It was therefore difficult to argue against the principle of faith schools. They were also proven to perform rather better than average on the government's own performance indicators. Further, in the spirit of social inclusivity and of the more participatory democracy championed, in theory at least, by Tony Blair in his period as prime minister, this seemed to be a clear case in point. The subtext was that Blair was known (not least through the choice of schooling for his own children) to support the notion of selectivity, contrary to many of those on the political Left of his party.

The position held by most traditional Labour Party supporters has long been that selection by schools based on academic or social criteria was inherently unfair. It was seen, further, as a means by which social elites reproduced themselves over generations, allowing little opportunity for upward mobility on the part of those outside these more privileged groups. Private schools, in particular, were seen as anathema to the egalitarian ideals of the Party. However, New Labour under Prime Minister Blair shifted ground somewhat much to the chagrin of those on the Left.

There were also some extremely compelling reasons why this new form of separatism might not represent a positive development. Acute spatial segregation in a small number of urban areas in England was largely responsible for a phenomenon labeled in national policy discourse as parallel lives (Home Office, 2001a, b; Cantle, 2005). Alluded to earlier, this stems from the presence of urban segregation by ethnicity and faith. The fact that many children were seen to grow up in largely mono-ethnic communities, went to segregated schools and workplaces, and did not even mix with those from other ethnic/faith backgrounds at leisure or prayer was deemed to be a major cause of urban tensions. This became even more of an issue in the wake of the urban unrest in a number of northern English towns in summer 2001 and the events of 11 September later that year (Kalra, 2003). The problem then for policy makers was how to de-segregate schools, not how to sponsor the creation of more (along religious lines). Realizing that her views would be highly unpopular with many fellow Muslims, Alibhai-Brown (2000) added to the voices of those opposing segregated schooling. Her view was that this would simply increase levels of distrust between communities and was not in the long-term interests of a cohesive, polyethnic Britain.

The government's position gradually became more equivocal. From an initial position of support for more

faith schools, ministers began to suggest that conditions might be applied prior to approval. The key argument was that school governors would not be permitted to operate an exclusivist policy with respect to those of other ethnic or faith backgrounds. In fact, a certain proportion of places would effectively have to be reserved for (in our example) non-Muslims. As to the argument that there were already many faith schools in Britain, the response was that these did not formally restrict entry to members of a particular faith community. Government ministers also suggested that, with the benefit of hindsight, the formation of such schools may not have been very wise.

Since 9/11 and the wars in Afghanistan and Iraq, there seems to have been a general change of tack by the government. Initially welcoming the celebration of difference (as well as diversity), the policy focus has shifted to modes of integration and, some commentators have suggested, even assimilation (if only by the back door). Further exacerbated by continuing flows of refugees and asylum seekers, there is a renewed emphasis on universal English language acquisition and a commitment to an (as yet ill-defined) notion of Britishness.

Concluding Thoughts: British Education Policy in the Early Twenty-First Century

Whereas, from the mid-1970s, racial equality was the keyword in British social policy discourse (including education); the focus since 2001 has gradually shifted toward the idea of promoting 'community cohesion' (Cantle, 2005). Although seen by its proponents, most notably Cantle, as a new means to the same end – equality – this is highly debatable. Furthermore, despite many protestations to the contrary the agenda has been driven largely by the Muslim question: in other words, how can Britain respond to those (sections of the) Muslim population who appear disenchanted by contemporary Western cultural norms and the geopolitical strategies of most Western nations? More pejoratively, radical Islam is viewed as evidence of an enemy within, the archetypal other. Cohesion is therefore driven more by a concern for social order than by a commitment to generate a more inclusive and equitable society. In terms of schooling, there are two core strands to this. One relates to segregation by faith/ethnicity and how to minimize it. The other concerns how schools might modify their pedagogical approach and normative value systems to promote cohesion.

As noted earlier, residential segregation on the basis of faith and ethnicity, although a relatively minor issue in the United Kingdom relative to the United States and a number of other Western societies, can and does generate parallel demographic profiles in schools (i.e., high concentrations of certain groups in particular localities). This phenomenon is then at times magnified by what has

been characterized by some writers as ‘white flight’ – white parents opting to send their children to a school in which white pupils predominate.

Current cohesion policies rely largely on selective bussing to facilitate special interschool events based on sporting or other activities. With wider demographic changes across urban Britain, however, certain areas have been presented with a unique opportunity to tackle the problem by deploying a far more radical solution. This involves razing to the ground all or most existing schools in a local authority area, and building entirely new schools in localities that are known to appeal to those from all communities, irrespective of ethnic and faith background (Department for Communities and Local Government (DCLG), 2006). With this *tabula rasa* the theory is that a more inclusive education may be more easily achieved.

The problem is that, even where this approach is successful in generating a more balanced pupil roll, it may not in itself deal with the problem of segregation within schools. As the DCLG study referred to in the previous paragraph amply demonstrated, friendship and intraschool/college networks have thus far tended not to transcend ethnic/faith boundaries. Central government policy, however, is based on the idea that a greater level of communitarianism has a better chance of flourishing in such multiethnic environments. In other words, it might ultimately serve to improve overall societal cohesion.

The quest for cohesion is seen as yet more urgent following the rapid expansion of the European Union since 2004. With ten new Accession countries, inward migration from Eastern Europe has increased substantially. More worrying for local education authorities is the fact that the impact on localities varies enormously and is highly unpredictable (both in terms of numbers and migrants’ countries of origin). This has resulted, not surprisingly, in significant pressures on certain schools required, at short notice, to add to their rolls pupils whose native language is not English. In many cases, the number of languages spoken by pupils creates major problems for schools (given the absence, in the foreseeable future, of appropriate (and substantially increased) resources).

To summarize, current national policy aims to tackle two key challenges faced by Britain’s school system:

- The need to minimize differential educational outcomes by ethnicity, faith, gender, and socioeconomic status (Cabinet Office, 2007; Department for Communities and Local Government (DCLG), 2007).
- The need to generate an educational system that works effectively both to integrate a highly diverse and rapidly changing student population and to serve the much wider social goal of achieving a more cohesive society over the longer term (Commission on Integration and Cohesion, 2007).

Glossary

Climate change – Any long-term significant change in the average weather that a given region experiences. Average weather may include average temperature, precipitation, and wind patterns. It involves changes in the variability or average state of the atmosphere over durations ranging from decades to millions of years.

Dark Green School – A school in which environment is taught, preached, and lived. This is an accreditation process initiated in the Philippines by the Environmental Education Network of the Philippines in which standards are set, and a review is undertaken to determine the level of greenness of an educational institution. The degree to which a school is committed reflects the degree it can be deemed green.

Dominion model – A model of man's way of relating to the environment characterized by the belief that man is above and apart from nature, and that his role in the world is to dominate or tame nature.

Ecosystems – The dynamic interactions between plants, animals, and microorganisms and their environment working together as one functional unit.

Enlightenment philosophy – A philosophical movement in the eighteenth century, identified with Western philosophy, which refers to the period when reason reigned supreme over mysticism and religious belief. This movement left a deep imprint in the intellectual, moral, and cultural life of the world, paving the way for a mindset of utilitarianism and human dominion over nature.

Environmental spirituality – This is also known as eco-spirituality. This is a spirituality that advocates kinship or closeness with the Earth and the natural world.

Gated suburban subdivisions – A social phenomenon in many urban and suburban places, where the rich sectors of society converge and build large and beautiful homes in exclusive subdivisions secured with high walls and a very tight security system.

Indigenous Peoples – A group of people or homogenous societies identified by self-ascription and

ascription by others, who have continuously lived as an organized community on communally bounded and defined territory, and who have, under claims of ownership since time immemorial, occupied, possessed, and utilized such territories, sharing common bonds of language, customs, traditions, and other distinctive cultural traits. Modern man can learn sustainable ways of living from the genuine Indigenous Peoples who have inhabited their territories for centuries without disturbing their ecosystems.

Judaean-Christian tradition – A term used to describe the body of concepts and values that are thought to be held in common by Judaism and Christianity, and considered by some as (often along with classical Greco-Roman civilization) a fundamental basis for Western legal codes and moral values.

Mindscape – Also worldview or paradigm, is a person's mental model of the world. It is a set of fundamental assumptions a person makes about how the world works, and his/her relationship with that world.

Paradigm shift – Sometimes known as extraordinary science or revolutionary science. It is the term first used by Thomas Kuhn in his influential 1962 book *The Structure of Scientific Revolutions* to describe a change in basic assumptions within the ruling theory of science. It is in contrast to his idea of normal science. In popular parlance, paradigm shift is a term used to denote a change in how a given society goes about organizing and understanding reality.

Sustainable development – A term coined by the group of Gro Harlem Brundtland in the book *Our Common Future*; it refers to development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs.

Transformation – A marked change, as in appearance or character, usually for the better. In this article, educational transformation refers to changes in the educational systems, content, and processes that favor a change in the mindsets of students toward a sustainable future.

United Nations decade of education for sustainable development – The 10 years from 2005 to 2014 has been declared the United Nations decade on education for sustainable development – a time when peoples around the world are asked to think about an educational approach toward a more sustainable planet Earth.

Introduction

The illiterates of the 21st century will not be those who cannot read or write, but those who cannot learn, unlearn and re-learn. (Alvin Toffler)

The world is changing very fast. Technology that is being peddled this year becomes obsolete even before one has completed payments for it on one's credit card. The irony is that with all the advances we are making in technology, we are also given the capacity to destroy the world faster. Thus, today we see a planet beset with problems in the face of this fast-paced change; environmental crisis, in particular, climate change is threatening many countries with disasters and social dislocation. Indeed, in our present world, we can no longer do things the way we used to. We have to change our ways of thinking, doing, and the way we confront present-day challenges.

Given the present situation, how do we prepare our students to face a world different from that into which we stepped after our own graduation? Is there a need to review and revise knowledge management? In the face of present cultural and societal realities, how should education be rendered?

Surely, we do not intend to graduate more engineers who will hasten the destruction of our ecosystems! Why is it then that our present graduates seem to be more interested in seeking jobs that would enable them to live in gated suburban subdivisions rather than in service-oriented professions that would satisfy both the pocket-book and the spirit? In the Philippines, many young people seek entrance into nursing or allied health professions that would ensure them job placements in other countries, such as the United States, United Kingdom, Middle East, and other more developed countries in Asia where wages would be much higher than those they would get in their own country. The worst scenario is the case of graduates in education and/or business management who acquire jobs as domestic helpers abroad. Do we want this situation to continue or worsen? Given these phenomena, educators need to review the content and process of education. What new teaching pedagogy should we employ in order to form the kind of citizen we envision for the future? What should

be included in the future curriculum and what campus culture should we develop so that we can ensure a world where people are productive, educated citizens who are positive agents of change toward a better global community?

UNESCO declared 2005–14 as the United Nations decade of education for sustainable development (ESD) saying that, with the present planetary conditions, ESD is no longer a choice but an absolute priority. In 1987, sustainable development was defined by the World Council on Environment and Development (WCED) as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” Can ESD be the key in the transformation of present societies toward a sustainable future?

Modern Society: Values and Culture

Our landscape, our seascape and our skyscape is a product of our mindscape.

What is mindscape? It is a person's worldview or paradigm; a mental model of the world. It is a set of fundamental assumptions a person makes about how the world works and his/her relationship to that world. This is usually a by-product of education, upbringing and culture – plus what the religions teach. This is called paradigm development, or the development of values that translate into culture, traditions, and mores.

In order to bring about ESD, there is a need to review the prevailing paradigms in our modern society and critically scrutinize how these paradigms somehow seep into what we teach our students, influencing their value systems, and even campus culture, thus unwittingly prodding them to a lifestyle that could threaten the Earth's ecosystems.

Thomas Berry, an American priest, cites two reasons for the shortsighted and misdirected way modern man has handled nature: (1) a lack of cosmology, that is, Father Berry says that modern people have lost a meaningful sense of identity due to the fact that they have lost their myths or their stories to account for the emergence of the world and their place in that world; and (2) the emphasis of Christian tradition on transcendence, where God is seen as separate from nature. The Christian tradition on transcendence is closely linked with the development of Western philosophy that has been dominated by the so-called Enlightenment mentality. In turn, the Enlightenment philosophy, with its proclivity toward science and industrialization, has brought about the unintended negative consequences that have been observed as detrimental to the environment. Some observers allege that the Judeo-Christian tradition beginning with the story of Genesis, in

which humankind is granted dominion over the Earth, has led civilization to its present dismal state. In its basic form, the charge is that this tradition assigns divine purpose to the exercise of virtually complete power to work human will over nature. This tenet of endowing human beings with a completely unique relationship to God, and then delegating God's authority over nature to human beings, sanctions as ethical all choices that put a higher priority on human needs and desires than on the rest of nature. Simply put, according to this view, it is ethical to make sure that whenever nature gets in the way of what humans want, nature loses.

Faced with environmental and ecological destruction, today's educators have started to reexamine this worldview. They say that the cure for the present crisis will come not only from a scientific or technological advance, but from a radical shift in philosophical outlook. This change includes rethinking metaphysical, epistemological, and political, as well as ethical concepts. It involves both personal and cultural transformations, and goes deep into the realm of values and beliefs, which others call the spiritual consciousness of humanity.

Albert Gore, one-time Vice-President of the United States stated: "The more deeply I search for the roots of the global environmental crisis, the more I am convinced that it is an outer manifestation of an inner crisis that is, for lack of a better word, spiritual. As a politician, I know full well the special hazards of using spiritual to describe a problem like this one. But what other word describes the collection of values and assumptions that determine our basic understanding of how we fit into the universe?" In his topic on environmentalism of the spirit, he adds,

the way we experience the world is governed by a kind of inner ecology that relates perceptions, emotions, thinking and choices to forces outside of ourselves. We interpret our experience through multiple lenses that focus – and distort – the information we receive through our senses. But this ecology threatens to fall badly out of balance because the cumulative impact of the changes brought by the scientific and technological revolution are potentially devastating to our sense of who we are and what our purpose in life might be. . . . To some, the global environmental crisis is primarily a crisis of values . . .

(Albert Gore, *Earth in the Balance: Ecology and the Human Spirit*, 241–243)

Given this worldview, Al Gore is calling for a new environmentalism of the spirit. Echoing these sentiments, the former Minister of the Environment of Brazil, Honorable Jose Lutzenberger, adds: "We humans find ourselves at war with the rest of creation. We must change our philosophy, our worldview; look at the planet and see it as something alive, that we humans are only part of an enormous symphony where millions of species participate. We are one

species among millions of others. Unless we realize that we are only part of a bigger system, we have no future."

In our quest for a new ethics, we look at a new metaphysics – an alternative view of reality. Viewing human beings as individuals with power over nature is the way that the dominant worldview has understood humans and broken up reality into a hierarchical pattern, but it is a dangerous and misleading metaphysics. What then, could be a reasonable model for understanding nature? It would be wise to review the different worldviews gleaned from other groups and derive from them a renewed model of conceptualizing the environment. For example, Native American spiritual teachers often tell of the importance of place to maintain one's spiritual connections to the earth. The Native American land ethic teaches that spiritual connections to the earth are born from the heightened awareness and identification that comes from staying in one place long enough to experience, learn from, and care for the spirit of the place one is in. That assumption of care and responsibility for the environment within which one lives thereby becomes natural and inevitable. The best illustration of this environmental spirit is manifested in the reply of Chief Seattle to the President of the United States of America in 1854 when he refused to sell their territory to the white colonizers:

How can you buy or sell the sky, the warmth of the land? The idea is strange to us. If we do not own the freshness of the air and the sparkle of the water, how can you buy them? . . . Every part of this earth is sacred to my people. . .

He adds:

the white man's dead forget the country of their birth when they go to walk among the stars. Our dead never forget this beautiful earth, for it is the mother of the red man . . . we are part of the earth and it is part of us. We know that the white man does not understand our ways. One portion of the land is the same to him as the next; he treats his mother the earth, and his brother, the sky as things to be bought, plundered, sold like sheep or bright bead.

The Kalingas of the Cordilleras echo the same sentiment expressed through the resistance of Makli-ing Dulag and his people when their lands were threatened by a development project of the government: "Such an arrogance to speak of owning the land, when you shall be owned by it. How can you own that which will outlive you. Only the race owns the land, because only the race lives forever."

In the Philippines, statistics report about 127 main groups of Indigenous Peoples (IPs) whose way of life manifests an environmental ethic that indicates their closeness to the environment. To them, ancestral domain is a sacred land area: God's gift to a tribe or tribal community, the source of their life where their ancestors live. Another tribe in Mindanao, the Lumads, claims that

“the reason for all this environmental degradation is that when foreigners came to the Philippines, they put God too high in the Sky.” We have suffered here because we can no longer see the sacred in the trees, flowers, and our fellowmen. It is sad to note that the IPs have been marginalized and disempowered, and are losing their lands to development aggression. Today, this is pungently observed in the brazen way some indigenous groups are forced to leave their lands to give way to mining concessions. In Southern Philippines, the tribal leader of the Subanons and his family are being persecuted due to their resistance to the mining activities of a foreign-owned company. On one occasion, he lamented,

X corporation has started its illegal operations, and has desecrated our altar, the tip of Mount Canatuan which is our most sacred place. They bulldozed the tip of the mountain, destroyed our most holy place, and in a matter of weeks, our community will be wiped out due to their mad drive for gold.

Thomas Berry put it very wisely when he stated that the “universal need at the present time is a re-orientation of the human venture toward such an intimate experience of the world around us.” He said that “a return to the mystique of the Earth is a primary requirement if we are ever going to establish a viable rapport between humans and the earth.”

So what new model should we adopt to bring about this new consciousness? This model need not be the creation of something new but a re-awakening of something very old. It involves the cultivation of an ecological consciousness – that is, an ecological, philosophical, and spiritual approach to the present crisis, that recognizes the unity of humans, plants, animals, and the Earth.

When the human subject is viewed as essentially one with the natural world, the rationale for clinging to a strict distinction between objective and subjective, between real and perceived, and between fact and value is weakened. The perception that the real world exists out there separate and apart from us would be transformed into one of we exist in the real world.” This is where an alternative metaphysics, one inspired by aboriginal spirituality, can offer a fresh insight into the meaning of man and his relationship to his environment. The following paragraphs will tackle indigenous spirituality discourse in the attempt to show how this attitude and value system has been respectful of the earth.

In ancient history, called the prehistoric hunter-gatherer and agrarian society, humans strove to live in harmony with nature; nature was all powerful. From that time to the scientific age, nature and its forces have been personified as deities to be worshipped and revered. In the horticultural societies of southeastern Europe in the period 7000–3500 BC, female deities represented the natural fertility and generative power in nature. In many aboriginal

and Native American societies, Mother Earth or the Great Mother was regarded as the beginning and end of all life on earth. The reverence for nature deities was present in the spiritual traditions of shamanism. For over 20 000 years, shamanic spiritual traditions have guided indigenous peoples throughout the world. In this holistic and integrative tradition, spirituality is not a religion with fixed set dogmas but rather, it pervades and infuses all forms of existence – human, animate, and inanimate. It informs the view that all that exists in nature is living and sacred, therefore deserving of respect and care. In sum, these nature-centered traditions emphasize human beings’ physical and spiritual connections with animate and sacred nature. As an ecological belief system, they teach the need for respect of all that exists in the natural environment as well as the need for transformational change to regain holistic balance and harmony in the cosmos. In addition to native spiritual traditions, there are also lessons that one can gain by studying other oriental-based religions that are holistic in the manner that they view man’s relationship with his/her environment.

Developing a sustainable relationship with the environment requires a deep awareness not only of the biophysical environment within which humans live but also of their own spirituality. Mankind needs to regain its sense of awe and interconnectedness with other creatures and the Earth.

Today, there is a worldwide call for a shift in paradigm by groups who believe that our present civilization could no longer afford to live with a business-as-usual attitude. They warn that doing so would lead twenty-first-century civilization to perish with the planet’s demise. In this call for a change of consciousness, educational institutions are challenged to take the lead through a review of educational contents and approaches. Educators are further urged to develop higher-order thinking skills in their students, so that graduates can wisely critique the basic structures and institutions, as well as philosophical underpinnings of the present-day order of things in society.

This call to lead in the task of transformation is indeed timely; it is about time education begins to serve as a catalyst in the change of the human mindset toward a new world order that promotes life, and not merely material or economic goods.

The Role of Education

In a world threatened by social collapse and environmental degradation, educational institutions are called upon to play a major role in the transformation of mindsets to develop citizens who are trained to think in terms of the common good. To the chagrin of some observers in Philippine society, some schools in the country have narrowed down the function of education from developing the dimensions of human potential, to the goal of simply

becoming competitive in the marketplace or bureaucratic defenders of one-sided economic policies. This concern is echoed in the call of educators to re-invent education to work toward participatory and sustainable development. This was the theme of the 11th UNESCO – Asia-Pacific Programme of Educational Innovation for Development (APEID) International Conference in Bangkok, Thailand in December 2007. APEID held a conference on Reinventing Higher Education – Toward Participatory and Sustainable Development. Beyond the Philippines and Asia Pacific, to what extent does education transcend the generation of wealth and the advancement of self-interest? It will be interesting to make a comparative analysis of this issue. Education is one of the most effective means that society possesses to shape the world of tomorrow. It plays a critical role in creating and disseminating knowledge, skills, and values for society. Colleges and universities prepare most of the professionals who develop, lead, manage, teach, work in, and influence society's institutions. Progress increasingly depends upon the products of educated minds: upon research, invention, innovation, and adaptation that schools impart to their students. As such, educational institutions have the privilege, the power, and the mandate to bring about the transformation of society.

Education therefore is called upon to guarantee that students are knowledgeable about the changes that are needed, capable of envisioning alternative futures, committed to ethical ways of achieving them, and sufficiently skilled and motivated to work actively for a better world. But for this to happen, it is necessary for educators and educational institutions to review, deconstruct, and re-construct their current mindsets. There is a saying that you cannot give what you do not possess. To become leaders in the movement toward a sustainable future, they need to understand, appreciate and own the concept of ESD.

Understanding ESD

What Is ESD?

ESD is a vision of education that seeks to balance human and economic well-being with cultural traditions and respect for the earth's natural resources.

ESD applies transdisciplinary educational methods and approaches to develop an ethic of lifelong learning; it integrates concepts and analytical tools from a variety of disciplines to help people better understand the world in which they live. It fosters respect for human needs that are compatible with the sustainable use of natural resources and the needs of the planet.

The four pillars of sustainable development have been identified as:

- society;
- culture;

- economy; and
- environment.

Sometimes only three are identified, with culture taken as part of society. The overall aim of ESD is to empower citizens to act for positive environmental and social change, implying a participatory and action-oriented approach.

Brief Background of ESD

ESD is a concept or paradigm that came about as part of an action plan formulated in the 1992 United Nations Conference on Environment and Development (UNCED) or the Earth Summit in Rio de Janeiro. Its aim was to provide a comprehensive set of principles to assist governments and other institutions in implementing sustainable development policies and programs.

The four major thrusts of ESD as articulated in Agenda 21, Chapter 36 are:

- The promotion and improvement of basic education – basic education must focus on imparting knowledge, skills, values, and perspectives that encourage and support citizens to lead sustainable lives;
- The reorientation of existing education at all levels to address sustainable development – that is, rethinking and revising education from nursery school through university to include more principles, skills, perspectives, and values related to sustainability in each of the three realms – social, environmental, and economic – as important to our current and future societies;
- The development of public understanding and awareness of sustainability, and making progress toward more sustainable societies requires a population that is aware of the goals of sustainability and has the knowledge and skills to contribute toward those objectives. Informed voting citizenry and knowledgeable consumers can help communities and governments enact sustainability measures and move toward more sustainable societies;
- Training – all sectors of the workforce can contribute to local, regional, and national sustainability. The development of specialized training programs to ensure that all sectors of the workforce have the knowledge and skills necessary to perform their work in a sustainable manner has been identified as a crucial component of ESD.

ESD means education that enables people to foresee, confront, and solve the problems that threaten life on the planet. Thus, education is that which produces professionals equipped with knowledge, competencies, and skills not only in their respective disciplines/professions, but also in valuing and taking responsibility for the need to balance economic and social progress with concern for the environment and the stewardship of natural resources.

There is, therefore, the need to reorient the curriculum. It should be reviewed, rethought, and reformed to be a vehicle of knowledge, thought patterns, and values required to build a sustainable world.

The ESD-integrated curriculum equips graduates with an understanding of the complexity and interrelationships of problems such as poverty, wasteful consumption, environmental degradation, urban decay, population growth, gender inequality, health, conflict, and the violation of human rights. ESD will look at the social transformation of the student: (1) on the personal level, ESD will be education for life; and (2) on the societal level, ESD will be education for the common good. The 2002 Johannesburg Summit stated that to promote the pillars of sustainable development, economic development, social development, and environmental safeguards should be seen as interdependent and mutually reinforcing.

Why ESD?

Modern society lives in an endangered planet. While information technology has grown very fast, the irony is that even with all our high technology, we live in a disturbed world – a violent world and we are destroying the world, our only habitat in the present. The signs of unsustainable growth are visible all around us. The economic growth rate is high, with environmental sustainability at risk. Yet, there are many unmet needs in developing countries of the South, like the Philippines, where there is evidence of high poverty levels, undernourishment, inadequate health services, high death rate, and natural disasters. There is also inadequate housing, energy, water, and sanitation. In developed countries, there is noticeable expansion of urban settlements, the proliferation of resource-intensive industries, with the accompanying hidden costs in health, increase in waste, and air pollution.

Meanwhile, the spread of the global consumer society has increased the demand for raw materials, energy, and water, taxing the finite resources of the planet Earth.

Education for the Future

Mankind needs to change the way they live, the way they consume, and the way they promote business if they want to ensure a sustainable world for the future generations. Green growth should be the policy in government, industry, and in school.

How should ESD be integrated in the school of the future?

1. Update educational practice with recent knowledge derived from research on sustainable development, while catalyzing changes in educational paradigms to

enable knowledge of sustainability to be naturally incorporated into the system and curriculum.

2. Conduct school-based longitudinal studies using student work samples to determine the impact of ESD curriculum on student-learning results.
3. Conduct research to establish and strengthen an open-ended research agenda to inform and strengthen key areas of ESD practice in teacher education, for example, in curriculum change; participatory action research; auditing of institutional resource management, and sustainability practices.
4. Conduct research to establish and strengthen a vibrant community of practice in education, which strengthens the teaching and research capabilities of educators involved in ESD.

One important component of ESD is the emphasis on the holistic approach to education. The three components of education, specifically higher education, which comprises of teaching, research, and extension, should be synergized to produce ESD. Systems thinking and systems analysis should be employed to develop a shared framework for understanding and addressing complex nonlinear systems that govern the natural world and society.

In the Philippines, the Environmental Education Network of the Philippines (EENP) is embarking on a project titled 'Institutionalizing the Dark-Green Schools Concept in the Accrediting System of Philippine Schools.' EENP is composed of 68 member institutions with the aim of promoting environmental education for sustainable development (EESD) through a strong and independent network of Philippine institutions able to provide, national and local governments, private firms, nongovernment organizations, people's organizations, and local communities, advice and expertise on environmental education.

The Dark Green School or DGS project sets standards and initiates a process to determine the level of greenness. Greening schools is a catch phrase that refers to a school committed to mainstream environmental learning and consciousness in all aspects of its educational function. The degree to which a school is committed reflects the degree it can be deemed green. A DGS, therefore, is one in which environment is taught, preached, and lived. The vision is to integrate the DGS concept in the accreditation system of the academic community of the country. The accreditation project looks into the following elements in schools: (1) school policy; (2) administration and finance; (3) academics (which includes research); and (4) outreach to see whether these contribute to the sound protection and sustainable management of the environment. This accreditation program will start with EENP schools but is expected to be adopted by the accrediting system of Philippine schools. The project is expected to encourage schools in strengthening the environmental base of all the aspects of their operation. Indirectly, it will gauge the

strengths and weaknesses of environmental education in the Philippines, and find out how these could be enhanced or mitigated.

Ultimately, the project aims at toward empowering the schools to effectively deliver EESD.

Imagine what the future could be if all educational institutions joined in this effort of transforming twenty-first-century society into sustainable communities? Imagine the kind of society that we would develop if all schools adopted ESD as their educational strategy? Students would learn the art of addressing issues as an interconnected system and not as fragmented problems with separate and often competing solutions. The curriculum would inculcate an appreciation of the human–environment interdependence, making biocentric values and ethics a central part in all the disciplines, rather than offering them as special subject only for certain courses. Education would be participative, democratic, and exploratory so as to facilitate real-world problem solving in the campus and in the larger community.

Education for a sustainable future involves a comprehensive approach to educational reform. May this generation bravely meet the challenge of transforming education toward a better world for everyone!

Glossary

Disidentification – A term used by stereotype threat researchers to describe students who no longer view academic achievement as a domain that is either important to them or their self-definition; the absence of a relationship between academic performance and self-esteem that has been associated with declining achievement from middle school to high school.

Entity theory or intelligence – The belief that intelligence is basically fixed, each person has their allotted share, and there is little they can do to increase that allotment.

Incremental theory of intelligence – The belief that intelligence is modifiable through increased effort.

Microaggressions – A subtle kind of discrimination that many people of color encounter on an almost daily basis, such as being ignored or overlooked

while waiting in line, being suspected of cheating because one received a good grade on a test, being followed or observed while in public places, or being mistaken for someone who serves others.

Model minority stereotype – A belief that Asian Americans are hardworking and intellectually gifted high achievers who are especially competent in math and science; originated in the 1960s to account for the seemingly unprecedented successful entry of East Asian immigrants into mainstream American society.

Oppositional identity – A tendency of some adolescent of color to show relative indifference, or even disdain toward achievement behaviors that are valued by the larger society because they are perceived as threatening to one's social identity.

Stereotype threat – The awareness that individuals have about negative stereotypes associated with

their group; in the achievement domain, it has been applied to African American students' awareness of the cultural stereotype associating their race with intellectual inferiority.

Motivation is the study of why people think and behave as they do. A person would be concerned with motivation if he/she were to ask, for example, why some students choose tasks so difficult that they are bound to fail; or why some students persist to task completion despite enormous difficulty, while others give up at the slightest provocation. Note that this focus on the 'why' or the 'why not' of achievement is quite different from the study of achievement itself. Educators sometimes confuse the topics of researchers who study motivation with the topics of researchers who study achievement and learning.

Most contemporary approaches to motivation as defined above fit within an expectancy-value framework. Motivation (e.g., choice and persistence) is determined by both the likelihood of goal attainment, which is the expectancy component, and how much that goal is desired, which is the value component. The study of expectancy addresses beliefs about ability (Can I do it?), whereas the study of values addresses preferences and desires (Do I want it?). The notions of 'can' versus 'want' closely correspond to the distinctions between aptitude and effort expenditure, which are two of the most important constructs in motivation theory and research.

In this article, the review of research on achievement motivation in children and adolescents of color is organized around overarching questions about 'can' and 'want.' With the focus on race and ethnicity, this approach differs from the general motivation literature in two ways. First, we start with the larger sociocultural context and factors unique to the everyday lives of people of color in the United States. Some of those factors are historical and structural in nature. Thus, we recognize that many racial and ethnic minority groups in contemporary America are positioned at the bottom of a status hierarchy wherein barriers to opportunity often override personal strivings for achievement. Second, we approach the study of motivation in ethnic minority youth from a social contextual perspective. We believe students' social lives and their academic lives are interrelated and that one cannot fully understand an individual student's motivation to achieve without also understanding his/her relationships with other people – in particular, what he/she thinks and feels about others and how others think and feel about him/her. The social nature of motivation is particularly important during adolescence when peer approval takes on a heightened significance.

We begin with how beliefs about ability (Can I do it?) are shaped by racial stereotypes about intelligence, students' implicit theories about intelligence, and coping

with discrimination. Next, we turn to achievement values (Do I want it?) in which we focus on oppositional identity, the valued characteristics of peers, and self-affirmation. The main topics reviewed here encompass vast interdisciplinary literatures that we cannot do justice to in this article. Our goal is to use our knowledge of the topics as a framework for highlighting the unique challenges of racial and ethnic minority youth as they strive to achieve and master their environment.

Beliefs About Ability: Can I Do It?

Racial Stereotypes About Ability

Stereotypes are culturally shared beliefs, both positive and negative, about the characteristics and behaviors of particular groups. There is a great deal of research from social psychology showing that the cultural stereotypes about African Americans remain largely negative. Many studies show respondents associate being black (and male) with low intelligence, hostility, aggressiveness, and violence. The much smaller stereotype literature on other ethnic groups in the United States also portrays the more marginalized groups in a negative light. For example, cultural stereotypes of Latino youth also depict them as unintelligent and with little personal ambition (e.g., Kao, 2000).

African Americans and stereotype threat

Research on stereotype threat (Steele, 1997) has provided important insights into the negative consequences of racial stereotypes about intelligence. Stereotype threat is the awareness individuals have about negative stereotypes associated with their group. Although considered to be a general psychological state applicable to any negative group stereotype, the construct originated in the achievement domain and it has been applied to African-American students' awareness of the cultural stereotype associating their race with intellectual inferiority; this awareness can be quite debilitating, especially for those African-American students who are invested in doing well in school. For example, in a series of studies with black and white students attending Stanford University, Steele and colleagues found that black students performed more poorly than whites on standardized test items when they were told the test was of a diagnostic nature to test their abilities. When the studies told the test was a problem-solving activity unrelated to ability, there was no difference in the performance of the two racial groups. In ability-related contexts, therefore, what became threatening for black students was the fear that they might confirm the stereotype or that they might be judged by others based on that stereotype. Stereotype-threatened students are often dividing their attention between the task itself (e.g., taking a Scholastic Aptitude Test (SAT)) and ruminating about the meaning of their performance (e.g., what

does this say about me or about members of my racial group?). Such ruminations have been shown to arouse anxiety as well as deplete the executive resources needed to do well on academic tasks. Furthermore, it is not necessary that a student should endorse the stereotype – mere awareness of its existence is sufficient to activate threat.

Stereotype threat researchers have documented two motivational consequences of the anxiety associated with thinking about race and intelligence in highly evaluative achievement contexts (Steele, 1997). Some students may choose to work especially hard as a way of disconfirming the stereotype. Of course, heightened effort in the face of increasing academic challenge may be difficult to sustain and may even lead one to question the students' abilities. Stereotype threat can also have the opposite effect, causing students to minimize effort and downplay the importance of doing well in school. Steele coined the term 'academic disidentification' to describe the state of students who no longer view academic achievement as a domain that is important to them or their self-definition. Disidentification has been operationalized as the absence of a relationship between academic performance and self-esteem and it has been associated with declining achievement from middle school to high school, particularly among African-American boys. A similar process, labeled academic disengagement, occurs when students begin to discount the feedback they receive about their performance or to devalue achievement altogether. Thus, while disidentification and disengagement may be self-protecting mechanisms for coping with negative racial stereotypes, in the long run, their detrimental effects on achievement strivings will probably outweigh any short-term, self-enhancing effects.

Asian Americans and the model minority stereotype

There is also a literature on the motivational effects of racial stereotypes related to intelligence at the other end of the ability spectrum. Unlike African Americans, the cultural stereotype about Asian Americans is that they are hardworking and intellectually gifted high achievers who are especially competent in math and science. The term model minority was coined in the 1960s to capture those characteristics and to account for the seemingly unprecedented successful entry of East Asian immigrants into mainstream American society. Many studies have now documented that Asians and non-Asians alike are aware of the culturally shared association between high academic achievement strivings and being an Asian American (e.g., Kao, 2000).

While it may be more tolerable to know that one's racial group is viewed as smart and hard working rather than dumb and lazy, that stereotype also has its own set of challenges. Ethnography, survey, and experimental

research all point to psychological and emotional costs associated with living up to the model minority stereotype. Ethnographic studies, for example, detail the anxiety many Asian-American students feel when forced to cope with the perception of their group as academic superstars. Many report feeling frustrated and pressured to attain or maintain high academic achievement because of the expectations placed upon them. As one Asian-American student poignantly disclosed: "When you get bad grades, people look at you really strangely because you are sort of distorting the way they see an Asian. It makes you feel really awkward if you don't fit the stereotype" (Lee, 1994: 419).

Thus, while some African-American students worry their performance might confirm a negative stereotype, some Asian-American students worry their performance might not confirm a positive stereotype. These worries may be exacerbated among groups from Southeast Asia (e.g., Cambodia and Lao) whose immigrant experience have been quite different from those of their East Asian and South Asian counterparts. We believe coping with ability-related stereotypes in the academic domain, negative or positive, can lead to performance-avoidance goals (doing whatever it takes to conceal low ability), which have well-established negative motivational consequences.

Entity Versus Incremental Theories About Intelligence

Whether individuals are vulnerable to racial stereotypes or to other challenges to 'I can,' is in part determined by their beliefs about the meaning of intelligence. For example, does it make a difference if students view their abilities as stable and essentially beyond their control ("either you have it or you don't") or as changeable and largely determined by how much effort they exert? To address this question, Dweck proposed a distinction between individuals who hold entity versus incremental theories of intelligence (Dweck, 1999). Some individuals are entity theorists: they believe intelligence is basically fixed, each person has his/her allotted share, and there is little he/she can do to increase that allotment. In contrast, other individuals appear to be incremental theorists: they believe intelligence is modifiable through increased effort. These implicit theories have been related to a variety of achievement-related cognitions and behaviors. For example, students who subscribe to the incremental theory of intelligence prefer challenging tasks so that they can increase their ability as well as achieve greater mastery. Entity theorists, on the other hand, often avoid challenge because their primary concern is with the adequacy of their presumably fixed ability and what failure might convey about that ability.

It should be evident that the negative motivational consequences of an entity theory of intelligence resemble the

vulnerability to stereotype threat discussed above. Recognizing this overlap, a number of social psychologists have designed interventions for stereotype-threatened students that focus on changing beliefs about intelligence (Good *et al.*, 2003). In these interventions, African-American college students and middle school students, who were trained to view intelligence as malleable rather than fixed, showed significant improvements in their academic performance when compared with peers who did not receive the intervention.

Coping with discrimination

Like people who hold entity theories of intelligence, individuals of color who believe they are treated unfairly because of their race or ethnicity can lose confidence in themselves and in their ability to be self-efficacious. Perceived discrimination can occur in almost any arena. It can be blatant, intended, and obvious; or subtle, unintended, and not easy to detect. Some researchers have used the term microaggressions to capture a particularly subtle but pernicious kind of degradation many people of color encounter on an almost daily basis (Solórzano, 2000). Examples of microaggressions include being ignored or overlooked while waiting in line, being suspected of cheating because one has received a good grade on a test, being followed or observed while in public places, or being mistaken for someone who serves others.

Among the most prevalent kinds of unfair treatment reported by ethnic minority youth are those that take place in school. In their study with high school students, Fisher *et al.* (2000) created an educational discrimination index that included such items as “you were discouraged from joining an advanced level class,” “you were given a lower grade than you deserved,” and “you were wrongly disciplined or given after-school detention.” African-American and Latino students were significantly more likely to endorse these items than their white classmates. Such experiences have been linked to decreased perceptions of mastery among early adolescents of color and increased negative attitudes about school. Perceived discrimination can lead to mistrust of teachers, and to the general belief that the school rules and policies are unfair. A number of studies now document that personal experiences with discrimination in combination with racial mistrust can contribute to academic disengagement and other problem behaviors at school. The best antidote to these motivational challenges seems to be a combination of strong racial/ethnic identity and parental socialization about race. For example, when African-American youth report that their race is central to their self-concept and that parental messages communicate both racial pride and vigilance against racism, then the relations between experience with discrimination and academic disengagement are weakened (e.g., Neblett *et al.*, 2008).

To summarize, in this section we have focused on how beliefs about ability can be challenged for ethnic minority

youth. Such youth must cope with stereotypes linking race to low or high intelligence and with the widely shared perception that intelligence is a fixed entity that cannot be changed. These youth also confront discrimination, both overt and subtle, that can undermine achievement strivings. Recognizing race or ethnicity as central to one’s identity and receiving parental messages that instill pride and prepare one for racism can buffer some of the negative consequences of discrimination.

Beliefs About Effort: I Can, but Do I Want To?

We now turn to the second big construct in motivation research – achievement values. Unlike expectancy, which is largely centered around beliefs about ability, values have to do with desires and preferences and are more concerned with the perceived importance, attractiveness, or usefulness of achievement activities. Like expectancies, values have motivational significance because they guide thoughts, feelings, and behavior. For example, what we judge to be important, attractive, or useful can influence the activities we choose, how we evaluate other people and events, and our worldviews. Values are also rooted in the moral constructs of ‘ought’ and ‘should’ as illustrated by the belief that one should try hard in school regardless of one’s perceived abilities. Particularly during adolescence, effort in school is sometimes compromised because of the tension between the need to achieve and the need to belong, both of which are fundamental human motives. James Coleman, writing in *The Adolescent Society*, reminded us nearly 50 years ago that adolescents care more about being popular than about being perceived as smart and they even downplay effort in order to be liked by popular peers.

Oppositional Identity

The tension between having friends and being a high achiever can play out in particular ways for youth of color, African-American youth in particular, in the phenomenon known as oppositional identity. Oppositional identity is a construct that has emerged from anthropological analyses, which take into account the historical circumstances that have shaped the experiences of ethnic minorities in this country. African Americans are what anthropologist John Ogbu calls an involuntary minority – that is, a group that has become part of the American fabric not by choice, but as a result of slavery, conquest, or colonization (Fordham and Ogbu, 1986). One consequence of this history is that the acceptance of mainstream values of hard work and school success may be perceived as threatening to one’s social identity. Particularly during adolescence, African-American youngsters

may adopt oppositional identities whereby they show a relative indifference, or even disdain toward achievement behaviors that are valued by the larger society. Fordham and Ogbu (1986) coined the term 'acting white' to describe African-American high school students' perceptions of their same-race peers who work hard to do well in school. Case studies of youth of Mexican-descent and Asian-American youth (in part reacting to the model minority stereotype) document similar findings. While scholars disagree about the level of empirical support for the acting white construct (e.g., Tyson *et al.*, 2005), there is more consensus among researchers that many ethnic minority high-achieving adolescents experience a particular kind of conflict between their achievement strivings and their desire to be accepted by the general peer group.

The discourse surrounding oppositional identity during adolescence has remained lively, in part at least because it provides a motivational explanation for the achievement gap between black and white students. One would be hard pressed to find an article on academic motivation in African-American adolescents in the last 10 years that does not explicitly or implicitly make reference to oppositional identity. This construct has also been linked to other motivational phenomena discussed earlier in this article, such as stereotype threat and disidentification, as a way to fully capture the academic challenges that African-American students face (Steele, 1997). Note that the argument is not that talented black students, who have a strong racial identity, will devalue doing well in school. By every indication, a strong racial identity is a buffer that promotes academic engagement. Rather, the question is whether some talented students of color experience more tension as they negotiate their identities both as students and as members of their racial/ethnic group. The evidence suggests that, they do, indeed.

Characteristics of Valued Peers

Survey methods that directly ask students of color whether they value effort in school have sometimes yielded disappointing findings, in part because of the social desirability built into such questions (almost everyone agrees that effort is important). Recent motivation research has offered innovative ways that are less reactive to measure the degree to which students of color value working hard and doing well in school. For example, Taylor and Graham (2007) used peer-nomination procedures in which they asked elementary and middle school African-American and Latino youth to list the names of classmates whom they admire, respect, and desire to emulate. The rationale for these questions was that researchers can identify the characteristics of classmates whom a student admires, respects, and wants to be like, and this can tell us something about the characteristics that the student values. The researchers were particularly interested in how nominations as someone that the

nominator admired, respected, and wanted to be liked varied as a function of the achievement level of the person nominated. Taylor and Graham reported that girls of all grade levels overwhelmingly nominated high achievers as classmates they most valued, whereas boys were less likely to nominate high-achieving peers as they approached middle school. By the time African-American and Latino boys reached adolescence, they appeared to look more admiringly upon less academically inclined peers.

Such findings highlight the particular motivational challenges of ethnic minority males, a gender pattern that has not been adequately acknowledged. In mainstream gender research on motivation, a dominant theme is the heightened vulnerability of girls to motivational deficits. Some argue that gender role socialization and cultural stereotypes about women and achievement lead many girls to question their academic competence more, particularly in math to display more maladaptive reactions to failure, and to perceive more barriers to success. We believe gender analyses in motivation research may need to be reframed because it is evident that ethnic minority males (i.e., African American and Latino) are faring more poorly than females (e.g., Way and Chu, 2004). The ethnicity by gender differences increase over the school years and are particularly apparent when the measures are so-called markers of adolescent success (i.e., high school graduation) and young adult mobility (i.e., enrolment in and completion of college). Harsh disciplinary practices such as from school suspension also fall disproportionately on African-American males. These findings indicate that ethnic minority boys, more than girls, must cope in unique ways with the dual stressors of academic challenge and stereotypes about their group, and that these stressors can undermine the endorsement of achievement values.

Self-Affirmation

Self-affirmation theorists have examined how an opportunity to express one's core personal values can have positive motivational consequences. In one novel intervention, Cohen *et al.* (2009) had African-American and white middle school students choose from a set of values (including those related to achievement) the two or three that were the most important according to them and to write a paragraph about why they had selected those values. Students in the control condition wrote about the values that were least important to them. The rationale for the intervention was that reflecting on personally important values can be self-affirming and can therefore buffer some of the challenges associated with ethnic minority status. This simple intervention yielded powerful effects. African-American students in the values affirmation condition attained higher grades over the course of the school year and were actually able to reduce the achievement gap between black and white students.

Conclusions

This discussion of motivation in ethnic minority youth has focused on the challenges to expectancy and value, due in part to the structural barriers that often accompany minority status in the United States. However, it is also important to acknowledge the resilience in youth of color and their successful efforts to overcome those challenges. There are promising motivation interventions, such as those related to beliefs about intelligence and self-affirmation, which foster achievement strivings among youth at risk for school failure, just as personal characteristics such as strong racial/ethnic identity and family characteristics such as parental socialization about race, also function as protective factors.

At the institutional level, in light of challenges to perceptions of 'I can,' teachers need to be especially vigilant about not employing instructional practices that can indirectly and unintentionally communicate low-ability messages. For example, it has been documented that undifferentiated praise for success at easy tasks, unsolicited offers of help, and too much sympathy following failure can lead students to attribute their academic setbacks to low ability (Graham, 1991). Furthermore, altering pedagogical practices to be more effort oriented rather than ability oriented can have an immediate impact on students' motivation, even among those who are highly identified with the achievement domain. Cohen *et al.* (1999) found that African-American college students displayed more subsequent task motivation when feedback about poor performance was accompanied by criticism and communicated high expectations than when the same criticism was accompanied by general praise as a buffer. Such wise feedback can shift the attribution for failure away from low ability and toward those factors, such as lack of effort, that are under volitional control.

There is a need for alternative methods of assessing educational progress that go beyond traditional standardized testing. As revealed in research on stereotype threat, the anxiety elicited by fear of confirming negative stereotypes about race and intelligence can deplete the cognitive resources needed to do well on standardized tests. These same concerns can be raised about high-stakes testing in general, which has had deleterious effects on children of color.

Reconciling equity, assessment, and the necessity of meeting the needs of diverse learners is a complex problem with no simple solutions. As long as assessment procedures rely mainly on established tests of cognitive abilities, there will be racial/ethnic imbalances. Reform-minded educators need to develop creative ways that not only meet standards of scientific rigor and accountability but also support talented youth of all racial/ethnic groups and of all ages. A motivational approach, which focuses on the why of achievement-related behavior rather than behavior itself, can offer fresh insights into the educational challenges faced by students of color.

Affirmative Action and Higher Education in Brazil

J T dos Santos and D M Queiroz, Federal University of Bahia, Salvador, Brazil

© 2010 Elsevier Ltd. All rights reserved.

In Brazil, over the last 5 years, 51% of the public state universities and 41.5% of the public federal universities have adopted some form of affirmative action. The majority of these institutions included some seat reservations in their courses. For this reason, the seat reservations are popularly known as quota systems for students who came from the public education system, blacks (blacks and mestizos), indigenous people, and people with special disability needs. Seven public universities adopted a system of points (bonus) without indicating, like the other institutions, a percentage of seat reservations.

This article examines the implementation of quota systems in the Federal University of Bahia (UFBA). Bahia is the state with the highest percentage of black people in Brazil, where more than 70% of the population are self-declared as black or mestizo. The quota system in the UFBA indicates reservation of 43% of the vacancies in the college for students from the public education system and black students. Eighty-five percent of those vacancies are reserved for black students from public schools, and 15% are reserved for white students from public schools.

If public school students do not reach the minimum grade to obtain a seat in the university through the system of quotas, the vacancies will be filled by black students from private schools. The benefit of the quota system to private-school black students is related to the perception that the number of black students in public universities is small, mainly in the courses considered as prestigious, such as medicine, engineering, dentistry, law, and architecture.

Initially, the article compares the results of two surveys conducted by the DataFolha Institute in 2005 and 2006, which reflect the changes in perception of Brazilian people regarding affirmative action for blacks. Second, the authors present the debate on quota systems between teachers in the UFBA. The article analyzes the performance of students who were admitted by the quota system during 2 years. The goal is to show how affirmative action affected the access of black students who came from public schools and its impact on Brazilian universities. At the same time, it is argued that affirmative action must be understood in different contexts, principally in relation to other countries such as the United States and India.

In the 23rd July 2006 edition of the *Folha de São Paulo* newspaper, the Instituto DataFolha (an institute of public opinion on various issues) published the result of a survey on the quota system. The scope of the research was about

6264 people, over 16 years old. The result of the research indicates that 65% of the Brazilian population do support the adoption of quotas for black people in Brazilian universities. The supporting percentage grows to 87% when the question refers to the adoption of quotas for poor people.

Such results point to a certain dynamics in Brazilian society concerning the perception of public policies. Toward this discussion, we propose to compare both the surveys. The first one refers to the results of the survey cited above; the second to the survey denominated *Racismo Cordial* (gentle racism), conducted in 1995, by the same institute (i.e., the DataFolha) at a historical moment when there was no adoption or discussion of the quota system in Brazilian public universities. The comparison between these two surveys shows the changes that occurred in the perception of the Brazilian people about public policies targeting underrepresented sectors of the population.

In the 1995 survey, a question was formulated on reservation of seats for blacks in the field of education and the labor market. The results showed that 49% of the interviewees disagreed and 48% agreed with the quota proposal. Among men, the percentage of blacks and mestizos who disagreed was different by one point percentage (47% and 48%). The proportion for whites was much higher – 53%. Among women, the rejection percentage was also high and it varied in racial terms, more than among men (40% among blacks, 46% among mestizos, and 58% among whites).

Education and family income are also variables that are important for the comparison to the 2006 survey. The disagreement toward the seat reservation increased with the interviewees' level of education, especially among those who had completed a high school level and those who had completed a degree. Among the latter, 67% of interviewees who were self-designated as white were against the proposal. Among blacks and mestizos, the proportion was even higher – 68% and 76%. When it came to the issue of family income, the rejection followed the pattern observed in the issue of education. For the individuals with higher income, the support was lower. Finally, among those who received more than minimum salaries – a value higher than \$2000 – the index of rejection was about 55% among blacks, 60% among the mestizos, and 58% among the whites (see *Racismo Cordial*, Turra and Venturi, 1995).

The results found in the 2006 survey reveal a shift in the perception of racial relations in the country: 65% of

the interviewees support the proposal. The support of quotas is observed in each and every racial group, and in the higher levels of education and income. Among those who reject the proposal, 55% have a university degree and 57% have a family income higher than ten minimum salaries. Although in a reduced proportion, the profile of those who show some resistance follows the same pattern observed in the research on *Racismo Cordial* (gentle racism): the higher the level of education and income, the higher is the rejection. In all of the racial segments, the support reaches a level over 60%; that is, the levels of rejection are low in all groups: 32% among whites and 23% among blacks and mestizos. It is important to highlight that in this dynamics of racial relations, the elements of a national and international conjuncture are present; and since the last decade, it has presented new demands, which come from the academic environment or from social movements, especially from the black awareness movement.

Since the 1990s, when proposals of affirmative action appeared on the Brazilian scene, there has been a tendency to update the history of privileges and perversions. The current rhetoric, a result of the end of military dictatorship, is necessary to establish citizenship, especially of the historically marginalized blacks, indigenous, and the socially excluded. The same rhetoric has a common denominator which appears in the media, for instance, through researches revealing the racial hierarchy among the Brazilian people. It is what is noticed when, starting from certain consensus, there is expressive racism in Brazil, not mere social prejudice of class. Some reactions even appeared against the proposals to create laws that would compensate for the countless debts owed to the Afro-Brazilian peoples.

It is important to consider the dilemma of race relations in Brazil and the United States and the Brazilian myth of racial democracy. In fact, the myth implies that the three races in Brazil – the black, the native, and the white – will live without conflicts.

Until the 1950s, racial democracy was thought of less as an ideology that is part of Brazilian society than as academic studies and official speeches; in fact this was true even in the 1960s for Afro-Brazilian and North American black intellectuals. In the 1970s, the reference takes on other colors and names: the racial democracy is referred to as a myth and identified as merely an ideology. In that process of denying racial democracy, the analytical rupture did not happen, but reflections about the racial inequalities in Brazilian society influenced political sense.

Since the 1980s, a growing number of journalists, historians, and North American social scientists have denounced the discrimination they claim to have suffered in Brazil. This was very curious since these individuals, who knew about the existence of discrimination against the blacks in the country, expressed surprise when confronted

with racism in Brazilian society. The dialogs between Brazil and the United States, therefore, will continue to be a dilemma. This is a discussion that will continue beyond the twentieth century. The official qualifying system in Brazil includes five categories for the definition of color: black, brown, white, yellow, and indigenous. The brown term refers to an individual who could be identified as mestizo in other contexts (the mixture of black with white). Black is a category that, if synonymous with black in the study of the racial inequalities, includes the sum of black and brown. It is necessary to point out that the use of the black category reflects an influence of the sociology of racial inequalities in the United States during the 1970s. (See Hasenbalg's studies, Hasenbalg (1997); on the use of the categories in Brazil, see Harris *et al.* (1993), and Telles (1995); and see also Fry (1995); Hanchard (1994); and Guimarães (1995).)

Conversely, the unequal access to Brazilian universities is one phenomenon that, only recently has attracted the attention of researchers. By the end of the 1980s, Ribeiro (1987) demonstrated that the majority of the students in a Brazilian universities were directly related to a certain family and educational heritage, mostly in the middle classes. Ivonne Maggie, at the time, pointed to this characteristic when she stated that poor students did not have access to this environment; she pointed out that to enter the university, it was necessary to have a certain level of income and cultural background (see Maggie). The research on the UFBA confirmed this analysis, revealing that traditionally, the students who had access to its courses were those whose parents had higher levels of scholarship and income, that is to say, a higher status (see Brito and Carvalho, 1978).

Until the end of the last decade, there was little information about the participation of several racial segments of the Brazilian population in higher education. From a survey done in the UFBA in 1997 and in other federal public universities in 2000, it was possible to have a first mapping of the racial inequalities that were present in universities considered to be prestigious in certain parts of the country (see **Tables 1, 2, and 3**) (see Queiroz, 2002).

These studies revealed that blacks and whites, especially those who come from the public educational system, were unequally represented in courses of great competition and high prestige, such as medicine, dentistry, law, architecture, electric engineering, computer sciences, psychology, and business administration.

By the end of the 1990s, besides a growing debate about the inclusion of black students in public universities, there were, in some federal institutions, actions surrounding affirmative action for black individuals. The Ministry of Justice determined that the directive and superior assessor posts would have a quota of 20% for Afro-descendent people, 20% for women, and 5% for physically disabled people. With resources from the

Table 1 Percentage of students in federal universities by race

Inter-American Bank of Development, the Ministry of Education has created a program called Diversity Program at University, which supports the preparatory courses for the black and indigenous people. All these actions initiated in a context marked by internal demands, which came from black activists and entities, and external demands from international organizations.

In August 2001, the 3rd International Conference on Racism, Xenophobia, and other forms of correlated intolerances, was held in Durban, South Africa. Promoted by the United Nations (UN), the conference had intense participation by entities from the Brazilian black movement, and in the months that preceded the conference, there were intense debates within the social movements about the formulation of the claims and the definitions toward the concepts of reparation.

In Brazil, the event that took place was a kind of follow-up of another event that occurred in Lagos in December 1990, when a group of intellectuals, government representatives, and leaders of other entities from all over the African continent, the United States, Great Britain, and the Caribbean, gathered to discuss the historical, legal, and moral dimensions of what reparation should be. In this meeting, an international committee was created for reparation, and in 1992, the African Union (AU), with the same objective, created a group made up of specialists and an executive secretary (see Araújo, 2001). In this period, the discussion on reparation for the blacks in Brazil reflected the proposals and the projects leading toward an indemnity to those of African descent in the country.

The Quotas in the Federal University of Bahia: Some Ethnographic Notes

Since 1998, some proposals have been introduced by the UFBA on the politics of affirmative action. In 2002, the Rectory constituted a task force for the elaboration of a proposal on strategies for social inclusion. Representatives of professors, staff, students, and the black movement participated in the task force. After a year of intense discussions, a report on the issue was presented and approved by the UFBA. In a period of 10 years, the objective is to increase the number of students from public schools, blacks and browns, and indigenous descendants in all of the courses because currently most of the students of the university come from the private system.

The proposal approved for UFBA in 2004 was marked by an initial absence of debate among professors, civil servants, and students. The task force attempted to hold several debates but was not successful. However, before the proposal could be approved by UFBA, there was a reaction via e-mail by a professor opposed to the system of quotas:

Dear friends,
the logic of the argument is impeccable. The discrimination really constitutes an element access trouble to the Higher Education. But why only solve the problem of the afro-descending ones? For the same logic, and since the socioeconomic position doesn't work as cut line, I propose immediately that others discriminated be mediated equally with: quotas of 51% for women; quotas of 4.7% to natives' descendants; quotas of 0.3% to people that suffered violence or sexual violence in the childhood; quotas of 0.8% to blind men or people with serious visual deficiencies; quotas of 2.1% to bearers of the Syndrome of Down; quotas (to be defined) for transvestites and transsexual; quotas of 1.2% to paraplegics or hemiplegics;

quotes of 0.1% to stutterers or affected people for other difficulties similar; quotas of 4.9% to vegetarians. The list certainly is not exhausting. But certainly it can be completed in the discussion process. Or will it be that it remains some common sense? Greetings,

This message provoked a great debate in the Web site of the university: The debate was marked by several opinions. Most of the professors were against the adoption of quotas for blacks and came up with the following arguments:

1. Brazil is a mestizo country;
2. the descent conception in Brazil does not resemble the United States's one-drop rule;
3. the race concept is no longer applied in the sciences;
4. the difficulty of access for blacks into universities is based on the class condition ("they are poor");
5. merit is the mark of access to the system of higher education;
6. the students in the quota system will find it difficult to study in the universities because the public schools are not good;
7. the system of quotas will result in a discriminatory system in the university;
8. quotas would be political opportunism and a demagoguery; and
9. the quota system is an imperialistic foreign proposal.

The teachers favorable to the system of quotas argued that

1. it would be a form of giving access to the black and indigenous populations to the university; and
2. it would change the color of the university in the courses considered prestigious.

An argument of a feminist was provocative:

Dear friends,

For terms certainty that it is not just treated of a defense of color privileges, it would be important that those emitting opinion against or in favor of the quotas identify themselves in color terms. I am white phenotypically and totally in favor of the politics of affirmative actions, among which is included our politics of social quotas now - of affirmative actions for no white. In fact, I should say that when reading the friends' positions (up to now, all men...) contrary the those politics, I am fearing for our conquest - the women's conquest - in relation to minimum quotas in the parties and unions. Until I can imagine the argument type that it will get up when us, women, we enter with our demands of 30% for women and black in the State legislatures, National Congress, etc. After all, the power was always in white men's hands; it is not easy to give up millenarian privileges.

The exercise of ethnography is a tradition in anthropology. How can we build an ethnography of colleagues?

That seems to be a fundamental question in attempting to understand the reactions of more than 100 professors. The anthropological exercise became difficult because the native point of view was too close for comfort. Those who were to be the subject of the study were in the same university and some were in the same departments.

The positions contrary to and in favour of the quota system in the universities do not imply there is a distinction in the scientific field, as it can be observed in Bourdieu (2000) when he argues about the meaning of scientific competition. It is not publish or perish. The scientific field is known for its constant tension, monopoly of ideas, maintenance of consolidated speeches, and disputes over current theories. It is fundamental to understand that these intellectual practices are really social in nature.

The Impact of Quota Policy

If one is to observe the origins from the schooling, the system of entering the universities with reservation has caused a great revolution in UFBA because it has provoked their most prestigious course students who come from public schools and who, at the same time, have been excluded from this space. The participation of students from the public schools, which was less than 27% in degree courses, such as medicine, architecture, law, media, dentistry, computing, civil engineering, and electric engineering, has increased extraordinarily, reaching more than the 43% of the vacancies reserved for them in the quota system.

The participation of students from public schools, at UFBA, which was around 38% before the introduction of the quota system, increased to 51% in 2005. Although it can be verified that in 2006 there was a reduction of this figure to 44.9 %, the level has stayed above the one that is intended by the quota system. In courses such as computing, civil engineering, electric engineering, and geophysics, for instance, there was a reduction of students from public schools compared to 2005, although, the quota remained the same. It is noteworthy to remember that the quota system adopted by UFBA does not imply a necessity to fill all the vacancies for, it relies heavily on student performance (**Table 4**).

Confirming the results of the previous research (Queiroz, 2003), these data show that the Brazilian public university is an extremely selective space, and that only through the adoption of specific policies of access, such as the affirmative actions directed to students from public schools, is it possible to assure them some chance to gain access. As shown in the data collected, it does not mean changes in the demands of the examination to get into the university - the vestibular - or the triviality of the teaching system as some may argue or suppose.

Table 4 Percentage of the distribution of the students selected according to the type of fundamental school attended (2003–06)

<i>School</i>	<i>Year</i>			
	<i>2003</i>	<i>2004</i>	<i>2005</i>	<i>2006</i>
Public	38.3	33.8	51.0	44.9
Private	61.7	66.2	49.0	55.1
Total	100	100	100	100

Academic Performance of the Quota Students and Nonquota Students in the Vestibular

The data for student performance in the vestibular examination are other important indicators, not only for the evaluation of the impact of the reservation policy, but also to dissolve pessimists' expectations about the adopted measures. The information about the performance of the quota and nonquota students shows that the gap between the averages of both groups is not so high expressive in the majority of the courses of higher social prestige, as can be observed in **Table 5**. The method of evaluation for the disciplines is measured by marks between 0 (zero) and 10 (ten). In medicine, for instance, considered to be one of the toughest to get into, at UFBA, the gap between the two groups does not even reach 1.0 (one) point. The same occurs in the law course, also one of the most targeted by students. The largest gaps observed were in the electric engineering course (1.7) and the mechanic engineering (1.4), both in 2006.
