LBGO, and 7.4% to the remaining school types. Over 30% had to repeat the sixth grade.

This level of education is confronted with the following problems: unqualified teachers, obsolete curricula, and a shortage of educational tools, high percentages of repeaters and drop-outs, low percentages of repeaters, and few possibilities of moving up horizontally.

Senior Secondary Education

This level comprises the following school types: university preparatory education (VWO, 3 years), senior general secondary education (HAVO, 2 years, night HAVO, 3 years), institute for natural resources and engineering studies (NATIN, 4 years), school for intermediate business education (IMEAO, 3 years), teacher-training college (4 years), secondary commercial night school (MHS, 2–3 years) and secondary technical night school (AMTO, 4 years) (see Figures 1 and 2).

For admission to VWO, HAVO, and NATIN, one must have passed the relevant entrance examination.

Participation in the exam is possible from the third or fourth year of MULO. For admission to the teacher-training colleges (SPI, CPI) and IMEAO, MULO diploma is a requisite. This school type is also confronted with several problems: lack of classrooms and buildings, lack of qualified teachers, high percentage of repeaters and drop-outs, etc. There is an increase in the demand for secondary education, especially for NATIN and IMEAO.

Adult Education

Within the framework of their nonformal education and development activities, many nongovernmental organizations (NGOs) are engaged in providing adult education. The duration of the course is approximately 1 year and classes of two periods are given on 2 days a week. The size of the classes varies from 12 to 20 participants, while the lessons are provided at two levels: completely illiterate and for people who have had 2–3 years of primary education.

Figure 2 The future structure of the educational system. BA, courses at bachelor's level; SO, special education; HAVO, senior general secondary education; HBO, higher professional education; IMEAO, Institute for Intermediate Business Education; IOL, Institute for Advanced Teacher Training; LNO, junior domestic science and technical education; LTO, junior technical education; MA, courses at master's level; MBO, upper secondary vocational education; PPR, pre-primary education; TR CEN, training center; VSO, secondary special education; VWO, preuniversity education.

Second-Chance Education

In the context of second-chance education, the courses offered by the foundation for labor mobilization and development (SAO) may be considered as supplementary education, just as the programs offered by the foundation toward a new alternative (TANA).

Higher Education

Higher education comprises all types of courses at postsecondary level. Such courses are provided by: the Anton de Kom University of Suriname (ADEKUS), the institutions for higher professional education (HBO); the Institute for Advanced Teacher Training (IOL), the Polytechnic College (PTC), the Teacher Training Vocational Education (LOBO), the Youth Dental Care (JTV), The Academy for Higher Education in Arts and Culture (AHKCO), and the Central Training for Nurses and Related Professions (COVAB).

JTV and COVAB fall under the Ministry of Health, the other courses fall under the MINOV. Furthermore, there are a few private institutions, including ones that offer courses in tourism/hotel and catering sector, and a part-time night course in business economics provided by the Hogeschool Inholland from the Netherlands.

The ADEKUS comprises three faculties and the Institute of the Graduate School (IGSR) in the academic year 2008–09. The IGRS offers several masters of science courses and leads the PhD trajects. The faculty of social sciences has six disciplines, 14 specializations, and 2400 students. The medical faculty offers two disciplines and 425 students and the technological faculty has six disciplines, 15 specializations, and 650 students. The university also has the *Schakelinstituut* (transition course) where students who do not meet the regular admission requirements relating to previous education, are prepared for admission to university studies.

The university also comprises of nine research centers: INTEC, IMWO, CELOS, IDPM, MWI, UCC, the National Herbarium, the National Zoological Collection, CMO, IKR, and IIR. The ADEKUS replaced the old 5-year doctoral studies, which are now dismantled, by a BA and MA (bachelors and masters) structure with the 3-year bachelor of science studies followed by the 2-year masters studies.

Suriname, like other countries, is facing numerous challenges in higher education. Adequate management and financing, organization of education, quality assessment of education and research, and establishment of national and international partnerships are some examples of these challenges. With the Flemish universities in Belgium, a sustainable relation was established for a duration of 10 years for

strengthening education, research, and services. The focus is set on six projects in transforming the ADEKUS Suriname from a primarily BSc-oriented education university to an accredited MSc-oriented research and education university.

Higher education is of great importance to the development of the country and is continuously under internal and external pressure. Internal because of the strong demand for highly trained staff (manpower requirement) and the great supply of students (social demand) involving considerable training costs: External, because of the need to satisfy international and regional-quality requirements despite the small scale and limited means.

In higher education, several issues need attention: legislation concerning higher education, alternative financing models, increase in the number of students, incompetent teaching staff and education reform (pedagogical competency of teachers, teaching large groups, use of new didactic methods, increase use of information and communication technology (ICT), laboratory courses, retraining, in-service training, etc.).

Administrative and Supervisory Structure

Education Administration

Government schools in Suriname operate under direct responsibility of the relevant MOECD, while nongovernment schools operate under authorities. The MOECD is in the stage of strengthening the core responsibilities and supporting services and processes of education. The changes will occur at departmental and school levels both. Much more focus will be given to the following key functions: strategy development, management of financial and material resources, human resources management, management of educational tools and means of development, quality control, information, communication, and responsibility.

Educational Finance

Suriname has to spend much more effort and money to develop the education system. There is a shortage of highly qualified staff and deficiencies in institutional and incentive structures in the education sector. Schools lack autonomy and financial allocation mechanisms are completely unrelated to performance.

The government in Suriname is financing almost financing the education sector. Which means 5–6% of the gross domestic product (GDP) is spent on the educational sector, which implies that annually between 20% and 25% of the current government budget is spent on it. The education budget for the period 1996–2000 averaged US\$37 million on an annual basis with a downward trend. In the last few years, this budget showed an upward trend once again. In 2002, it was US\$56 million and in 2003,

(US\$63 million). Roughly 80% hereof is spent on primary and junior secondary education (VOJ), 7% on senior secondary (VOS), and 13% on tertiary education (IOL, ADEKUS). (See **Tables 1** and **2**.) Government funding for higher education comes mainly from the Suriname government. For the financial year 2009, total government education and training operating expenses are projected to be 5.3% of GDP.

Assessment of the Performance of Schools

In Suriname, the assessment of the performance of schools is a matter of growing concern. This has to do with the national efforts to raise the standards of individual schools, both objective external assessments and advice from professionals or peers, who know the school, are equally important. Performance indicators can provide important evidence of a school's achievement but there should be a clear attempt to identify information which is genuinely related to the quality of education a school offers its students. Evaluation systems simply making schools accountable, whether to parents, the community, or to others, are unlikely, on their own, to lead improvements in performance. But to require accountability of a school's stewardship of its resources, mission, and educational responsibilities is highly desirable in the interest of transparency and democracy in education. Care should be taken to build on the expertise and professionalism of teachers, and to provide programs of staff development which enable the staff of an institution to develop and extend their professional activities into new forms of autonomy.

Major Changes and Issues for the Coming Years

Managing Information, Monitoring, and Evaluation

A factor to be considered is whether Suriname has the necessary human, technical, and infrastructure resources for a successful implementation of education reforms. The use of educational change at the level suggested here and the technological level required, demands a

Table 1 Education expenditure as % GDP 1990–2008, human development index (HDI) 2008

culture to support it. This culture cannot be present only at the higher levels; it has to be all over the system. Not only the coordinators and the technical-support personnel, but also the data generators and even the users have to be part of this handling and distribution of information. The fact that there are computers and the need of information is felt, is not enough to guarantee a good system or an effective performance. The personnel using it need to believe in its value and to know how to use it to their own advantage. The information needed is to understand what is necessary to know. If the country is dealing with information to be the framework of policy, information to support the development of policy, it is necessary to develop a clear understanding of what is to be achieved. Education needs to have a comprehensive and shared vision of what is desired. Only in that framework will it be possible to define what is the information needed to show progress.

An education management information system (EMIS) has been developed for MOECD. It is a system for the collection, integration, processing, maintenance, and dissemination of data and information to support decision making, policy analysis and formulation, planning, monitoring, and management at all levels of the education system.

Many times the systems of education provide a significant amount of raw data. Lots of information is produced describing what is happening, sometimes in great detail. But if it is only that, a description, it might not provide much help to establish whether there is progress or not. Actually, some might think that it signifies a lot of effort, time, and resources just for the sake of getting some information that will only be valuable for researchers, who will, most of the time, use it only to be critical of the system. Other times, it goes beyond the raw data and the records to provide some analysis. Nevertheless, it is still felt that the results are not valuable enough.

These analyses are done out of context providing some comparisons or even looking for causes and explanations of what are individual phenomena sometimes taken out of context or in an individual fashion. In these cases, the information provided does not and cannot provide a comprehensive understanding of the situation.

What is lacking in most of these cases is a framework that can provide the basis to interpret the information that would lead to policy decisions. In simple terms, what makes the information relevant is the framework in which it is analyzed and understood. If the educational system lacks a vision and a sense of purpose, the information will never be understood to its fullest. Only when there is a coherent strategic view is it possible to have information that makes sense and that can guide policy. Once the goals are defined and the road clarified, then the indicators can be defined and the numbers can become meaningful.

But direction and a strategic view, although necessary are still not sufficient. Once the road has been defined, the next step is to travel it. Once the strategy has been determined, the next step is to have an achievable and sustainable plan.

How many times are the proposed goals and objectives reached? How many times are they really expected to be reached? Experience says that not many. On most occasions, because the action plans are unrealistic in the context in which they are to be implemented.

ICT Promotion in Education

The MOECD has to promote more ICT in education. A policy on ICT in education should be designed and disseminated which will provide the framework for the integration of ICT into the operation and management of the business of the ministry. Additional ICT initiatives include the establishment of fully equipped computer laboratories at primary schools; networking of secondary schools and maintenance of ICT infrastructure; provision of instructional ICT training to educators; and provision of tools for educators to develop instructional software and collaborative classroom systems.

Decentralization of Education

The MOECD will restructure and decentralize as key strategy for transforming the education system. This strategy aims to improve learning, teaching, and management in the education system, as well as organizational

performance and effectiveness. In addition, the establishment of the national system of local school boards to assist school will be taken into consideration at primary and secondary level.

Curricular Policies

The MOECD has to identify the essential learning outcomes which will help define standards of attainment for all primary and secondary school students (esthetic expression, citizenship, communication, personal development, problem solving and technological outcomes, and prepare students for further study or for entry into the world of work). The national curricula should also provide all students with the maximum opportunity to develop their potential and should therefore reflect and support the Suriname national ideals: be flexible and responsive to the developmental needs, life experiences, and unique abilities of each individual, provide learners with the resources to construct knowledge that is relevant to their needs and interest, and equip all learners with the knowledge and skills to attain a good quality of life.

Glossary

Cram schools – Cram schools (called “bu-shi-ban” in Taiwan) are specialized private institutions that offer classes after normal school time or on weekends to meet customized goals, most commonly to pass the entrance examinations of high schools and colleges or universities. Cram schools offer instruction in areas such as mathematics, natural sciences, English, and certain kinds of talented competencies, which are necessary for entering a higher level of schooling.

General Background

Taiwan, which includes a series of islands with a total area of nearly 36 179 km² and a population of 22.8 million, is located in eastern Asia and separated from the People's Republic of China (PRC) by the Taiwan Strait. From the 1500s to the 1660s, Taiwan was subject to the influence of a series of Portuguese, Spanish, Dutch, and English powers. Han Chinese settlements were established during the Ching Dynasty from 1683 to 1895; Japanese colonization from 1895 to 1945 had a great impact on Taiwan's culture as well. When the Chinese Communist Party established the PRC on the Chinese mainland in 1949, the Republic of China (ROC) government, led by the Kuomintang (KMT; the Nationalist Party), had already relocated to Taiwan and proceeded to rule the country until 2000.

Ethnically, the people of Taiwan consist of two groups: an indigenous minority of Austronesian origin comprising 14 aboriginal tribes, and a Han majority including the Southern Min, Hakka, and Mainlanders. Ethnic Han came in two large waves from China, one from the 1650s onward and the other around 1949. Beginning in the early 1990s up until 2007, around 38 000 people from Southeast Asia and China married Taiwanese and immigrated to Taiwan. Over the past five decades, the KMT government made Mandarin the official language, completely suppressing other dialects. Today, Taiwanese (also known as Minnanese) as well as Hakka and aboriginal languages are promoted and taught in elementary and junior high schools.

The KMT government lifted martial law in 1987 and launched a series of political reforms, which strengthened

the process of democratization. In the 1996 general election, Taiwanese elected their own president directly for the first time. In the elections in 2000, five decades of KMT rule came to an end and the opposition party, the Democratic Progressive Party (DPP), took power in a peaceful transition. In the 2004 election, the DPP won again. But in 2008, following the presidential election, the KMT has regained power. Taiwan has a dynamic capitalist economy with increasing liberalization by the government in investment and foreign trade. As a result, Taiwan has now transformed into a knowledge-based and high-tech country with a per capita annual GNP reaching US \$16 471 in 2006.

Owing to Taiwan's rapid political and economic development in the last 20 years, the government has been able to take a more active role in facilitating human rights and providing children, the aged, the handicapped, and underprivileged groups with better care and protection. In addition, the government has implemented the National Health Insurance (NHI) program with the objective of offering universal medical care to all citizens and residents. Article 13 of the constitution of Taiwan guarantees freedom of religion as a right of all people. Polytheistic and syncretic, Taiwan's religious and spiritual environments are dominated by ancestor worship, Taoism, Buddhism, and Confucianism but have never excluded the addition and development of other indigenous and foreign religions.

Goals of the Educational System

Taiwanese society has transformed from being authoritarian to democratic step-by-step. Accordingly, its educational system is moving from uniformity to diversity, from authoritarian centralization to deregulation and pluralism. From 1949 to the 1970s, the ultimate goal of Taiwan's educational system was to fulfill and reinforce the ideals enumerated by Dr. Sun Yat-Sen, the founder of ROC, and stated in his Three Principles of the People: nationalism, democracy, and the people's livelihood. Education was seen as a means of indoctrinating political ideology and Chinese traditional culture into the populace. Since the 1990s, educational reform has become a part of several social movements and introduced to meet the needs of a greatly changing and emerging democratic society as well as to make manifest the intrinsic value of education.

The sustained goals of the educational system stated in writing are the five educational goals in the National Education Act, promulgated in 1979 and amended later in 2004. According to Article 1, "The purpose of education is to cultivate the citizens with a comprehensive and balanced development in moral, intellectual, physical, social and aesthetic dimensions." Moreover, the Educational Fundamental Act, promulgated in 1999 and amended in 2006, indicates in Article 2 multiple aims for educational goals:

The purposes of education are to cultivate modern citizens with sense of national identity and international perspectives. The methods are to foster the development of wholesome personality, democratic literacy, ideas of rule of law, and humanities virtues, patriotic education, native soil care and information capability. Strengthening people's physical health as well as their abilities to think, judge and create is critical, too. In addition, it is indispensable to enhance respect for basic human rights, protection of ecosystems and natural environment, and understandings of and concerns for different countries, ethnic groups, sexes, religions and cultures. (Educational Fundamental Act, 1999, 2006)

The Taiwan Ministry of Education (MOE) announced the educational goals of New Campus, Sustainable Campus, Healthy Campus, and Friendly Campus which were enforced in 1999. In 2004, the MOE declared four major tracks for current educational policies in order to enhance students' capabilities in all fields with creativities and global vision, namely, cultivating modern citizens, affirming Taiwanese identity, developing global views, and improving social concern.

Structure and Operation of the Educational System

The Taiwanese government has laid a strong emphasis on the expansion and improvement of education over the past four decades. Since 1968, compulsory education has been extended from 6 years to 9 years (ages 6–15). Furthermore, a wide range of other educational options is available to citizens of all ages. The entire educational process covers 2 years for preschool education from age 4, 6 years for elementary school, 3 years for junior high school, 3 years for senior secondary education, 4–7 years for college or university, 2–4 years for a graduate school program, and 2–7 years for a doctoral degree program. There are also technological/vocational educational programs, special education programs, supplementary education, and adult/continuing education programs. **Figure 1** shows the completion times of the entire process of the educational system. The key statistics of Taiwan's major education levels are in **Table 1**.

Preschool and Early Childhood Education

In Taiwan, there are two subsystems of preschool and early childhood education. The first subsystem is the kindergarten system, which is the responsibility of the MOE in the central government and Bureaus/Departments of Education (BOEs/DOEs) in local governments. According to the Kindergarten Act, amended in 2003, the main purpose of Taiwan's kindergartens are to improve health education, life education, and ethical education. In 2006, around 200 000 students, aged 4 to 6, were attending 3329 kindergartens in 1507 public and 1822 private schools. The second sub-system is childhood care and nursery school system, which is under the purview of the Ministry of Interior (MOI). Around 300 000 children, aged 2 to 6, were attending 5526 centers and schools in 1404 public and 4122 private schools. Children 5 years and above attending both kindergartens and nursery schools reached 93.9% of that age demographic.

The government has provided subsidies to support Taiwan's remote district, ethnic minority, and lower-income families of children in private childcare and preschool programs since 2004. A new policy of preschool and early childhood care has been implemented since 2005 and is expected to integrate the above two subsystems by the end of 2009. The new policy has two phases for children up to 6 years of age. For toddlers up to age 2 there will be babycare centers and for children aged 3–6 kindergartens. In addition, the government is planning to make education compulsory for children of ages 5 and above.

Primary and Secondary Education

Taiwan's primary and secondary education is mainly composed of elementary school (six years), junior high school (three years), and senior (vocational) high school (three years). Elementary and junior high schooling are compulsory for children from the ages of 6 to 15. In February 2007, the MOE announced a 12-year basic education plan at primary and secondary education level in the near future and has been revising the Senior High School Law for that purpose. In 2006, there were 2651 elementary schools (98.6% public and only 1.4% private) and 736 junior high schools (98% public and 2% private). The student–teacher ratio in elementary schools was 17.86 and that in junior high schools was 15.7. However, the average class size for elementary school was 29.3 and for junior high school 35.6 in 2005. The enrolment rate in elementary school was 99.02%, compared with that age demographic. The enrolment rate of junior high school students who graduated from elementary school was 99.65%. The school day of elementary school and junior high school is normally of about 7 class hours of tuition and comprises around 200 school days per year.

In the past decade, Taiwan's MOE has undertaken a revolutionary educational reform program that has had a

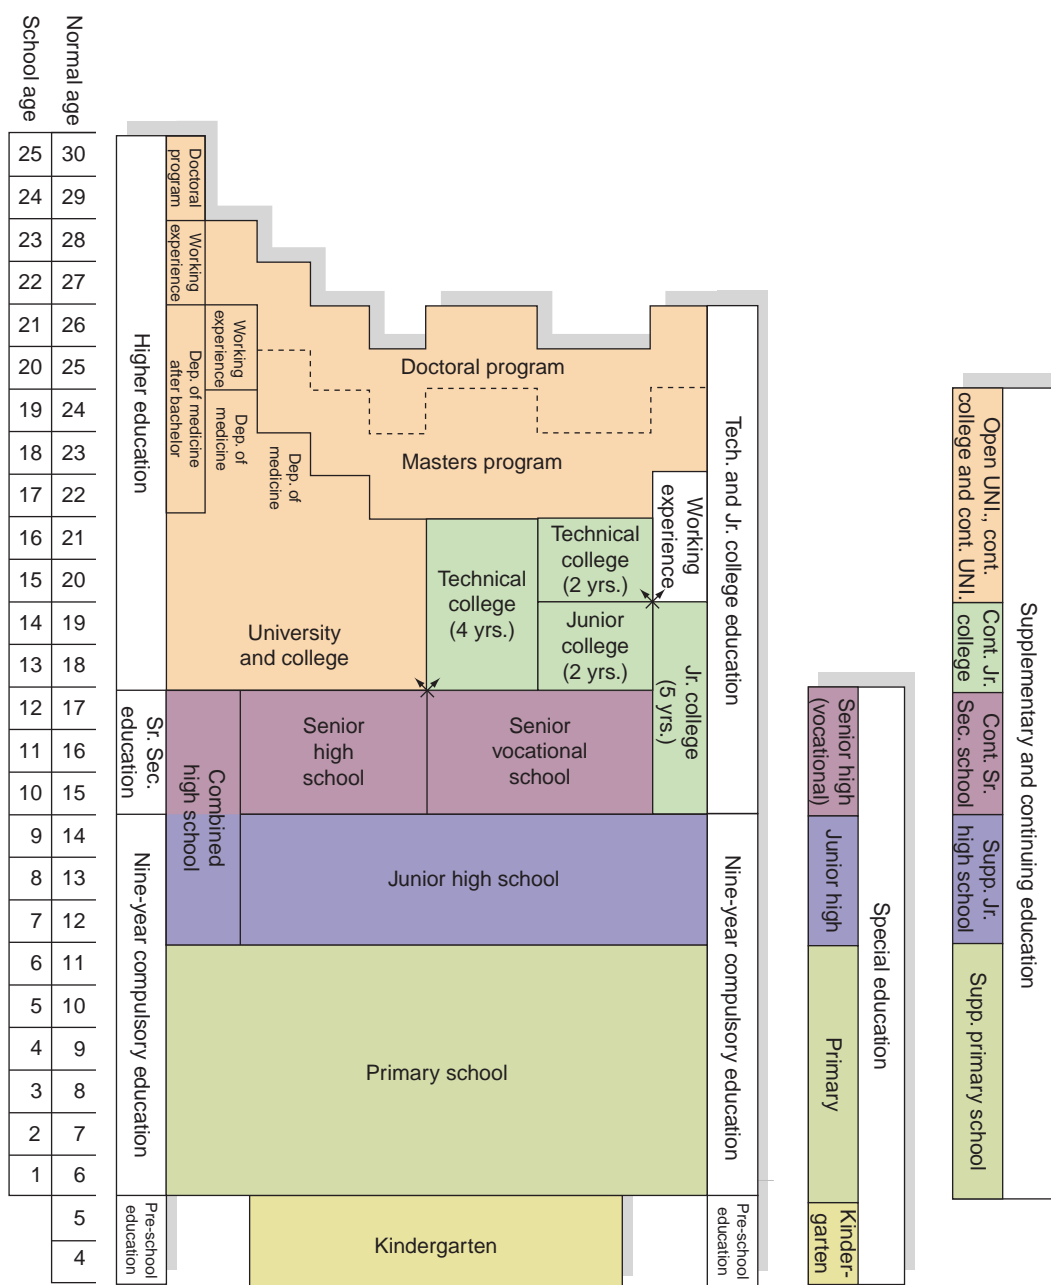

Figure 1 Taiwan's current educational system. Adapted from Taiwan Ministry of Education (2007). *2007 Education in Taiwan*. Taipei: Ministry of Education, p. 9.

huge impact on elementary and junior high schools. The MOE promulgated the Guidelines of Grade 1–9 Curriculum of Elementary and Junior High School Education in 1998 and implemented it fully by August 2004. The curriculum guideline encompasses seven major learning areas supplanting previous individual subjects and contains several important issues integrated into the overall curricula. The learning areas are language arts, health and physical education, social studies, arts and humanities, mathematics, science and technology, and integrative activities. The important issues are information

education, environmental education, gender education, human rights education, career development education, and home economics education. The guidelines emphasize ten goals as follows:

1. to enhance self-understanding and explore individual potential;
2. to develop creativity and the ability to appreciate beauty and bring one's own talents into full play;
3. to promote abilities related to career planning and lifelong learning;

Table 1 Key statistics in Taiwan's major educational levels 2007

<i>Educational levels</i>	<i>Schools</i>	<i>Students</i>	<i>Teachers</i>
Schools ^a	8254	5 287 226	273 971
public school	5870	3 635 373	208 485

Higher education	163	1 313 993	50 388
Special education	24	6588	1736

^aThe total number of schools include preschool, primary, secondary, higher (tertiary), special education, and supplementary and continuing education. Cited from the Department of Statistics, Ministry of Education (Taiwan) http://www.edu.tw/EDU_WEB/EDU_MGT/STATISTICS/EDU7220001/ebooks/edusta/edusta.htm (in Chinese).

4. to cultivate knowledge and skills related to expression, communication, and sharing;
5. to learn how to respect others, care for the community, and facilitate teamwork;
6. to have further cultural learning and global understanding;
7. to strengthen knowledge and skills related to planning and organizing;
8. to acquire the ability to utilize technology and information;
9. to encourage the attitude of active learning and studying; and
10. to develop abilities related to independent thinking and problem-solving.

At the end of grade 9, students should attend the Multiple Admission Process to Senior High Schools and Vocational High Schools, which is based upon their scores of Basic Achievement Test and in conformity with the Grade 1–9 curriculum guidelines. In 2006, 145 308 students entered senior high schools, 119 533 students went to vocational high schools, and around 71 800 students attended other tracks of schools such as various supplementary schools or five-year junior colleges that cover part of the students' high school education and certain practical technical programs.

Regarding Taiwan's senior secondary education, there were around 318 senior high schools (56% public and 44% private) and 156 vocational high schools (59% public and 41% private) in 2006. The average number of students per full-time teacher in senior high schools was 19.3 and 18.38 in vocational high schools. The enrollment rate of senior (vocational) high school students who graduated from junior high school was 96.23%. The Curriculum Guidelines of Senior High Schools and the Curriculum Guidelines of Vocational High Schools (both promulgated by the MOE

on a trial basis in 2006, to be formalized in 2009 or 2010) are there to provide national standards of educational goals and the content for teaching all the courses of senior secondary education.

Technological and Vocational Education

The Technological and Vocational Education (TVE) system has several different levels in Taiwan: junior colleges (2-year and 5-year systems), colleges and universities of technology (2-year and 4-year systems), and the vocational high schools mentioned earlier. In 2006, there were 29 universities of technology, 46 colleges of technology, and 16 junior colleges in Taiwan. The total number of students was 1 001 098 including 331 604 vocational high schools students, 180 886 junior colleges students, and 465 840 undergraduates and 22 768 graduate students of colleges/universities of technology.

In 2001, the Taiwan MOE provided funds to establish the Testing Center for Technological and Vocational Education and the Committee of Recruitment Policy Advancement for Technological Colleges and Universities. The main purpose of those two institutions is to meet the needs of over 70% vocational high school students expecting to go on to further education and around 25% of senior high school students qualified to study in colleges/universities of technology. Their chief undertakings are to improve the research and development on the TVE joint college entrance examination and integrate diversified entrance schemes, simplify the admission process, enhance test quality, and allow the TVE colleges autonomy in recruiting students. Furthermore, the MOE has established six Centers for Regional Industry-Academia Collaboration and 40 technical research centers affiliated to various universities to foster more school–industry collaborations.

Higher (Tertiary) Education

In the past 10 years, Taiwan's higher education policies, among other factors, have led to a substantial increase in the number of colleges and universities. More than 80% of the senior high school graduates and 70% of the vocational high school graduates are able to enter institutions of higher education. The higher education system, including the technological and vocational colleges and universities, is made up of 97 universities (42 public and 55 private), 50 colleges (10 public and 40 private), and 16 junior colleges (3 public and 13 private). In 2006, the total higher education enrolment was around 1 313 993 (including 29 839 PhD program students), 163 583 masters program students, 966 591 undergraduate students, and 153 978 junior college students. The enrolment rate in that age demographic in Taiwan was 82.02% (79.14% male and 85.08% female).

Besides the track of technological and vocational education system, the MOE adopted the multiple admission channels for entrance to colleges and universities for senior high school students in 2002. One channel is based on the requirement of the score of General Scholastic Ability Test and refers to recommendation (school recommendation or individual student's application) and screening. The second channel is via the Subjects Competence Tests, in which three to six subjects would be designed by individual departments of the colleges and universities, and the schools will then assign students according to their test scores and applications by the Joint Board, College Recruitment Community (JBCRC). The College Entrance Examination Center (CEEC) conducts the General Scholastic Ability Test and Subjects Competence Tests nationwide.

Special Education

Special education in Taiwan incorporates that for the talented and gifted (including general intelligence, academic aptitude, creativity, and leadership) and the disadvantaged students (including mental retardation, health impairment, speech disorders, learning disabilities, severe emotional disturbances, multiple impairments, autism, developmental delays, and other significant disorders). The Special Education Act of 1997, first announced in 1984, showed that the trend of special education has shifted from separation to mainstream, integration, and overall inclusion.

In Taiwan there are special education units (the Special Education Task Force Unit) in MOE and several Special Education Units in local DOEs/BOEs, which are in charge of supervising the instruction, counselling, assessment, and placement for special education. There are 25 special education schools (23 public and two private) providing a comprehensive learning environment to cover each category of disadvantaged students. Besides, there are also various types of placement in regular education institutions such as special classes, resource programs, and regular classes receiving special education in elementary, junior, or senior high schools. At the college and university level, there are several resource classes for visually and hearing impaired students.

Supplementary and Continuing Education

Supplementary education has decreased and transformed its functions because a great majority of Taiwan's children have been able to receive formal education over the past four decades. In 2006, there were only 318 supplementary schools for primary education and 470 for secondary education. These schools provide basic education and work-skills for out-of-school youth. In addition,

supplementary schools emphasize lifelong learning and provide educational programs to enhance adult literacy, and in the last 10 years programs to enhance the educational services for foreign spouses as well.

Cram schools (called *bu-shi-ban* in Taiwan) are specialized private institutions that offer classes after normal school time or on weekends to meet customized goals, most commonly to pass the entrance examinations of high schools and colleges or universities. Cram schools offer instruction in areas such as mathematics, natural sciences, English, and certain kinds of talented competencies which are necessary for entering a higher level of schooling. Taiwan's cram schools have increased from 3478 in 1998 to 16 982 in 2007; however, the quality of cram schools varies considerably.

In Taiwan, an assortment of learning modes for adult and continuing education has greatly increased its depth and breadth. These modes contain libraries, museums, art education centers, science education centers, extension division of colleges/universities for in-service and continuing education, four national social education centers, two open universities, 276 social work stations, and more than 30 community universities, a program strongly advocated by the educational reform movement in the private sector and aiming to liberalize the dissemination of knowledge and advance the formation of civil society.

The Teaching Profession

In 2006, there were 19 037 full-time kindergarten teachers, 150 441 elementary and junior high school teachers, and 50 749 senior high school teachers in Taiwan. Among them, more than 85% are instructional faculty in public schools, more than 85% are younger than 50 years, and around 70% are female. Under the Teacher Education Act, first issued in 1994 and last revised in 2003, around 75 institutions including Normal Universities, University of Education, and colleges/universities with teacher education departments or centers, are eligible to provide the initial training for student teachers from kindergarten to secondary education level. The initial training generally includes a four-year program and a half-year of teaching practicum in order to obtain the certificate. Starting from 2005 the students have to take the six-month practicum and then pass a qualification examination held by the MOE for the affirmed teacher certification. As of today, more than 55 000 people with teaching qualifications are waiting for teaching jobs.

Regarding Taiwan's higher education, there were 10 393 full-time junior college teachers, 11 225 college teachers and 37 790 university teachers. Among them, about 32% are instructional faculty in public institutions, more than 73% are younger than 50 years, around 34%

are female, and 76.6% are teachers with a PhD degree in public schools and 51.7% in private schools. However, like many other countries, there is no preservice training program for higher education faculty in Taiwan.

Administrative and Supervisory Structure

The administrative and supervisory structure in Taiwan consists of two levels: the MOE at the central government level and the DOEs/BOEs at the county and municipal government level. The MOE mainly takes charge of nationwide educational and cultural affairs, and supervises around 24 affiliated institutions for social/civic education, national colleges/universities, and around 170 affiliated elementary and high schools. The DOEs/BOEs administrate elementary and high schools and social education units or organizations within their jurisdictions. Private schools of all levels in Taiwan are subject to the supervision of the MOE and DOEs/BOEs, but their personnel and financial policies still have to follow the regulations of the Private School Act, last amended in 2007. In addition, according to the University Act, last amended in 2007, colleges/universities are guaranteed academic freedom and autonomy as specified within related laws and regulations. The MOE is gradually empowering the colleges/universities and improving higher education quality through financial subsidies, grants, and school evaluation.

Educational Finance

The Educational Budget Allocation and Management Act, passed in 2000 and executed in 2002, stipulates that Taiwan government must guarantee a stable educational budget and establish a committee to regulate the use of the educational budget at different levels of schools. In 2005 the educational expenses reached NT\$ 676 billion (6.07% of GNP, 18.41% of total governmental budget), of which public education took up 72.46% (4.39% of GNP) and private education 27.54% (1.68% of GNP). The distribution of total educational expenditure at all levels of schools was 3.23% for kindergarten education, 40.26% for compulsory education, 15.56% for senior secondary education, 0.66% for special education, and 40.29% for higher education.

Over the last 10 years, revenue sources for Taiwan's higher education have undergone a significant transformation. Government funding for public colleges/universities have diminished from two-thirds to one-half of each public school's budget and less than one-third for private school budget. In addition to standard government funding, colleges/universities may receive special grants for research or instructional excellence from the government. The remainder of the school budget comes from the

private sector, school service, and revenue from student fees. In 2006, the average tuition fees for full-time college/university students was US\$1793 for public schools and US\$ 3265 for private schools. The fees in public higher education schools was 12.74% and that in private ones was 23.21% as related to per capita income of US\$ 14 070. The MOE supports the financially disadvantaged students with full scholarships, grants, and financial loans totaling nearly NT\$ 10 billion per year.

Performance Monitoring, Evaluation, and Research

The MOE and DOEs/BOEs are responsible for monitoring and supervising performance of each sector of the educational system. In addition, the government has to collect data through agencies like the Department of Statistics of MOE and to conduct research on the outcomes of the educational system. Scholars of teacher-training and education-related colleges/universities undertake most educational researches. Professional institutions, such as the Center for Educational Research of National Taiwan Normal University, have been playing an active role in educational research. The National Academy for Educational Research Preparatory Office, established in 2000, focuses on developing its functions on educational research, consultation, and in-service training of teachers and principals. In addition, the Higher Education Evaluation and Accreditation Council of Taiwan, founded in 2005, is responsible for university evaluations.

Several educational statistics and indicators reveal Taiwan's educational achievement. Overall education participation rates in 2006 were nearly 100% for the 6–12-year-olds, 99.83% for the 12–15-year-olds, and 82.02% for the 15–18-year-olds. In 2005, the national illiteracy rate for those over 15 years old was 2.7%. The number of elementary and junior high school dropouts was 1785 (around 0.06% of the students of the same age group). The percentage of the population that have acquired at least senior secondary education was 64.2% for the 25–64-year-olds and 87% for the 25–34-year-olds, and those with a higher education diploma was 30.7% for the 25–64-year-olds and 47.9% for the 25–34-year-olds.

At the international level, Taiwan consistently ranks among the top ten highest performing countries in the Trends in International Mathematics and Science Study (e.g., both grade 4 and grade 8 won the second prize in science and the fourth in mathematics in 2003) and International Olympiad for high school students. In 2007, Taiwan got two gold and two silver medals in chemistry; two gold, one silver, and one bronze medals in information technology; one gold, two silver, and two bronze

medals in physics; two gold and two bronze medals in biology; and two gold, three silver, and one bronze medals in mathematics. In addition, Taiwan's research papers of higher education presented in Science Citation Index ranked 18th and 11th in Engineer Information in 2005.

Major Changes and Issues Since the 1990s

Taiwan has gone through continual educational reforms beginning in the 1990s. Many educational officials and nongovernmental committees on educational reform have published numerous white papers and educational reports. Several education-related laws and policies have been promulgated, amended, and implemented. According to the MOE, the goals of educational reforms are to enhance the quality of education by establishing a flexible school system, reduce the pressures of entering higher schooling, shorten the gap between the educational resources of rural and urban areas, balance the resources allocated to public and private schools, promote lifelong education, build a learning-oriented society, and reinforce international cultural and educational cooperation. In general, Taiwan's educational reforms are oriented towards diversification, liberalization, and globalization. However, the effectiveness of Taiwan's educational reforms still needs to be carefully reviewed.

Taiwan still has to resolve numerous issues at different educational levels. In preschool and early childhood education, the main issues are how to integrate kindergartens and childhood care centers effectively, and the possibility of extending the compulsory education to include 5- to 6-year-olds. In primary and secondary education, the essential issues are how to plan the 12-year mandatory education for primary and secondary education in order to reduce students' academic pressure in entering high schools, how to enhance the educational equity for minorities, and how to revise and continuously monitor the curricula guidelines through school performance. As for the teaching profession, some critical issues are how to encourage the professional development and how to resolve the oversupply of preservice teachers. In technological and vocational education, the issues are how to emphasize the licenses of technical expertise and how to strengthen the connection between schools and industries. Finally, several major issues in higher education are of concern. Those issues include how to improve the globalization and competitiveness of Taiwan's colleges/universities, how to evaluate those colleges/universities properly, and how to improve the quality, and achieve successful transformation of the higher education system.

General Background and History

The United Republic of Tanzania includes a large area of mainland East Africa and the islands of Zanzibar (Unguja, Pemba) and Mafia. It covers an area of 0.9 million square kilometers and has a population of around 39.4 million. The vast majority (80%) of the workforce are involved in agriculture, which accounts for around 40% of Tanzania's GDP. Since 2001, Tanzania has experienced a growth rate in GDP of around 6%. In spite of this economic growth, Tanzania remains one of the poorest economies in the world with a GDP per capita of US\$744 in 2005. By international standards, the majority of the population would be considered to be living in poverty, surviving on under a dollar a day.

The United Republic of Tanzania was formed by the union of Tanganyika and Zanzibar in 1964. Tanganyika became a German colony in 1885. After World War I, it was handed over to the British as a mandated territory under the League of Nations and, in 1961, it gained its independence. Zanzibar was ruled by the Portuguese in the sixteenth and seventeenth centuries and by Oman in the eighteenth and nineteenth centuries. In 1890, it became a British protectorate. It gained its independence in 1963.

Prior to German colonization, the only schools in Tanganyika were a limited number of small mission schools and Koranic schools restricted to the coastal areas. Some tribes had highly organized initiation-training periods, but otherwise there was no formal education. The Germans set up a limited number of schools to provide for the manpower needs of the administration. The first government school was opened in Tanga in 1892.

World War I shattered the education system that had been set up by the missionaries and colonial German powers. The missionary societies soon resumed their activities, but it was not until 1925 that the British developed a clear education policy for the territory. The overall policy was one of education for adaptation. It supported a broad-based, relevant education system with the curriculum adapted to rural African life. The education system was racially segregated into separate systems for Africans, Asians, and Europeans. The curriculum for African schools stressed agriculture, vocational skills, and hygiene.

During the interwar period, the priority was mass education, giving basic education to as many as possible, rather than focusing resources on the higher levels of education. Due to this policy, the colonial government

did not start developing secondary education until relatively late. In the last few years of colonial rule, the colonial administration paid greater attention to secondary education. This led to a proportionately dramatic increase in the number of secondary school places, but there were still only 700 African pupils in form 4 at the eve of Independence.

Immediately after Independence, the education system was desegregated and progressively indigenized through the replacement of colonial staff, curricula, and examinations. Education policy focused on manpower development, as it had in the final years of colonial rule, and secondary education expanded rapidly. Education was seen as a tool for bringing about rapid modernization. The curriculum was academic with science and technology strongly promoted.

Higher education became available in 1961, with the opening of the University College of Tanganyika as a college of the University of London. The college later became a constituent college of the University of East Africa and then, in 1970 it became an independent national university and was established as the University of Dar es Salaam.

In 1967, education policy in Tanzania was dramatically reoriented according to *Education for Self-Reliance* (ESR), a philosophical treatise on education by Julius Nyerere, the country's first president. Nyerere presented a bottom-up model of development based on a predominantly rural economy and a socialist ideology. ESR returned the focus of educational development to the provision of basic, relevant education for all. Agricultural activities became a central part of school life. Expansion of secondary education was tightly controlled and all non-government-run schools, with the exception of seminaries, were nationalized.

The Musoma Resolution of 1974 set the goal of achieving universal primary education (UPE) by 1978. The nation made an enormous effort to train new teachers and build new schools. Primary enrolment soared from 1.2 million in 1974 to 3.5 million in 1981, while secondary enrolment stagnated. However, many of the school structures built by communities were of poor quality and soon fell into disrepair. Teachers were recruited straight from primary schools and were trained by distance training.

The world economic recession of the 1980s and structural adjustment policies imposed by the International Monetary Fund led to a huge reduction in the level of public spending on education, compounding the decline

in quality from the push for UPE. The expanded primary cohorts reached the end of primary schooling only to find that the vast majority could not progress to secondary school. This reduced the incentive for parents to enrol their children in primary schools and absolute primary enrolments fell from 1983 to 1986. Although total enrolments rose slowly thereafter, the rise did not keep up with population growth and the net enrolment rate fell to below 60% by the end of the twentieth century.

While the state education system declined throughout the 1990s, liberalization enabled the private sector secondary education system to flourish and, by 1999, there were almost as many private secondary schools as state schools. More recently, liberalization and reform within the higher education system has led to a boom in the private university sector.

International donors have had a major influence on educational development in Tanzania throughout its history. In the 1970s, vocational biases were introduced into secondary schools with strong support from the World Bank. Since then the World Bank's thinking on the effectiveness of diversified secondary education has changed and more recent support to secondary education was only granted once the government agreed to remove vocational biases from secondary schools.

The new millennium saw major changes in the approaches to international development by multilateral and bilateral donors, both in terms of priorities and the mode of delivery. Poverty reduction and attainment of the millennium development goals, including universal, free, and compulsory primary education and gender equity in education, have become the priority of international development agencies. Tanzania has responded to these changes by producing a poverty-reduction strategy paper and by increasing the amount it spends on primary education. International aid, debt relief, and government reform with a focus on poverty reduction have enabled a major reversal in the decline in the state education system, and enrolments at all levels of education have increased dramatically since 2000.

Goals of the Education System

The goals of education and training in Tanzania are set out in the *Education and Training Policy* (United Republic of Tanzania, 1995). This gives the aims and objectives for the sector as a whole and specific aims for each sub-sector. Promotion of national unity through the acquisition and appreciation of Tanzanian culture, customs, and traditions is one of the overall goals.

Nyerere's vision of education for self-reliance saw education as a means to enable the country to develop through the efforts of its own people, without support or intervention from outside. It saw the primary goal of

education as preparing all children for life as self-reliant citizens in a primarily rural agricultural economy. The current *Education and Training Policy* (United Republic of Tanzania, 1995) has maintained some of Nyerere's language of education for self-reliance but the interpretation is very different, with a much greater emphasis on development of scientific and technological capacity. Whereas Nyerere argued that primary education should focus on preparing children to enter work on completion of the first 7 years of schooling, the current education and training policy focuses more on the role of primary education in preparing children for further education and training. Preparation of the child for the world of work is given as an aim of primary education, but it comes at the bottom of the list.

Tanzania's development vision, Vision 2025, sees education as a tool for national development. It stresses the importance of expanding tertiary education in order to develop a "critical mass of high quality human resources required to effectively respond and master the development challenges at all levels" (United Republic of Tanzania, 1999). At the same time, it stresses the importance of scientific literacy for all, stating that the education system "must instill a science and technology culture from its lowest levels, giving a high standard of education to all children between the age of 6 to 15." Attainment of computer literacy is also becoming a more prominent goal and in 2007, the Ministry of Education and Vocational Training produced its *Information and Communication Technology Policy for Basic Education* (United Republic of Tanzania, 2007b).

Since 2000, education has become more explicitly linked with poverty reduction in Tanzanian policy. In the *Education and Training Sector Development Programme Document* (United Republic of Tanzania, 2001) the goal of poverty reduction is given as a rationale for allocating the majority of educational spending to the primary level. While the language of poverty reduction is relatively new in Tanzania, the idea of prioritizing basic education for all over post-primary academic education for some was at the heart of Nyerere's *Education for Self-Reliance*.

Structure of the Education System

The official entry age into formal education in Tanzania is 5 years. Mainstream education on the mainland involves 2 years pre-primary, 7 years primary, 4 years lower secondary, 2 years upper secondary, and 3–4 years university degree. On Zanzibar, lower secondary school is split into two cycles, one of 3 years and a second cycle of 2 years. Primary school leavers can also enter vocational education training colleges, although increasing competition for the more popular classes means that primary school leavers often miss out to secondary leavers. Secondary graduates can enter a range of non-university-based training courses, most of which lead to a certificate or diploma.

Table 1

Level	NER (%)	GER (%)	GPI
Pre-primary	33	35	1.05
Primary	97	114	0.99
Lower secondary (1–4)	21	30	0.92
Upper secondary (5–6)	1	4	0.59

Table 1 shows the net enrolment ratios (NERs) and gross enrolment ratios (GERs) for the various levels of education. It also gives the gender parity index (GPI), calculated by dividing the number of females enrolled by the number of males.

In 2007, around one-third of children aged 5 and 6 attended pre-primary schools. Almost all (97%) children aged between 7 and 13 were enrolled in primary school. As illustrated by the higher GER, around 10% of children in primary schools were older than 13 years. In 2006, around two-thirds of primary school leavers were able to enrol in form 1 of secondary school and the secondary NER in 2007 was 21%. Recent expansion of secondary education has meant that many children over the official entry age of 14 years who missed out on selection for secondary school in previous years are now enrolling. In 2007, around 80% of form 1 pupils were 15 years or older. Because of this, the GER is much higher than the NER. Similarly, most pupils in upper secondary are above the official age (18–19 years).

At pre-primary schools, there are more girls than boys, but the enrolment levels become steadily more biased toward males going up the system. At the primary level, there is almost gender parity. At lower secondary level, boys outnumber girls by nearly 10% and at the upper secondary level, there are over twice as many males as females. At higher education levels, around one-third of the students are female.

Public examinations take place at the end of the fourth and seventh years at primary school, and at the end of the second, fourth, and sixth years at secondary schools. The key national qualifications from schools are the Primary School Leaving Examination (PSLE), the Certificate of Secondary Education (CSE or O' level), and the Advanced Certificate of Secondary Education (ACSE or A' level).

Pre-Primary

Formal pre-primary education for children aged 5–6 has expanded significantly since the turn of the millennium. Preschools provide 2 years of early education taught mainly in Kiswahili, following a national curriculum. The vast majority of children in registered pre-primary schools are in government schools (97.5%). Pupil–teacher ratios (PTRs) in government pre-primary schools have improved from 55 pupils per teacher in 2004 to 45 in 2007.

PTRs in non-governmental pre-primary schools are considerably lower (average PTR of 14 in 2007).

Primary

Primary education is free and compulsory. In all but one region, enrolment of primary school age children is over 90%. The vast majority of primary school students (99%) are in government schools. The medium of instruction is Kiswahili, and English is taught as a subject. Private primary schools are mainly English medium and tend to serve elites. The curriculum includes Kiswahili, English, mathematics, social studies, science, and vocational studies. The PTR is around 50, although it is as high as 70 in some regions.

Secondary

Within the government system, there are a small number of national secondary schools, most of which are boarding. Places are allocated based on students' success in the PSLE. Most government schools are community schools, built by the local community and staffed and run by the government. Nineteen percent of secondary students are in non-governmental schools. In 2006, there were 679 non-governmental schools. Some are run by faith-based organizations, others are run for profit. There are around 100 religious seminaries (56 Christian and 42 Muslim) that provide secondary education alongside preparation for religious service. Seminaries have tended to have the highest academic performance in national examinations.

The secondary curriculum for the first 2 years includes basic mathematics, English, Kiswahili, history, geography, civics, biology, and physics with chemistry. In the third and fourth years, students can choose to specialize in either arts or sciences. Religious education (Christian or Islamic) is taught by local religious leaders. French, further mathematics, and information and computer studies are also taught at some schools. At upper secondary level, students can choose a combination of three subjects to study.

The medium of secondary and higher education and training is English. Most secondary students and some teachers struggle with comprehension in English and it is seen as a major barrier to effective learning. In practice, Kiswahili is used extensively in most secondary schools. This has prompted many linguists and educationalists to lobby for a change to Kiswahili medium at secondary level. However, English medium education remains the popular choice because it is seen as vital for students to learn English.

Higher Education

In 2006, there were 30 universities in Tanzania, 11 of which were public and 19 private. The total student

population was 52 657 students, of whom 33.5% were female. The Open University of Tanzania (13 000 students) and the University of Dar es Salaam (12 000 students) together account for around 50% of all of the students in higher education in Tanzania. The other public universities are mainly specialist institutions. These include Sokoine University of Agriculture, Muhimbili University College of Health Sciences, and the University College of Lands and Architectural Studies. There are many other smaller higher education institutes. In 2006, these accommodated 16 372 students, 14.6% of whom were female.

Technical and Vocational Education

There is a wide variety of state-run vocational training institutes, including small post-primary colleges and folk development colleges offering 2-year courses in manual trades. There are also national vocational training colleges in the urban centers offering courses in areas such as secretarial skills, computing, catering, and tourism. Much of the vocational training in rural areas is provided by faith-based organizations. They tend to deliver 2-year courses in manual trades such as tailoring, masonry, and carpentry. They have relatively low fees and train mainly primary leavers. Private centers run for profit are mostly located in urban areas and offer shorter, more expensive courses in computing and commercial skills. Vocational courses are accredited through a national trade test.

The Teaching Profession

Teacher training is carried out through a network of colleges and the faculties of education at universities. Potential primary school teachers must study for the certificate of education. This is a 2-year course with 1 year in college and 1 year in school. Trainees must have passed their CSE, and they specialize in arts or sciences. The certificate qualifies teachers as grade-A teachers. Teachers currently in service who have not completed secondary school are classified as grade-B or -C teachers, depending on the level of training they have received. All grade-B/C teachers are expected to upgrade through a Kiswahili medium distance-learning teacher training program.

The diploma in education qualifies teachers to teach at lower secondary. It is a 2-year residential course and candidates must have successfully completed upper secondary education. University faculties of education deliver 3-year degree courses in education. Graduates from other degree programs can also qualify as teachers through a 1-year postgraduate diploma in education. A growing number of teachers with diplomas are studying part-time for education degrees through the Open University of Tanzania.

The official minimum qualifications for teachers at the various levels are:

- Pre-primary – pre-primary certificate of education
- Primary – CSE and certificate of education
- Lower secondary – diploma of education
- Upper secondary – degree in education or degree with PGDE

In practice, only a minority of pre-primary teachers are qualified (15%). The majority of primary school teachers are qualified at grade A and there are a small number of diploma holders working in primary schools. In 2007, around a quarter of the teaching force were still graded at B/C level.

According to the *Education and Training Policy*, teachers of forms 3 and 4 at secondary schools should be degree holders. In practice, there are very few degree holders teaching at O' level and most secondary school teachers who teach forms 1–4 are diploma holders. A growing proportion of lower secondary teachers are licensee teachers – these are ACSE holders who are given crash training. This involves 3 weeks of college-based training followed by in-service training through self-study.

Administrative and Supervisory Structures

Formal education from pre-primary to upper secondary school, adult education, and vocational training are the responsibility of the Ministry of Education and Vocational Training (MoEVT). Higher education and research are the responsibility of the Ministry of Higher Education, Science and Technology (MoHEST).

Curriculum development is carried out by the Tanzania Institute of Education (TIE). Earlier, TIE was the main producer of school textbooks, but in recent years it has relinquished this role, opening up textbook production to the commercial market. The National Examinations Council of Tanzania (NECTA) is responsible for national examinations at primary and secondary schools (PSLE, CSE, ACSE), and for qualifications from teacher training colleges (certificate and diploma).

Earlier, vocational education and training used to come under a number of ministries; however, since 2005 it has been administered together with formal education through the MoEVT. The Vocational Education and Training Authority (VETA) runs the national vocational training centers and is responsible for the administration of the trade tests.

Zanzibar remains semi-autonomous and has its own Ministry of Education, Culture and Sports. This ministry is responsible for pre-primary, primary, secondary, adult, and higher education.

Educational Financing

State Funding

In 2005/06, primary education and supporting services received around 64.5% of all spending on education. Twelve and a half percent went to secondary education, 22% to higher and tertiary education, and 1% to teacher training.

Primary education is officially fully financed by the state, with school fees being abolished in 2001. In practice, some schools raise additional funds through a system of parental contributions. State secondary schools charge school fees of around US\$20 per year but the main costs are met by the state. The government provides free higher education for a restricted number of candidates. Individuals can also fund themselves as private candidates at state or private universities.

VETA raises funds to run its centers through a levy on businesses. Non-government providers of vocational and technical education raise their funds through user fees and donations. They pay a fee to VETA for accreditation.

Donor Support

Throughout the 1990s, most of the donor funding was through the project approach and did not contribute to recurrent costs such as teachers' salaries. While having a major influence on educational development, it only constituted around 6% of all government spending on education. Donor support to education is now done largely through basket funding, which goes toward both recurrent and development costs. From 2002 to 2006 this was targeted at the primary sub-sector. The support has become proportionately much more significant. In the financial year of 2002/03, foreign support to education was 219 billion TSh out of a total of around 520 billion TSh, constituting over 40% of spending on education (United Republic of Tanzania, MoF 2003).

Performance Monitoring, Evaluation and Research

There are eight school inspectorate zones. According to policy, each school should be inspected once a year; in practice schools are inspected once every 2 years. National and regional education statistics for pre-primary to upper secondary education are published every year by MoEVT in the *Basic Education Statistics for Tanzania (BEST)* series. MoEVT and MoHEST make education statistics available on their websites, and progress in the education system is reported in annual budget speeches by the ministers. School performance in the national examinations is published each year by NECTA.

For the primary education development plan, which had major donor support, annual joint reviews were carried out by the government of Tanzania together with representatives from the donor community. There were also monitoring reports published by the President's Office – Regional Administration and Local Government (PORALG).

All research in Tanzania, including research into education, comes under the supervision of the Commission for Science and Technology (COSTECH). The commission has the power to award research grants. In practice, most academic research into the education system in Tanzania is funded by, and often conducted by, non-Tanzanians. The staff of the Faculty of Education in the University of Dar es Salaam are heavily involved in research, but most work on projects commissioned by or in partnership with international organizations. There is, therefore, a tendency for research to reflect the concerns of the international development community.

There are a number of independent research organizations that commission and conduct research into education, including The Economic and Social Research Foundation (ESRF), Research on Poverty Alleviation (REPOA), and HakiElimu, a Tanzanian non-governmental organization committed to publishing accessible research and analysis of education development within Tanzania.

Major Changes and Issues Since the 1990s

At the end of the twentieth century, the education system in Tanzania was in a state of disrepair. The first global monitoring report of Education For All (EFA) (UNESCO, 2002) grouped Tanzania in the lowest quadrant of countries, those that had a net enrolment ratio of below 70% (the figure given for Tanzania being 47%) and where enrolment rates had fallen since 1990. This group of countries was classed as at serious risk of not achieving the goal of universal primary education by 2015.

Since the year 2000, the number of children enrolled in primary schools has almost doubled, increasing from 4.4 million in 2000 to 8.3 million in 2007. Net enrolment rates have increased to above 95%. This rapid growth is a result of the decision to drop primary school fees in 2001 and the initiation of the primary education development plan (PEDP) in July 2002. PEDP received huge budgetary and technical support from the international donor community and also increased government spending on primary education. Besides mainstream education, the plan included programs, such as complementary basic education in Tanzania (COBET) and the integrated community based adult education (ICBAE) for youth and adults who have missed out on primary education.

In terms of quality, PEDP aimed at reducing PTR to 40:1, providing teachers with in-service training and providing a US\$10 grant per student to be spent by the schools on teaching–learning materials. These changes took longer to take effect than the quantitative changes but, by 2005, capitation grants were reaching schools and the output from teacher training programs had increased. There has been an apparent leap in quality as measured by the results of the PSLE, with over 70% passing in 2006 as compared with 22 % in 2000.

In 2004, the Secondary Education Development Plan (SEDP) was launched with financial support (in the form of a grant and a loan) from the World Bank. Government spending on secondary education was increased considerably and community mobilization, encouraged by matched government funding, led to the construction of hundreds of new secondary schools. In the first 3 years of SEDP, form 1 enrolment increased by a factor of 3 from 147 490 (2004) to 448 448 (2007), and the net enrolment ratio at lower secondary increased from 8.4% (2004) to 30.5% (2007). To accommodate for the huge influx of new students, upper secondary school leavers have been trained as teachers through a crash teacher training program. Aside from the World Bank, international support for SEDP has been much more limited than for PEDP. There is, therefore, less funding available for improving quality and it is yet to be seen what the full impact of the rapid expansion will be on the quality of secondary education.

Glossary

Basic education – The education provided before the level of higher education.

Lifelong education – The education resulting from the integration of formal, nonformal, and informal education so as to enhance ability for continuous lifelong development of quality of life.

General Background

The kingdom of Thailand was formerly known as Siam until 11 May 1949 when there was an official proclamation declared that the country would henceforth be known as Thailand, meaning land of the free, since the kingdom has never felt the harness of direct European colonialism.

The country is situated in the heart of the Southeast Asian mainland, covering an area of 513 115 square kilometers. According to the National Statistical Office, the total population was 64.86 million in 2006 and was estimated at 65 068 149 in July 2007. Thailand's population growth rate is on a decline, from 0.91% in 2006 to 0.68% in 2007. It is also reported that approximately 25% of the population is under the age of 15 years and population below the poverty line is 10.4%.

Since the political reform of the absolute monarchy in 1932, Thailand has had about 18 constitutions and charters. However, it is noteworthy that regardless of just a constitutional monarchy, as far as the Thai public is concerned, the authority of the much beloved king contributes a great deal to the nation unity and stability.

The official national language is Thai. Buddhism, the national religion, is the professed faith of 95% of the population. Islam (3.8%), Christianity (0.5%), Hinduism (0.1%), and other religions (0.6%) are embraced by the rest of the population. There is absolute religious freedom. The king of Thailand, under the constitution and in practice, is a patron of all major religions.

The Thai public administration is structured into central and local administration. According to the Department of Local Administration, Ministry of Interior, as of 30 September 2007, there are 75 provinces, 1276 municipalities and sanitary districts, as well as 6500 provincial administrative organizations (PAOs). Moreover, there are

two special forms, which are the Bangkok Metropolitan Administration and the city of Pattaya.

Traditionally, the kingdom economy has been solely based on agriculture; however, in the 1980s, Thailand emerged as one of Asia's leading tiger economies. However, after the economic crisis in the summer of 1997, primarily due to a renowned Orient syndrome, the country has revised its development goals. The present 10th National Economic and Social Development Plan (2007–11) has placed His Majesty King Bhumipol Adunyadej's philosophy on sufficiency economy as its foundation, and aims at three main objectives: people-centered development; balancing between economic, social, and natural resources and environment capitals; and leading to the green and happiness society.

The country's real gross domestic product (GDP) growth in 2007 was 4.7%, driven mostly by a strong export sector. The Bank of Thailand, the Thai Finance Ministry, and the Thai National Economic and Social Development Board have estimated that real GDP growth in 2008 will be between 4.5% and 5.5%.

Similar to other Asian countries such as China and India, the Thais highly value education. The literacy rate in Thailand is quite high. According to the national 2000 census, 92.6% of the population aged 15 years and above (94.9% male and 90.5% female) can read and write. In recent years, there has been an increased emphasis on education. The development of the kingdom's human resources is its highest priority.

The modern school system was initiated by His Majesty King Chulalongkorn or King Rama V. The first public school for commoners was set up in 1884, followed by the establishment of Ministry of Education in 1892, and a reorganization of the school system with the proclamation of early form of the national education plan in 1898. During the reign of King Rama VI, a law on compulsory primary education was issued in 1921, requiring every 7-year-old child to receive free primary education until the age of 14 years; in addition, the first university, Chulalongkorn University, was established in 1917.

With drastic social changes in the age of globalization, the prime concern of the government is on educational reform that will prepare and strengthen Thai people to cope with such changes, move through the crisis, and contribute to the social and economic development of the country. It is necessary that human development focuses on human worth, potential, morality, and ethics as the main aspects in moving toward a knowledge-based, and a peaceful and caring, society.

The first successful attempt of comprehensive educational reform was the inclusion of various provisions relating to education in the 1997 Constitution, followed by the promulgation of the 1999 National Education Act and Amendments (Second National Education Act BE 2545 (2000) and the preparation of the National Education Plan (2002–2016)) as mandated by Section 33 of the 1999 National Education Act.

Framework and Goals of the Education System

“Education Builds the Nation, Empowers the Individual, and Generates Employment” has been the principle which the Thai government adopts as a means of educational reform movement since the 8th National Economic and Social Development Plan (1997–2001) until the present 10th Plan (2007–11). Toward this end, education policy is integrated with the overall policy on social development and is called “Policy on quality human and societal development: Building a lifelong learning society.” This policy also emphasizes improvement of the country’s human resources in terms of knowledge, morality and ethics, as well as readiness to respond to the measures required to ensure the nation’s development and competitiveness.

The main goals of educational reform reflected in the principles and challenging guidelines of the 1997 Constitution, the present 2007 Constitution, and the 1999 National Education Act and Amendments (Second National Education Act 2000) are better equity and quality in education, and increasing the quality of life of Thai citizens.

Constitution of the Kingdom of Thailand

The Constitution BE 2540 (1997) has greatly increased the rights of Thai people to political participation and to voice public opinion on major problems. Relating to education, Section 81 of the constitution required that the state:

Provide education to attain knowledge and morality; issue laws relating to national education; improve education so as to be attuned to economic and social change; create and strengthen knowledge and inculcate sound awareness of politics and a democratic system of government under a constitutional monarchy; promote research in various disciplines; accelerate the application of science and technology for national development; promote the teaching profession; and encourage the revival of local wisdom, art and culture of the nation.

Improving education to be in harmony with economic and social change means that the government is committed to initiate educational reform whenever it is

necessary to keep up with the pace of change. Besides, it is provided in the constitution, for the first time, that all Thai people will have an equal right to receive basic education, for at least 12 years, of good quality and free of charge (Section 43). The constitution ensures that all people will have both the right and duty to receive education and training (Sections 30 and 69) as well as academic freedom (Section 42). It also includes the right to receive care and education for children, youth, women, the elderly, the underprivileged, and the handicapped as provided in Sections 53, 55, and 80. These provisions will protect the right to education of all Thai people, thereby moving forward toward a knowledge-based economy and society.

In providing education, maximum public benefit in national communication resources (Section 40) and the conservation and restoration of local wisdom (Section 46) will be taken into consideration. The role of the private sector in the provision of education at all levels is also emphasized (Section 43). It ensures the right of local organizations to participate in the provision of education which will promote the decentralization of educational management (Section 289). Furthermore, participation of local people and communities in educational provision will be enhanced, which will make education both relevant to the needs of the people and responsive to changing environments, demands, and opportunities at a local level.

These challenging guidelines mandated by the 1997 Constitution have been assured in Thailand’s 2007 Constitution, which has just been promulgated in August. Education rights and liberties are assured in this latest constitution. It emphasizes that a person shall enjoy an equal right to receive basic education for the duration of not less than 12 years which shall be provided by the state thoroughly, up to the quality, and without charge. Indigent, disabled, and handicapped persons are eligible for assistance and support from the state to enjoy equal education opportunities. Moreover, education and vocational training provided by private organizations, educational alternatives, self-education, and education for life shall be protected and promoted by the state (Section 48). As for academic freedom, it states that education, training, learning, teaching, researching, and disseminating such research according to academic principles shall be protected, provided that it is not contrary to his/her civic duties or good morals (Section 49).

The 1999 National Education Act

In order to meet the requirements of Section 81 of the 1997 Constitution, the first National Education Act was promulgated in August BE 2542 (1999), followed by its amendments in BE 2545 (2000). The act serves as the fundamental law for the administration and provision of education and training. It includes nine chapters prescribing the objectives

and principles; educational rights and duties; educational system; national education guidelines; educational administration and management; teachers, faculty staff, and educational personnel; resources and investment for education; and technologies for education.

The framework of education reform included (1) learning reform toward learner-oriented education; (2) administrative reform aiming at adjusting administrative structure to promote decentralized and school-based management; reorganizing systems for teachers, faculty staff, and educational personnel to upgrade the teaching profession; and increasing efficiency in the utilization of resources and investment for educational purposes; and (3) legal reform by preparing and/or amending a range of legislations and regulations according to the act.

The ultimate goals of education are to foster full development of the Thai people in all aspects: physical and mental health, intellect, knowledge, morality, integrity, and a desirable way of life so as to live in harmony with other people (Section 6). Various measures are now undertaken to make sure that morality development be inculcated in the young. In her 2005 lecture on “Education is the golden key,” Her Royal Highness Princess Maha Chakri Sirindhorn also emphasized that:

One important part of education is to help a person realize the importance of virtues and righteousness, so that you will not commit wrongdoings. . . . The expectation of good education is intellectual development and mental exercise.

As for the provision of education, according to the National Education Act, it shall be based on three principles, namely, participation by all segments of society, continuous development of the bodies of knowledge and learning processes, and lifelong education for all (Section 8).

The National Education Plan (2002–16)

As mandated by Section 33 of the 1999 National Education Act, a 15-year National Education Plan was prepared by the Office of the Educational Council to serve as a framework for formulating the development plans pertaining to basic education, vocational education, higher education, religion, and art and culture as well as to provide guidelines for formulating operational plans at the levels of educational service areas and educational institutions. This long-term reform plan brought together the relevant provisions of the constitution, the National Education Act, and the government policy. It centers on the integration of all aspects of the quality of life, including comprehensive and balanced human development, and the forging of a society of morality, wisdom, and learning. Authorized for subsequent implementation by the Council of Ministers on 17 June 2002, the plan stipulates three objectives: all-round and balanced human development; building a society of morality, wisdom, and learning; and development of social environment (see Figure 1).

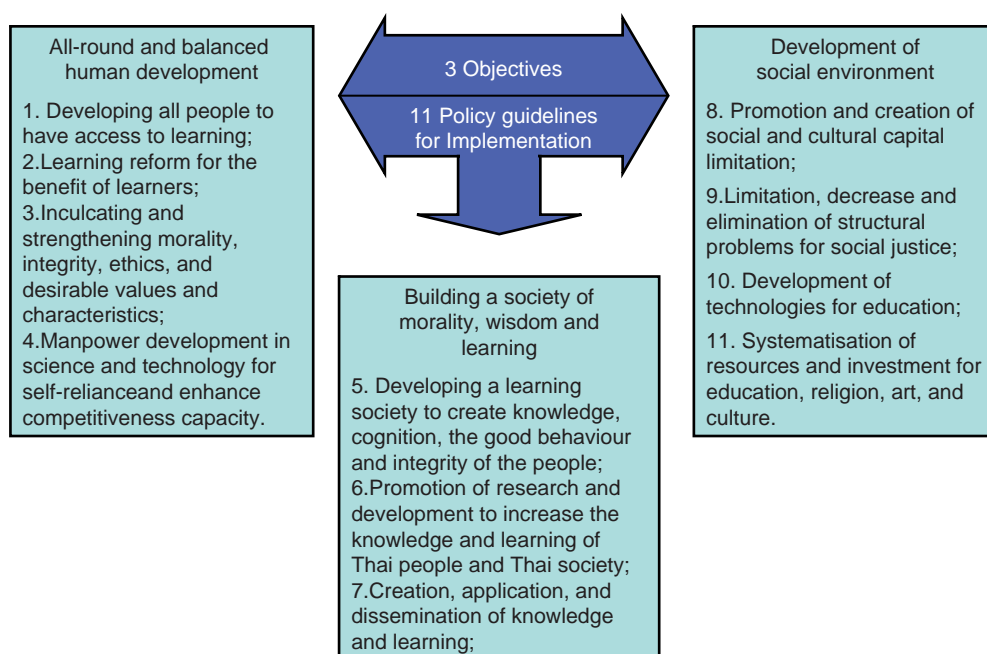

Figure 1 Objectives and policy guidelines of the National Education Plan. From Office of the Education Council, Ministry of Education (2004). *Education in Thailand 2004*. Bangkok: Amarin Printing and Publishing. With kind permission from Amarin Printing and Publishing.

Structure and Operation of the Education System

The 1999 National Education Act classifies education approaches into formal, nonformal, and informal. Formal education, comprising basic and higher education, is primarily provided in the school, while nonformal approaches are for all those outside schools and informal activities are available for self-learning through various sources. However, all types of education can be provided by educational institutions as well as learning centers organized by individuals, families, communities, community or private groups, local administration organizations, professional bodies, religious institutions, welfare institutions; and other social institutions.

The school system at basic education level is 6:3:3, covering preprimary education, 6 years of primary (level 1 or grade 1–3), 3 years of lower secondary (level 2 or grade 4–6), and 3 years of upper secondary education (level 4 or grades 10–12). It is provided by early childhood development institutions, schools, and learning centers (Figure 2).

The 12 years of free basic education (grades 1–12) were made available to students throughout the country for the first time in 2002. The government later increased that number to 14 years to include 2 years of preprimary education. On 25 March 2008, the Council of Ministers approved additional budget to provide 14 years of free

basic education. This measure is expected to begin in May or the first semester of the academic year 2008.

In the academic year 2007, as of 31 December 2007, the total number of formal educational institutions at both basic and higher educational levels are 38 509 (1524 in Bangkok and 36 985 in provincial and local areas). In addition, it was reported that, in that year, there were 14 467 833 students and 683 538 teachers and faculty members (Table 1).

Preprimary Education and Early Childhood Care

Harmonious physical, intellectual, emotional, and social development of children in the 0–5 years age group is highly recognized by the government. Preprimary education programs are provided by early childhood development institutions, day-care centers, nursery schools, or kindergarten and learning centers. However, most children in the range 3–5 years of age receive preprimary education through noncompulsory basic education services. In 2004, Office of the Education Council (OEC), Ministry of Education, reported that only 17.5% of the 3–5 years age group were under the full-time care of their families, while the majority, or 82.5%, participated in child development centers, kindergartens, and preschool classes. In the 0–3 years age group, 97.7% were cared for by their families, with the remainder, or 2.3 %, attending nurseries.

From Office of the Permanent Secretary, Ministry of Education (2007). *Education Statistics: Academic Year 2007*. Bangkok: Ministry of Education. With kind permission from Ministry of Education.

According to the Ministry of Education, 1 754 328 pre-school children enrolled in both public and private institutions in academic year 2007. Among these, 1 591 410 were in institutions under the auspices of Ministry of Education and the remaining 162 918 were in centers of other government organizations such as Ministry of Interior, Ministry of Social Development and Human Security, the Bangkok Metropolitan Administration, and the Border Patrol Police.

Primary and Secondary Education

The compulsory education requirement covers 6 years of primary and 3 years of lower secondary education. Children are expected to be enrolled in basic education institutions from age 7 through the age of 16, except for those who have already completed grade 9.

The Basic Education Curriculum BE 2544 (AD 2001) consists of 12-year core curricula prescribed by the Ministry of Education. The substance of the curriculum is assembled into eight subject groups of learning processes: (1) Thai language; (2) mathematics; (3) science; (4) social studies, religion, and culture; (5) health and physical education; (6) art; (7) career and technology; and (8) foreign languages. Educational institutions are required to develop school-based curricula relating to the needs of community and society, and include local wisdom and desirable attributes for members of family, community, society, and the nation. The proportion of core curriculum to local content developed by the institution should be approximately 70:30, flexibly applied in compliance with the nature of each subject.

For several years until 2005, the percentage of students in primary education institutions had exceeded 100% because of the underage and overage student population added to the percentage of children in the 6–11 years age group. In the academic year 2007, the total number of primary school students was 5 561 768. The majority of students (4 001 470) studied in government schools under the auspices of the Office of the Basic Education Commission (OBEC), Ministry of Education. Another 1 001 969 students were in private schools; 15 034 enrolled in university demonstration schools; and 543 295 were in primary schools organized by other government agencies.

At the lower secondary education level, the percentage of students in classes compared to the population aged 11–14 years increased from 2.34 million, or 82.8%, in 2000 to 2.63 million, or 96.7%, in 2006. In the academic year 2007, the total number of lower secondary students was 2 790 190. The majority, that is, 2 634 163 students, studied in schools under the auspices of the OBEC.

The proportion of students enrolled in upper secondary classes per population aged 15–17 years during the academic years 2000–06 also increased from 57.3% in 2000 to 65.8% in 2006. According to the Ministry of Education, it

is reported that, in the academic year 2007, the total number of students in general education program was 1 174 014 and vocational education program was 773 895.

The number of children aged 3–17 years enrolled in basic education during the coming academic years is expected to increase because of the extension of free basic education from 12 to 14 years and the extension of compulsory education from 6 to 9 years. It is also very likely that students who have completed compulsory education will opt to continue on to 3 years of upper secondary instruction, and to pursue higher education at an increasing rate because the Income-Contingent Loan Fund will be available to pay for their tuition, and hence provide them with greater access.

Basic Education of Children with Special Educational Needs

The OBEC, Ministry of Education, has formulated a strategic plan for gifted and talented students. Suitable curricula, appropriate means to accelerate growth and development, a dynamic and vibrant environment, and well-trained mentors are approaches being implemented to nurture gifted children with talents for science and mathematics, languages, sports, music, computing, visual and performing arts, and many other fields. Incentives for teachers and schools, advice to parents, as well as the establishment of the National Centre for the Gifted and Talented are expected to further stimulate the development, promotion, and support of children with special talents.

Most of the socially and/or culturally disadvantaged students study in regular schools, while others study in special institutions, such as those established by the Border Patrol Police and the welfare schools supervised by the OBEC.

Nine types of disability are recognized: (1) hearing impairment; (2) mental impairment; (3) visual impairment; (4) physical or health-related impairment; (5) learning disabilities; (6) autism; (7) emotional and behavioral disorders; (8) speech and language disorders; and (9) multiple disabilities. These students receive formal education provided by the Bureau of Special Education Administration, the Department of Social Development and Public Welfare, as well as by some university demonstration schools, municipal schools, and private foundations and some hospitals which organize classes for disabled children suffering from chronic conditions. With an emphasis on individualized education programs, and commensurate with their potential, disabled students receive education from various types of schools: (1) special schools, (2) special centers, and (3) inclusive schools.

Education for Ecclesiastics

General education is also provided to novices and monks in general ecclesiastic schools in various Buddhist temples.

They offer lower and upper secondary education curricula equivalent to those provided by the OBEC. Apart from general subjects, the courses include learning units related to religious practice, Buddhist doctrine, and the Pali language. There are also two Buddhist universities in Bangkok, with various campuses elsewhere, offering courses at undergraduate and graduate levels. In the academic year 2006, there were 10 455 institutions and a total number of 1 303 605 students in Dharma and Pali sections.

Technical and Vocational Education

Thailand recognizes the important role of technical and vocational education and training as a critical tool for producing manpower with the necessary skills required for employment and/or entrepreneurship as well as for poverty alleviation. This type of education and training is provided in public and private educational institutions, enterprises, or through programs organized through cooperation between educational institutions and enterprises.

Several activities, organized by the Office of Vocational Education Commission and the Office of Higher Education Commission under the Ministry of Education, the Ministry of Labour, as well as the business sector, have been undertaken to improve the image of vocational education institutions, including improvement of the curriculum and increased collaboration between educational institutions and the production and service sectors. These include the improvement of curriculum and instruction, establishment of Thai Vocational Qualification, validation of experience, research and innovation, and career development.

Formal technical and vocational education and training is conducted at three levels: upper secondary, leading to the lower certificate of vocational education; post-secondary, leading to a diploma or the associate's degree in vocational education; and university level, leading to a degree. Under the supervision of the Office of the Vocational Education Commission, technical and vocational education is provided in 12 types of colleges: (1) technical; (2) vocational; (3) agricultural and technology; (4) commercial; (5) industrial and ship-building technology; (6) fishery; (7) administration and tourism; (8) polytechnic; (9) industrial and community; (10) automotive industry; (11) arts and crafts; and (12) the Golden Jubilee Royal Goldsmith College. At present, nine major fields of study are offered: trade and industry, agriculture, home economics, fishery, commerce and business administration, tourism, arts and crafts, textiles, and information technology and communication.

Higher education

The Office of the Higher Education Commission, Ministry of Education, currently supervises 88 limited admission

public universities, which include 38 public universities/institutes, autonomous universities, and open universities, 41 Rajabhat universities or former teachers colleges, nine Rajamangala universities of technology, 68 private universities and colleges, and 17 community colleges. Other ministries and agencies also organize 94 specialized institutions. The University Council of each institution is authorized to approve the offering of additional programs so long as the curriculum is in line with the criteria specified by the Board of Higher Education Committee. The Office of the Higher Education Commission acknowledges and reviews the council-approved curriculum.

The demand for higher education increases constantly. Student enrolment at diploma, bachelor, and graduate degree levels in higher education institutions, including that in open universities, rose continuously from 1 797 840 in 2000 to 2 993 499 in 2004. Compared to the population aged 18–21 years, the percentage of students in higher education institutions was 68.05% in the academic year 2006.

Systematic and continual improvement of higher education is essential in order to meet the rising demand of students and enable institutions to produce graduates of high caliber in accordance with the requirements of the country's social and economic development needs, and to serve as centers of excellence for innovation, research, and development. The First 15-Year Plan for Higher Education (1992–2007) identified five key areas of competencies, namely, pursuit of excellence, equality in educational opportunity, administrative efficiency, internationalization of higher education, and flexible management and promoting the role of the private sector. Consequently, the main goal of the Second 15-Year Plan (2008–2022) is the system of high quality through mechanisms and measures of good governance, financing instrument, higher education standards, and university networking; the foundation to this is university academic freedom, diversity, and unity of the system.

The admission system was reviewed and the newly modified university admission system can be summed up as (1) the direct university admission system, (2) the central university admission system, and (3) special programs and the quota system. Beginning academic year 2006, students completing grade 12 are obliged to take national educational tests of two types: the Ordinary National Educational Test (O-NET) and the Advanced National Educational Test (A-NET) administered by the National Institute of Educational Testing Service.

Continuous effort has been made to encourage public higher education institutions to transform to autonomous universities so that they can generate innovation, cost effectiveness, accountability, performance-based assessment, good governance, and long-term social and economic development. In addition, a pilot project of the Thailand Cyber University was initiated in early 2005.

Research and development in universities is strongly promoted in response to the government policy to enhance Thailand's competitiveness as well as to generate new products and innovations for commercial purposes.

Adult and Nonformal Education

Nonformal education services such as fundamental education for literacy, general education, technical and vocational education and training, family-based early childhood development programs, and activities for the improvement of quality of life are provided by both public and private bodies. Target groups of the Office of the Non-formal Education Commission primarily are those outside the school system, that is, the early childhood population, school-age population who have missed formal schooling, and the over-school-age population; however, services have now been expanded to include specific target groups such as the hill tribes, prison inmates, the disabled, the aged, farmers, local leaders, slum dwellers, and those having no opportunity to further their studies in formal schooling after compulsory education. In the academic year 2006, the enrolment number of all non-formal programs was 1 840 333 and the graduate number was 852 007.

Lifelong learning sources such as community learning centers and village reading centers are promoted, in accordance with Section 25 of the National Education Act, so that they will be in sufficient number and with efficient functioning. Several ministries are involved in providing informal education through information dissemination, educational activities, or academic and professional programs for different target groups relating to the responsibilities of each organization. It is noteworthy that nonformal and informal education services are provided to promote and support lifelong learning activities based on active participation from all segments of society.

The Teaching Profession

Chapter 7 of the National Education Act mandated that a system for teachers and educational personnel, including production and further refinement of personnel, shall be promoted so that teaching will be further enhanced and become a highly respected profession. Accordingly, the preservice curriculum was extended from 4 to 5 years, with the first 4 years dedicated to coursework and a final year devoted to teaching practice at an approved school. Besides a bachelor's degree in education, a professional teaching license is required of in-service teachers and school directors. College graduates with a bachelor's degree in fields other than education must complete a

1-year graduate certificate program in education before being certified.

The Teachers' Council has established a set of standards and a code of ethics for educational professionals, in line with the 2003 Teachers and Education Personnel Council Act, which specifies that professional standards be comprised of professional knowledge and experience, performance, and conduct. The National Institute for Development of Teachers and Educational Personnel was established as an independent organization for teacher development.

Several measures have been undertaken to attract qualified individuals to the teaching profession and retain them. Special salary scales have been introduced and a strategic plan has been formulated to solve the problem of teacher indebtedness. Contributions of outstanding teachers are recognized by organizations such as the Teachers' Council of Thailand, the Association of Science Teachers, and the OEC. OEC has selected outstanding teachers under three categories: national teachers, master teachers, and teachers of Thai wisdom.

In the academic year 2007, the total number of teachers and faculty members was 683 538. Among these, 634 981 are employed in educational institutions under the auspices of the Ministry of Education and another 48 557 are employed by other ministries.

Administrative and Supervisory Structure

Educational administration and management in Thailand is conducted by the state, local administration organizations, and the private sector. The Ministry of Education is responsible for promoting and overseeing all levels and types of education under the administration of the state. Overseeing administration, management, and monitoring the quality and standards of private educational institutions are also responsibilities of the state. However, local education administration is under the supervision of the Ministry of Interior. In addition, other ministries undertake management of education in specialized fields or for specific purposes (**Figure 3**).

Under the principle of decentralization, the main functions of the Ministry of Education at the central level are formulating policies, plans, and standards; support of resources; and monitoring and evaluation. There are five main bodies under the Ministry: the Office of the Permanent Secretary; the OEC; the OBEC; the Office of the Vocational Education Commission; and the Office of the Higher Education Commission. The ministry decentralizes powers in educational administration and management regarding academic matters, budget, personnel and general affairs administration directly to educational service areas and educational institutions in the areas.

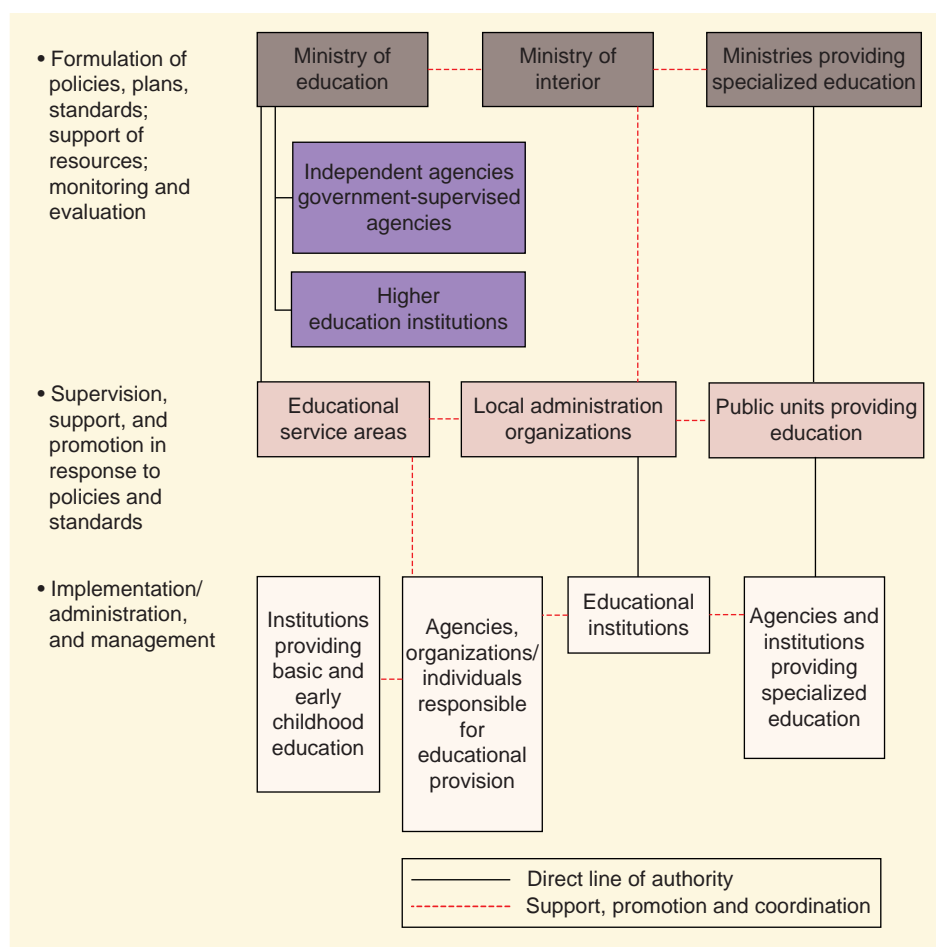

Figure 3 Educational administration and management structure. From Office of the Education Council, Ministry of Education (2006). *Education in Thailand 2005/2006*. Bangkok: Amarin Printing and Publishing. With kind permission from Amarin Printing and Publishing.

The OBEC has established 175 educational service areas with 172 areas in the provinces and the remaining three in Bangkok. At present, each educational service area comprises an area committee for education, with its office responsible for approximately 200 educational institutions and a student population of 300 000–500 000. Educational service areas are responsible for supervision, support, and promotion in response to policies and standards.

Administration and management of basic educational institutions are supervised and supported by a board consisting of representatives of parents, teachers, community groups, local administration organizations, alumni, and academicians. State universities are moving toward transformation to state-supervised institutions that function as legal entities which will enable each institution to develop its own administration and management system with greater flexibility and academic freedom under the supervision of the institutional council empowered by its own act.

Local administration organizations can provide education services at any or all levels commensurate with their

readiness, suitability, and the requirements of the local area. The Ministry of Education prescribes criteria and procedures for assessing readiness to provide education services, and assists in enhancing their capability in line with the policies and required standards. Additionally, the ministry advises on the budgetary allocations provided by local administration organizations.

Educational Finance

The current reform proposal encourages greater support for education from local resources. However, the major source of local funding for education still comes from the central government.

The Thai government has, for the last decade, allotted a generous proportion of the national budget to the education sector. The share of education as a proportion of the GDP has remained fairly constant, declining only slightly from 3.9% in 1997 to 3.7% in 2006. Over the past decade, the education share of the budget was largest

in the year 2000 at 25.7% and declined to 21.7% (Bht. 295 million) in 2006. The largest proportion of educational funding in 2006 (43.6%) has been allocated to preprimary and primary education. Secondary education and higher education received 26.6% and 15.3%, respectively, while only 1.3% of the total educational budget was allocated to nonformal education.

In 2004, two laws were enacted to increase private sector participation in educational provision, one exempting income tax and value-added tax on imported learning materials, and the other granting property tax exemptions.

Educational Standards and Quality Assurance

In order to ensure improvement of educational quality and standards at all levels, the 1999 National Education Act mandates, for the first time, that there shall be a system of quality assurance. Educational institutions follow guidelines for internal quality assurance standards developed by their supervising agencies. The Office for National Education Standards and Quality Assessment (ONESQA), established as a public organization in November 2000, employs the Amicable Assessment Model, to oversee external quality assessment at least once every 5 years.

Basic, vocational, and higher education institutions are assessed following standards relating to educational achievement (output/outcome); input/processes; and efficiency in administration and leadership. Moreover, on 26 October 2004, the Council of Ministers approved national education standards which will also serve as the basis for setting assessment standards of internal and external quality assurance mechanisms.

The national education standards comprised of three categories: (1) desirable characteristics of the Thai people, as both citizens of the country and members of the world community; (2) guidelines for educational provision; and (3) guidelines for creating a learning society/knowledge society.

Indicators for desirable characteristics consist of sound physical and mental health; required knowledge and skills sufficient for leading a meaningful life and social development; skills in learning and self-adjustment; social skills; and righteousness, public-mindedness, and consciousness of their citizenship of Thailand and the world.

The guidelines for educational provision consist of three indicators: development of a diversified curricula and ambiance enabling learners to develop themselves in line with their natural inclinations and to the best of their potential; systematic and effective development of administrators, teachers, faculty staff, and education personnel; and practice of school-based management.

The three indicators of guidelines for creating a learning society/knowledge society are provision of academic services and establishment of cooperation between educational institutions and community so as to transform educational institutions into a learning society/knowledge society; research and study, promotion of and support for learning sources and mechanisms; and generation and management of knowledge for the benefit of all levels and components of the society.

Concluding Remarks

The government has been supporting educational reform with the aim to prepare and strengthen Thai people to cope with rapid changes in the globalization age and to develop a knowledge-based society as a prerequisite for a knowledge-based economy. The first 1999 National Education Act was promulgated as a legal framework for education. Based on the principle of education for all and all for education, the major aspiration in the reform is to provide quality education and equal access to lifelong education and training. Participation from all stakeholders and support from government policy on education are, inevitably, the key success factors in pushing forward educational reform.

Background Information

The Gambia was a former British colony used as a port of transiting slaves from the West African subregion to Europe and other continents during the transatlantic slave trade. It acceded to independence in 1965 and to the status of Republic in 1970.

Physical and Climatic Characteristics

The Gambia is a small Sudano-Sahelian country in West Africa, lying between latitudes 13.0° and 13.7° North and longitudes 13.7° and 16.0° West. It consists of a narrow strip of land some 400 km long, and from 30 km wide in the west to 10 km wide in the east, on either side of the River Gambia. It is bordered on three sides by Senegal and on the west by the Atlantic Ocean. The country has a subtropical climate, typified by a long dry season (November to June) and a short wet season (July to October). Rainfall distribution is irregular and ranges from 800 mm a year inland to 2200 mm in the coastal areas. Average temperatures range from 18°C to 30°C during the dry season and 23°C to 33°C during the wet season.

Demographic Characteristics

The Gambia has a human population of some 1.4 million people (Gambia Bureau of Statistics (GBoS) 2003 census report), with an annual growth rate of 2.7% and a density of 127 km⁻² – one of the highest in Africa. Compared to the 4.2% growth rate in the 1993 census, this shows a decline of 1.5 points over the decade, albeit still higher than the 2.5% average for sub-Saharan Africa.

In addition, the 2003 census data shows that 42% of the population is under the age of 15 years, and the economic dependency ratio is 1.22, meaning every 100 persons working takes care of another 122 persons for their livelihood. Similarly, the youth (15–24 years) and adults (15 years and over) constitute 22% and 57% of the population, respectively (GBoS, 2003).

The population distribution in the Gambia is highly uneven with much of the population concentrated around the urban areas, about 50.4% compared to 49.6% in rural areas (GBoS, 2003). This is evident in the density of 2867 and 4272 persons per square kilometer in urban areas such as Banjul and Kanifing, and 45 and 77 in rural areas such as Mansakonko and Kerewan administrative regions, respectively (GBoS, 2003). At the national

level, population density averaged about 127 persons per square kilometer in 2003, indicating an increase of 31 persons per square kilometer from a 1993 density of 97 persons per square kilometer. The implications of these high population densities, especially in the urban area, calls for both expansion and diversification of educational facilities and programs to cater to the growing demand for educational services in the country.

Economic Characters

The Gambia has a very narrow economy with no important mineral or other natural resources and has a limited agricultural base. About 47% of the population depends on crops and livestock for their livelihood (GBoS, 2003). Small-scale manufacturing activity features the processing of groundnuts, fish, and hides. Agriculture accounts for about 27% of the gross domestic product (GDP) while industry and services account for 10.7% and 62.9% respectively (GBoS, 2007).

According to the 1993 census, approximately 51% of the population was categorized as economically active. Only about 32% of the population was classified as employed, although a substantial part of the remainder of the population was occupied in subsistence agriculture. The age structure of the population suggests that there is a high dependency ratio: those in employment support a large number of young children. Of those employed, some 82% are engaged in agriculture, fishing, and related activities; 8% in industry and related activities; and the remainder in the service sector. Eighty-six percent are employed in the informal sector and 14% in the formal sector of the economy, with 77% of the latter working in the Greater Banjul Area.

Sociocultural Characteristics

The Gambia is a multicultural society with a variety of ethnic and linguistic groups composing the nation, namely *Mandinka/Jabanka* (35.9%), *Wolof* (14.5%), *Fula/Tuklor* (21.9%), *Sarabule* (8.2%), *Fola/Karoninka* (11.4%), *Serere* (3.1%), *Manjago* (2.0%), *Bambara* (1.1%), *Creole/Aku* (0.5%), others (1.4%) and ethnicity not stated (0.2%). The main religions are Islam and Christianity, with minority following traditional African religions. Muslims constitute about 90% of the population, Christians about 8%, while other traditional believers account for the rest (GBoS, 2003). Despite the ethnic and religious diversities, people of different

ethnic or religious groups have always lived together happily in a social framework characterized by mutual respect, trust, and tolerance toward one another since independence. This social setup has greatly enhanced the delivery of educational service throughout the country, in that ethnic groups live together in many settlements and communities.

Goals of the Education System

The National Education Policy (NEP) 2004–15 and the Education Sector Strategic Plan (ESSP) 2006–15, from which this medium-term plan has been developed, is tied to The Gambia's Vision 2020; that is:

to transform the Gambia into a financial center, a tourist paradise, a trading, export-oriented, agricultural and manufacturing nation, thriving on free market policies and a vibrant private sector, sustained by a well-educated, trained, skilled, healthy, self-reliant and enterprising population, and guaranteeing a well-balanced eco-system and a decent standard of living for one and all, under a system of government based on the consent of the citizenry.

Thus, the NEP is grounded in the overall goal of ensuring that by 2015, universal access to relevant and high-quality education has been achieved. Another guiding precept is the mission statement of the Department of State for Basic and Secondary Education (DoSBSE), which seeks to:

- provide access to relevant and high-quality basic education for all,
- provide high-quality education services,
- ensure gender equity in education,
- provide relevant life skills, and
- promote the principle of lifelong learning.

To situate education within the national context, the major goals pursued by the basic and secondary education sector are closely linked to the Poverty Reduction Strategy Paper (PRSP); hence, education provision in the Gambia aims at reducing poverty. It is understandable, therefore, that the sector is guided by the following motto: 'A Provision of Responsive, Relevant and Quality Education for All Gambians for Poverty Reduction.'

While the legal basis for education-service delivery responds to upholding the right of everybody to quality basic education, as contained in the 1997 Constitution of the Gambia, the Education for All (EFA) goals and the education-related Millennium Development Goals (MDGs) continue to mark such service delivery. Therefore, these instruments have been fed into the current NEP (2004–15), which clearly articulates the basic aims and objectives of education.

In pursuance of the education sector's goals, aims, and objectives, several key areas have been prioritized. These

include access; quality education; teacher education, deployment, and utilization; technical and vocational education and training (tvvet); tertiary and higher education and sector management.

Structure of the Education System

The government's strategy is to develop the industrial and infrastructural subsector comprising manufacture, transport and communications, and energy. For the education sector, the strategy implies an emphasis on basic education (grades 1–9), increased access and quality; expansion of senior secondary education (grades 10–12) to ensure up to 50% transition from grade 9 to 10; skills training; the development of scientific and technological competencies; improved acquisition of numeracy and literacy skills; and the establishment of the University of the Gambia initially for a limited number of students in some critical disciplines to fill the dearth–capacity gaps in the labor force.

The DoSBSE in the Gambia has the sole responsibility for the provision of the full range of educational services. The formal system consists of 6 years of lower basic, 3 years of upper basic, and 3 years of senior secondary schooling followed by 3 years of continuing education at tertiary institutions or 4 years at the university level. The first 9 years of education constitute the basic education cycle, which is mainly provided by government while the senior secondary, technical and vocational, and tertiary and university education are funded largely through the grant-in aid arrangement and the private sector.

Basic Education

The Gambia's NEP (2004–15) provides for a unified basic education system, covering years 1–9, through an automatic transition with no transition examination at the end of the lower-basic cycle. Thus, there is a rapid expansion taking place at the upper-basic level, and a policy of integrating basic education facilities through the creation of basic-cycle schools and stand-alone upper-basic schools. (These are schools that combine within the same structures the lower and upper-basic components (grade 1–9) and administered by a single headteacher.)

The overall basic-education program consists of early childhood development, basic education (grades 1–9) and adult and nonformal education.

Early Childhood Care and Development

Under the expanded vision of basic education, preschool education is provided to children between the ages of 3 and 6. Until 1995, the number of preschool centers registered was 125, found mainly in the capital city, Banjul,

and the immediate surroundings. However, by 1998, this number had significantly increased to 265.

According to The Gambia's EFA 2000 assessment, early childhood care and development (ECCD) is entirely provided by the private sector, while the role of government continues to be one of coordination and supervision of service delivery. From the same study too, it was reported that only 46% of urban children and less than 17% of rural children have access to ECCD. This is mainly due to the high fees and parental inability to pay the fees charged in preschools.

The impact of the expanded vision of basic education is expected to raise the admission rate of 39.4% of 3-year-olds, which represented 40 124 children in 2006, to 45% by 2011. The enrolment output of this is expected to be 91 076.

Lower-Basic Education

At the level of the lower basic, enrolments for the period 2001/02 to 2006/07 increased from 157 544 to 220 423 registering a gross enrolment ratio (GER) increase from 82% to 92%, taking into account the Madrassa enrolment, which formed 10% and 15% of the total enrolment in 2001/02 and 2006/07, respectively. (This includes only the officially recognized Madrassas.) During the same period, the GER for boys showed a decrease from 85% in 2001/02 to 82% in 2004/05 but a slight increase to 92% in 2006/07, while the GER for girls registered an appreciable increase from 80% to 95%.

Upper-Basic School

In the area of upper-basic education, there has been rapid expansion between 2002 and 2006 with enrolment increasing from 42 094 to 68 024 translating into a GER growing from 43% to 65%. This growth in enrolment represents an annual growth rate of 15%, which exceeds the target of 12.7%. However, the period under review witnessed a drop in the GER from 65% to 61%, with the enrolment for girls dropping slightly from 32 597 in 2005/2006 to 32 047 in 2006/07, while that of boys increased from 33 433 to 34 442.

Madrassa Education

The Madrassa (Islamic Arabic Schools) is a formal education-delivery institution with Arabic as a medium of instruction and a strong Islamic orientation in content and practice. There are about 149 registered Madrassas, double the number initially planned. Between 2004 and 2006/07, Madrassas accounted for 65% of the enrolment increase in primary schools, and the Madrassas now account for an estimated 16% of lower-basic-school enrolment, up from 10% a decade earlier, and the majority of this increase is in Madrassas that have synchronized with the national curriculum.

Adult and Nonformal Education

According to the census report, 2003, cited in The Gambia CONFINTEA VI Report 2008 (GBoS, 2003), the literacy rate in the Gambia for the population aged 10 years and over is estimated at 52.1%, 40% for female, and 64% for males.

On the literacy levels for the official age cohorts for adult literacy in the Gambia, the 15–24-year cohort captures 63%, while 15-year-and-above cohort is estimated at 42.5%, with 30.6% for women and 55.1% for men (The Gambia report for CONFINTEA VI, 2008). Although these literacy rates have fallen below the average for sub-Saharan Africa (77%), there have been appreciable levels of improvements from the 1998 levels of the 15–24-age categories for men and women, which stood at 48.5% and 25%, respectively.

As many as 13 450 women and out-of-school youths in 309 communities are literate in the local languages (*Mandinka, Pular, Wolof, Fula, and Sarabulleb*) and 21 828 women and youths trained in various skills.

Secondary Education

In the Gambia, secondary education continues to be a major problem for the education sector as most of the schools at this level are privately operated, thereby, rendering access quite difficult for children from poor families, particularly those in the peri-urban areas. Notwithstanding the fact that majority of the secondary schools are located in the urban areas (regions 1 and 2), provincial children are not left out and have experienced an upsurge of secondary schools of late, which have resulted in an increase in enrolment of children into secondary schools in these regions.

Second, although not as bad as it used to be in the past, girls still continue to lag behind at this level in terms of numbers (boys, 18 661; girls, 14 330). Tuition fees and other cost (uniform, textbooks, transportation, private tuition/classes, etc.) of secondary education, including considerable opportunity costs, represent severe barriers to access for children from poor families.

The quality of secondary education, as reflected by performance of students at the West African Senior Secondary Certificate Examination (WASSCE), leaves a lot to be desired. In 2007, 90.93%, 66.65%, and 63.82%, of candidates failed mathematics, English, and science, respectively. On average, more than half of the candidates failed all the courses. Thus, the desire to achieve postbasic education (secondary education) will continue to be an important activity for the sector. These daunting problems warranted the sector to have the following targets and objectives set in the 2008–11 education medium-term plan.

Technical Vocational Education and Training

Expenditure on vocational and technical education has remained constant in real terms, at about 3% of the recurrent budget. This represents a sharp fall since the 7% in 1990, largely explained by the absence of a comprehensive policy on vocational education and technical training for the sector.

TVET in the Gambia has a variety of forms and a range of purposes, by far the most important of which is to mobilize human resources in response to manpower needs and employment opportunities in the Gambia.

Institutionally, the main providers of TVET are the Gambia Technical Training Institute (GTTI) and a network of other institutions, which are categorized under technical institutes, vocational and skills training, with the GTTI being the lead technical institution for technician training.

During the policy period (2004–15), there are plans to institutionalize accredited postbasic education programs such as apprenticeship or on/off-the-job vocational and technical training.

Since government recognizes the importance of TVET provision in relation to sustainable postbasic and secondary education and training systems, which builds on the skills base of our people and encourages the long-term development of the country, the National Training Authority (NTA) has been set up to offer the opportunity and the platform to launch a major initiative in the expansion of TVET provision in the Gambia. Through this instrumentality, efforts are being made to design and develop a variety of national diploma and higher national diploma programs to meet the existing shortages of trained manpower in the country.

The NTA, which is private sector led, will be issuing National Vocational Qualification (NVQ) in association with educational and training establishments and employers. Awarding bodies will be established to develop nationally accredited examinations for skills areas, trades, and professions, which are based on international best practice.

The NTA's role as a link representing the transition from secondary to higher levels of education through a variety of programs and courses that could be the building blocks for higher professional-degree programs is also being strengthened and developed.

Tertiary and Higher Education

In the Gambia, the tertiary-education program refers to all postsecondary programs, including universities, colleges, teacher-training institutions, professional institutes, and other postsecondary technical training. During the 2004–15 policy period, Government of The Gambia

(GOTG) will ensure that the tertiary education subsector provides a flexible and dynamic system of education and training that will address the demands of access and equity on the one hand, and the need for quality and standards (excellence), on the other.

There are, at present, four main public tertiary institutions in the Gambia that together provide a variety of programs at the postsecondary level: the Gambia College (GC) in education, agriculture, nursing, and public health; the Gambia Technical Training Institute (GTTI) in technical and vocational education; and the Management Development Institute (MDI) in the area of management studies provide trained and skilled human resources at the middle levels of services and industry. The programs provided by these three institutions are below the bachelor's degree level. The fourth tertiary institution, the University of The Gambia (UTG), provides programs leading to only the bachelor's degree in the basic sciences, agriculture, humanities, and medicine. Together, these four institutions serve only about 5000 students.

Each of the four institutions is autonomous with its own governing council/board and academic structures. Although all four institutions rely on government support, students also contribute toward their own education through tuition fees.

There were significant increases in enrolment at the GC and the UTG between 2005 and 2007, representing 69.8% and 61.3%, respectively. During the same period, the MDI and GTTI experienced significant drops in enrolment by 34.3% and 13%, respectively. These were due to the high rate of competition for program options with newly established institutions offering either cheaper or better programs of the same kind.

Teacher Education

Although tertiary education no longer falls under the purview of this Department of State, teacher education and training still continues to be the responsibility and interest of the sector. Thus, their training mechanism and supply remain to influence our drive toward attaining access and quality education as we endeavor to achieve the MDGs and EFA targets.

The Gambia Training College significantly enhanced its intake of Primary Teachers' Certificate (PTC) and Higher Teachers' Certificate (HTC) students over the past 5 years, resulting in an increase of 1024 qualified PTC teachers and 1034 HTC in the system.

Improved Sector Management

The Department of State for Education, which has always been responsible for the management and coordination of

education programs and services in the Gambia has, with effect from the year 2007, been divided into two departments of state namely, the DoSBSE and the Department of State for Higher Education, Research, Science and Technology (DoSHERST).

Under the new arrangement, the DoSBSE will continue to be responsible for policy development, management, and coordination in the basic and secondary education subsector. In spite of the separation, DoSBSE is still the largest employer of civil servants, numbering 7689, which represents 39.8% of the civil service. (July 2007 IFMIS payroll and quoted in the study 'The Gambia Improving Civil Service Performance,' February 2008. It must also be noted that the figure does not include staff in subvented institutions.) In an attempt to improve the management of the sector, six directorates have been established at headquarters and six directorates at regional level, each headed by a director. While the headquarter directorates monitor and evaluate policy implementation across the system, the regional directorates are responsible for program implementation at the regional level.

At another level of monitoring, two separate structures, namely, the senior management team (SMT) and the coordination committee, have been established to formulate policy and monitor policy implementation, respectively, on the ground. Both committees comprise all the directors and are chaired by the permanent secretary with the secretary of state serving as a member of the SMT only. In addition to the directors and the two deputy permanent secretaries, the coordinating committee is composed of key stakeholders in the education sector. These stakeholders include, among others, nongovernmental organizations operating in the education sector, the Gambia Teachers' Union, the West African Examinations Council (WAEC), and the GC, responsible for teacher training.

Education Expenditure

The Gambia has an average per capita income of US\$ 420 (2007). It ranks 155 out of the 177 countries in the 2007 human development index. The poverty head count is 58%, with higher pockets of poverty in rural communities. The economy has a small internal market and lacks diversification.

Total Recurrent Expenditure

Government expenditure on education during the late 1990s to date reflects an increased public allocation to education of 39% in current prices (19% in real terms). The 2001 planned expenditure is an increase of 50% in current and 23% in constant terms from 1998.

This translates to 7% per annum, substantially more than the planned target of 4.3% annual growth.

Education's share of total government expenditure (excluding debt service) rose from 24% in 1998 to 25% in 2000 and 2001. As a proportion of overall recurrent spending, it varied between 14% and nearly 17%. Compared with the GDP, recurrent education spending rose steadily, from 3.2% of GDP in 1998 to 4.1% in 2001.

A large proportion of investment spending is financed through project grants or loans by external donors plus government local fund (GLF). Total Gambian public sector spending on education (current and capital) grew from 3.6% of GDP to 4.3% over the period.

The shares of expenditure allocated to the different levels of education continue to reflect the policy priorities of the sector. Allocation to basic education increased from 56.8% in 1998 to 64.1% in 2001. This is as a result of the accelerated expansion at the basic education level, particularly in upper basic education, compared to senior secondary education whose share dropped from 14.5% in 1998 to 11.0% in 2001.

Given that the education recurrent budget grew faster than expected, the growth targets set for each level of education, with the exception of technical/vocational education and adult education, were far exceeded. In particular, expenditure on basic education increased at a real annual rate of 11%, reflecting the rapid increase in enrolment. Secondary spending actually fell in real terms by 2.3% a year. Real spending on the quality and relevance component (including spending on preservice and in-service teacher training) grew by 7% a year.

While most sub-Saharan countries spend well over 90% of their recurrent budgets on salaries, leaving very little for maintenance and books, expenditures on these items at the basic-education level (including grant in aid), in the Gambia, continues to be maintained below 80% on average. Operation and maintenance receives 4.2%, teaching and learning supplies receives about 2% of the recurrent budget, while approximately 3% is allocated to examinations, and about 15% to grant in aid.

Recurrent Expenditures

The education policy 2004–15 calls for private participation in the delivery of educational services. The current national expenditure for education is projected at GMD 615 966 000. Government commitment to the sector continues to be unwaveringly strong. However, due to economic constraints and external pressures, budgetary allocations to the sector had suffered significant drops in proportionate share over the past years. The Department of State for Finance and Economic Affairs (DOSFEA) has expressed its commitment to restoring the sector's share to a minimum of 20% by the end of the medium term.

This has already been demonstrated in the allocations to the sector in the 2009 round of bilateral budget discussions, in which allocations to the education subsector increased from 14.4% (11.3% for basic and secondary education) in 2008 to 19.1% (16.2% for basic and secondary education) in 2009. This has been possible sequel to receipt of government attainment of heavily indebted poor countries (HIPC) completion point and subsequent receipt of the multilateral debt relief initiative (MDRI) support. There is, therefore, a strong basis that this increase will be sustained over the medium term.

It would be observed that government is funding 17.3% (14.3% and 3.0% for investments and recurrent costs, respectively) while the donor partners are financing 31.4% and 10.3%, respectively. The catalytic funding is projected at 15.4% of the overall program cost (11.5% and 3.8% of investment and recurrent, respectively). The funding gap thereof stands at 34.9% of investments and 6.2% of recurrent expenses, an overall funding gap of 41.1% of the program cost.

Sector Monitoring and Evaluation

In order to ensure that an monitoring and evaluation (M&E) system is fully functional, the DoSBSE will ensure that monitoring and tracking reports are produced and circulated on time to all concerned parties for possible actions. It is expected that follow-ups to the reports, amendments, or reevaluations of the situation would be considered while targets, objectives, and timeframes would be redefined to address the realities on the ground.

The M&E system for the education system has the purpose of ensuring compliance of its educational objectives and goals by means of a continuous monitoring of ongoing activities, intervention strategies, and the products to be obtained in its six components. The system will function with a set of indicators defined in numerical values showing the real progress expected by the education action plan. The impact indicators will be measured annually.

To this end, annual data collection will be jointly conducted by the Planning, Policy Analysis, Research and Budgeting Directorate (PPARBD) and Human Resource Directorate (HRD). As regards quality targets, the Standard and Quality Assurance Directorate (SQAD) will ensure that the Learning Achievement Target (LAT) is conducted annually followed by the community participatory approaches to assess school performances. HRD will continue the instituted staff-appraisal schemes to inform the training and promotion prospects of teachers.

In order to provide guidance to the implementation process for the strategies outlined above, the bimonthly SMT and coordinating committee meetings (CCMs) will be maintained and strengthened to focus more on outcomes of and results for interventions.

The institutionalized arrangements of annual sector and donor reviews will be maintained and conducted regularly.

Since civil society has much experience and a crucial role to play in identifying barriers to EFA goals, and developing policies and strategies to remove them, participation in monitoring and evaluation will be attracted from civil-society organizations. This is essential in order to foster the development of accountable, comprehensive, and flexible educational-management frameworks.

Major Changes and Issues Since 1990s

Based on both normative and summative evaluations of various interventions conducted with support from the EFAI/Fast Track Initiative (FTI) and other bilateral and multilateral donors, there is evidence to indicate that significant successes have been registered within the sector. These include expanded access to education across all levels of the school system, particularly by girls in the rural area, where, in some instances, interventions led to the unintended decline of boys' enrolment. Whereas, for instance, the GER in 1998 was 85%, it rose to 92% in 2007. Concurrently, the GER at the upper-basic level, which stood at 29% in 1998, has risen by over 30 percentage points to 65%. These achievements have ultimately contributed to the attainment of gender parity at the basic level (i.e., from grades 1 to 9). Similarly, the GER at the senior-secondary level has doubled from 15% in 1998 to 32% in 2007.

Generally, resources are more equitably distributed and better utilized for program implementation. The reviews and updates of the curriculum have also resulted in a more relevant, and therefore, more responsive curriculum to stakeholder needs. (This is in accordance with the study commissioned by the Association for the Development of Education in Africa (ADEA) for the 2008 Biennale.) The acute shortage of instructional materials for effective learning that was lamented in the past has been reversed through substantial investments in various items, including core textbooks and teachers' guides, supplementary learning materials, especially books written by Gambian writers. Added to these, the sector has registered the following achievements:

- The expanded vision of basic education, which comprises early childhood education, adult, and nonformal education, and formal schooling of 9 years (i.e., from grades 1 to 9) is now being implemented in full and stands out as a successful model in Africa.
- The partnership between the DoSBSE and the Madrassa proprietors, through the General Secretariat for Islamic/Arabic Education, continues to enhance access, while improving the quality of education provided.

The teaching of English language in the Madrassas that are being granted aided by the DoSBSE and the harmonization of the various syllabuses of the Madrassas and their synchronization with the curriculum of the conventional schools have contributed to this success.

- There is a more equitable distribution of qualified teachers, as shown by the impact reports from the regional directorates on the hardship allowances currently paid to teachers.
- The textbook rental scheme has been abolished, and the student–textbook ratio is 1:1 for the core subjects at the lower-basic level; that is, from grades 1 to 6.
- While the transition from the lower-basic (primary) level to the upper-basic level increased from 72% in 1998 to 88%, in 2005 as a result of phasing out the Primary School Leaving Certificate Examination, the transition rate from the basic level (grade 9) to the senior-secondary level (grade 10) has exceeded the 50% target. (This is as a result of children repeating and dropping out at the end of grade 6.)
- The PTC extension program for unqualified teachers, being piloted in region 5, promisingly stands to contribute to addressing teacher requirements in the school system, particularly with regard to the training of female teachers (Gender Education Unit Evaluation Report, 2007).
- Interest and public involvement in education is broadening and deepening, as evidenced by participation in the weekly televised (Education Forum), and radio, programs as well as other discussions on education. The DOSBSE continues to hold monthly *Bantabas* (town hall meetings) to discuss pertinent issues with stakeholders. Early childhood development (ECD) is no longer considered a luxury but an integral part of the basic education program.
- As evidenced by the 2006 and 2007 results of the WASSCE and The Gambia Basic Education Certificate Examination (GABECE) respectively, the performance

of students is steadily improving (analyses of examination results by the planning directorate, DoSBSE, 2006 and 2007).

- Through the cluster monitors, a more effective and decentralized monitoring mechanism has been established with effect from 2007.
- The process has begun for instituting a performance-management system (PMS). Thus, operational unit and individual plans have now been developed, leading to the profiling of the sector personnel for appraisal purposes.

Country Profile

The Philippines is an archipelago comprising 7107 islands and stretches from China in the North to the Indonesian archipelago in the south. Its northernmost island is located south of Taiwan (Chinese Taipei) and southernmost islands are just 24 km away from the coast of Borneo. It is divided into three main island groups: Luzon, Visayas, and Mindanao, which are geographically divided into 17 regions and 71 provinces.

The Philippines had a population of about 88.5 million as of 2007 and Metro Manila had a population of almost 11 million, the largest in the whole archipelago (NSB, 2007). The Philippines had a predominantly Christian population, 85% of which is Catholic, about 10% is Muslim, and the rest account for other religions.

The national language of the Philippines is Filipino. For the purposes of communication and instruction, however, its official languages are Filipino and, unless otherwise provided, English (Philippine Constitution, 1987). It has 171 regional dialects and about ten main languages, including Tagalog, Cebuano, Hiligaynon, Tausog, Mindanaoan, Pangasinense, Waray, Iloko, Kapampangan, and Bicol.

The climate in the Philippines is generally tropical and varies according to its topography. The southwest monsoon lasts from June to November, which brings sultry wet weather. The northwest monsoon, on the other hand, occurs in December. The average temperature is 80°F/26.6°C–90°F/32°C.

Brief Historical Account of the Philippine Educational System

The Philippine educational system shows lasting influences of the Spanish, American, and Japanese regimes. After nearly four centuries of Spanish rule, an educational system covering the elementary to collegiate levels was established through the promulgation of the Educational Decree of 1863. The decree made possible the establishment of complete secondary and collegiate levels of instructions, the provision for government supervision and control of these schools, and the establishment of teacher training institutions (Estioko, 1994).

When the Americans occupied Manila in 1898, they immediately reopened the schools. The American regime was marked by an extensive public educational system that used English as medium of instruction. The regime

attempted to unify the archipelago, to spread the ideals of democracy, and to facilitate colonial rule. During this period, the Philippine educational system, particularly the public school system, became unified and well organized, enabling every citizen to enjoy the benefits that education provides. This was also the time when the educational system was overhauled, when grade 7 was eliminated and when the double-session plan was introduced to accommodate more students (Zwanopoe, 1972).

During the brief Japanese occupation (1941–44), the Japanese redirected the political and cultural orientation of education from Western to Japanese values rooted on love for neighbor. Vocational education and the use of Niponggo as medium of instruction were also introduced. The Japanese also stressed the importance of physical education and music, particularly singing Japanese songs (San Mateo and Tangco, 1997).

After the Philippines was granted independence on 4 July 1946, the government focused on rehabilitating the educational system and on conserving the Filipino heritage. The Philippine educational system also stressed the importance of attaining socioeconomic development, nonformal education, and vocational training. The system was revolutionized to bridge the gap between manpower development and the country's industrial needs.

Today, the Philippine educational system adopts a more quantifiable measure of performance, promotes values of good citizenship, English instruction, global education, and strong technical–vocational education (TVE). It aims to address multiple and diverse challenges and support a system of capacity building and institutional streamlining (Figure 2).

Goals of the Philippine Educational System

The 1987 Philippine Constitution serves as the major legal basis of the Philippine educational system, to wit:

The state shall protect and promote the right of all citizens to quality education at all levels and shall take appropriate steps to make education accessible to all.

The Philippine Education Act of 1982 or Batas Pambansa Blg. 232 provided the impetus for the establishment and maintenance of an integrated system of education that endeavors to achieve and strengthen national unity and consciousness and to preserve, develop, and promote desirable cultural, moral, and spiritual values in a changing world.

Governance of Education

The Congressional Committee on Education (EDCOM) restructured Philippine educational system. Congress passed laws to support trifocalization of education and refocused the educational governance as follows:

1. *Basic education.* The Department of Education (DepED) was mandated by the Basic Education Act of 2001 or Republic Act (RA) No. 9155 to cover elementary, secondary, and nonformal or alternative learning system (ALS). The DepED was vested with the authority to raise standards of basic education and enhance the efficiency of the system. It comprises three bureaus – the Bureau of Elementary Education, the Bureau of Secondary Education, and the Bureau of ALS. Each bureau is headed by a director who manages and supervises its operation and implements its projects to fulfill its functions.
To ensure the implementation of the DepEd's policies throughout the country, it has 17 regional offices, one in each region, in addition to a central office in Metro Manila. A region typically covers four to eight provinces; each DepEd regional office has a secondary education division unit responsible for implementing policies in and for supervising secondary schools.
2. *Technical education.* Midlevel skills education and training falls under the purview of the Technical Education and Skills Development Authority (TESDA), which was established through the enactment of RA No. 7796, also known as the Technical Education and Skills Development Act of 1994. TVE provides the country with skills training and development for a particular occupation or for midlevel skills training by adopting a competence-based approach.
3. *Higher education.* The Commission on Higher Education (CHED) was created under Republic Act 7722. It is mandated to oversee higher education programs in the country. It endeavors to inculcate values and attitudes for nation building, to develop professions and technologies appropriate for national development, to attain high standards of excellence and efficiency, and to strengthen academic freedom. The CHED is headed by a chairman ranked as department secretary and four commissioners ranked as undersecretaries. It has three major central offices – the Office of Programs and Standards; the Office of Policy, Planning, Research, and Information; and the Office of Student Affairs. It also has 17 regional offices that serve as extensions of its regional offices.

Philippine Educational Ladder

The Philippine educational system can be categorized into formal and nonformal. Formal education is defined

as a sequential progression of academic schooling in three levels – elementary, secondary, and tertiary. Education is compulsory from age 7 to 12 years, covering the six elementary grades. The number of years of formal schooling in the Philippines is shown in **Figure 1**.

The Philippine educational ladder has a 6 + 4 + 4 structure, that is, 6 years of elementary education, 4 years of secondary education, and, typically, 4 years to gain a bachelor's degree, which is considered one of the shortest cycles in the world. A bachelor's degree in the Philippines is obtained after 4 years, which may be extended up to another 4 years for courses such as engineering, medicine, and law. Postgraduate education is, on the other hand, usually completed in 2 years.

The academic school year (SY) in the Philippines starts in June and ends in March, covering a period of 40 weeks. An academic year (AY) usually comprises two semesters, after which students may opt to take optional summer classes.

English was the official language of instruction from 1935 to 1987 in the Philippines. However, the 1987 Philippine Constitution prescribed that both Filipino and English be used as official languages of communication and instruction. English continues to be widely used from the higher primary grades onward, owing to the dearth of materials and resources written in Filipino as well as Filipino-speaking teachers. This is especially true in technical–vocational fields.

Salient Features of the Educational System

Early-Childhood Education

Early-childhood education is governed by the Early Education Act or RA No. 6972, which establishes a daycare center in every *barangay* and institutes therein an overall children's development and protection program. This act mandates that the state shall defend the right of children to assistance, including proper care and nutrition, and to the provision of special protection against all forms of neglect, abuse, exploitation, and other conditions prejudicial to their development. There is a 6-month preschool program for prospective grade 1 pupils in fifth and sixth class municipalities and urban poor areas. However, there are elite preschools that also offer 4-year preschool programs, including nursery, kinders 1 and 2, and preparatory. These are optional, however, for children aged 3–6 years.

Elementary Education

Elementary education is the first stage in formal education. It is free and compulsory, comprising 6 years (grades 1–6) for children aged 6–11. Some elite private elementary

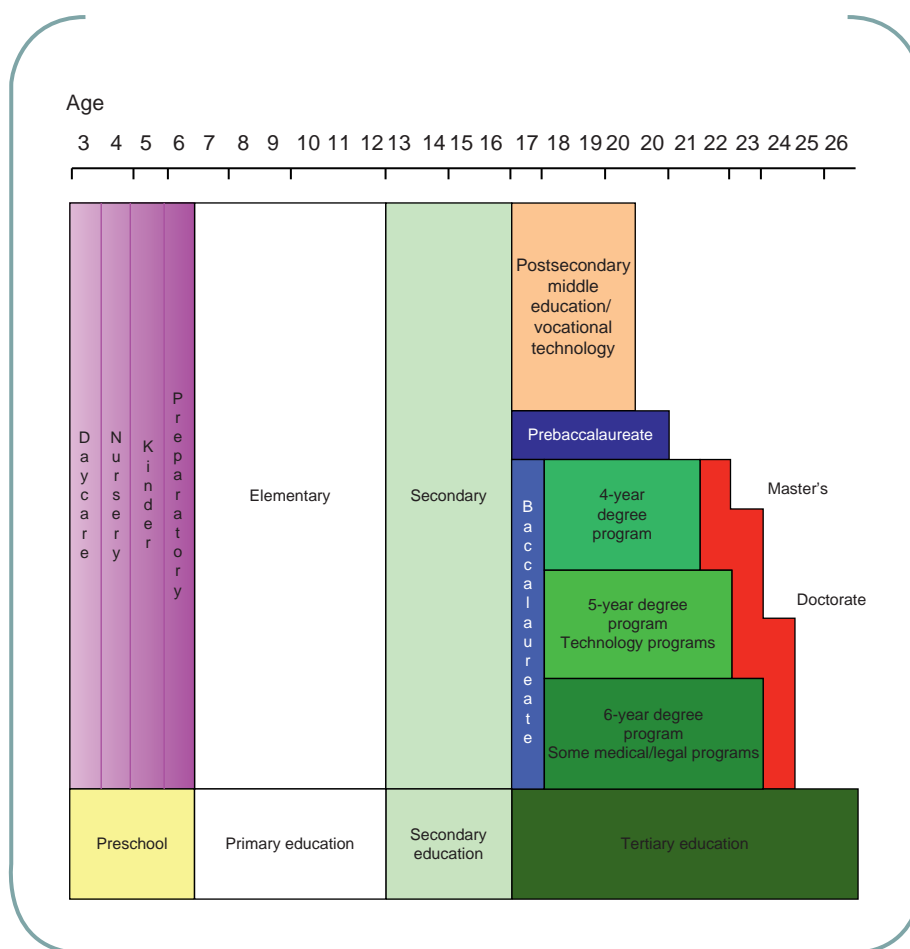

Figure 1 The Philippine education system.

schools also offer an extended elementary level, grade 7, which is optional. The basic education policy of the country prescribes a set of specific competencies in language arts (English and Filipino); mathematics; science; and social studies; or *Makabayan*, which is generally oriented toward civic development; music; arts; physical education; home economics; and livelihood education. The DepEd also prescribes a cumulative rating system where the passing grade is 75%. The students receive a certificate of graduation after completing 6 years of elementary education.

Secondary Education

Secondary education in the Philippines provides general education for students aged 12–15. It is defined as a 4-year comprehensive level, which prepares students for higher education or for the world of work. There are two kinds of secondary education – general and TVE. There are also special secondary schools in the country such as science, cultural, and sports high schools.

A general high school offers academic secondary education while a technical–vocational high school offers three specialized courses – fishery, arts and trade, and agriculture. Secondary school students are rated four times a year with a passing grade of 75%. If a student fails to get a final rating of 75% or higher in a particular subject, he/she repeats it the next year, but is, nevertheless, promoted to the next year. A certificate is issued to technical–vocational secondary school graduates. Philippine secondary schools are dominated by private schools, which require passing an entrance examination prior to admission. All science high schools require passing a competitive examination while admission to general public secondary schools is automatic for elementary education graduates.

The following subjects are taught in general education secondary schools– communication arts (English and Filipino); social studies, including history, economics, geography, and sociology; mathematics; science and technology; technical and livelihood education; computer education; youth development training (YDT); and elective subjects. Technical–vocational high schools, on the

other hand, follow a different curriculum. The first 2 years in such schools are similar to those in a general high school. However, in the third and fourth years, technical–vocational students specialize in any of the following fields – arts and trade, fishery, or agriculture.

Science high schools offer a highly specialized curriculum, which includes advanced science and mathematics courses. The Philippine Science High School (PSHS) falls under the jurisdiction of the Department of Science and Technology (DOST) while other regional science high schools fall under the supervision of the DepEd.

Every secondary education student takes a National Career Aptitude Examination (NCAE) to determine what collegiate courses he/she can take. The NCAE is administered by the DepEd every last week of August. A student who completes secondary education is awarded a diploma and a report card or Form 138, which provides a listing of all the classes he/she took and the corresponding grades he/she earned.

ALS or Nonformal Education

The DepEd boasts of a well-organized ALS to cater to out-of-school youth (OSY) and adult learners with a well-designed accreditation and equivalency (A&E) program developed by the Bureau of ALS, formerly known as the Bureau of Nonformal Education.

The nonformal education A&E system provides an alternative means of learning and certification for basically literate Filipinos and foreigners aged 15 and above who are unable to avail of formal education or who dropped out of a formal elementary or secondary school. It has four components – the NFE A&E curriculum framework, NFE A&E learning materials, the NFE A&E learning support delivery system, and NFE equivalency testing in the elementary and secondary levels. The system uses a range of innovative strategies designed to break

down traditional learning barriers – time, accessibility, and resources. It also uses a range of delivery modes within a framework of flexibility, providing learners with more control over what to learn, how to learn, when to learn, where to learn, and when to enter and exit the system (SEAMEO INNOTECH, 2007).

Higher Education

The Education Commission Report (EDCOM) recommended the creation of the CHED in 1994. The CHED is an independent government agency that is tasked to oversee higher education institutes (HEIs) in the country. The CHED currently oversees more than 1943 HEIs in the country, 451 of which are state universities and colleges (SUCs), local universities and colleges (LUCs), and other government-funded schools while 1589 are privately owned (**Table 1**). At present, there are 2 438 855 higher education students enrolled in these colleges and universities.

The CHED MIS (2007) reported the total enrolment in HEIs as 2 483 645 as of SY06–07. The bulk of enrollees are in the baccalaureate stage (2 134 856). There are 76 048 masters and 8939 doctoral students. The projected enrolment, however, shows a declining trend.

The Commission identifies centers of excellence (COEs); monitors the quality of higher educational programs; regulates the establishment or the closure of private HEIs, their program offerings, curricula, and teaching forces; enforces quality assurance and accreditation; and sets the ceiling for tuition-fee increases. Generally, private higher education institutions (PHEIs) abide by the regulations of the CHED. COEs are granted autonomy or deregulated status. The CHED also encourages HEIs to seek accreditation to receive benefits such as fewer regulations and other grants and benefits such as entitlement to student financial assistance and other awards.

Table 1 Distribution of HEIs by type (SY06–07)

<i>Sector</i>	<i>Institutional type</i>	<i>With/without satellite campuses</i>	<i>Total</i>
Public	SUCs	Main	111
		Satellite	260
	LUCs		65
	CHED-supervised institutions (CSIs)		1
	Other government-funded schools		9
Total public	Special schools		5
		Without satellite campuses	191
		With satellite campuses	451
Private	Sectarian		358
	Nonsectarian		1134
Total private			1492
Grand total		Without satellite campuses	1683
		With satellite campuses	1943

From CHED-management information system (MIS), December 2007.

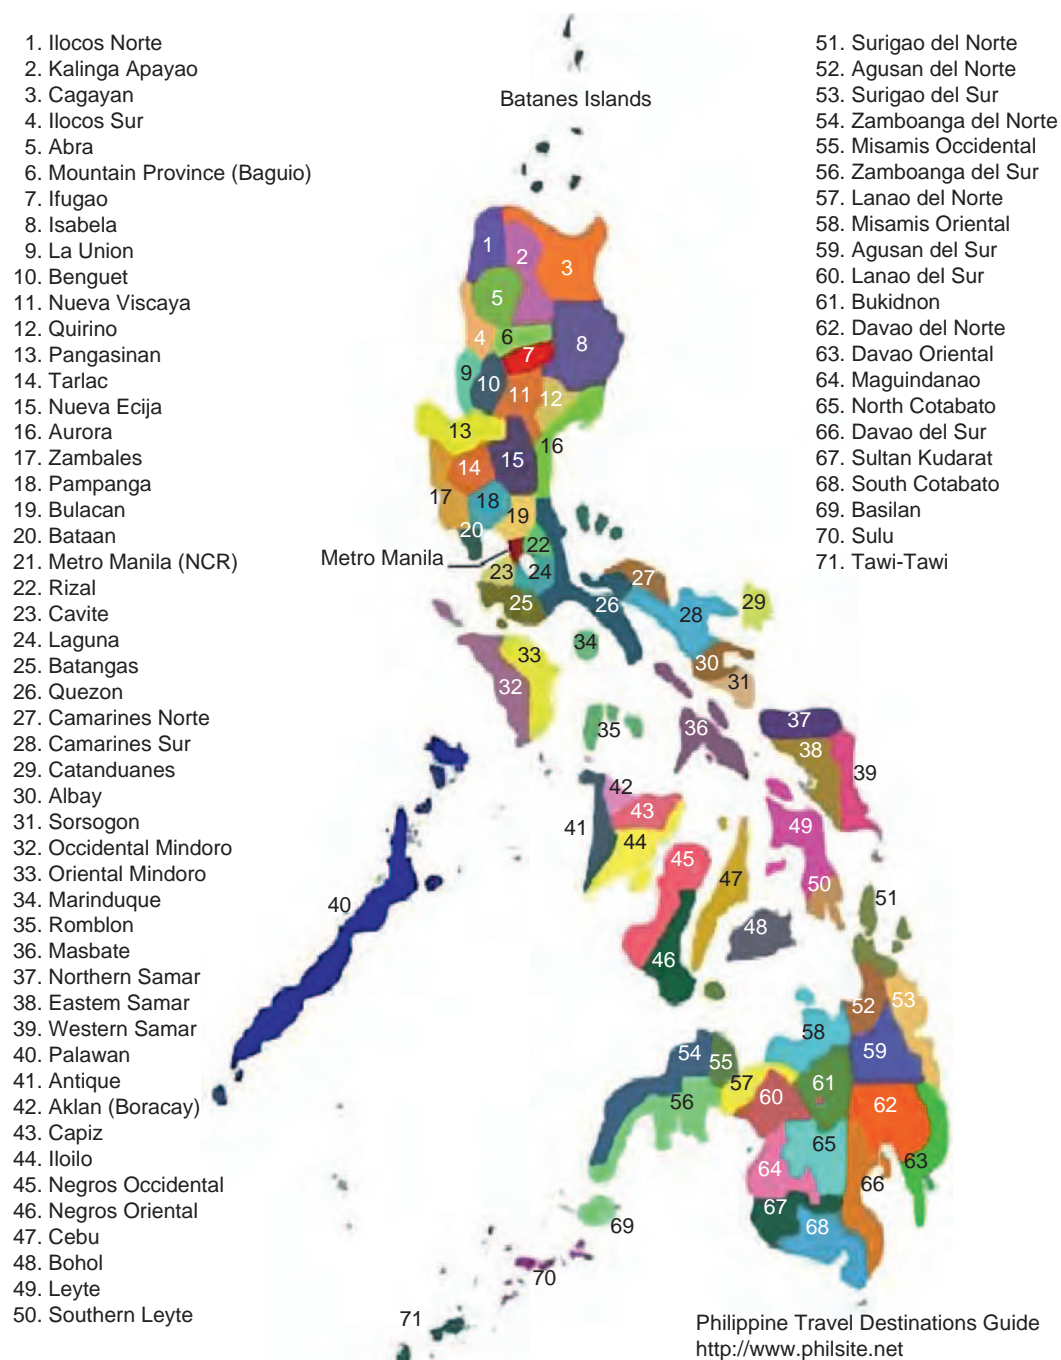

Figure 2 Regional map of Philippines.

State Universities and Colleges (SUCs)

SUCs are funded by the national government and are governed by their own charters. The funds for the local government universities and colleges (LGUCs) come from local governments. As such, their policies and programs are governed by elected local government officials. SUCs' charters ensure their autonomy and academic

freedom. They are empowered to develop their own curricula, to introduce competitive institutional programs, and to award their own degrees. The CHED ensures that SUCs adhere to the Higher Education Modernization Act or RA No. 8292, which provides for the uniform composition of the governing boards of SUCs with the CHED as chairman.

Private HEIs

Private HEIs are owned and administered by private individuals, groups, or organizations. They are classified as either sectarian or nonsectarian. Sectarian schools are usually nonstock, nonprofit educational institutions owned and operated by religious orders (Catholic and Christian schools) while nonsectarian schools are operated by private corporations, which are not affiliated with any religious organization. Majority of nonsectarian schools are stock corporations and only a few are nonstock, nonprofit corporations while a number are registered as foundations.

Private HEIs experience some degree of freedom only when their programs are recognized by CHED and when they have attained accreditation from the Federation of Accrediting Agencies of the Philippines (FAAP). Recognition of academic programs is awarded to private HEIs who comply with the minimum requirements prescribed by the CHED. Around 80 private HEIs are recognized as autonomous and have attained deregulated status according to the commission.

Admission Requirements for HEIs

Entrance to universities and other HEIs depends on possessing a high school diploma and a report card (Form 138) and, in some cases, on the results of the NCAE or, in many PUCs, the results of their own entrance examinations.

Higher education degrees

Bachelor's degree programs are usually for 4 years in length. With the short cycle of basic education, during the first 2 years, the students usually take general education courses (63 credits). In the remaining 2 years, they take professional or major courses. Some bachelor's degrees, however, require more than 4 years of study. Some of the 5-year programs are teachers' education, engineering, and architecture (226 credits). Dental and veterinary medicine, on the other hand, require 6 years of study.

Degrees such as bachelor of laws (LLB or LIB) also require 4 years of study, following a bachelor's degree. The newest program, Juris Doctor (JD), requires an additional eight units (two to four) of coursework and a thesis beyond the requirements for LLB. JD students are expected to complete an internship lasting not more than 12 months, the completion of which combined with completion of an LLB/JD degree, qualifies a student to take the bar examinations administered by the Supreme Court.

A master's of art or science degree in the Philippines usually requires 2 years of full-time study and a thesis or comprehensive examination. Admission to a master's degree requires a bachelor's degree in an appropriate discipline with an average grade equal to or better than 2.00, 85%, or B.

A doctorate in philosophy (PhD) or education (EdD) and in management (DM) requires a substantial amount of coursework. The main requirement for a PhD is a dissertation, which makes up a quarter or fifth of the degree's total credits. PhD, EdD, or DM programs usually require 2 or 3 years of full-time study beyond a master's degree. Admission to a doctoral program requires passing an entrance examination and a master's degree with an average grade of 2.00 or B.

Rating System in HEIs

The system of grading in Philippine colleges and universities is weighted according to a system of instructional units based on the number of class hours where one unit of instruction equals 1 h of lectures or 3 h of lab work per week. Four-year bachelor's degree programs in arts and sciences require a minimum of 120 units for graduation, although the minimum in many schools is likely to be 140–160 units. Some programs may require as many as 185 units.

Quality Assurance and Accreditation System

The Philippine quality assurance system is based on the concept of voluntary accreditation modeled on the regional accreditation system practiced in the United States. Four accreditation associations recognized by the DepEd and CHED were organized to encourage private institutions to raise their programs' levels above the minimal standard. These accreditation bodies are the Association of Christian Schools, Colleges and Universities Accrediting Agency Incorporated (ACSCU-AAI); the Philippine Accrediting Association of Schools, Colleges, and Universities (PAASCU); the Philippine Association of Colleges and Universities Commission on Accreditation (PACUCOA); and the Accrediting Agency of Chartered Colleges and Universities of the Philippines (AACCUP).

The FAAP coordinates and certifies the activities of individual accreditation agencies. To date, there are 221 HEIs with 832 programs in various stages of the accreditation process (Pijano, 2003). A voluntary accreditation system in the technical and vocational sector is currently being implemented by the Technical and Vocational Education Accrediting Agency of the Philippines (TVEAAP).

In the higher education system, there are four levels of accreditation. As defined by the CHED, Level I gives applicant status to schools that have undergone a preliminary survey and have been certified by the FAAP as capable of acquiring accredited status within 2 years. Institutions with programs accredited at Level II receive full administrative deregulation and partial curricular autonomy, including priority in funding assistance and subsidies for faculty development. Programs with Level III

accreditation status are granted full curricular deregulation, including the privilege to offer distance education programs. Level IV institutions are eligible for grants and subsidies from the Higher Education Development Fund and are granted full autonomy from government supervision and control. This level of accreditation is reserved for academic programs considered comparable in quality to those of internationally renowned universities. To date, there is only one institution in the country whose programs have been granted Level IV status – De La Salle University (Pijano, 2007).

Teacher Education

Admission to a teacher education program requires passing secondary education and a high NCAE score. The most common courses are bachelor's degrees in elementary education (BEEd), in secondary education (BSEd), and in another area with the addition of at least 18 units in professional education. All these programs require 4 years of study. Over the years, the teacher education sector has been vigorously and relentlessly exerting efforts to improve its existing curriculum, teacher educators' conditions, and purview. Toward this end, several reform strategies are being advocated, implemented, and revisited. The DepEd, the CHED, and the Teacher Education Council (TEC) now implement a singular competency-based development model – the national competency-based teacher standards, (NCBTS), which defines all aspects and phases of effective teacher development.

Educational Financing

Public education is generally supported by the Philippine government. It is annually appropriated by the House of Congress. Aside from this, local government units (LGUs) also offer a special education fund (SEF) as provided for under the Local Government Code of 1990. Local school boards determine the annual budgetary requirements for operating and maintaining public schools. The main source of SEFs is real property and other taxes collected by the government. The national appropriation for education covers payment of teachers and other school personnel's salaries; purchasing school materials, equipment, and textbooks; and funding for school officials' travels and other expenses. Funds for educational infrastructural projects are taken from the Department of Public Works and Highways (DPWH)'s budget. In higher education, SUCs are supported by government appropriations and matriculation fees paid by students. They also get a substantial amount of funding from income-generating projects and donations. Private educational institutions, on the other hand, do not receive government allocations or support. They mostly derive funds from tuition and other fees collected from their students.

Research in higher education

CHED prioritizes research and development activities of higher education institutions. It issued its National Higher Education Research Agenda and identified Zonal Research Centers. CHED supports incentives to higher education institutions in order to publish Refereed Journals. It also provides grant to those who conduct quality research outputs, studies, and professional papers for possible publications in high impact journal.

Major Changes and Issues since the 1990s

Trifocalization of Education

The Congressional Commission on Education (EDCOM) in 1990 recommended a major reform program that trifocalized the educational system. It created the Legal Education Board to improve the quality of law schools. It also institutionalized the dual training system that allows students to pursue technical vocational courses while pursuing their studies. It also established the CHED and the TESDA.

Ladderization Programs

The Philippine government espouses seamless education. This initiative was launched through Executive Order (EO) No. 358 (2005) entitled Institutionalizing a Ladderized Interface between TVE and Training and Higher Education. EO No. 358 stipulates a unified and articulation mechanism between the TESDA and CHED. It promotes credit transfer and recognition from technical–vocational training to a degree program or vice versa. It also establishes an enhanced equivalency system and a modularized program approach to promote accessible educational programs for all.

Quality Assurance

In the Southeast Asian region, there is a growing trend to move toward a modicum of standards. This development resulted in the identification of COEs and centers of development (CODs). This provides incentives to educational institutions, which consistently exhibit excellent qualities in instruction, research, and extension. A COE is given financial assistance to further improve the quality of its programs and activities in a particular field of study while a COD is further developed to become a COE. Given certain challenges, there is a need to develop more COEs and CODs that will emit quality assurance.

International Education and Mutual Recognition Programs

Globalization has brought about various perspectives and challenges, especially in recognizing and comparing

degrees. The country issued strict policies to regulate cross-border education (CBE) providers through a transnational education (TNA) policy. One concern is that cross-border education cannot guarantee quality of educational degrees, studies, and diplomas. As of now, the country lacked the monitoring and evaluation system governing CBE providers.

Language-in-Education Policies

The present regime supports English as a medium of instruction in response to globalization and booming business-process outsourcing trend in the country. This directive poses challenge to many educators especially for those serving the marginalized and minority groups who learn faster with the mother tongue.

Broadening Access to Education

The country is high in implementing education for all pursuant to the UN millennium development goals. It has instituted policies to provide access to education for Muslim learners and other disadvantaged groups. It has developed a Madrasah curriculum in the basic education sector and expanded the open high school program. There are also new scholarship programs enacted to enable the poor Filipino children to complete their basic education.

Uruguay

B Guinovart and C Troncoso, National Administration for Public Education (ANEP), Montevideo, Uruguay

© 2010 Elsevier Ltd. All rights reserved.

General Background

Uruguay is located to the southeast of South America, its total area is 176 220 km² and it has 3.2 million inhabitants (52% women and 48% men). It is a Spanish-speaking country with a democratic government, organized in three different powers, administratively divided into 19 departments (**Figure 1**).

Of the population, 41% reside in the capital city (Montevideo) and 92% in urban areas. It has a low population growth rate. In the next 20 years, there will be a rise in the proportion of the older layers of society, with consequent impact on public expenditure, due to the huge burden of paying retirement benefits (**Figure 2**).

Uruguay is one among the countries with a high human development. It holds the third place in South America in terms of gross domestic product (GDP) per capita. Regarding the distribution of income, Uruguay is among the most equitable countries. Despite the fact that in the last 2 years poverty was mitigated, 18.3% of the homes and half the population under 13 years of age is poor (with income below US\$160).

The GDP in 2006 amounted to US\$19 308 million. Agro-industrial production is very important, and service areas, such as financial, communications, transportation, and software services, apart from the significant increase of forestry exploitation since the 1990s, have become increasingly relevant. According to official projections, for the 5-year term 2005–09, the GDP is expected to grow at a yearly rate of approximately 5% in average.

Unemployment has decreased in the last 3 years, reaching one-digit levels (9.4%).

In the last few years, inflation has reached one-digit figures (about 6%).

The median household income is approximately US \$800. The recovery of the same, which started in 2004 after a significant fall between 2001 and 2003, is basically due to the recovery of salaries and retirements.

José Pedro Varela established in the late nineteenth century – quite early when compared to the other countries in the region – the basic principles of public education, as being cost free, lay, and compulsory. These principles were also closely linked to the consolidation of the national state with a strong capacity for social integration.

At present, the public system of education has 85–87% of students registered at all levels (960 000 students approximately), with the exception of preschool, where the percentage is lower: 67%.

Goals of the Education System

Within the framework of the goals for the millennium, **Table 1** shows the existing gaps in the case of Uruguay and the main goals that are yet to be achieved.

General objectives

The general objectives mentioned in the 2005–09 strategic plans are:

- Contributing to sustainable human development by promoting the democratization of the educational system.
- Aiming at scientific, technological, and artistic development.
- Improving the quality of education at all levels.
- Diversifying educational offers, increasing their presence outside Montevideo.
- Dignifying the work conditions and improving the existing buildings to enhance production function of the education-related staff.
- Decentralizing management at all levels.
- Fostering management modernization processes which allow for an efficient support of the transformations.

Specific Objectives

The specific objectives mentioned in the 2005–09 strategic plans are:

- Introducing studies in recent history, sexual education, and human rights at primary and middle levels.
- Strengthening the pedagogical bond.
- In primary education: globalizing the educational coverage for 4- and 5-year-olds as well as ensuring the completion of primary education level; broadening the coverage by means of full-time schools (FTSs); developing a primary attention school model for critical sociocultural environments; and achieving effective results in the practice of physical education.
- In middle school: globalizing the coverage of the basic cycle; improving the levels of coverage of middle high school; significantly reducing dropout and fall-behind levels; and reducing excessive rotation of teachers.
- In teacher education: strengthening graduate education; fostering postgraduate education; and giving it a university-level status.
- In technical-professional education: developing and consolidating middle-school and professional and

Figure 1

Figure 2 Distribution of the population according to the gender and the age range. From own elaboration based on Census Step 1 2004.

technological tertiary education within the framework of the country's productive and social development.

- In the education of young people and adults: raising the educational level of those members of society who have not completed primary studies.
- In tertiary education: generalizing advanced education establishing links with productive sectors; fostering creation of a tertiary education system; broadening and strengthening the offer of postgraduate and masters courses; playing an active role in the national innovation systems; and creating a national assessment and accreditation agency.

Table 1

Diagnosis for Uruguay (November 2003–March 2004)	<ul style="list-style-type: none"> • Six out of 10 children do not receive preschool education. • The highest dropout levels in Uruguay are at the middle-school level. • Half of the young people population are not able to finish middle high-school. • Twenty percent of the young people between the ages of 17 and 24 neither study nor work.
Uruguay's goals	<ul style="list-style-type: none"> • Globalization of the preschool education. • Globalization of the middle basic cycle education. • Extension of the middle high-school education.
Challenges	<ul style="list-style-type: none"> • Reduction of the inequities in primary school. • Teenage dropouts who do not enter the labor market. • Teacher professionalization.

Structure of the Education System: Regulations, General Functioning, and Main Institutionalities

The regulations in force set forward 10 years of compulsory education (11 years as of 2009): 1 year of preschool (5 years until now and 4 and 5 years as of 2009), 6 years of primary education, and 3 years of middle basic cycle.

Public education is free at all levels.

Figure 3 summarizes the education cycles and the type of administration.

The main institutions related to education are: the Ministry for Education and Culture (MEC), which is a part of the Executive Power; the National Administration for Public Education (ANEP), the organization in charge of planning, managing, and administrating preschool, primary, middle school, technical, and teacher public education as well as controlling private education at those same levels; the University of the Republic (UDELAR), the organization in charge of public university education and private education institutions at all levels; and the Commission for the Coordination of Education (CCE), a consultant organization.

The MEC is responsible for coordinating education nationwide. Unlike other countries, the design and application of educational policies are not its direct aims. It is also responsible for supervising private institutions at early childhood, tertiary, and university levels.

The centers for education and production (CECAPs) are also part of the MEC, providing 780 young school dropouts with basic skills. The Industrial Design Center (CDI) is in process of integration into the UDELAR.

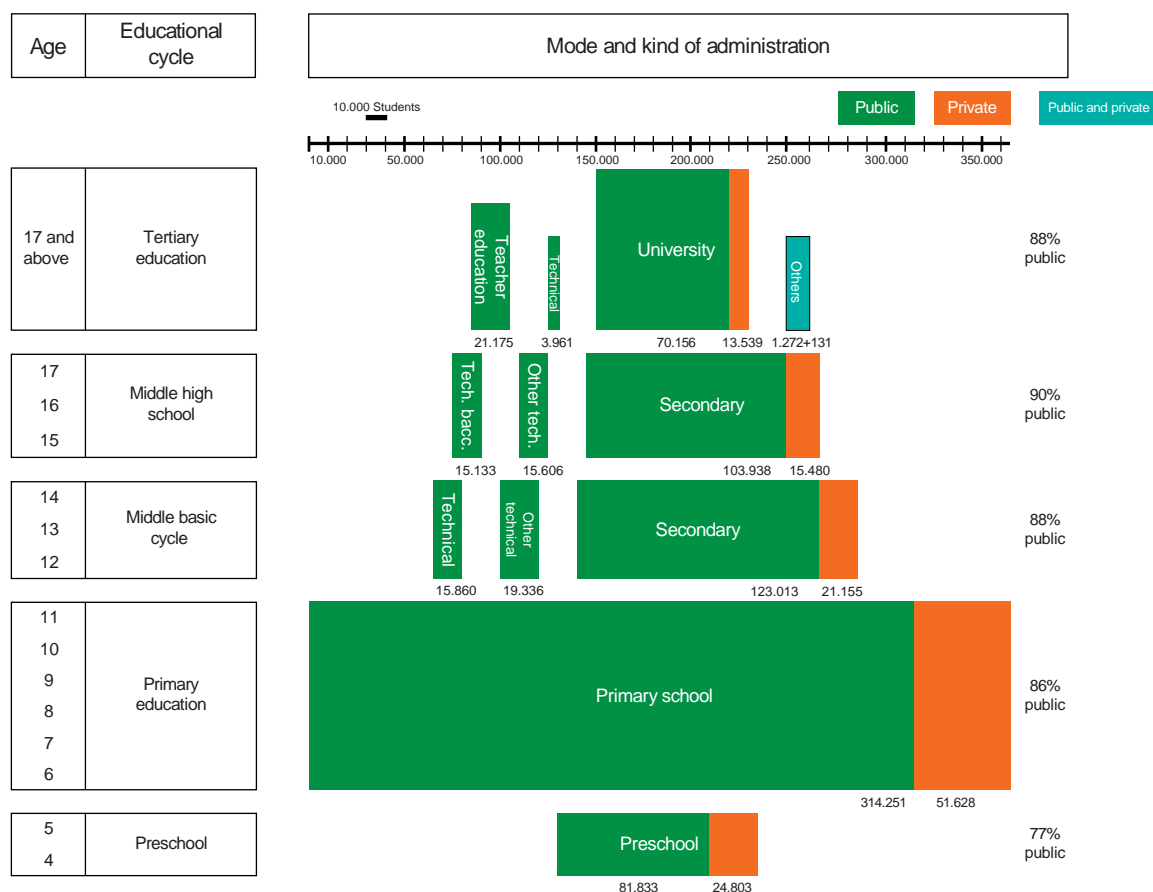

Figure 3

ANEP, which consists of 85% of the total number of students at all levels, is directed by five members of the Central Directorate Council (CODICEN). This agency is responsible for setting up the general orientation for primary, secondary, and technical-professional education plan of studies and curricula, as well as approving the plan of studies.

Within CODICEN, there is the Directorate for Teacher Education and Further Training (DFPD), and the program which is offered by them for young people and adults.

Preschool and primary as well as secondary and technical educations are directed by three independent councils, each one of which is integrated by three members: the Primary Education Council (CEP), the Secondary Education Council (CES), and the Technical-Professional Education Council (CETP). The decentralized councils above are in charge of providing education at the corresponding levels and supervising the approved private institutes at the mentioned levels.

The UDELAR – which represents 64.7% of the total number of tertiary-level students, 83% of the university students, and consists of 14 schools, three institutes, two university centers, four graduate services outside Montevideo, and one hospital – is an autonomous body that is

co-governed. Its responsibilities are higher public education, fostering scientific research and artistic activities and contributing to the study of general interest problems.

University education and university institutions were open to the private sector in 1985. Those institutions which offered teaching, research, and extension activities in three or more independent areas of knowledge were granted the status of university', whereas those which developed these activities in one or more related areas or in two independent ones, were considered university institutions.

At present, there are four private universities (Catholic University, ORT University, University of Montevideo, and University of the Enterprise) and seven private university institutions.

The private institutions are represented by two different associations: the Uruguayan Association for Catholic Education and the Association of Private Education Institutions. There is also a Council of the Presidents of Uruguay's Private Universities.

The Teacher's Meetings (ATD) held at primary, middle, and teacher public education schools are very important in the Uruguayan education system, as are the national teachers' meetings of each independent council.

This institutional order promotes and organizes teacher participation, giving teachers the rights of initiative and consultation regarding technical-pedagogical issues in their corresponding area of education.

Teacher and employee unions as well as student unions at the university level have existed for a very long time and constitute powerful groups within the educational system.

Parents and friends commissions established by public schools form the link between the community and the education centers.

Performance of the System

Population Literacy and Schooling

- The literacy rate is 97.8% (2006).
- Eighty-three percent of the population over the age of 15 have completed at least the primary education level (Figure 4).
- The population between 20 and 25 years of age have an average of 10.5 years of schooling, with significant differences depending on their levels of income (Figure 5).

Figure 4 Educational level of the population aged 15 and above – year 2006.

Figure 5 Years of schooling of the population between the ages of 20 and 25 – year 2005. From own elaboration based on ECH-INE.

Enrolment

The evolution of enrolment shows the following:

- There have been increases at the following levels: early childhood, private preschool, private primary school, public rural middle school, teacher education, and public and private university.
- After consistent increases until 2004, there were decreases at the following levels: public early childhood, public primary school, public middle school, public technical-professional middle-school education, teacher education, and tertiary technical-professional education (Table 2).

Schooling ages 3–17

The coverage rates in preschool show an upward growth curve.

At the primary education level, schooling is nearly global; 95% of the school-aged population attends school.

At the secondary education level, 70% of the population between 12 and 14 years of age attends an educational center, whereas the coverage for 15–17-year-olds is between 40% and 50% (Figures 6 and 7).

The differences in the coverage rates in relation to the level of income are significant at the preschool level and from the age of 14 (Figures 8 and 9).

Repeating and Dropping Out in Public Primary and Secondary Education

Repeating rates in public primary schools (8%) have shown a downward trend in the recent years, especially in full-time schools. The gap between schools belonging to different sociocultural contexts was narrowed (Figures 10 and 11).

Dropout rates in public primary education have decreased in different socioeconomic contexts, going from a 1.4% average in 1992 to 1.0% in 2005. Schools in unfavorable and very unfavorable contexts showed a higher dropout rate (Figure 12).

In public secondary school, repeating and dropout rates increased in the first 4 years (Figure 13).

Young People between the Ages of 15 and 17

Fifty-eight percent of the young people between the ages of 15 and 17 attend an educational center and 21% are over-age students. Of the 21% who are out of the educational system, 27% work, 23% are looking for a job, and 50% neither work nor look for a job.

Table 2

	Enrolment 2000–06

Uruguay in Programme for International Student Assessment (PISA) 2006

Upon comparison of the two tests (2003–06) it is possible to see that:

- Reading shows the lowest average for all the institutions. In mathematics, scores have not varied significantly.
- There have been decreases in the averages for all the sociocultural contexts, with the exception of the unfavorable one (Table 3).

For 2006:

- Forty-two percent of the Uruguayan students did not reach the competency threshold in science (409 marks),

while 30% did not reach the minimum performance, and 28% passed.

- Forty-six percent of the Uruguayan students did not reach the minimum score (407) in reading, 23% did, and 31% passed.
- Forty-six percent of the Uruguayan students did not reach the minimum score (419) in mathematics, 25% did, and 29% passed.
- Nearly three-quarters of the students from centers located in very unfavorable sociocultural areas scored below the threshold (Table 4).

Notwithstanding the above, Uruguay has had better results than other countries in the region in reading and mathematics (Table 5).

Teaching Profession

The preschool, primary, and middle teacher education courses are offered by the ANEP, through the DFPD established in 1986.

The DFPD has 32 centers which cover 92.1% of the student teachers – 23 296 in 2006 – and one further education and postgraduate center. In 2006, 72% of the students enrolled with DFPD were student teachers for secondary education, 27.7% for primary education and

preschool, and 0.2% for technical education. The first postgraduate course was designed in 2007, to be put into practice together with three others as of 2008.

The oldest centers in the country belong to the primary school teacher education institute (Table 6).

The enrolment at the universities which educate teachers was below 1119 students in 2006, which represented 4.8% of the total enrolment. About 40% of these students entered different postgraduate courses offered by private universities.

In UDELAR, access to a teaching position is gained through a series of competitive examinations in which the candidate's academic background – especially in the corresponding area – teaching experience, work experience, research, and extension are assessed, as along with the candidate's capacity in the educational aspect.

In the year 1968, but gaining momentum only in the 1990s, UDELAR started creating teaching support units at different schools – 16 at present – in charge of training professors in the different didactic and pedagogical aspects (Table 7).

University institutes represent 1.6% of the total enrolment, whereas nonuniversity tertiary institutes gather 1.5% (Tables 8 and 9).

ANEP has 41 139 teachers (2007 census), UDELAR has 7284 professors (2006 estimate), which represent altogether 93.7% of the total academic staff of the different educational institutions, estimated at 51 652.

Table 10 shows some of the characteristics of the ANEP and UDELAR teachers:

The salaries of ANEP teachers and UDELAR professors range from US\$250 to US\$600 for 20 h/week, depending on their seniority and academic degree. In 2002, there was an important loss in the purchasing power, which could be recovered only in 2009. However, the recovery could not fulfill the Union's ambitions, whose goal amounted to 50% of the standard household consumption basket (US\$1390).

Table 3

Table 4 Averages per area of assessment depending on the sociocultural environment and the Institutional Sector of the Education Center in 2006

<i>Environment</i>	<i>Sector</i>	<i>Science</i>	<i>Mathematics</i>	<i>Reading</i>
Very unfavorable	Public secondary school	371.8	354.6	345.0
	Technical	362.0 (ns)	370.3 (ns)	326.2
Unfavorable	Public secondary school	422.2	415.9	405.9
	Technical	381.0	381.6 (ns)	341.3
Medium	Public secondary school	448.0	452.2	448.3
	Technical	414.5	431.3 (ns)	376.4
Favorable	Private secondary school	441.0 (ns)	435.0 (ns)	456.5 (ns)
	Public secondary school	493.8	502.7	483.6
	Technical	520.9	529.6	452.2
	Private secondary school	473.4 (ns)	474.7 (ns)	478.1 (ns)
Very favorable	Private secondary school	526.3	525.6	517.9

(ns) The difference is not statistically 5% significant regarding the scores obtained by public secondary school students in the sociocultural environment in question.

Public Expenditure in Education

In the year 2006, public expenditure in education represented 3.31% of the GDP, 73% of which was given to ANEP, 19% to UDELAR, and 8% to the MEC. The ratio of public expenditure to GDP increased from 1995 with a decrease in the crisis of 2002–03 (Figures 14 and 15).

The expenditure for education represents between 11% and 12% of the total public expenditure (Figure 16).

In 2006, wages represented 81% of ANEP's expenditure and 84% of UDELAR's. Operational expenditure represented 12% and 13.5%, respectively, whereas investments represented 8% and 2.6%.

Most of ANEP's budget is financed with local resources which come from taxation (88%), 10% through a specific tax for primary education, and 2% through foreign debt. The 52% of the investments are financed through debt (Table 11).

Table 5 Trends in reading and mathematics for the Iberoamerican countries

	Reading			Mathematics		
	2003	2006	Diff. 06–03	2003	2006	Diff. 06–03

Uruguay	434	413	–21	422	427	5
OECD	498	492	–6	500	498	–2
Average						

In the case of UDELAR, more than 90% of its budget is financed through funds which come from taxation. Finance is also obtained through projects in collaboration with the productive sector.

Two relevant points need to be highlighted:

- The Mutual University Fund was created in 1994, through which UDELAR graduates and tertiary education CETP graduates contribute to financing scholarships for students attending these institutions, as well as MEC's Education and Work Program. The 81% of the scholarships granted in 2005 (3777) were for students from the departments, except Montevideo.
- The legal provision under which, from 2007, ANEP and UDELAR have additional funds to finance educational and investment projects. In the case of investment projects, the sum amounts to 20 million dollars per year.

Private education institutions are financed through the fees paid by the students, as well as by contributions from the private sector.

Research, and Monitoring and Evaluation

Research

In the year 2002, Uruguay had 3120 researchers, 89% of who worked at UDELAR; 42% of these researchers worked in the area of natural and exact sciences, 23% in medical sciences, 12% in engineering and technology, 11% in agricultural sciences, and 12% in humanities and social sciences.

Some support policies in this area are mentioned:

- The creation of the Program for the Development of Basic Sciences (PEDECIBA) in 1986, aimed at training human resources in the basic scientific disciplines and at financing research projects.

Table 6 ANEP – CODICEN teacher education centers–Directorate for Teacher Education and Further Education (DFPD)

Name	Aim	Established	Number and location
Primary School Teacher Education Institute	Education of teachers for primary school and pre-school levels	1882	One in Montevideo
Artigas Teacher Institute	Education of teachers for secondary school	1951	One in Montevideo
Technical Teacher Education Institute	Education of technical teachers for technical education	1964 depending from CETP; 1997 depending from DFPD.	One in Montevideo
Teacher Education Centers	Primary school teacher education and middle school teacher education implying presence or semipresence courses	1977	22 nation wide The semi-presence course center is conducted from Montevideo.
Regional teacher centers	Education of teachers for secondary school	1997	Six nationwide
Further education and higher studies institute	Refresher, specialization and postgraduate courses. The first postgraduate course in education and development started in 2007		One in Montevideo

- The creation of the Sectorial Commission for Scientific Research (CSIC) to foster research within UDELAR.
- The creation of the National Researcher's Fund in 1996, aimed at funding full-time researchers residing in the country, through the MEC.
- The creation of the Technological Development Program in 2001, within the MEC.
- The creation in 2006 of the National Agency for Research and Innovation, to advise the Executive Power in the areas of science, technology, and innovation, to carry out plans, and to coordinate.
- The fund forecasting for research and innovation for the 2007–09 period amounts to 19 million dollars, 30% of which corresponds to foreign debt.

Monitoring and Evaluation

The Constitution of the Republic sets forth the obligation of the public organizations to submit their public 5-year budget plans and annual accountability and execute budgeting reports to the Legislative Power. Annual reports present the amounts spent and the programs and aims associated to the same, as well as their relation to goals established in the strategic 5-year plan. The Legislative

Power may give its opinion on these matters, propose adjustments, and, after the legal terms for analysis and discussion, pass the annual accounts and budget acts.

The country has improved the submission of its annual accountability reports and has made progress in terms of defining strategic guidelines, associating objectives and

goals in executing public programs and policies. ANEP has established its strategic plan for the period 2005–09 and has put the system of indicators for the follow-up of guidelines, objectives, and goals into practice in its programs, based upon which it has been submitting its annual reports since 2006. On the other hand, UDELAR's strategic development plans define different institutional projects which guide the institution's management follow-up.

The participation of ANEP in the PISA program in 2002, the learning assessment census in the last year of primary education, and the educational monitor are crucial follow-up tools.

UDELAR's University Information System, created by the government has, among its aims, the organization of an information system which allows for the planning, follow-up, and evolution of educational management.

In terms of evaluation and accreditation systems, the points on university education are as follows:

- The Central Commission for Institutional Evaluation was created in 1998 in UDELAR, proposing the guidelines for an evaluation program. Based on this, the different member institutions started their own self-evaluation processes.
- In 2001, an external peer committee carried out the assessment of UDELAR's Strategic Plan in the areas of content, adequacy, and degree of fulfillment.
- Participation in the experimental accreditation mechanism for MERCOSUR, Bolivia, and Chile (MEXA). Four universities, nine courses, 11 309 students, and 2305 professors participated in it.
- All the courses presented by Uruguay were credited.
- The ORT University in 2007 was ranked again among the best 500 universities in the world according to the Times Higher Education Supplement of London.

In terms of evaluation and accreditation systems, the points on teacher education are as follows:

- The Coordinating Commission for Self-Evaluation of DFPD was established in 2006. Its aim is to contribute to the development of the academic conditions

necessary to raise the levels of quality and to tend toward the development of an autonomous and self-regulated university teacher education center.

Major Changes and Issues since the 1990s

Certain policies and actions have been adopted by educational institutions for the achievement of the goals and objectives presented above:

- Early education and education for life:
 - There is a project to globalize the enrolment of 4-year-olds and to advance the incorporation of 3-year-olds.

- Ongoing education units have been installed at most of the tertiary-level institutions.
- Attention to students from less-favorable contexts:
 - Full-time schools (CEP since 1992): extension of the pedagogical time, less children per class, socialization workshops, and school meals.
 - Community teachers (CEP since 2005): to favor the educational insertion of children coming from unfavorable contexts through community teachers working with the schoolchildren and their families.
 - Community classrooms (CES since 2005) to achieve the reinserion of 12–15-year-olds who have drifted away from the educational system.
 - Basic professional education for 15-year-olds and above, who have not completed basic secondary education (CEPT 2000).
 - School meals program (CEP from 2001) under which children are provided lunch at public schools.
 - Scholarship plan for students attending teacher education institutes of ANEP.
 - Economic support scholarship and housing program for UDELAR students (since 2002).
 - Scholarship programs at the different private universities under which students are exempted from the payment of the whole or part of the tuition fees.

- Strategy design and development to handle an effective number of students in order to achieve an optimum relationship between the staff and the students in public institutions.
- Incorporation of ICTs as part of the teaching-learning process and for the improvement of the academic and administrative management:
 - Creation of multimedia classrooms in 1995 at different levels to be used as pedagogical spaces.
 - Distance and half-distance educational proposals put into practice at the tertiary-education level.
 - The launch of Plan Ceibal by the present government in one department outside Montevideo to reduce technological illiteracy. By 2009, all children attending public schools shall be integrated into the one laptop per child program not only in its technological dimension but also in the pedagogical one (**Figures 17–19**).
- Territorial and management decentralization and emphasis on the education center:
 - Introduction of regional teacher inspections by ANEP.
 - Strengthening teacher training centers outside Montevideo (started in 1996).
 - Distribution of financial allotments to ANEP's education centers to be managed by them in agreement with the local educational community (started in 2006).
 - UDELAR created the Regional Norte in the department of Salto (1997) in order to strengthen the educational offer in the provinces and broadened its academic offer to 17 graduate courses, making it possible for 1000 students to access university studies.
- Private tertiary institutions have also begun to make educational offers outside Montevideo.
- The proposal of a new Education Act which is under study establishes that the education centers shall be relatively autonomous.
- Creation of coordination and decision-making spaces:
 - Creation of co-government commissions within UDELAR to foster and articulate the different university services and stakeholders involved in research, teaching, and extension.
 - The organization of graduate courses in areas of knowledge within UDELAR since 1999.
 - Joint projects between ANEP and UDELAR.
 - Willingness to organize a national system of public education and a tertiary education network.

Figure 18

Figure 17

Figure 19

Figure 20

- Updating and reformulation of study plans as a strategy to update and reach consensus:
 - In 1996, the Education Reformation was carried out in ANEP. Actions were taken regarding preschool education and full-time schools. Likewise, Plan 1996 was launched for secondary education, which implied a curricular transformation based on teaching in areas of knowledge as well as increasing pedagogical time. The Plan did not have the support of many of the members of the teaching staff. The new administration is designing a new plan referred to as Reformulation 2006 to be implemented progressively in all education centers with active participation of the different groups. Teaching shall be done in subjects again but the strategy of extending the pedagogical time shall be kept.
 - CETP technological baccalaureate: it started in 1997 and it was reformulated in 2007. It provides specific technical training for the work market, and it also enables students to enter university.
 - The graduate course study plans at UDELAR were updated between 1989 and 2002. The largest update since 2002 was the growing offer of postgraduate courses.
- The creation of educational offers that connected students to the world of employment:
 - New technological courses were launched in 2005 by ANEP-UDELAR.
 - Training of technicians for the new production processes at CETP since 2006. Private universities have outlined strategies to provide support for integration into the labor market and to undergo traineeships while studying.
- Progress has been made in terms of conceiving the building infrastructure as an intelligent and flexible

Figure 21

space, which enables pedagogical bonding as well as research. Two examples:

- UDELAR's FARO multifunctional building: three schools located nearby share this building which has large spaces and flexible facilities for different uses and different numbers of students, admitting incremental annexing even when it is in use (2007) (Figure 20).
- ANEP's multimedia learning rooms which combine a library and multimedia resources center within a space designed for teaching, studying, interaction with peers and teachers, and research.
- The creation and search for new institutionalities (Figure 21):
 - Between 1996 and 2004, three of the four existing private universities were created. In the period between 2000 and 2006, these universities had an 81% increase in the enrolment and 86% in the

graduation of students.

- The proposal to turn DFPD into an autonomous pedagogical university;
- The National Debate on Education carried out in 2006–07 in order to generate input for the creation of the new Education Act in an interactive way. The debate ended with the celebration of the National Education Symposium, which saw the participation of 1200 representatives.
- For its achievements, the government has defined a strategic plan and has undertaken to increase the public expenditure in education from 3.3% in 2006 to 4.5% of the GDP by 2009.

General Background

The US encompasses approximately 3.54 million square miles of the North American continent, positioned south of Canada and north of Mexico. Its 13 original colonies split from British rule in 1776 and were recognized as an independent, united nation in 1783 under the Treaty of Paris. Today, the US is comprised of 50 states and its capital is the District of Columbia. Its culturally diverse population is estimated to be approximately 303 000 000 people. Currently, the majority of immigrants to the US come from Mexico, the Philippines, Haiti, China, the Dominican Republic, India, Vietnam, Jamaica, Cuba, and South Korea.

The US has a per capita gross domestic product (GDP) of approximately \$46 900, making it one of the world's largest economies. Just over 12% of the population lives below the poverty line, and the country faces a number of challenges that suggest it will be difficult to reduce this percentage. The labor market is becoming more stratified such that those without some college education or professional/technical skills receive lower compensation and employment benefits. The economy also faces significant challenges related to an aging population, financial market crises, and increased medical and retirement expenses.

The first schools in the US varied by geographical region. In the northern colonies, education was first provided in homes for the sake of reading and learning religious principles. By the 1640s, laws were established increasing the number of children attending schools with teachers. In larger northern towns, Latin grammar schools were created for college preparation for boys. Southern colonies relied upon in-home tutoring and private schools for the wealthy.

By 1860, the concept of a tax-supported, free, secular public school system was adopted in the North. Following the Civil War (1865), the South established and accepted this concept for children. Today, a majority of students attend public schools, with private schools continuing to educate a significant portion of the school-aged population.

Major Goals/Historical Shifts in Educational Purposes

Four major educational goals are regarded as paramount in the US today: intellectual development, vocational preparation, training for citizenship, and social mobility. These

purposes, which have often been promoted through a discourse of equality, excellence, and efficiency, have shifted over time in response to social, political, and economic demands. There also have been regular changes in pedagogy and curricula, including shifts in mathematics between the development of basic skills and critical thinking; in literacy education between whole-language and phonics approaches; in early-childhood education between social development and academics; and in higher education between vocational training and liberal arts education.

At the turn of the twentieth century, social and civic goals were regarded as educational responsibilities. Public schools were expected to resolve social conflicts, assimilate immigrants, transition students from school to work, and teach students to be responsible citizens. After the Soviet Union's launching of Sputnik (1957), reforming science and technology education to increase national security became a priority. Subsequent responses, including the National Defense Education Act (1958), continue to shape the evolution of US education.

In the 1960s, legislations such as the Civil Rights Act, the Economic Opportunity Act, the Elementary and Secondary Education Act, and Head Start brought a shift from quality for the talented to equality for all. Throughout the 1970s, efforts were made to enhance curricular relevance, improve teaching, imbue textbooks with more gender-neutral and racially inclusive material, and more fully involve parents and communities in the educational process.

In 1983, following a report by the Commission on Excellence in Education, the public again turned attention to the quality of schooling. Policymakers issued calls for programs to achieve both equality and excellence, with emphasis on preserving federally funded programs directed at improving equality in schools. The next two decades witnessed a political struggle over school choice, organization, and finance. This struggle led to new forms of standards-based assessment and accountability, as well as increased numbers of alternative and charter schools. The political struggle also contributed to the passage in 2002 of the largest federal school reform legislation in the nation's history, the No Child Left Behind Act (NCLB). The goals of the act were to decrease disparities in educational outcomes and increase academic achievement at the elementary-secondary level through stricter school and teacher accountability measures and curricular standards.

Structure and Operation of the Education System

Preschool and Early-Childhood Care

In 1965, the federally funded program Project Head Start was established. The program continues to provide support for preschoolers (typically ages 3–4) characterized as being at risk of social and/or cognitive developmental delays. Despite a lack of funding for all preschool-aged children, since 1970, enrolment rates in center-based early education, including those subsidized by Head Start, have increased from 20% to 56%. In 2005, there were approximately 4 million children enrolled in nursery school, about 49% of eligible children.

Elementary and Secondary (K-12) Education

Attendance laws for elementary and secondary education vary by state such that compulsory schooling begins between ages 5 and 8, and ends between ages 14 and 18. School days average 7.4 h, and the school year lasts 181 days. In 2005, 55.2 million full-time students enrolled in grades PK-12 in a reported 97 382 public and an estimated 34 000 private schools. Of these students, 49.1 million enrolled in public elementary and secondary schools; and 6.1 million enrolled in private elementary and secondary schools. They were taught by some 3.6 million teachers.

Enrolment rates, both in public and private schools, vary by geographic region. In 2005, the South served the most public school students in the US, and the Northeast had the highest regional concentration of private school enrolments. In 2005, minority enrolments constituted 42.4% and 24.6% of public school and private school enrolling populations, respectively.

English-language learners (ELLs) and students with disabilities also contribute to the heterogeneity of school populations. In 1975, The Individuals with Disabilities Education Act (IDEA) was passed and required that public schools serve children aged 3–21 with disabilities. In the fall of 2006, approximately 6.7 million students – 13.5% of enrolled public students – received IDEA services.

In 2006, 10.8 million students spoke a language other than English – most commonly Spanish – in their homes. Of these children, 2.7 million spoke English with difficulty. The number of students speaking another language in the home has nearly tripled since 1979. In order to serve the needs of this population, schools receive federally assisted funding for students with limited English proficiency (LEP).

Elementary education begins in prekindergarten or kindergarten and extends through 8th grade. In 2005, the average student/teacher ratio was 15.8, varying by the size of the elementary school, often with lower ratios in smaller schools. The elementary curriculum varies by

state but generally includes mathematics, science, language arts, social studies, computer/technical skills, and physical education/health.

Secondary education begins in the 9th grade, around age 14, and extends through 12th grade. In 2005, the average student/teacher ratio was 16.6, also varying by school size. The requirements for completing secondary school and earning a standard diploma differ by state and by type of school or program (see **Figure 1**). Graduation rates vary by race, gender, and geographic location. In 2005, some 3.3 million students completed high school, 300 000 of whom were in private schools. The 4-year high school completion rate for all students that year was 74.7%. Another 400 000 individuals completed high school through passing the General Educational Development exam in 2005.

Other Schooling Arrangements

While a majority of school-aged children attend regular public schools, students may also choose a charter, magnet, or private school; be homeschooled; and/or receive supplemental educational services. In 2005, just over 1 million students enrolled in 3780 charter schools. Charter schools are publicly funded but free from many state and local regulations. These schools operate under a charter with the state establishing the curricular and organizational standards for which the school is accountable. In 2005, 2.1 million students enrolled in 2736 publicly funded magnet schools. Funding sources, curricular foci, operational structures, and/or enrolment qualifications vary among magnet schools. Students who spend less than 25 h per week in a private or public school and are educated in part in the home by parents, tutors, or Internet programs are classified as homeschooled. In 2003, 1.1 million students, 2.2% of the school-aged population, were homeschooled.

Teaching and Professional Staff

During 2003–2004, teachers accounted for approximately 57% of the total public school staff and 59% of total private school staff. In public elementary and secondary schools, principals, instructional coordinators and supervisors, librarians and media specialists, as well as counselors, comprised 7% of the total staff. Those same groups comprised 12% of the total staffing of private schools. Nurses, social workers, psychologists, and speech therapists made up approximately 5% of staff in both public and private schools. Instructional and noninstructional aides represented 13% of public and 7% of private school staff. The remaining 18% of both public and private school staffs included clerical support staff and food service, custodial maintenance, and security personnel.

Full-time teachers were predominantly female (74.8%). Among secondary schools, this percentage was lower – 56.5%; while among elementary schools, the percentage was 84.1. Of this, 78.7% were between the ages of 30 and 59. While private schools had a greater percentage of white and Asian teachers, the racial distribution of full-time elementary–secondary school teachers was as follows: 83.3% white, 7.8% black, 6.2% Hispanic, 1.4% Asian, 0.2% Pacific Islander, 0.5% American Indian/Alaska Native, and 0.7% identifying with more than one race.

The US system for preparing teachers for the classroom includes 4-year undergraduate programs in which bachelor's degrees in education are earned; 5-year undergraduate/graduate programs in which bachelor's degrees in a content area and masters of teaching/education are earned; and alternative pathways that may not require traditional

postsecondary coursework, especially in high-demand content areas. During 2003–2004, 1.3% of public school teachers had no degree, 0.4% had an associate's degree, 52.1% had a bachelor's degree, 39.3% had a master's degree, and 6.8% had a specialist or doctoral degree. Within private elementary schools, the percentages of teachers having no degree or a bachelor's degree were higher (5.6% and 65.1%, respectively), while the percentage of those with master's degrees was lower (23.3%).

Teacher salaries generally increase with increases in educational attainment and years of experience. In 2003–2004, public and private school teachers earned on average \$47 700 and \$34 700, respectively.

Teacher attrition is a significant concern for elementary–secondary education. During 2003–2004 and 2004–2005, 8.1% and 5.9% of public and private school teachers,

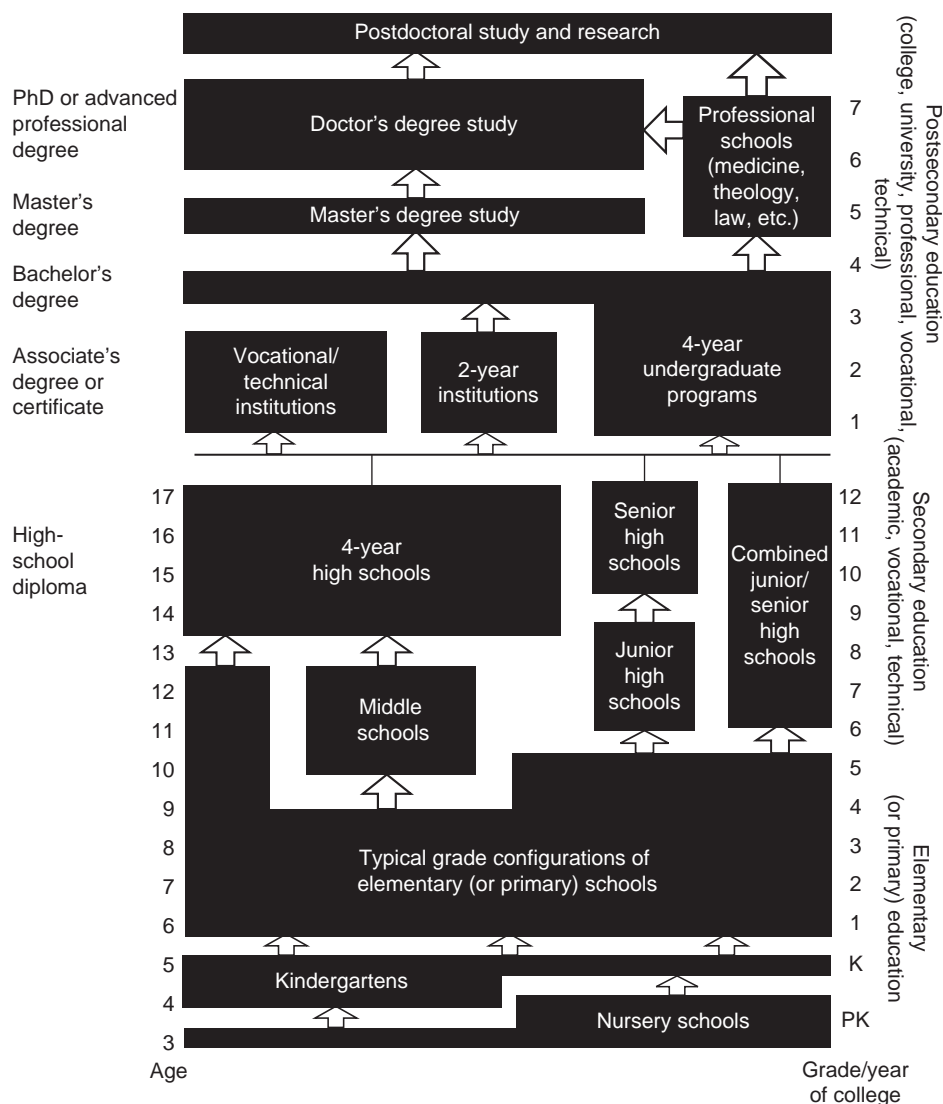

Figure 1 The structure of education in United States. From US Department of Education, National Center for Education Statistics (2007). Digest of Education Statistics: figure 1.

respectively, transferred to different schools and 8.4% of public school teachers and 13.6% of private school teachers left the profession. Schools in urban areas were most affected by attrition, as disproportionately high percentages of teachers transfer or leave urban schools. The same holds for teachers of ELLs, special education, mathematics, and science.

Administrative and Supervisory Structure

Governance at all levels of the educational system is highly decentralized. For public and private elementary education, state and local authorities play a major role in policymaking, regulation, and finance. Through the Department of Education, federal regulations and subsidies also influence school district and school-site behaviors. Public elementary and secondary schools are generally organized into districts governed by boards and administered by superintendents. At school sites, principals are chief administrative officers in public schools, and a principal or headmaster holds a similar position in private elementary and secondary schools.

Public postsecondary institutions are generally directly overseen by a board of trustees or regents, typically made up of appointed members and ex-officio members, such as elected officials and representatives of alumni associations. Boards may oversee single campuses or entire state systems of institutions. Boards have fiduciary responsibility for postsecondary institutions and hire the president or chief executive officer. Except where public institutions have codified autonomy under state charter, the state legislature, governor, and key political leaders play important roles in shaping governance policy, particularly over tuition setting and admissions. Private university boards also have fiduciary responsibility and hire presidents. To a greater degree than for public boards, private trustees are central to university development and fundraising activities.

Educational Finance

Educational expenditures by public and private institutions totaled \$972 billion for school year 2006–2007, about 7.3% of GDP. Of that total, \$373 billion, about 2.8% of GDP, was spent by postsecondary degree-granting institutions. Public elementary–secondary schools spent \$599 billion, while private schools at the elementary–secondary level had expenditures of \$46 billion in 2006–2007. Public postsecondary degree-granting institutions had expenditures of \$239 billion compared with \$134 billion at private postsecondary degree-granting institutions in that same year. The federal government provided approximately \$170 billion for education in 2006. Of that total, \$72.5 billion was spent on elementary–secondary education, \$59 billion was provided to postsecondary education, and \$31.4 billion was directed to postsecondary

research. State and local governments provided \$473.5 billion in current expenditures and capital outlay for elementary–secondary education in 2004–2005. This funding amounted to approximately \$1600 per capita and some 23.6% of total expenditures by state and local governments. These governments also provided \$182.2 billion in current expenditures and capital outlay for colleges and universities in that year, representing approximately \$615 per capita and 9.1% of state and local expenditures on all functions.

A major source of revenue for postsecondary education comes from student tuition and fees. In 2006–2007, the average annual tuition and fees were \$5685 at public 4-year institutions, \$2017 at 2-year nonprofit institutions, and \$20492 at private 4-year colleges and universities. In fiscal year (FY) 2006, tuition revenue totaled \$34.5 billion (17% of total revenue) for public 4-year institutions. Other key sources of institutional revenue for 4-year nonprofit institutions were state appropriations, \$45.5 billion (22.5% of total), and federal grants and contracts of \$25.5 billion (12.6% of total revenue). In that same year, private nonprofit 4-year institutions received \$43.9 billion in tuition and fee revenues (some 28.9% of their total revenue). Revenue for private, nonprofit 4-year institutions in 2006–2007 also came from federal grants and contracts, \$19.6 billion (12.9% of total revenue), private gifts, grants and contracts, \$18.2 billion (12.0% of total revenues) and return on institutional investments, \$35.6 billion (23.4% of total revenues). Two of the largest providers of federal research funding to both public and private research universities were the National Science Foundation and the National Institutes of Health. At 2-year public institutions, income from tuition and fees totaled \$7.2 billion in FY 2006 (some 16.6% of total revenue). State appropriations to that sector totaled \$13.1 billion (30.1% of total revenue), with local appropriations adding \$7.9 billion (18.1% of total revenue). Federal grants and contracts to 2-year public nonprofit institutions, often linked to workforce development and vocational training programs, provided \$4.7 billion, representing 10.9% of total revenue. Private nonprofit 2-year institutions drew \$318.4 million from tuition, 53.6% of total revenue, and \$75.4 million, 12.7% of total revenue from federal appropriations.

The US system of higher education depends to a significant degree on federal, state, and institutional student aid, which totaled \$130.5 billion in 2006–2007. Of that total, federal grants to postsecondary students amounted to more than \$20.7 billion; federal loans comprised \$59.5 billion, institutional grants provided \$26.3 billion, and private loans totaled \$17.1 billion.

Contemporary Assessment

The primary source of national data on elementary–secondary performance for the past 40 years has been the

National Assessment of Educational Progress (NAEP). NAEP tests are administered to public and private school students in the 4th, 8th, and 12th grades in a number of subject areas, including reading, writing, US history, mathematics, and science. Longitudinal federal NAEP data on student performance at ages 9, 13, and 17 in mathematics and science are also collected. Long-term, NAEP results have shown mixed performance with some improvement in both reading and mathematics but considerable variation on the basis of various demographic variables. In the Organization for Economic Cooperation and Development (OECD)'s 2006 Programme for International Student Assessment (PISA) study of the knowledge and skills in science and mathematics of 15-year-olds in 57 countries, the percentage of students in the US at both the highest and lowest levels of proficiency were at or above the average. Overall, the US was ranked statistically significantly below the average on both the science and mathematics scales.

Under NCLB, each school must provide detailed school-level information on the number of students who meet state proficiency standards in areas such as mathematics, language arts, and science. The goal of the Act is that all schools will meet 100% proficiency by the 2013–2014 school year. Those schools that consistently fail to make adequate yearly progress toward meeting state proficiency standards are initially required to develop improvement plans and ultimately subject to restructuring and the imposition of alternative governance plans.

Over the past two decades, assessment has been one of the most politically contested issues at every level of education. Driven by political demands for new forms of access and finance at the elementary–secondary level and by neo-liberal models calling for greater efficiency, effectiveness, and institutional competitiveness in the postsecondary arena, assessment promises to continue to generate conflict in the years to come.

Higher Education

The hallmark of the higher education system has long been the diversity of its institutional types and degree programs. From its origin in the public and private colonial colleges opened in the seventeenth century, the system has evolved to encompass open-access public and private 2-year and 4-year institutions, selective 4-year public and private colleges and universities, and a wide range of proprietary institutions. The private sector is particularly diverse, incorporating small 2-year and 4-year nonprofit institutions, liberal arts colleges, as well as large research universities and for-profit colleges.

In Fall of 2006, there were 17.8 million students enrolled in US degree-granting higher education institutions, 6.9 million in public 4-year institutions, 6.2 million in public 2-year institutions, 4.3 million in private 4-year

institutions, and 293 000 in private 2-year colleges (Tables 1 and 2).

Over the past three decades, the postsecondary system has enrolled an increasingly diverse cohort of students, including a significant proportion of women, adult students, international students, and part-time learners (Table 3). In 2006–2007, minorities comprised 27.9% of enrolments in public 4-year institutions, 37.2% of those in public 2-year institutions, and 27.8% of those enrolled in private 4-year institutions. The percentage of minority students enrolled in higher education increased from 16.1 in 1980 to 30.9 in 2005. In 1980, women comprised 42% of total postsecondary enrolments. By 2006, 58% of those enrolled in higher education were women. In 2006–2007, there were just over 500 000 international students enrolled for the first time in US higher education.

Table 37; and US Department of Education, National Center for Education Statistics, Integrated Postsecondary Education Data System (IPEDS), Spring 2007, Enrollment component. Table 2.

The US's share of about 25% of all international postsecondary students was the highest in the world. Over 40% of international students studying in the US were from India, China, South Korea, or Japan.

Both public and private postsecondary institutions also offer credentials and degrees in a variety of formats, including Internet-based programs. Degrees include the associate of arts and associate of science, bachelor of arts, bachelor of science, master's degrees, doctoral degrees, and a variety of professional degrees. Students in virtually all types of accredited postsecondary institutions are eligible to seek need-based federal aid and federal student loans. In order to receive various forms of federal financial aid, students must attend colleges and universities that have either regional or national accreditation.

The past three decades have also seen a rapid growth in the endowments of the most prestigious public and private 4-year institutions, along with rapid increases in student tuition. Since World War II, there has also been a massive growth in funded research at the leading research universities. Support for research and development at colleges and universities increased from \$6.9 billion in 1966 to just under \$43 billion in 2004 (all 2004 dollars). The postsecondary system also has the world's most comprehensive system of competitive athletics. In 2006–2007, over 400 000 students participated in competitions sanctioned by the National Collegiate Athletic Association and other governing bodies.

Assessment and accountability have recently become significant issues in the political economy of US higher education. Public institutions, in collaboration with state legislatures, coordinating boards, and regional or national

accreditation agencies, have long held a primary role in determining admissions standards, curricula, standards for credit and transfer of credit, faculty hiring and tenure standards, and student graduation requirements. Private institutions have had similar levels of autonomy with less direct intervention by state or federal elected officials. Despite intensified lobbying efforts and a national review of higher education commissioned by the Secretary of Education, few changes were made to norms of assessment and accountability in the reauthorization of the Higher Education Act signed into law in 2008.

Adult and Nonformal Education

The education system also offers a significant number of access points for adult learners. Adults may complete secondary school through passing a series of tests that lead to a General Educational Development (GED) credential. Many vocational and technical training programs are available for adults in public and private institutions, often supported with state- and federal-funding programs such as Title I of the Workforce Investment Act. Traditionally, the majority of adult learners in postsecondary education has attended community colleges and proprietary schools, or comprehensive 4-year colleges. Until quite recently, few adults have enrolled as undergraduates in residential-life colleges or highly selective 4-year universities. The 1990s witnessed a dramatic increase in adult enrolments in degree-granting proprietary colleges. Significant attention has also been turned to adult education as a vehicle to address a growing skills gap in the

twenty-first-century economy, given predictions that over the next two decades the US will need to substantially increase the number of workers with baccalaureate degrees. Currently, some 4.9 million adult learners are enrolled in degree-granting programs in US higher education.

Emerging Issues

Perhaps no factor has had more influence on education in the US over the past three decades than the rise of neoliberal and market-based approaches to the finance and organization of education. As implemented by conservative administrations at the state and federal levels, the neoliberal project has advocated increased market competition, outsourcing, and consumer choice in key public sector institutions and enterprises. In the elementary–secondary system, this has led to calls for more administrative and management systems modeled after corporate and private sector systems, privatization of school functions, voucher systems for educational finance, and support for charter and other alternative schools.

At the postsecondary level, neoliberal policies have promoted a decrease in state support for higher education, higher tuitions, and market models for the provision of higher education. The increasing pressure to prepare students for global economic competition has led to significant changes in the organization and curriculum of community colleges in particular.

National and international competitiveness remains a key topic in the political economy of education. This has inspired calls for increased education and training for both national economic competitiveness and individual income and social mobility. In 2007, the US ranked 10th among industrialized nations in the percentage of its citizens aged 25–34 with college degrees. In 2004, the median annual income for workers aged 18 and over was \$24 108. For those who had not completed high school, the median income was only \$12 437. For those who had completed high school, earned an associate's degree, or earned a bachelor's degree, median income was \$20 733, \$30 026, and \$38 880, respectively. For those who had earned a master's degree, a professional degree, or a doctoral degree, median income in 2004 was \$50 693, \$74 207, and \$72 073, respectively. As these data suggest, the foremost challenge for the nation remains creating equal educational outcomes for all.

Zanzibar

I M Hija, Ministry of Education and Vocational Training, Zanzibar, Tanzania

© 2010 Elsevier Ltd. All rights reserved.

General Background

Zanzibar consists of two main islands, Unguja and Pemba, and several other smaller islands some of which are uninhabited. Zanzibar is located in the Indian Ocean, about 30 km off the East Coast of Africa between latitudes 5° and 7° south of the equator. The island has a total area of 2654 km²; out of this, Unguja, which is the largest, has an area of 1666 km² while Pemba has an area of 988 km².

According to the 2002 population and housing census, Zanzibar had a population of 981 754 with a growth rate of 3.1% and a population density of 370 per square kilometer. Of the total population, 40% lived in urban area and the remaining 60% settled in rural areas. The outburst of the population growth rate was mostly attributed to high fertility rate of 5.3. The projected population in 2005 was 1 072 000.

Zanzibar is part of the United Republic of Tanzania, but is semiautonomous. It has its own government, a legislative assembly known as the House of Representatives, the Executive, headed by the President of Zanzibar and its own judicial system. Zanzibar is divided into five administrative regions (three in Unguja and two in Pemba), ten districts two in each region, and 50 constituencies.

Zanzibar's major economic sectors include agriculture, trade and industries, and tourism. Agriculture is the mainstay of the economy largely due to the clove industry, which is the main foreign currency earner for the Indian Ocean islands of Zanzibar and Pemba. Historically, trade has been second to agriculture but many years of isolation and the socialist policies adopted after the 1964 revolution completely undermined its potential in Zanzibar economy. Recently, tourism has emerged as a possible successor to the ailing clove industry.

Soon after the 1964 Revolution, education was proclaimed free to all Zanzibaris irrespective of color, creed, or gender. Much has changed in the intervening years, a number of policy documents have come up, ostensibly addressing, in the main, the issues of access, equity, and quality. In 1991, the government issued the Zanzibar education policy, which articulated key sectoral objectives and targets. This document was amended in 1995 in order to incorporate a number of goals pronounced in important international conventions and declarations.

In order to implement the amended 1995 policy, in 1996, the Ministry of Education issued the 10-year Zanzibar education master plan (ZEMAP). The key issues

which featured in ZEMAP included those pertaining to access and equity, quality, relevance, promotion of science and technology, and expansion of the provision of early-childhood education.

Vision and Mission of Education

The vision and mission statements of education are:

- Vision: a democratic and peaceful society enjoying a high quality of education and livelihood and committed to lifelong learning to effectively respond to development challenges.
- Mission: to strive for equitable access, quality education for all, and promotion of lifelong learning.

Zanzibar Education System Structure

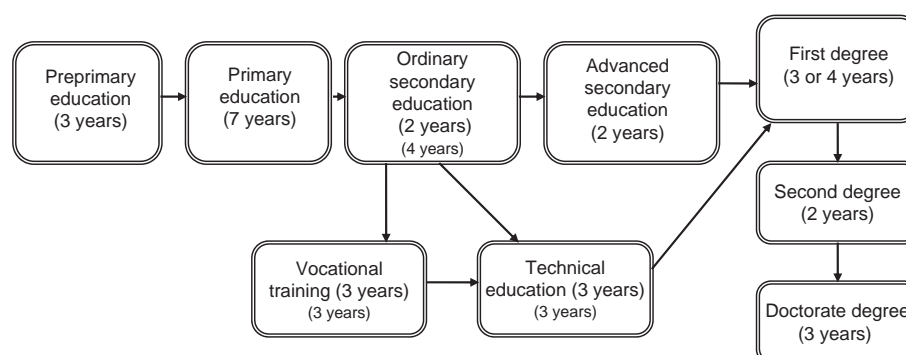

The system is characterized by the existence of several levels (**Case study 1**). These include primary levels which are of 7 years duration, a secondary level which has two channels, one which is subdivided into a first cycle of 3 years and a second cycle of 2 years, and the other a full uninterrupted secondary cycle of 4 years. Both these lead to high school level of 2 years or technical education of 3 years and 3 or more years of higher education.

Early-Childhood Education

Early-childhood education is provided to children of 4 and 6 years by the public preschools, private organizations, associations, and individuals. Currently, there are about 181 preschools providing early-childhood education including 24 public and 154 private. In 2007, 21 538 or 22.2% of the children of this age were enrolled.

Primary Education

Primary education is part of universal free basic education offered to children within the age group of 7–13 years. This level covers the first 7 years of basic education. In 2007, 214 096 pupils, equivalent to 104.6% gross enrolment ratio were enrolled in 224 public and 48 private schools. Rapid increases in enrolment have been possible through community initiatives in the construction of classrooms (**Tables 1 and 2**). Although primary school is free and

compulsory, the net enrolment is relatively low. This implies that there are a number of children of school-age who are either not in school or over-aged.

Secondary Education

Secondary education at the lower level is characterized by a two-pronged system. One prong is of 5 years subdivided

into 3 years of first cycle lower secondary at the end of which students sit for entrance examinations for admission into the secondary cycle of lower secondary lasting for 2 years. At the end of this second cycle, students sit for the certificate of secondary education examination (CSEE). In 2007, 73 417 students were enrolled in 69 public secondary schools, while 3630 were enrolled in private secondary schools (Table 3).

Postbasic Education

The overall aim of the postbasic education is to increase the opportunity for further learning and to prepare students to enter professional careers or acquire marketable skills. It also instills desire for lifelong learning.

Postbasic opportunities include entrance to second phase of secondary education for the successful candidates in the main stream. The majority of students who fail the form two national examinations either join continuing-education classes, vocational training institutions, or join the army of unemployed basic-education graduates.

There are now a number of postbasic education institutions in Zanzibar, both public and private, that offer a range of learning opportunities in both vocational and academic fields.

Table 3 Pupil–teacher ratio at the level of primary and lower secondary education, 2003–2007

Higher Education

The aim of higher education is to equip learners with high level I in intellectual, professional, and managerial capacities necessary for high-level performance. It offers opportunities for decision makers, professional cadres, and for leaders in public and private sectors to acquire new development skills, innovation, and ability to make informed decisions.

Higher-university education is provided in one public university and two private universities. All of these universities are autonomous, self-accrediting institutions responsible for their own governance and coordinated by Tanzania Commission for Universities. Other tertiary institutions in Zanzibar include: Zanzibar Institute of Finance Administration, College of Health Sciences, Kizimbani Institute of Agriculture, and College of Hotel and Tourism. There are also a number of Zanzibari students pursuing courses in Tanzania Mainland higher-learning institutions. In addition to that, there are opportunities for higher education provided through the Open University of Tanzania and outside Tanzania (Table 4).

Education for Learners with Special Needs

Learners with special needs include those with different kinds of disabilities, slow learners, and those who are exceptionally gifted.

The nature and extent of disability among school-going children has not been fully documented. However, impairment of hearing, speech, and sight are the most common-known disabilities. In 2007, there were 46 schools with the classes for children with special needs, with the total enrolment of 1523 pupils. However, this number does not include slow learners and exceptionally gifted ones. Recently, inclusive education has been promoted to ensure that the children with special needs get equal opportunities, barriers to learning are addressed, and the diverse range of learning needs are accommodated. Inclusive-education curriculum in teacher training was introduced and in 2007, a total of 290 teachers were trained on the tactics of teaching in the classes of learners with special needs.

Technical and Vocational Education and Training

The need for technical skills in wealth creation is increasing where the application of science and technology is becoming a must. Hands-on learning and knowledge in

mechanization and automation is constantly demanded in the labor market. One way of getting skilled laborers is by providing them with technical and vocational education and training. Technical and vocational education and training is a necessary ingredient toward poverty reduction as it provides opportunity for self-employment.

At present, there is a very limited capacity for technical and vocational education and training in the country. There are few well-equipped institutions which offer this type of education/training in Zanzibar. In 2007, there were four technical secondary schools and one technical college with a total of 644 students, of which 33% of this total enrolment were girls. In addition, there were five formal institutions providing vocational education and training and 68 informal vocational training centers with the total of 1325 learners.

The main fields offered in those institutions are agriculture and fishing industry, construction industry, manufacturing industry, repair and service industry, and trade and service industry.

Nonformal and Adult Education

Nonformal education is designed not only to eradicate illiteracy, but also to increase efficiency and productivity. It plays a major role in poverty reduction. Since nonformal education is a lifelong learning, it needs to be dynamic and flexible to respond to learners' needs.

Adult education is generally provided to adults who because of one reason or another are not reached by the formal system of education and to those who would like to advance their education and skills.

These types of education are provided through a number of programs such as literacy programs, continuing education, vocational training, and alternative education.

Adult education is provided by both public and private institutions. In 2007, there were 61 literacy centers with an enrolment of 5215 learners.

Alternative Education

Basic education is a right which the state is duty bound to make accessible to all children, pupil who for some reasons have missed out on basic education or are unable to complete basic education through normal schooling. They need to be provided with alternative routes to complete their basic education.

The alternative learning program is still at infancy stage and has not spread throughout the country. In 2007, there were 18 centers with an enrolment of 760 learners and 317 learners were mainstreamed into the normal school classes (**Case study 2**).

The Teachers and Teaching Profession

Efficient teacher recruitment, proper deployment, and utilization are necessary to ensure good professionalism. Clearly defined criteria and guidelines to identify, attract, train, and retrain good teachers must be in place so as to facilitate the selection of trainable teachers capable of preparing students to successfully face the emerging local and global challenges.

In 2007, there were 10 520 teaching staff in the public sectors and 540 teachers in private sector of whom 57.7% were females. While the system seems to have enough number of teachers, their distribution or deployment is questionable. Even though the recruitment of teachers for public schools is centralized, the efficiency of the ministry's information management system very often leads to the recruitment and posting of teachers with little regards to demand.

Although the number of teachers has been increasing, the increase has been skewed in favor of some subjects, English, mathematics, science, and technology subjects remain understaffed, resulting in an unfair distribution of teaching load.

The average pupil teacher ratio in 2007 was 31:1 for public schools while that of private schools was 18:1.

The training of teachers is now undertaken by three universities and three teacher-training colleges and is normally 2 years for primary and 4 years for secondary school teachers. There is also a program for training teachers through distance education.

Ministry of Education and Vocational Training Organizational Structure

Public schools in Zanzibar function under the direct responsibility of the ministry, while the private schools are established and operate under conditions determined by the ministry and the ministry's office of registrar (**Case study 3**). The ministry is currently headed by the minister assisted by the deputy minister. The two have more political rather than professional responsibility for the promotion of education. On matters of policy implementation, the minister is advised by the education council whose members are appointed as per Education Act. Technical and professional tasks are the responsibility of the Principal Secretary who is also the head of civil service as well as chief accountant officer. In the execution of duties, the principal secretary is assisted by deputy principal secretary. In the case of Pemba Island, management responsibilities of the principal secretary are executed by the officer in-charge.

Under the principal secretary, there are two deputy principal secretaries (for academics and for policy, planning, personnel, and administration) and a commissioner supervising 11 directorates.

Case study 2 Percentage of adults literate in any language**Monitoring, Evaluation, and Research**

Education programs have intended outcomes or products that need to be monitored and evaluated. Monitoring and evaluation is central to government's regulatory and quality assurance roles.

The statistics division of the ministry is responsible for monitoring educational programs through data collection, analysis, and dissemination of information. The division administers questionnaires to educational institutions and collects information on student and learner enrolment, attendance, and number of teachers and tutors. Quarterly and annual progressive reports on the status of schools, including physical, material, and academic aspects are also submitted to the division.

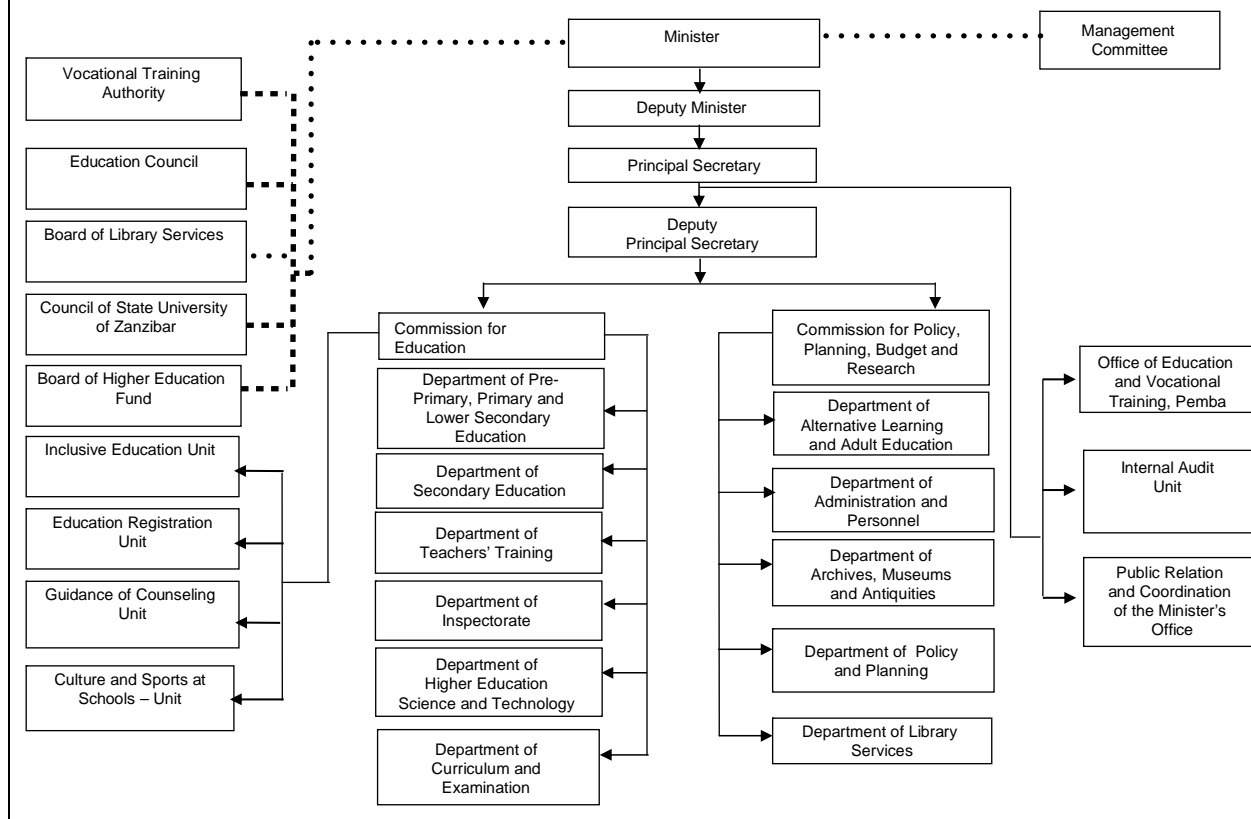

Inspectors, school committees, and school boards also provide data for monitoring purposes. Implementation of development programs is monitored by respective departments in collaboration with the department of planning, policy, and research. Evaluation is very rarely conducted.

Education management information system division also exists in the ministry to develop a sustainable statistical information system for education policymaking. Education management information system division provides information on student enrolment, performance, physical, and human resources. The education management information system division is the main custodian of statistical data and other information systems. Its main activities include development of instruments for collecting, processing, and analysis of data and when required, provision of training to headteachers and school statisticians.

The division, however, has not fully integrated into the planning and management process at the national and local levels due to technical and organizational shortfalls.

Research findings provide information to support the implementation of policy decisions and reforms. Educators and policymakers use researches to improve the education system.

Currently, research activities are being coordinated by the department of planning, policy, and research; however,

Case study 3 Organization Structure of the Ministry of Education and Vocational Training

it has not receive its due recognition, attention, and emphasis in current education efforts. Most of the policy changes in education have been reactive rather than proactive, attempting to solve immediate problems rather than addressing issues based on research findings. Most of the researches are donor funded and focused on curriculum innovation and project implementation.

Education Financing

The Revolutionary Government of Zanzibar is fully committed to the provision and funding of education. Construction of schools, procurement of equipment and educational materials, provision of services, administrative support, and technical backstopping is mainly financed by the government. However, around 90% of the ministry's recurrent budget covers personal emoluments and leave no-salary components, including core items of improving quality of education, grossly underfunded. For a certain time to come, the government will continue to be the major source of financing education.

The government allocated a total of TSh 18.5 billions which is 91.4% of the estimated budget for the financial year 2006/2007 and 20% of the total government budget of the said year up to May 2007.

A higher education fund has also been established to finance higher education, research, and studies and to provide scholarships to the talented needy students.

Community participation has made an important contribution to the provision of essential education materials, building of new classrooms, and assisting in the management of the schools.

Private-sector contribution to education is gradually increasing. Private investors in tourism and hotels as well as local business peoples have contributed significantly to the construction of school buildings and provision of utilities. In community schools, private individuals contribute to the payment of teachers' salaries, tuition, and materials. The private sector also contributes to post-graduate training. In addition, private investors have built and are operating private schools. In general terms, the private sector has acknowledged the importance of education and hence it actively supports and finances its provision.

Table 5 Education recurrent cost projection 2007–16 (billion Tsh)

Level of education	2007/08	2008/09	2009/10	2010/11	2011/12	2012/13	2013/14	2014/15	2015/16

Source: Zanzibar Education Development Programme.

Development partners play significant roles in financing development expenditure such as construction and innovation of buildings, production or procurement of school furniture, teaching and learning materials, laboratory equipment, and transport facilities. In the area of technical assistance and capacity building, they have provided scholarships in the field of education to the members of staff. In addition, the development partners finance experts attached to some departments of the ministry, fund education-sector studies, reviews, and innovative projects, and provide links with institutions outside Zanzibar. Development of partners' contributions in education is significant and appears to be increasing, priority being given at the moment to basic and secondary education.

Inherent Challenges

It is evident that the government has strenuously struggled in the face of limited resources to achieve a number of universally cherished goals. It has incorporated in its previous policy documents, key objectives relating to access, equity, and quality. It has expanded provision of basic education to essentially all segments of the society, and can now boast of achieving gender parity in the 10-year compulsory basic education and in the additional 2 years of secondary education.

However, there are a number of goals which remain elusive. For example, only about one in seven children attend some form of preschool before starting primary education, while enrolment in primary schools exposes some worrying weaknesses.

There is also widespread lamentation that the quality of education now offered or attained by young learners has fallen considerably. Graduates of basic education are weak in languages, both the vernacular and English. They lack effective communication skills and their general knowledge in current affairs, science, and arithmetic has serious gaps when compared to children of comparable age in the neighboring countries. Complaints are also heard that

basic-education graduates leave school without usable skills and hence they are unprepared to enter the world of work.

The new education policy (2005) which will be fully implemented by the year 2015, aims at addressing the existing weaknesses of Zanzibar education system by making it more responsive to current needs of the society. It has highlighted the need to set realistic goals and to realign the government's effort with those in the region in accelerating socioeconomic development. Among the essential elements of education reforms are: extending basic education from 10 to 12 years, improving the quality of education, strengthening teachers' training, providing alternative learning for out-of-school youth, and developing general skills.

In order to support the new education policy (Table 5), the Zanzibar education development program (ZEDP) has been developed. ZEDP represents the first comprehensive and sector-wide approach to the educational challenges facing Zanzibar. It identifies, establishes, and plans for substantial targets for the education system, both in terms of equitable access and quality. The ZEDP is strategic in its approach, seeking to develop immediate, medium- and longer-term goals for education which are achievable and sustainable.

The ZEDP is also characterized by a practical focus on where learning takes place and how that environment can be strengthened and enriched. The classroom learning environment, the management structures which support and surround it and the planning and development approaches which guide it remain the critical areas which the ZEDP addresses. By focusing on the fundamentals of learning and teaching, the program draws together all the significant elements necessary for the qualitative changes deemed essential if the learners of Zanzibar are to fulfill their potential over the coming decades.

PREFACE

A preface usually provides a brief introduction to a work, intended to set the stage, provide some background insight, and whet the appetite of the reader. In our case, however, this preface has to address a fundamental question, one that was in our minds at the time we were recruited as Editors-in-Chief for the International Encyclopedia of Education. The question was “Why do we need an Encyclopedia? Its subtext was inspired by the ever-growing, ever-popular Internet. We believe that *this* Encyclopedia is desperately needed and will become a valued resource in education and associated social sciences and arts. The reasons are intellectual and procedural. Anyone with a modicum of knowledge knows that finding and trusting information gleaned from the Internet are two separate actions. The reliance on browsers to help discover references and comments result in resources based on popularity not quality. Pithy titles catch the eye and references rise in the ranks of browser searchers. Related to this is the “editing” in the Internet realm of populist efforts at encyclopedia, references, and other compilations. Once again, after removing offensive material, the accuracy, completeness, lack of bias, and other provenance for entries simply do not exist. Experienced researchers in education can sort through and make intelligent choices. Novices and many journeyman, or practitioners, parents, and policy makers cannot. Contrast how this Encyclopedia was built. Key domains of educational research were identified, and a tentative list of sub-domains or useful applied areas was posited. Then the Editors-in-Chief (apologies for the awkwardness of the term) identified the leading researcher in a particular domain, and with surprisingly little effort, recruited them to participate. They in turn identified the two best researchers in a sub-domain, such as formative assessment or the training of pre-school teachers. The authors of the sections of the Encyclopedia do not represent a collective group of friends and acquaintances, although friendships have been made. Rather they embody a deep and broad scholarly community. The difference from compiled Internet resources is the built-expertise and intellectual engagement of the authors. The summary of the developments and futures in their personal areas of scholarship have been filtered through their years of experience, both as scholars and communicators. Quality, then, is endemic to each piece, developed through this top-down identification of expertise, and made indelible by the bottom-up application of high standards from people leading the sub-domains – the authors, and the domains themselves, the section editors.

On a procedural level, the publishers early committed to the notion that this Encyclopedia would also be an online resource, and access would be available through print, for those with strong bookcases and the persisting love of turning real pages. The Internet version will allow multiple prisms through which the reader may access articles and provide, as it were, an emulation of the Internet in our field, albeit bounded by expertise and high quality.

What must be underscored in the assessment of this effort are the Editors-in-Chief and the publishers’ commitment to find excellence worldwide. We tried very hard to persuade notable scholars from all parts of the world to make contributions. Less than to fulfill the title of “International,” we were on the hunt for perspectives that would enrich the scope and depth of the sections. Our section editors put in enormous time attempting to find the best in the field, wherever they resided. Yet, not everyone is in the volume. Some were overcommitted. Many were not fully confident of their English, and the automated translation software has not yet met standards for technical writing. We believe that such writing and editing tools will make the outreach to an even broader International group of scholars possible in future revisions, or online updates. Furthermore, the birth of the World Educational Research Association (in 2009) will provide a better set of interlocking networks to find and evaluate scholarship from any place on the globe.

Finally, the scope of the effort must be acknowledged: 28 section editors, 926 articles were commissioned, drafted, reviewed, redrafted, edited, and put together in the space of four years. The publishers underwent some internal changes, and alterations in management. We as Editors-in-Chief, changed roles, moved, and also had to keep our own research and development enterprises afloat. Deadlines wobbled; authors dropped from view and had to be replaced.

Yet, at times frustrating as all development is, we find the final product exhilarating. We are enthusiastic not simply because it came into being at all, but because the collective light of the minds that wrote have left a bright resource for the future, one that will impact the way our colleagues understand and experience the educational knowledge, improvement, and impact in the future.

HOW TO USE THE ENCYCLOPEDIA

The International Encyclopedia of Education is intended for use by students, research professionals, and interested others. Articles have been chosen to reflect major disciplines in the study of education and common topics of research by academics in this domain. Each article serves as a comprehensive overview of a given area, providing both breadth of coverage for students, and depth of coverage for research professionals. We have designed the encyclopedia with the following features for maximum accessibility for all readers.

The contents of the encyclopedia are arranged alphabetically by section, and within sections, alphabetically by article. The Subject Index is located in Volume 8. Some topics are covered in a multitude of articles from differing perspectives, while other topics may have only one entry. We encourage use of the index for access to a subject area, rather than use of the Contents list alone, so that a reader has a full notion of the coverage of that topic.

The articles include cross-references to other related encyclopedia articles, suggested further readings where applicable, and many contain relevant websites for additional information. We encourage readers to use the cross-references to locate other encyclopedia articles that will provide more detailed information about a subject.

The Further Reading sections include recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research articles that are considered of primary importance to the understanding of a given subject area are also listed. These suggested further readings are not intended to provide a full reference listing of all material covered in the context of a given article, but are provided as next steps for a reader looking for additional information.

The Efficacy of Educational Vouchers	<i>R Zimmer and E P Bettinger</i>	380
Tiebout Sorting and Competition	<i>T J Nechyba</i>	388

Economics of Education – Production of Schooling

Desegregation, Academic Achievement and Earnings	<i>S Rivkin</i>	394
Education Production Functions: Concepts	<i>D N Harris</i>	402
Education Production Functions: Developed Country Evidence	<i>E A Hanushek</i>	407
Education Production Functions: Evidence from Developing Countries	<i>P Glewwe and S Lambert</i>	412
Family Environment in the Production of Schooling	<i>R Rothstein</i>	423
Neighborhoods and Peers in the Production of Schooling	<i>J Vigdor and J Ludwig</i>	431
Teacher Quality in Education Production	<i>I Pelayo and D J Brewer</i>	438
The Economics of Class Size	<i>D W Schanzenbach</i>	443
The Economics of Early Childhood Interventions	<i>M Nores</i>	450

Economics of Education – Teaching Labor Markets

An Overview of Teacher Labor Markets	<i>H Lankford and J Wyckoff</i>	456
Compensating Differentials in Teacher Labor Markets	<i>J Chambers</i>	465
Economic Approaches to Teacher Recruitment and Retention	<i>S Loeb and J Myung</i>	473
Teacher Incentives	<i>L Santibañez</i>	481
Teacher Supply	<i>P Dolton</i>	489
Teacher Training and Preparation in the United States	<i>M Podgursky, M G Springer, and R Hutton</i>	498
Teachers in Developing Countries	<i>F H Rogers and E Vegas</i>	504
The Economics of Teachers' Unions in the United States	<i>K Strunk</i>	512

Education of Children with Special Needs

Adapted Physical Activity for Students with Special Needs	<i>S R Hodge</i>	519
Assessment Accommodations for Children with Special Needs	<i>R J Kettler and S N Elliott</i>	530
Assistive Technology and Educational Practice	<i>H P Parette and G R Peterson-Karlan</i>	537
Augmentative–Alternative Communication	<i>C Mason and K M Chinn</i>	544
Community Integration and Employment of Youth with Special Needs	<i>B A Ford and A W Daviso III</i>	550
Cooperative Learning for Children with Special Needs	<i>E A Dooley and K R Kossar</i>	555
Co-Teaching	<i>E D Cramer</i>	560
Cultural and Linguistic Diversity and Children with Special Needs	<i>J M Patton, N Day-Vines, and A McSwain</i>	565
Curriculum-Based Assessment and Students with Special Needs	<i>D J O'Shea and J D Katsafanas</i>	571

Diagnosis and Classification	<i>M Sapp</i>	577
Direct Instruction and the Education of Children with Special Needs	<i>T Mehring</i>	584
Disabilities and Gifted Education	<i>V I Daniels and M J McCollin</i>	588
Early Childhood Special Education: Birth to Eight Years Old	<i>T S Lovelace, R Gardner III, J B Axe, and D M Sainato</i>	594
Early Intervention for Students with Special Needs	<i>P A Grant</i>	608
Early Transition of Children with Special Needs	<i>S A Fowler</i>	613
Educating Children Who are Deaf-Blind	<i>J Wood and K M Chinn</i>	621
Educating Children with Deafness and Hearing Impairments	<i>G M Mukuria and C J Eleweke</i>	628
Educating Children with Other Health Impairments (ADHD)	<i>G M Mukuria and F E Obiakor</i>	634
Educating Children with Physical Disabilities	<i>Z P Nkabinde, F E Obiakor, M T Ofor, and D J Smith</i>	640
Educating Children with Specific Learning Disabilities	<i>P A Grant and P B Grant</i>	646
Educating Children with Speech and Language Disorders	<i>S L Green and C D Qualls</i>	654
Educating Students with Autism and Related Disorders	<i>T T Dyches</i>	661
Educating Students with Cognitive Disabilities	<i>J P Bakken</i>	669
Educating Students with Emotional and Behavioral Disorders	<i>S W Smith and G G Taylor</i>	678
Educating Students with Special Needs: An Overview	<i>F E Obiakor, M K Harris, P Harris-Obiakor, and G M Mukuria</i>	688
Educating Students with Traumatic Brain Injury	<i>S Burkhardt and A Rotatori</i>	695
English Language Learners with Special Needs	<i>R Rueda and G Ragusa</i>	701
Functional Behavioral Assessment	<i>J P Bakken</i>	708
History of Special Education	<i>L M Garrick Duhaney and S J Salend</i>	714
Inclusion of Students with Special Needs in General Education Classrooms	<i>M A Prater</i>	721
Instructional Accommodations for Children with Special Needs in Inclusive Settings	<i>A L Yurick, S Musti-Rao, and G Cartledge</i>	727
Interagency Agreements	<i>L A Owens</i>	733
Interdisciplinary Collaboration in Early Childhood	<i>N File</i>	739
Language Development in Children with Special Needs	<i>M S L Stewart</i>	745
Large Scale Assessment and Accountability and Students with Special Needs	<i>M L Thurlow</i>	752
Literacy Instruction for Students with Special Needs	<i>L H Mason</i>	759
Math Instruction for Children with Special Needs	<i>B A Bottge</i>	767
Overrepresentation of Culturally and Linguistically Diverse Students in Special Education	<i>S C Trent</i>	774
Paraprofessionals in Special Education	<i>B Y Ashbaker, S C Dunn, and J Morgan</i>	780
Parent and Family Involvement in the Education of Children with Special Needs	<i>L P Prater</i>	788
Peer Relations and Socialization of Children and Adolescents with Special Needs	<i>L M Bullock, M Wong-Lo, and R A Gable</i>	794
Peer-Tutoring	<i>L J O'Shea and D J O'Shea</i>	802
Postsecondary Participation of Students with Special Needs	<i>R A Stodden and K D Roberts</i>	808
Prereferral Strategies	<i>C G Simpson and J P Bakken</i>	815

Preventing Antisocial Behavior and Delinquency: A Comprehensive School-wide Approach <i>P R Hallam, K R Young, P Caldarella, D G Wall, and L Christensen</i>	820
Programs and Instructional Strategies for Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	829
Related Services for Children with Special Needs <i>S O Obi</i>	834
Risk and Resilience Frameworks in Understanding Special Education <i>W-Y Hsieh and M L Donahue</i>	840
School Dropout Prevention <i>F E Obiakor</i>	845
School-Based Services for Children with Special Needs <i>S O Obi</i>	850
Self-Determination <i>M L Wehmeyer</i>	857
Social Competence <i>L A Owens and S Johnston-Rodriguez</i>	865
The Identification of Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	870
Transition from School to Adult Life <i>M J McCollin and F E Obiakor</i>	876
Visual Impairment <i>W Sapp</i>	880
Workforce Issues in Special Education <i>E Carlson and B Billingsley</i>	886

VOLUME 3

Education of Professionals

An Overview of Accreditation, Certification, and Licensure Processes <i>J J Norcini and M van Zanten</i>	1
Educating America's Military Officers <i>M H Adamshick</i>	7
Education for Architecture in the United States and Canada <i>S Schreiber</i>	13
Education for Medicine <i>M B Anderson</i>	19
Education for the Legal Profession <i>J W Wegner</i>	25
Education of Clergy <i>D O Aleshire</i>	31
Framing Professions Education <i>P S O'Sullivan</i>	37
Issues in Accounting/Business Education <i>W H Gijsselaers and R G Milter</i>	39
Professions – Engineering <i>J Heywood</i>	45
Professions – Health-Related <i>G M Jensen and C B Royeen</i>	51
Professions – Pharmacy <i>D E Beck</i>	58
Teaching for the Complex Practice of Nursing <i>P Benner and M Sutphen</i>	65
Veterinary Education <i>K M Edmondson</i>	71

Education Research Methodology: Quantitative Methods and Research

Abductive Research Methods <i>B D Haig</i>	77
Field Experimentation in Education <i>M A Constat</i>	83
Internal Validity <i>M H Clark and S C Middleton</i>	90
Methods for Approximating Random Assignment <i>B Schneider and S-K McDonald</i>	97
Methods for Approximating Random Assignment: Regression Discontinuity and Propensity Scores <i>L M Scheier</i>	104

Multitrait–Multimethod Designs	<i>M Bong and S Hong</i>	111
Multivariate Longitudinal Data Analysis	<i>H Liu and L Chang</i>	120
Quasi-Experimentation: Two Group Design	<i>E Hong</i>	128
Regression Discontinuity Designs	<i>A Kelava, S Rohrmann, and V Hodapp</i>	134
Sampling	<i>R S Brown</i>	142
Statistical Conclusion Validity	<i>P L Busk</i>	147
Survey Research Methods	<i>A Fink</i>	152

Educational Assessment

An Overview of Educational Assessment	<i>M James</i>	161
Assessment and the Evaluation of Institutional Effectiveness	<i>S M Thomas</i>	172
Assessment in Schools – Dispositions	<i>R D Crick</i>	181
Assessment in Schools Related To Literacy: Reading	<i>K J Topping</i>	189
Impact of Assessment on Students' Learning Strategies and Implications for Judging Assessment Quality	<i>M Segers, F Dochy, and D Gijbels</i>	196

Educational Assessment – Assessment Activities

Alternative Assessment	<i>G Stobart and C Gipps</i>	202
Classroom Assessment Tasks and Tests	<i>J Phelan and J Phelan</i>	209
Dynamic Assessment	<i>J G Elliott, E L Grigorenko, and W C M Resing</i>	220
Instructional System Provided Feedback	<i>H F O'Neil, S Chuang, and T Huang</i>	226
Peer and Self-assessment	<i>C Harrison</i>	231
Portfolio Assessment	<i>V Klenowski</i>	236
Records of Achievement: Beyond Traditional Tests	<i>P Broadfoot</i>	243

Educational Assessment – Assessment in Domains

Assessment in Higher Education	<i>D R Sadler</i>	249
Assessment in Schools – Affective Domain	<i>M Ventura, R D Roberts, and M Zeidner</i>	256
Assessment in Schools – Creative Subjects	<i>T E Costantino and L Bresler</i>	262
Assessment in Schools – Learning to Learn	<i>A Hautamäki, J Hautamäki, and S Kupiainen</i>	268
Assessment in Schools – Literacy Writing (Extended)	<i>J M Parr and L Earl</i>	273
Assessment in Schools – Mathematics	<i>M Brown and J Hodgen</i>	279
Assessment in Schools – Oracy	<i>A L Bailey</i>	285
Assessment in Schools – Primary Science	<i>W Harlen</i>	293
Assessment in Schools – Secondary Science	<i>J Shemwell, A Fu, M Figueroa, R Davis, and R Shavelson</i>	300
Assessment in Schools – Technology Education and ICT	<i>A Jones, B Cowie, and J Moreland</i>	311
Assessment in the Early Years	<i>M J Drummond</i>	316
Assessment in the History, Civics and Social Studies Domains	<i>P G Avery</i>	323
Assessment in the Workplace of Performance, Developing Expertise and Competence	<i>A J Brown</i>	330
Assessment in Vocational Education	<i>K Ecclestone</i>	337

Educational Assessment – Concepts and Issues

Assessing Group Work	<i>M Galton</i>	342
Assessment and the Regulation of Learning	<i>L Allal</i>	348
Challenges of Developing and Implementing Formative Assessment Practices in Schools	<i>R Sutton</i>	353
Formative Assessment	<i>P Black</i>	359
Formative Assessment and Instructional Planning	<i>B Marshall</i>	365
Progression and Assessment: Developmental Assessment	<i>M Forster and G Masters</i>	369
Students' Rights in Assessment and Evaluation	<i>J Gardner and B Holmes</i>	378
Summative Assessment by Teachers	<i>R Daugherty</i>	384
The Multiple Purposes of Assessment	<i>P E Newton</i>	392
The Relationship between Assessment and the Organization and Practice of Teaching	<i>L B Resnick, D William, R Apodaca, and E S Rangel</i>	397

Educational Assessment – Enhancing Quality and Use

Assessment Conversations: Reading and Writing Conferences with Students and with Parents	<i>M Barrs</i>	403
Assessment: Pre-service and In-service Teacher Education	<i>A Davies</i>	410
Classroom Assessment in Policy Context (Australia)	<i>J J Cumming</i>	417
Classroom Assessment in Policy Context (England and France)	<i>M Osborn and M Raveaud</i>	425
Classroom Assessment in Policy Context (French Sources)	<i>D Laveault</i>	432
Classroom Assessment in Policy Context (Hong Kong)	<i>D Carless</i>	438
Classroom Assessment in Policy Context (New Zealand)	<i>T J Crooks</i>	443
Classroom Assessment in Policy Context (Sub-Saharan Africa)	<i>S J Howie, L Zimmerman, and K Draper</i>	449
Moderation of Student Work by Teachers	<i>G S Maxwell</i>	457
School Policies and Practices to Support Effective Classroom Assessment for Learning	<i>D Pedder</i>	464
Student Assessment: Policy and Practice in Eastern Europe	<i>G Bethell</i>	472

Educational Assessment – Key Relationships

Assessment Practice in Policy Context: Latin American Countries	<i>F M Rizo</i>	479
Impact of Assessment on Learner Groups (Boys/Girls)	<i>J Elwood</i>	486
Impact of Assessment on Learner Groups (Disabilities)	<i>M Rouse</i>	492
Impact of Assessment on Students' Test Anxiety	<i>P Buchwald and C Schwarzer</i>	498
Impact of Assessments on Classroom Practice	<i>J L Herman</i>	506
Social Practices in School Assessment and their Impact on Learner Identities	<i>A Pollard and A Filer</i>	512

Educational Evaluation – Concepts, Practice, and Future Directions

Educational Evaluation: Concepts, Practice, and Future Directions	<i>Y J Ni</i>	518

Higher Education

Higher Education: An Overview	<i>P Scott</i>	217
-------------------------------	----------------	-----

Higher Education – Management, Leadership and Governance

Academic Managers – Heads of Departments/Schools	<i>S Marshall</i>	229
Leading and Managing the University – Presidents and their Senior Management Team	<i>R Middlehurst, T Kennie, and S Woodfield</i>	238
Management of and in Higher Education Institutions	<i>B Sporn</i>	245
Managerialism and Collegialism in Higher Education Institutions	<i>M Shattock</i>	251
Strategic Planning in Higher Education	<i>L Zechlin</i>	256
The Changing Role of University Presidents, Vice-Chancellors and Rectors	<i>M F Green and P D Eckel</i>	264
The Changing Roles of University Governing Boards and Councils	<i>J Fielden</i>	273

Higher Education – Research and Scholarship

Funding of University Research	<i>G Harman</i>	279
Mobility of PhD Students and Scientists	<i>S Avveduto</i>	286
National Science Policy and Universities	<i>M Henkel and U Kogan</i>	294
Research Commercialization	<i>S Slaughter</i>	300
Research Quality Assessment	<i>I McNay</i>	307
The Management of University Research	<i>J Kirkland</i>	316
The Training of New Scientists	<i>R Neumann</i>	322

Higher Education – Society

Academic Freedom	<i>S F Macintyre</i>	328
Access and Equity in Higher Education	<i>G Baldwin and R James</i>	334
Boundaries of Institutional Autonomy and their Impact on Higher Education	<i>V L Meek</i>	341
Diversity of Higher Education	<i>U Teichler</i>	347
Employability of University Graduates and Graduate Outcomes	<i>J Brennan</i>	354
Higher Education and the Knowledge Society	<i>J Välimaa</i>	360
Higher Education and the Labor Market	<i>J Enders</i>	365
Higher Education and the Transformation of Society	<i>P Scott</i>	370
Quality Assurance in Higher Education – Practices and Issues	<i>D Dill</i>	377
The Role of Accreditation of Higher Education Institutions	<i>J S Eaton</i>	384
Universities and Regional Development	<i>J Goddard and J Puukka</i>	390
Universities' Engagement with Society	<i>D Watson</i>	398

Higher Education – Teaching and Learning in Higher Education

Distance Education and Open Universities	<i>A Kanwar and J Daniel</i>	404
Education Development in Higher Education	<i>Y Ryan and K Fraser</i>	411
Effective Use of Technology in Teaching and Learning in HE	<i>D Laurillard</i>	419

Facilitating Students' Success – Student Support and Learning Resources in Universities	<i>E Woodberry and C Barnes</i>	427
Faculty Values and Expectations and Their Implications for Teaching, Learning and the Organization of Higher Education Institutions	<i>K Harman</i>	433
Flexible Learning in Higher Education	<i>S Alexander</i>	441
Innovation in Teaching and Curriculum Design	<i>J M Dearn</i>	448
Productivity of University Faculty Staff	<i>S Kyvik</i>	455
Promoting Effective Student Learning in Higher Education	<i>K Trigwell</i>	461
Student Attrition from Higher Education Institutions	<i>M Hayden</i>	467
University Students' Experiences of Higher Education	<i>C McInnis</i>	473
What Do University Students Learn?	<i>G D Kuh and B K Bridges</i>	479

Higher Education – Tertiary Education in a Globalized World

Associations of Universities	<i>G F Moodie</i>	485
Collective Bargaining in Higher Education	<i>C Allport, K McAlpine, and S Roberts</i>	491
Financing of Higher Education	<i>B Chapman and P Tulip</i>	499
Higher Education Crossing Borders	<i>J Knight</i>	507
Higher Education in Post-Conflict Societies	<i>M Daxner</i>	514
Higher Education in the New Economies	<i>J Fielden</i>	520
Human Resource Issues in Higher Education	<i>E El-Khawas</i>	527
International Accreditation in Higher Education	<i>A Stella and D Woodhouse</i>	533
Internationalization of Higher Education	<i>M van der Wende</i>	540
National and International Rankings of Higher Education	<i>S Marginson</i>	546
Steering of Higher Education Systems – The Role of the State	<i>K Yokoyama and V L Meek</i>	554
Student and Faculty Transnational Mobility in Higher Education	<i>U Lanzendorf and B M Kehm</i>	559
The Bologna Process in European Higher Education	<i>D Rich</i>	566
The Economics and Finance of Higher Education	<i>A Wolf</i>	573
The Role of the OECD in the Development of Higher Education in a Globalized World	<i>R Yelland</i>	584
Transforming Higher Education in Developing Countries: The Role of the World Bank	<i>J Salmi and R M Bassett</i>	590
UNESCO's Role in the Development of Higher Education in a Globalized World	<i>S Uvalić-Trumbić</i>	597

Higher Education – The Organization and Financing of Higher Education

Higher Education in Federal Systems	<i>M A M Cortés and U Teichler</i>	603
Pathways and Articulation into Higher Education	<i>G F Moodie</i>	609
Unitary, Binary and other National Systems of Higher Education	<i>L Goedegebuure</i>	616

International Comparisons

IEA Studies in ICT	<i>N Law</i>	644
IEA Studies in Mathematics and Science	<i>F K S Leung</i>	650
IEA Study in Civic Education	<i>J Torney-Purta, J-A Amadeo, and J Schwillie</i>	656
IEA: Globalization and Assessment	<i>H Wagemaker</i>	663

International Organizations in Education

Education and the European Union	<i>S Hegarty</i>	669
National University on Educational Planning and Administration, New Delhi	<i>J B G Tilak</i>	676
On School Management – International Council on School Effectiveness and Improvement, Commonwealth Council on Educational Administration and Management	<i>A Walker and T Townsend</i>	681
UNESCO's International Institute for Educational Planning	<i>S J Hite and M Bray</i>	688

L**Leadership and Management**

Leadership and Management Overview	<i>B Mulford</i>	695
------------------------------------	------------------	-----

Leadership and Management – as a Field of Study

Contexts for Leadership at the Beginning of the 21st Century	<i>M Bottery</i>	704
Educational Leadership: Philosophical Issues	<i>C W Evers</i>	710
Ethical/Moral Issues in Educational Leadership	<i>R J Starratt, L Langlois, and P Duignan</i>	717
History of Educational Leadership/Management	<i>R Bates</i>	724
Educational Leadership as a Field of Study: Professional Journals 1994–2006	<i>A R Thomas</i>	731
Research on Educational Leadership – Approaches/Promising Directions	<i>W A Firestone and V M J Robinson</i>	740

Leadership and Management – Leader Preparation

Leaders for Productive Schools	<i>J Murphy, S N Elliott, E B Goldring, and A C Porter</i>	746
New Approaches in Preparing School Leaders	<i>S G Huber</i>	752
Research for Leaders: The National College for School Leadership	<i>G Southworth</i>	762
School Leadership Standards	<i>L Ingvarson</i>	768

Leadership and Management – Leadership Issues

Effective Leadership in Challenging Schools	<i>A Harris</i>	777
Esthetics, Educational Leadership and Management	<i>R Bates</i>	783
Leader Mistreatment of Teachers	<i>J Blase and J Blase</i>	790
Leadership and Gender	<i>J Blackmore</i>	797
Leadership and Student Voice	<i>C Lanskey and J Rudduck</i>	803
Leadership and Urban Education	<i>K A Riley</i>	809
Leadership for Learning	<i>J MacBeath</i>	817
Leadership in Diverse Cultures	<i>A Walker and P K Yu-kwong</i>	824

Leading Diverse Schools	<i>J Ryan</i>	832
Supervision and Personnel Administration	<i>P D Tucker and D G Pounder</i>	839
The Big Challenge: Leadership for Inclusion	<i>M Ainscow and A Sandill</i>	846
The Educational Leader's New Work	<i>P Gronn</i>	852

VOLUME 5

Leadership and Management – Leadership Types

A Distributed Perspective on School Leadership and Management	<i>J P Spillane</i>	1
Leadership: Authentic	<i>P T Begley</i>	7
Leadership: Democratic	<i>J Møller</i>	12
Leadership: Instructional	<i>P Hallinger, K Leithwood, and R H Heck</i>	18
Leadership: Transformative	<i>C M Shields</i>	26
Strategic Leadership	<i>B Davies and B J Davies</i>	34
Teacher Leadership and Organizational Development	<i>A Harris</i>	40
Understanding How Leadership Influences Student Learning	<i>K Leithwood and B Levin</i>	45

Leadership and Management – Politics and Governance

Equity and Educational Effectiveness	<i>P Sammons</i>	51
Leading/Managing Schools in Communities Made Poor	<i>P Thomson</i>	58
Principals Role in Restructuring Schools	<i>G M Crow and K D Peterson</i>	66
School Reform and Restructuring: Self Managing School	<i>B J Caldwell</i>	72
System Leadership	<i>D Hopkins and R Higham</i>	78

Leadership and Management – School and Community

Educational Leadership and Social Capital	<i>J West-Burnham</i>	85
Networked Learning Communities School-to-School Collaboration as an Essential Component of a System Reform Strategy	<i>D Jackson</i>	92
Networks and Communities of Knowledge	<i>T Schuller and H Theisens</i>	100
School Community Relations	<i>R L Crowson and E B Goldring</i>	106
Social Capital, Educational Institutions and Leadership	<i>S Kilpatrick, S Johns, and B Mulford</i>	113

Leadership and Management – School Effectiveness and Improvement

Leadership and Technology	<i>C F Webber</i>	120
Leadership in the Implementation of Innovations	<i>I E Bogotch, T Townsend, and M Acker-Hocevar</i>	128
Leadership: School Improvement	<i>R H Heck and P Hallinger</i>	135
Organizational Learning in Schools	<i>B Mulford and H Silins</i>	143
Professional Learning Community	<i>L Stoll</i>	151
Transformational School Leadership	<i>K Leithwood</i>	158

Learning and Cognition – Issues and Concepts

Attention in Cognition and Early Learning	<i>M Heimann, T Tjus, and K Strid</i>	165
Concept Learning	<i>S J Unsworth and D L Medin</i>	172
Cooperative Learning	<i>R E Slavin</i>	177
Intelligence	<i>R J Sternberg</i>	184
Learning from Multiple Information Sources	<i>H I Strømsø and I Bråten</i>	191
Memory	<i>S Magnussen and T Brennen</i>	197
Metacognition	<i>L Baker</i>	204
Personal Epistemology in Education: Concepts, Issues, and Implications	<i>I Bråten</i>	211
Piaget: Recent Work	<i>L Smith</i>	218
The Adult Development of Cognition and Learning	<i>E A L Stine-Morrow and J M Parisi</i>	225
Vygotsky and Recent Developments	<i>J V Wertsch</i>	231

Learning and Cognition – Issues and Concepts – Focus on Cognition

Cognition and Emotion	<i>F Pons, M de Rosnay, and F Cuisinier</i>	237
Cognition: Overview and Recent Trends	<i>J Wiley and B D Jee</i>	245
Development of Creativity	<i>M A Runco</i>	251
Knowledge Domains and Domain Learning	<i>L Maggioni and P A Alexander</i>	255
Problem Solving and Human Expertise	<i>T J Nokes, C D Schunn, and M T H Chi</i>	265
Problem Solving and Reasoning	<i>R E Mayer</i>	273
Reasoning, Moral and Social	<i>N S Jampol, C B Richardson, and M Killen</i>	279
Remembering as Social Activity	<i>D Middleton</i>	285

Learning and Cognition – Issues, Concepts, Types

Computer-Supported Collaborative Learning: Basic Concepts, Multiple Perspectives, and Emerging Trends	<i>S R Ludvigsen and A I Mørch</i>	290
Learning as Inquiry	<i>S R Goldman, J Radinsky, S Tozer, and D Wink</i>	297
Learning Through Narrative Socialization	<i>A Fasulo</i>	303
Neuroscience Bases of Learning	<i>M H Immordino-Yang and K W Fischer</i>	310
The Neuroscience of Reading	<i>U Goswami</i>	317

Learning and Cognition – Issues, Concepts, Types – Focus on Learning

Learning Strategies	<i>C E Weinstein, J Jung, and T W Acee</i>	323
Learning Through Play	<i>K Aronsson</i>	330
Situated View of Learning	<i>A Collins and J G Greeno</i>	335
The Neuroscience of Aging and Cognition	<i>W J Hoyer and B Bessette-Symons</i>	340

Learning and Cognition – Language, Literacy and Subject-Related

An Overview of Language and Literacy in Educational Settings	<i>V G Aukrust</i>	345
Bilingualism and Learning	<i>L S Verplaetse and E Schmitt</i>	355
Classroom Discourse and Student Learning	<i>L Hemphill</i>	361
Early Writing	<i>B E Hagtvet</i>	367

First Language Acquisition	<i>N B Ratner</i>	375
Foreign Language Learning	<i>C Kinginger</i>	382
Learning Science	<i>J Leach and P Scott</i>	387
Learning to Read	<i>M S Burns and J K Kidd</i>	394
Mathematics Learning	<i>L Verschaffel, B Greer, and E De Corte</i>	401
Music Learning	<i>S Hallam</i>	407
Reading Comprehension: Reading for Learning	<i>C E Snow</i>	413
Second Language Learning	<i>J S Arnfast, J N Jørgensen, and A Holmen</i>	419
Writing: Advanced	<i>R Andrews</i>	426

Learning and Cognition – Other Issues

Gender and Learning	<i>L Yates and J McLeod</i>	432
Parent–Child Relationships in Early Learning	<i>C P Edwards, S M Sheridan, and L L Knoche</i>	438
Peer Interaction and Learning	<i>S Blum-Kulka and S Dvir-Gvirsman</i>	444

Learning and Cognition – Places of Learning

Learning in a Cross-Cultural Perspective	<i>L-F Zhang and R J Sternberg</i>	450
Learning Outside of School	<i>T Nunes</i>	457
Reasoning and Explanatory Talk: Learning in Everyday Settings	<i>D E Beals</i>	464

Learning and Cognition – Theoretical Perspectives – Learning

Apprenticeship Approach to Learning	<i>K Nielsen</i>	469
Connectionism and Learning	<i>T R Shultz</i>	476
Constructivism and Learning	<i>S Sjøberg</i>	485
Cultural–Historical Activity Theory	<i>A Havnes</i>	491
Learning in a Sociocultural Perspective	<i>R Säljö</i>	498
Self-Regulated Learning and Socio-Cognitive Theory	<i>P H Winne and A F Hadwin</i>	503

N

National Systems of Education

Australia	<i>C N Power</i>	510

VOLUME 6**P****Philosophy of Education**

Philosophy of Education: Overview	<i>P Enslin</i>	1
-----------------------------------	-----------------	---

Philosophy of Education – Contemporary Issues

Neoliberalism, the Market and Performativity	<i>M A Peters</i>	11
Parents and Children's Rights	<i>M Clayton</i>	17
Peace Education	<i>I Gur-Ze'ev</i>	22
Philosophy and Educational Research	<i>D Bridges</i>	29
Race, Critical Race Theory and Whiteness	<i>B Applebaum</i>	36
School Choice and the Common School	<i>G Haydon</i>	44

Philosophy of Education – Philosophical Perspective

African Philosophy of Education	<i>K Horsthemke</i>	50
Feminism	<i>L Stone</i>	56
Hermeneutics	<i>C Bingham</i>	63
Islamic Education	<i>Y Waghid</i>	69
Liberalism and Education	<i>W Feinberg</i>	74
Phenomenology and Existentialism	<i>B Levering</i>	80
Pragmatism	<i>B Thayer-Bacon</i>	86
Psychoanalysis and Education	<i>P Smeyers</i>	92
Social and Cultural Capital in Education	<i>M Print</i>	97
The Aims of Education	<i>R Marples</i>	103
The Analytical Tradition	<i>D Carr</i>	108

Philosophy of Education – Philosophical Themes

Adult Learning: Philosophical Issues	<i>D Beckett</i>	114
Autonomy	<i>C A Wringe</i>	121
Bildung	<i>J Masschelein and N Ricken</i>	127
Critical Theory and Pedagogy	<i>M Mason</i>	133
Critical Thinking	<i>H Siegel</i>	141
Environmental Education	<i>M Bonnett</i>	146
Identity	<i>M S Merry</i>	152
Inclusion	<i>R Cigman</i>	158
Justice and Care	<i>M Tjiattas</i>	164
Lifelong Learning	<i>J Halliday</i>	170
Post-Structuralism and Education	<i>M Mason and M Clarke</i>	175
Reason and Rationality	<i>P Hogan</i>	183

Religious and Spiritual Education	<i>J C Conroy and S J McKinney</i>	189
The Capabilities Approach	<i>L Terzi</i>	194

Primary and Secondary Education – Learning and Teaching in School Age Education

Class Size – Arguments and Evidence	<i>P Blatchford and K C Lai</i>	200
Continuing Professional Development of Teachers	<i>P Earley</i>	207
Homeschooling	<i>P Farenga</i>	214
Innovations and Early Intervention in the Teaching of Literacy	<i>R E Slavin</i>	221
Personalized Learning in School Age Education	<i>D Hopkins</i>	227
Perspectives on Schooling in the Middle Years	<i>V J Russell</i>	233
Reform of the School Workforce	<i>H M Gunter and G Forrester</i>	242
Secondary Education in Developing Countries	<i>P Hughes and A Walker</i>	249

Primary and Secondary Education – Social Justice Issues in School Age Education

Community Focused Schools	<i>A Dyson</i>	255
---------------------------	----------------	-----

Primary and Secondary Education – The Effectiveness of School Systems

Reforming the American School System	<i>M Barber</i>	261
School Effectiveness in Developed Societies	<i>D Reynolds</i>	269
School to School Collaboration: Innovation and Improvement	<i>R Higham</i>	274
Studies of School Improvement in Developing Countries	<i>S E Anderson</i>	281
Sustainable Educational Reform	<i>A Hargreaves</i>	289
The Role of the District in Tri Level Reform	<i>M Fullan</i>	295
Whole School Designs for Enhancing Student Achievement	<i>S Stringfield and J Nunnery</i>	303

Q

Qualitative Research

Action Research in Education	<i>E Stringer</i>	311
Classroom Ethnography	<i>F Erickson</i>	320
Computer Assisted Qualitative Data Analysis	<i>C Silver and A Lewins</i>	326
Conversational Analysis	<i>H G Levine</i>	335
Critical Ethnography	<i>D Foley</i>	337
Critical Race Theory	<i>D Gillborn and G Ladson-Billings</i>	341
Critical Theory	<i>J J Ryoo and P McLaren</i>	348
Cultural Studies	<i>R Gaztambide-Fernández and K Cairns</i>	354
Cultural–Historical Activity Theory	<i>Laboratory for Comparative Human Cognition</i>	360
Design Experiments	<i>A Collins</i>	367
Discourse Analysis	<i>P Nikander and S Vehviläinen</i>	373
Document Analysis	<i>T Rapley and K N Jenkins</i>	380
Ethnography	<i>M Hammersley</i>	386

Ethnomethodology in Education Research	<i>D Macbeth</i>	392
Focus Groups	<i>D L Morgan and K Hoffman</i>	401
Grounded Theory	<i>K Charmaz and A Bryant</i>	406
Hermeneutics	<i>J Dyer</i>	413
Interpretive Research	<i>E Rauscher and M E Graue</i>	419
Interviews and Interviewing	<i>A Marvasti</i>	424
Life History	<i>J A Hatch and S K Newsom</i>	430
Narrative Inquiry	<i>D J Clandinin and J Huber</i>	436
Participant Observation	<i>J Schostak</i>	442
Phenomenology	<i>M van Manen and C A Adams</i>	449
Qualitative Case Studies	<i>S B Merriam</i>	456
Qualitative Data Management	<i>C Grbich</i>	463
Semiotics	<i>M Danesi</i>	475
Symbolic Interactionism, Naturalistic Inquiry, and Education	<i>J A Forte</i>	481
The Quality of Evidence in Qualitative Research	<i>S K Biklen</i>	488
Visual Data in Education Research	<i>J Wagner</i>	498

Qualitative Research – Standards of Proof

Validity: Mapping Diverse Perspectives	<i>G B Rossman, S F Rallis, and A M Kuntz</i>	505
--	---	-----

Quantitative and Qualitative Approaches to Research – Integration

Mixed Methods	<i>A Tashakkori and I Newman</i>	514
---------------	----------------------------------	-----

Quantitative Methods and Research Design

External Validity	<i>G E Matt, A Brewer, and M Sklar</i>	521
-------------------	--	-----

PHILOSOPHY OF EDUCATION

Philosophy of Education: Overview

P Enslin, University of Glasgow, Glasgow, UK

© 2010 Elsevier Ltd. All rights reserved.

How Do Philosophers of Education Contribute to Educational Enquiry?

What do philosophers of education do and how does their work relate to other ways of studying and reflecting on education? As in all areas of philosophical work, what philosophers of education do, and should do, is a matter of ongoing debate – especially among philosophers themselves. Indeed, philosophy, in general, is characteristically preoccupied with reflection on its own purposes and methods – concerning which there is ongoing dispute. At the same time, philosophy of education is, sometimes, assumed – from outside the discipline – to be a matter of providing definitions of complex concepts, of articulating a personal manifesto or a social group's shared educational ideals, of adopting the educational ideals of one of a number of rival schools of thought or 'isms', such as empiricism and rationalism, or, perhaps, of applying the wise reflections of great thinkers, such as Plato or Rousseau.

Although not all of these possibilities will be thoroughly rejected in the introductory overview that follows, the collection of philosophical articles gathered in this encyclopedia suggests a different and more complex view of what is distinctive about philosophy of education. However, a useful place to start introducing this selection of articles by philosophers of education, the range of approaches they exemplify, and issues they address, is precisely with some attention to what the discipline is not.

Philosophy of education should not be assumed to be a matter of providing definitions, studying the ideas of great thinkers, or of selecting and applying one or another theoretical position to the practice of education. Instead, philosophers of education set out to throw light on the meaning and aims of education, as well as on a

range of problems to which this project gives rise. As a preliminary indication, it can be said that this line of enquiry involves analyzing arguments, identifying and probing assumptions, assessing claims, clarifying concepts, and more – to which we will return in the course of this overview.

The Role of Definitions

The types of problems that the philosophy of education addresses are not amenable to quick solution by offering definitions. A short definition will inevitably be contestable: so complex are many issues in education and other fields that, while a working definition or initial characterization may, sometimes, serve to get a discussion going – probably for later reformulation – a considered account that grapples with conceptual and other complexities is likely to be required (see, e.g., the extended treatment of the concept of experience in 'Adult learning: Philosophical issues,' in which Beckett uses an account of experience to develop a social, intersubjective account of learning).

For example, to define education as being centrally about learning might look succinct and clear. However, what about learning that might be undesirable, such as learning to lie or to be a thief? Also, what of possibly crucial considerations about the nature of education that do not focus just on learning, but also on well-being or the development of capacities such as, say, autonomy? As these examples suggest, a definition may be too broad or too narrow, failing to exclude features necessary to a concept's meaning or failing to include necessary elements. At best, it has a useful role to play in starting exploration of a philosophical issue, rather than settling it (see how Marples' article on 'Aims of education' avoids

defining the aim of education and, instead, explores competing expectations of publicly funded education, i.e., preparation for work, providing knowledge for its own sake, and for well-being).

Philosophy of Education as Expressions of Personal or Group Beliefs

Nor can philosophy of education be equated with a philosophy in the sense of a set of beliefs, whether interpreted as a kind of personal philosophy, as in my personal philosophy of teaching, or a philosophy of life or worldview and its accompanying doctrine of education, shared with a group of others. Such a loose use of the term “philosophy” belies its necessary critical function, its role in probing assumptions and sets of beliefs, however deeply and dearly individual persons might hold them. Yet, having said this, two philosophical articles in this collection do raise current concerns with regard to the significance and status of various groups’ shared views concerning the nature and aims of education (‘African philosophy of education’ and ‘Towards an Islamic philosophy of education’) – an issue to which we will return later.

Schools of Thought

A more viable candidate for the name ‘philosophy’ in educational inquiry than individuals’ or groups’ beliefs could be one of a number of theories that offer more systematic perspectives – often named by a term that includes the noun-forming suffix *ism*, such as ‘rationalism’ or ‘empiricism’ (which differ with regard to the extent to which we depend on experience in acquiring knowledge), or realism and idealism (which differ with regard to whether material things exist independently of minds that perceive them). This common interpretation of philosophy of education was evident in teacher-education curricula across several decades and retains a presence, if less widely so. Accompanying textbooks (e.g., Brubacher, 1962) presented a range of competing schools of thought and readers were commonly invited to consider which best applied to understanding the practice of education, and to extrapolate implications for a range of problems, which could be applied in their work as educators.

One obvious problem with such an approach is that while some such competing theories marked out by the *ism* suffix stand up to critical scrutiny better than others, the range of theoretical positions available for consideration and scrutiny is no longer limited to a set of distinct and clearly opposed positions, as might previously have been the case. Some of the many positions now identified by the *ism* suffix – quite a few of which are relatively new compared with those traditional schools that featured in

textbooks based on a fairly neat typology – are controversial because they are widely agreed among philosophers of education to undermine the educational enterprise. To take a contemporary example – in recent years, philosophers of education have devoted considerable attention to neoliberalism as a contemporary doctrine that has exerted a destructive social influence – not least in education (for an account of neoliberalism and its influence in education, see Peters on ‘Neoliberalism, the market and performativity’ and Halliday’s exploration of the shift in social policy from social justice to economic rationalism in his article on ‘Lifelong learning’). Some such theoretical positions, then, are interesting not because they might offer a possible philosophical stance to adopt as one’s own, but rather because of the importance of subjecting them to ongoing criticism. This is what is wrong about them that often makes them worthy of attention, especially if they are widely held and influential.

Noting the presence of various *isms* in educational discourse prompts us, if considering them philosophically, to raise questions about how we might go about evaluating their competing claims to knowledge concerning the world, including what education is about and how it ought to be pursued. While there is no neutral position from which to evaluate their claims, philosophically regarded, all must be open to criticism, and it is probable that none will successfully claim adherence to the exclusion of all others. To think, furthermore, that one might be able to do so would be to confuse the activity of philosophy with doctrine or dogma.

In addition, there is likely, in any case, to be some diversity and even disagreement among writers who have contributed to the development of any of these theoretical approaches (see Levering’s account of the relationship between Sartre and Camus as existentialists in ‘Phenomenology and existentialism,’ which shows that their views diverge). To assume that a choice could be made among theories as alternative doctrines that might be adopted – or simply learned from – to the possible exclusion of others would be to mistake the nature of the discipline. Feminism is a case in point. As Stone’s contribution (‘Feminism’) illustrates, there is great diversity within the range of theories loosely described as feminist theory, although all share a commitment to ending gender oppression. An informed and sensitive reading of the various approaches to theorizing in education reveals an ebb and flow of, sometimes, overlapping influences (see Mason on ‘Critical theory and critical pedagogy,’ which shows diverse influences on critical theory, including Hegel and Marx as well as elements of Anglo-American thought). The complex interrelationships among the theoretical trends, tendencies, and positions addressed in this collection – which number several dozens – show that developments in social and educational ideas may prompt established theoretical approaches to adjust some aspects

of their position or methodology to accommodate new insights or to meet objections to weaknesses. Some might be obviously opposed but others stand in more ambiguous and arguably more synergistic relationships to one another.

Yet, in spite of these qualifications, it remains the case that a number of theoretical positions and orientations exert considerable influence both on ideas about education and in the discipline of philosophy of education. Of these, pragmatism's continuing influence is a prominent example. Like other major approaches discussed in this collection, pragmatism does not present itself as a single, unified doctrine vying with one or two particular others for our loyalty. In addition, uptake of pragmatism in recent work is not a restatement of earlier ways in which philosophers of education have engaged with this current in philosophy (see Thayer-Bacon on 'Pragmatism').

The usefulness of various theoretical movements shifts over time, both in our interpretation of them and in the multiple ways in which they can illuminate the changing educational scene. Marxism, for example, is less prominently present in educational enquiry than it was in the 1970s and 1980s, arguably as it has been overtaken as an explicit focus of theoretical interest by post-structuralism (see Mason and Clarke on 'Post-structuralism and education') – although its influence as a strand in the history of educational thought continues (see 'Hermeneutics,' 'Critical Theory and critical pedagogy,' 'Peace education') and there has been a recent resurgence of interest in the Marxist theory's relevance to education (Rikowski, 2007).

An approach to understanding philosophy of education, focused on competing schools of thought, shares some difficulties with a related misapprehension, which is that philosophical inquiry about education is a matter of studying the writings of great thinkers – the classic texts in the history of educational thought.

Great Thinkers

Alongside, a tendency to present philosophy of education as a catalog of competing theoretical positions has been a similar approach in which the ideas of great thinkers such as Plato, Kant, or Dewey are presented for respectful consideration and application to contemporary educational issues. Indeed, education has been an issue of interest to many of the major figures in the history of philosophy, broadly viewed across its traditional branches, especially those of metaphysics, epistemology, ethics, and political philosophy.

Although major figures do undoubtedly enjoy a strong presence in educational thought (see, e.g., the frequent references to Wittgenstein, Dewey, and Foucault in this collection), philosophy of education cannot be reduced in this way to an anthology of their ideas – for reasons

already largely indicated above. None has succeeded in articulating a single grand theory of education that successfully addresses all educational issues and controversies, and the very idea that this might be possible has been thoroughly debunked by recent post-structuralist influences (see, e.g., Lyotard, 1984). None has achieved a body of work of such wide reach or consistent success. All have been vulnerable to generative critique from competing theories, or from other philosophers – such as in the cases of Aristotle or Plato or Hegel or Kant – or from others working within a closely related approach who dispute particular issues on which their views and arguments differ. In addition, all four of these philosophers retain an influential presence today – indeed, most of contemporary philosophy of education can be located within either the Kantian or Hegelian traditions. As we see in the current selection of articles on philosophy of education, engagement with the ideas of key figures in the history of educational ideas remains a strong component of what philosophers do.

In philosophy of education, however, such engagement does not take the form of deferential, axiomatic application of the ideas of major thinkers to classroom practice by simple extrapolation from theory to practice. Even the most astute philosophical insights require critical evaluation and interpretation on the way to application, and different issues in policy and practice might benefit best from insights of different writers. Our beliefs, values, knowledge, and educational principles comprise a complex web from which it is not possible to draw conclusions in the form of principles for application in educational situations and practice (Hirst, 1966). Even those who agree on certain beliefs may support different views with regard to education. No straightforward deductive relationship is plausible here. Furthermore, some aspects of the theories of even the most innovative of thinkers are simply more convincing than others and there is much philosophical work to be done, requiring a range of critical tools, in deciding which these are, which may, in turn, depend on the relevant educational and background contexts.

However, to observe that neither major schools of thought nor the work of great thinkers represent what philosophy of education offers to educational enquiry is not to thoroughly dismiss their presence in educational thought. Instead – and while acknowledging the need for a sense of the history of philosophical thought about education – we need to see their role differently, in relation to the use of several critical tools, to which we now turn.

Philosophy of Education as a Distinctive Type of Educational Inquiry

A useful way to distinguish between philosophical and other approaches to educational inquiry is by taking into

account the distinction between first- and second-order questions and discourses. In education, first-order discourse could comprise everyday talk concerning classroom practice, or policy discussion with regard to educational situations and issues. Take, for example, a call for education to be inclusive. Second-order philosophical discourse would focus on the concept of inclusion differently, reflecting on it to develop a critical discourse that tries to clarify the concept of inclusion and similarly complex, related concepts – to scrutinize assumptions and arguments concerning them, and to develop sound arguments about the issues they raise. Thus, Cigman's article ('Inclusion') probes the meaning of inclusion by exploring the conceptual history of inclusive education – from its early formulation in terms of handicap, through attention to the meaning of related concepts such as fairness as equality and fairness as attention to individual or special need, and integration and inclusion.

Philosophers of education work with concepts in several ways. A central feature of analytic philosophy of education (see Carr on 'The analytical tradition') – whose history will be discussed shortly – has been to clarify the meaning of concepts, which can involve several dimensions. The articles in this collection, which exemplify clarification of the meaning of concepts, include Applebaum's analysis of race, racism, and whiteness ('Race, critical race theory, and whiteness'). In order to develop her account of racism, Applebaum emphasizes both the relevance of related concepts such as systematic oppression, and also distinguishes, crucially, between race and ethnicity. A number of articles raise and use well-established conceptual distinctions that continue to illuminate; for example, Terzi reminds us of that between schooling and education ('The capabilities approach'), Hogan of that between instrumental and practical rationality ('Reason and rationality'), and Clayton of the distinction between rights in law and moral rights ('Parents' rights and children's rights'). By contrast, some of the articles question the usefulness of old, accepted distinctions – as in Bridges' observation that the distinction between objectivity and subjectivity is, sometimes, expressed too crudely ('Philosophy and educational research') and in Mason's mention of the Frankfurt School's objection to the separation of questions with regard to values and interests from those concerning the production of what are regarded as objective facts ('Critical theory and critical pedagogy'). Gur-Ze'ev suggests in his proposals for a different focus on peace education that philosophers might begin by analyzing the concepts of peace and education as reciprocal ('Peace education').

In their work on concepts and issues of significance for education, philosophers of education also pay attention to argument – again, in several ways. The most obvious of these is close scrutiny of arguments, their structure, and the assumptions on which they rest, as well as the ways in

which concepts are used. Siegel ('Critical thinking') questions the coherence of reasoned arguments against reason itself in criticisms of critical thinking as an educational ideal. Tjiattas' article constructs an argument against the popular assumption that, in moral education, theories of care and of justice are strongly opposed, rival positions ('Justice and care'). Haydon's contribution ('School choice and the common school') exemplifies both conceptual sensitivity and careful construction of an argument – in his account of the concepts of the common school and school choice – in which he asks whether the topic should be set up as a debate between two sides and continues to examine assumptions with regard to what each involves in order to discern whether the two ideas are mutually exclusive. Bingham's article ('Hermeneutics') shows how the hermeneutic approach challenges the assumption that language is a conduit for transferring thought from one mind to another, while Bonnet ('Environmental education') argues that prevailing background assumptions with regard to nature in educational debate and policy rely too heavily on traditional views of science.

Conceptual exploration and arguments in philosophy and philosophy of education frequently explore examples – often from real or imagined educational issues and contexts. Sometimes, they also draw illuminatingly on what are called thought experiments. In this collection, for example, Hogan ('Reason and rationality') refers to perhaps the most well-known thought experiment in modern political philosophy – Rawls' (1971) thought experiment in which imagined participants derive principles of justice from behind a veil of ignorance, in an original position in which they have no knowledge of their own identities, social position, or commitments. Marples ('The aims of education') refers – in questioning whether happiness could be an aim of education – to Nozick's (1974) experience machine, which could provide us, if plugged in, with pleasurable experiences.

Philosophy of Education Since the Mid-Twentieth Century: Analytic Philosophy and Beyond

Twentieth-Century Trends in Philosophy

While this article opposes the assumption that philosophy of education can be usefully described as predominantly either a study of major theoretical positions or of great thinkers in its history, to understand its present state, one does need to note how the discipline – as it has been described so far – has developed historically, especially since around the mid-twentieth century, when a distinctive approach to philosophy developed and was influential in setting the predominant direction of philosophy of education for decades to come. This marked a shift from the tendency to focus on major theorists and

philosophical doctrines to an analytical approach that reflected major trends in mainstream philosophy and turned, instead, to analyzing key concepts as a central role of the discipline.

The development of a distinct approach to philosophy of education that came to prominence in the 1960s and remains highly influential was fostered by the establishment of linguistic philosophy as the dominant approach in English-speaking countries. With its emphasis on ordinary use, its origins can be traced to Socrates (see 'The analytical tradition'). However, its contemporary development was prompted by the work of figures such as Austin (1962) – through his attention to ordinary language – and, most especially, Wittgenstein (1953) – whose emphasis on language games and forms of life fostered a tradition in philosophy of education that remains vibrant, not just within what came to be called analytical philosophy of education. For his work was later to be productively taken up outside the analytical tradition by some philosophers of education inspired as much by post-structuralist influences as by the analytical approach.

In order to appreciate the philosophical influences on post-war philosophy of education – and for reasons that will become clearer later in this article – the reader need also note the powerful attraction of Logical Positivism – as expressed, for example, in Ayer's *Language, Truth and Logic* (Ayer, 1936). Ayer's suspicion of metaphysical statements – which he described as meaningless because they were unverifiable – was to exert a powerful influence, as was his emotivist theory's dismissal of ethics. Distinguishing between fact and value, there being no moral facts, no cognitive significance could be attached to moral utterances, which Ayer dismissed as mere expressions of attitudes. Although mainstream epistemology was to move away from this brand of empiricism, popular perceptions of metaphysical and ethical statements outside of philosophy and even in the wider community of educational enquiry were to remain wedded to the type of positivism expressed by Ayer, and the persisting influence of positivism has outlived the heyday of logical positivism. Ayer's positivism was echoed in an influential textbook by O'Connor, which set out to apply the revolution that had occurred in philosophy.

In *An Introduction to the Philosophy of Education*, (1957) O'Connor's reflected the climate of the time by likening valuations to superstitions; there are no means available for deciding on ethical issues as, unlike matters of empirical fact, they are not amenable to being settled empirically – whether through observation or experiment. We have been far more successful at addressing problems in mathematics and the natural sciences. Based on this model, philosophy does not offer knowledge beyond the modest role of clarifying and weighing up the logic of evaluative claims. This reductionist dismissal of moral values and metaphysical beliefs was resisted by analytical

philosophers of education, for example, by Hirst – who defended the necessary role of both in educational theory's concern with the rational formulation of principles for practice (Hirst, 1966: 38–42).

O'Connor assigned a major role to psychology in theory of education, given its closer affinity to the natural sciences. In the face of such judgments with regard to the relative respectability of disciplines such as psychology and sociology of education, it is not surprising that philosophers of education would have sought to establish their discipline as having its own distinct methods and criteria of rigor.

R. S. Peters and the London School

The publication of the first of many impressions of O'Connor's narrow construal of the role of philosophy of education was followed by a period in which the discipline flourished, in the conditions of post-war economic prosperity that prevailed in many Western countries. Policy development favored systematic teacher education that prevailed until the increasing influence of neoliberalism, in the 1970s, began to foster a climate that was less encouraging of theoretical reflection on education. In the United States, conditions also favored expansion of schooling and a growth of the discipline – both countries seeing the flourishing of professional associations in philosophy of education as well as the publication of work in the discipline that reflected both an upsurge of philosophical research on education and its growing presence in teacher education.

The leading figure in analytical philosophy of education in Britain during this period was R. S. Peters – whose appointment to a chair in philosophy of education at the University of London, in 1962, opened the way for him and others to foster analytical philosophy of education through the analysis of key concepts such as teaching, reason, indoctrination, and education itself as well as through attention to clear and careful argument as a precondition for the formulation of soundly reasoned principles. Working within the Kantian tradition, Peters' work developed a liberal conception of education – premised on autonomy – most notably in his landmark book *Ethics and Education* (Peters, 1966). Other leading contributions of this era included Hirst's *Knowledge and the Curriculum* (Hirst, 1974) and White's *Towards a Compulsory Curriculum* (White, 1973). Working within the analytical tradition, in the United States of America, Scheffler's publications included *Conditions of Knowledge* (Scheffler, 1965) and *Reason and Teaching* (Scheffler, 1973), although Dewey's influence on philosophy of education in the United States of America marked a difference in approaches taken by philosophers of education in the two countries (see 'Pragmatism').

While Peters and Hirst stressed their focus on the analysis of our use of central concepts in ordinary language, articulating their defining characteristics and the

principles governing their use in order to better understand the logic of education (Hirst and Peters, 1970), Peters himself also addressed ethical questions that fell – in O'Connor's terms – outside a strictly analytical framework. In fact – as a body of work – analytical philosophy of education was to become increasingly interested in ethical and political issues. In doing so, it matched similar developments in the major branches of philosophy – most prominently in Rawls' definitive work in political philosophy (Rawls, 1971, 1993), which has had a huge influence on philosophy of education and is discussed by Tjiattas ('Justice and care') and Feinberg ('Liberalism and education') among other articles in this collection that engage with Rawls' work.

During this period, philosophy of education self-consciously fashioned itself as one of the central disciplines of the systematic study of education, and teacher-education curricula came increasingly to reflect the presence of the disciplinary branches of history and psychology – as well as the more recently developed sociology and philosophy of education – denoted as the disciplinary branches of theory of education (Tibbles, 1966). The defense of philosophy of education as an autonomous discipline remained a commitment of the philosophy of education community, even as a less unified conception of its approach emerged following early criticisms of analytical philosophy of education – from both within and without its membership.

A dissenting voice in the years that ensued following what he called "the heyday of analytic philosophy of education" was that of John Wilson – whose publications, since *Thinking with Concepts* (Wilson, 1963), defended a version of philosophy of education that remained focused on conceptual analysis and the study of education as a logical discipline. Wilson marked out conceptual questions as neither questions of fact nor questions of value (Wilson, 1963: 11) but as concerned with "the uses of words and with the criteria or principles by which those words are determined." While Wilson's call for ongoing attention to concepts continued for decades (e.g., Wilson, 2003), it was this emphasis on use that provoked one of the most powerful reservations of critics of philosophy of education conducted in this style. Although Wilson was to remain an enthusiastic defender of this mode of philosophy of education, his own emphasis on conceptual analysis came to be seen as too limiting of the discipline's focus and content.

Beyond Conceptual Analysis

The analytical movement has had a considerable and enduring influence on philosophy of education. Most of the articles in philosophy of education in this encyclopedia show its influence – if only in their close attention to concepts and careful argument – although a number of them are located within different theoretical traditions.

Yet, its role in the discipline has been far from uncontroversial and key aspects of its approach, and the views of education and its aims that the analytical movement has produced, have been subject to strong criticism – both from within mainstream philosophy of education and without.

From its early stages, philosophers of education in Britain, the United States of America, and elsewhere were skeptical with regard to the methodological directions taken by the analytic movement. For example, Edel (1973) raised doubts, which others shared, concerning attempts to exclude ethical and social dimensions on the assumption that they might be brought into consideration after the process of analysis had been completed. Instead, argued Edel: "they are integral to the analysis at the points of choice throughout, together with the empirical, scientific, and historical considerations" (Edel 1973: 252). Edel (1973: 234) claimed that the "Analytic method was given a certain cast by the dogmas it inherited from logical positivism," particularly the sharp separation between philosophical and empirical enquiry.

Such misgivings with regard to the form that some purist approaches to conceptual analysis took are confirmed by the present-day widespread recognition that ordinary language is highly contextualized, and that to refer to our use of particular words and the way in which we distinguish them from others is to invoke the very specific location in which they have developed and are employed. In retrospect, Dearden's (1984: 31) suggestion that "I do not myself think that philosophy of education stands in any need of a single paradigm," while at the same time describing its analytical role in terms of attention to concepts and arguments, looks mistaken – even if one grants the usefulness and contribution of this approach to philosophy of education. For, in writing this, Dearden was invoking a particular paradigm or approach (Burbules, 2000) – one that was soon to come under fire. For this reason, while this article has argued against viewing philosophy of education – in the first instance – in historical terms centered on a series of theoretical positions or significant philosophers, it is essential to see recently dominant approaches, as well as current alternatives – to which we will turn shortly – as part of an evolving history. No single view of what philosophy of education is about should be assumed to be the final word with regard to what this discipline offers to educational enquiry.

Critical responses to analytic philosophy of education from without the discipline focused not only on its account of its method but also on the substantive positions this approach produced with regard to the meaning of education and associated concepts, as well as its aims. As Wringe shows ('Autonomy'; see also 'The analytical tradition' and 'The aims of education'), philosophers of education – from the 1960s onward (e.g., Peters, 1969; Hirst and Peters, 1970; Dearden, 1972) – developed an account of

education in which the virtues of rationality and autonomy were viewed as achievements developed over generations and whose acquisition requires systematic teaching. Marxist criticisms – in the 1970s and 1980s – tended to view the depictions of education in analytical philosophy of education as highly specific expressions of hegemonic class interests. Their emphasis on the social construction of knowledge, the role of schooling in the reproduction of labor, and the role of ideology in social control (e.g., Bowles and Gintis, 1976; Willis, 1977) reflected the influence of Marxist theory and, particularly, the new sociology of education (Young, 1971).

Criticisms of autonomy as the aim of education – associated with liberalism and liberal education (see Feinberg on ‘Liberalism and education’) – were also inspired by communitarians, who objected to what they saw as the liberal tendency to assume an atomistic, unencumbered subject and to ignore its location within a particular community and its traditions (e.g., Sandel, 1982; MacIntyre, 1981). As philosophers of education in English-speaking countries have come to pay more attention to continental philosophy and its implications for education, consideration has, of late, been given to a wider range of conceptualizations of education. Masschelein and Ricken’s article on ‘*Bildung*’ for example, develops a close account of education as a process in which human beings are incorporated into society through self-formation, by appropriation of the world, although they do note affinities between *Bildung* and notions of liberal autonomy. Bingham’s article (‘Hermeneutics’) offers an alternative to the liberal paradigm’s separation – from a Hermeneutic perspective – of the personal from the cultural, treating the two as inseparable, while also attending to tacit understandings, focusing less on knowledge transmission and more on dialogue and interpretation. In ‘Phenomenology and existentialism,’ Levering echoes the focus of Hermeneutics on the relationship between individuals and the world and explores the role of phenomenology and existentialism in the continental European tradition, noting its attention to upbringing and the family. Drawing on the work of Freud and Lacan, Smeyers’ article on ‘Psychoanalysis and education’ demonstrates the relevance of the unconscious and of the notion of Otherness to our understanding of education. Even within the liberal tradition, there are recent developments that mark out reformulations of the aims and purpose of education. Terzi’s article on ‘The capabilities approach’ explores the implications for education of this normative framework for the evaluation of well-being in which capabilities to function are central to the justice of public institutions, including schools.

Thus, by the early twenty-first century, philosophers of education in the analytic tradition found themselves working in a theoretical climate offering a range of alternative perspectives; however, see Wringer’s article on ‘Autonomy,’ among others, for critical evaluations – both of the veracity

of critiques of analytical philosophy of education’s approach and its view of education as well as an indication of how it has adjusted aspects of its position, including its defense of autonomy, in response to such critiques.

Prospects for Philosophy of Education: The Challenges of Diversity

Philosophers of education are now engaged with a wider array of areas of enquiry relevant to education, such as cultural studies, media studies, literature, and development economics. In drawing on a complex mix of ideas, traditions, and approaches, philosophy of education currently takes on various contentious issues and roles in contemporary education, including a growing role in policy critique, having – by now – moved beyond an erstwhile preoccupation with analysis of concepts – useful though this tool remains in the ongoing task of critical vigilance in the face of education’s vulnerability to fads and fashions. What does the present selection of articles in philosophy of education reveal with regard to the current state of the discipline and likely areas calling for future development? This concluding section takes up these questions in relation to the theme of diversity from several angles.

First, in addition to the variety of theoretical approaches on offer in this collection, the theme of diversity is also evident in many of the topics addressed. ‘Feminism’ is a prominent example; the influence of feminist theory has been significant – both methodologically and for the issues it raises, such as those around distinctions between the public and the private (‘Justice and care’). In this context, the recent development of queer theory and its relevance is to be welcomed for the contribution it makes in bringing to attention issues of gender and sexual orientation in education (see, e.g., Pinar, 1998). Merry’s article explores various theoretical perspectives on ‘Identity,’ including some from outside the discipline of philosophy. Conroy and McKinney (‘Religious and spiritual education’) demonstrate the contested place of faith schools and of religious education in the school curriculum in the context of cultural diversity in postindustrial, Western liberal democracies – drawing on different models of religious education, including a phenomenological one. Taking into account the challenges to social cohesion presented by social and cultural diversity, that article is one of several articles that focus on citizenship. Print’s ‘Social and cultural capital in education’ also raises the problem of declining social capital eroding political engagement, as well as the role of civics and citizenship education in the development of social capital. Siegel’s article on ‘Critical thinking’ emphasizes the role of fostering abilities and dispositions of critical thinking in enabling democracy to flourish (on citizenship education, see also Enslin and White, 2003; McDonough and Feinberg, 2003).

A second and ongoing issue in current philosophy of education concerns the relationship between analytical philosophy of education and what is generally called the continental tradition. Is the diversity marked by these two contrasting approaches to be welcomed, or should disagreements regarding fundamental differences in approach be resolved in favor of one of the two? For a time, philosophers of education in English-speaking countries who took an interest in European philosophy found themselves marginalized by those committed to the analytic approach (Standish, 2007). Hopefully, the selection of articles collected here reflect the current diversity across traditions as a strength, although many resist easy classification and – in spite of this, or perhaps because of it – are able to throw useful light on contemporary issues in education. To some extent, the type of approach best taken to a particular topic in philosophy of education may depend on the questions being asked.

Ironically, those who might take the view that, here, there is a standoff in which one or the other approach to philosophy of education could emerge as the winner, reflect a similar assumption with regard to the nature of philosophy of education to those proposing to frame it by schools of thought or great thinkers. A polarizing tendency to require that, ultimately, reflection on competing orientations should be resolved by deciding to adopt a particular one as one's own, to the exclusion of others, implicitly assumes the ahistorical tendencies of the schools of thought or great thinkers' views of philosophy of education.

Third, what of philosophy of education's presence among other approaches to theory – and especially to research – in education (see 'Philosophy and educational research')? If a strength of contemporary philosophy of education is its diverse openness to other disciplines and to different theoretical orientations within the ranks of philosophers of education, is this view of diversity reciprocated by those working in other domains of educational inquiry? While efforts to establish philosophy of education as a discipline with a systematic and rigorous method may initially have enabled it to compete successfully with other elements of theory of education in teacher-education curricula, it remains vulnerable to the lingering effects of the assumptions that underpinned logical positivism in assessments outside the discipline of what it might offer to educational inquiry as a whole. Bridges' article on 'Philosophy and educational research' considers philosophy as a form of educational research in its own right, proposing how philosophical inquiry has an essential role to play in informing research methodology. This article also draws critical attention to a tendency – in the present-day interest in evidence-based practice – to assume that educational research can best inform policy by providing evidence that excludes philosophical and, especially, normative considerations. In raising these concerns, Bridges reminds

us that the status of philosophy of education is a political question.

Fourth, and finally, we come to the global context in which philosophers of education now work and the challenges of diversity this poses. Growing recent interest in the diversity within Western democracies takes into account the consequences of globalization – as migration has changed relatively homogeneous societies, prompting the attention to diversity and its consequences in philosophy of education, which has already been discussed in this article. Recognition of globalization's consequences also prompts philosophy of education to take postcolonial theories (e.g., Said, 1978; Spivak, 1988) into account – centrally, in their attention to the relationship between Western cultures and economies and peoples in developing countries attempting to deal with the aftermath of colonialism and the hegemony of Western capitalism. While future work in philosophy of education will pay continuing attention to this theme, two articles in the present collection represent a challenge to Western philosophers of education and take us back to the critical position taken toward philosophy of education conceived as world views attached to particular cultural groups. Horsthemke's article on 'African philosophy of education' considers the position that there is a distinctly different African philosophy of education, underpinned by its own concepts and values. Although Horsthemke's response is a skeptical one, an intriguing contrast emerges between this article and the stance taken in Waghid's 'Towards a philosophy of Islamic education' – in which the author's exploration of constitutive features of an Islamic philosophy of education includes drawing some similarities between an Islamic approach to education based on justice and recent theories of deliberative democracy. This implies that there is room for further development and debate in this area, not least with regard to tensions between universality and particularity, and between philosophy of education as worldview and as a critical activity.

In engaging with the many implications of globalization, perhaps the most challenging for Western philosophers of education – if diversity is taken truly seriously – is the role their discipline could play in countering Western cultural hegemony and the injustices of the global economic system. An obvious dimension of the problem of hegemony lies with the dominance of the West in the production of discourses in the philosophy of education – in itself a consequence of the wealth and influence of higher education and associated publishing industries in those countries. The English language dominates international exchanges. Tackling such hegemony suggests the need for philosophers of education to engage further with philosophical issues concerning both cultural recognition and inequitable distribution of resources – in addition to the predominant focus on the largely domestic or Western problems exemplified in the philosophical work published in this collection.

Glossary

Homo economicus (Economic human) –

A concept in neoclassical economics of humans as rational and self-interested individuals who have the ability to make judgments towards their subjectively defined ends.

Methodological individualism – A philosophical method aimed at explaining and understanding broad society-wide developments as the aggregation of decisions by individuals.

Mt Pelerin Society – An influential post-war foundation established by Hayek in 1947 against socialism and the 'big' state and in defence of liberalism as the open society.

Neoliberalism – A doctrine of economic liberalization in global capitalism associated with the rise of the New Right and the so-called Washington Consensus, aimed at structural adjustment, privatization and 'free trade.'

New Right – A right-wing in UK, Australia and NZ who advocated economic liberal and socially conservative policies; strongly associated with Margaret Thatcher.

Performatives – A concept that is related to speech act theory and to the work of J. L. Austin. It accounts for situations where a proposition may constitute or instantiate the object to which it is meant to refer, as in so-called 'performative utterances'.

Performativity – J.-F. Lyotard talks of 'performativity' as that which legitimates knowledge in the

postmodern condition – a logic based on the efficiency of how well something performs, or enables a person to perform. In a cybernetic society, knowledge is legitimated by how performative it is, if it effectively minimizes the various required inputs for the task and maximizes the desired outputs. This conception leaves no room for ethics.

Postmodern condition – Lyotard defines postmodern as incredulity towards metanarratives, a suspicion towards the grand ideological stories of the enlightenment.

Spontaneous order – A doctrine associated with Hayek that describes the spontaneous emergence of order out of seeming chaos and the emergence of various kinds of social order from a combination of self-interested individuals who are not intentionally trying to create order.

Washington Consensus – Refers to a set of policies advocated the privatization of state assets, economic deregulation, and redirection of public expenditure priorities toward fields offering high economic returns; trade liberalization, the liberalization of interest rates and rules for foreign direct investment, and the floating of the exchange rate and tax reform (to lower marginal rates and broaden the tax base) together with enforcement of property rights and the encouragement of greater fiscal discipline.

Performance will be to the twentieth and twenty-first centuries what discipline was to the eighteenth and nineteenth centuries, namely, an onto-historical formation of power and knowledge. (McKenzie, 2001b: 176)

Introduction: The Birth of Neoliberalism

Neoliberalism is a popular label for the doctrine of political and economic liberalism and set of policies, originating in the 1970s, that wielded together classical liberal political theory as exemplified by the Mont Pelerin Society following World War II (WWII) and neoclassical economic theories that became identified with the so-called Chicago school under Milton Friedman, in the 1960s. It is not a unified and coherent doctrine and it has taken on different manifestations at different times and places – sometimes with contradictory results. For an ultimately moral doctrine based on a classical account of political and economic freedom – a marriage of the free market and the open society – paradoxically, beginning with Chile in 1973, administrations and policy regimes based on the minimal state and open global market were brutally established with force and coercion, against the rule of law, and in an antidemocratic way. This imposition became commonplace, during the 1980s, with structural adjustment policies of the International Monetary Fund (IMF) and the World Bank (WB) that forced the transitional economies of Latin America and elsewhere to liberalize trade and monetary systems, to open up their economies, and to privatize state assets and cut-back state welfare.

For analytical purposes, we can postulate several historical stages of neoliberalism:

1. The development of the Austrian, Freiburg, and Chicago schools in neoclassical economics in the first part of the twentieth century.
2. The first globalization of neoliberalism with the establishment of the Mount Pelerin Society, in 1947, through the intellectual conduit of Hayek.
3. The development of the Washington consensus during the 1970s.
4. The Central Intelligence Agency (CIA)-sponsored coup of Salvador Allende in Chile and the imposition of neoliberal market reforms by General Pinochet.
5. The New Right ascendancy of the Thatcher–Reagan years during the 1980s.
6. The emergence of structural adjustment loans and institutionalization of neoliberalism through a series of world policy agencies such as IMF, WB, Organization for Economic Cooperation and Development (OECD), and World Trade Organization (WTO).
7. The transition to knowledge economy and knowledge for development in the 1990s and beyond.

This article briefly considers the role that Friedrich von Hayek played in contemporary neoliberalism prior to detailing the rise of the New Right and the emphasis on accountability and performativity in education.

The Centrality of Friedrich von Hayek

Friedrich von Hayek (1899–1992) was a major circuit for liberal economic and political ideas, as well as an organizer and a social and political thinker following WWII. He began his studies under Eugen von Bohm-Bawerk and von Mises, was invited to the London School of Economics (LSE) by Lionel Robbins, in 1931, and became a British subject in 1938. He took up a professorship at the University of Chicago in 1950, which he held until 1962. He won the Nobel Prize for Economics in 1974 and taught and eventually retired at the University of Freiburg in his later years.

Friedrich Von Hayek is probably the single most influential individual economist or political philosopher to shape what is now understood as neoliberalism, although he is best regarded – and considered himself – as a classical liberal. Hayek's own theoretical direction sprang out of the so-called Austrian School established by Carl Menger, Eugen Boehm-Bawerk, and Ludwig von Mises during first decade of the early twentieth century. What distinguished the Austrian School from the classical school of political economy pioneered by Adam Smith and David Ricardo was their subjective – as opposed to the objective – theory of value. Leon Walras (1834–1910) of the French Lausanne School presented economics as “the calculus of pleasure and pain of the rational individual” and Carl Menger – developing the subjective theory of value – launched what some have called a “neoclassical revolution” in economics.

In 1930, Hayek was invited to the LSE to lecture on trade cycles, where he was, soon after, appointed to a chair in economics and statistics. While at the LSE, Hayek was involved in two famous debates: first, with Keynes over interventionism (and, in particular, Keynes' alleged failure to understand the role that interest rates and capital play in a market economy), and, second – during the early 1920s – with Oskar Lange and others over the nature of socialist planned economy. However, Keynes' star was on the rise during the 1930s and Hayek's criticisms were downplayed by the international economics community. In 1950, Hayek moved to the University of Chicago, where he wrote *The Constitution of Liberty* (Hayek, 1960) – his first systemic treatise on classical liberal political economy. In 1962, Hayek moved to the University of Freiburg where he developed his theory of spontaneous order. The market, he argued, was a spontaneously ordered institution that had culturally evolved in the same way that the institutions of language and morality had evolved. They

were not the product of intelligent design; such social institutions – like their counterparts in the physical world (crystals, snowflakes, and galaxies) – had evolved as spontaneously ordered institutions. The market, then, while the result of many millions of human (trans)actions over many generations – Hayek maintained – is not the result of human design.

Hayek addressed himself, again, to the problems of the nature of the planned socialist economy in one of his most famous and populist works, *The Road to Serfdom* (Hayek, 1944) – a book that suggested that the absence of a pricing system would prevent producers from knowing true production possibilities and costs. It also warned about the political dangers of socialism, in particular, totalitarianism – which he thought came directly from the planned nature of institutions. Following WWII, in the year 1947, Hayek set up the very influential Mont Pelerin Society – an international organization dedicated to restoring classical liberalism and the so-called free society, including its main institution – the free market. Hayek was concerned that even though the Allied powers had defeated the Nazis, liberal government was too welfare-oriented – a situation, he argued, that fettered the free market, consumed wealth, and infringed the rights of individuals. With the Mont Pelerin Society Hayek there gathered around him a number of thinkers committed to the free market, including his old colleague Ludwig von Mises as well as some younger American scholars who were to become prominent economists in their own right. These included Rose and Milton Friedman, James Buchanan, Gordon Tullock, and Gary Becker – economists who went on to establish the main strands of American neoliberalism: the monetarism of the third Chicago School (see e.g., Friedman, 1962), public choice theory (see e.g., Tullock and Buchanan, 1962), and human capital theory (e.g., Becker, 1964). Most significantly, Hayek invited his old friend Karl Popper – who was resident at the University of Canterbury in New Zealand from 1937 to 1945 where he wrote his now classic two-volume work *The Open Society and Its Enemies* (Popper, 1945), which was an attack on historicism and a defense of liberal democracy as the open society. Hayek had arranged for Popper to take up a position in philosophy at the LSE and their association had gone back many years – Hayek refers to Popper's *The Logic of Scientific Discovery* and adopts his falsificationism in his early-1937 *Economica* paper 'Economics and knowledge' (Hayek, 1937). Both were in Vienna at the turn of the century, both were committed to forms of individualism – epistemological and methodological – and both fiercely defended the notion of the free society. Hayek argued that political freedom depended on economic freedom. Together, Hayek and Popper were formidable Cold War warriors who held that Hegel's and Marx's historicism were the basis of twentieth-century totalitarianism. Together, Popper's *The Open Society*, and Hayek's *The Road to Serfdom* (1949) served as polemical tracts that, at one and the same time, warned against going

down the socialist road while extolling the virtues of the open society and its relationship with the open market.

Hayek's liberalism was also very influential in Britain – especially with the Institute of Economic Affairs – and with Margaret Thatcher, who came to power as the leader of the British Conservative Party, in 1979. We might say that neoliberalism, historically, was at its strongest during the era of the trans-Atlantic partnership between Ronald Reagan and Margaret Thatcher – during the decade of the 1980s – and its dominance began to wane in the 1990s.

The Rise of the New Right

Hayek, then, emphasized the limited nature of knowledge: the price mechanism of the 'free' market conveys information about supply and demand that is dispersed among many consumers and producers and cannot be coordinated. In addition, Hayek's liberalism emphasized: methodological individualism; *homo economicus* – based on assumptions of individuality, rationality, self-interest; and the doctrine of spontaneous order. It was during the decade of the 1980s that Hayek's political and economic philosophy was adopted by Thatcher and Reagan to legitimate the New Right attack on big government, State ownership of enterprises, and the bureaucratic welfare state, including the State unions, with a policy mix based on free trade and the establishment of the open economy: economic liberalization or rationalization characterized by the abolition of subsidies and tariffs, floating the exchange rate, the freeing up of controls on foreign investment; the restructuring of the state sector, including corporatization and privatization of state trading departments and other assets, downsizing, contracting out, the attack on unions, and abolition of wage bargaining in favor of employment contracts; and, finally, the dismantling of the welfare state through commercialization, contracting out, targeting of services, and individual responsabilization for health, welfare, and education. On this view, there is nothing distinctive or special about education or health; they are services and products like any other – to be traded in the marketplace.

These policies were designed to restructure or adjust national economies to the dramatic changes to the world economy that have occurred in the last 20 years: the growing competition among nations for world markets; the emergence of world trading blocs and new free trade agreements; an increasing globalization of economic and cultural activities; the decline of the postwar Keynesian welfare-state settlement in Western countries; the collapse of actually existing communism and the 'opening up' of the Eastern bloc; and the accelerated worldwide adoption and development of the new information and communications technologies.

Neoliberalism received its definitive statement by Williamson (2004) who coined the term Washington

Consensus, in 1990, to refer to a set of policies addressed to Latin American countries by Washington-based institutions. These policies essentially involved an attack on big government – a shift in control and resources from the public to the private sector and the substitution of the market or market-like arrangements for the state at every opportunity. The Washington consensus advocated the privatization of state assets, economic deregulation, and redirection of public expenditure priorities toward fields offering high economic returns. It strongly encouraged trade liberalization, the liberalization of interest rates and rules for foreign direct investment, and the floating of the exchange rate. Finally, it proposed tax reform (to lower marginal rates and broaden the tax base) together with enforcement of property rights and the encouragement of greater fiscal discipline. Williamson himself reflecting on these policies a decade later suggests the three big ideas are “macroeconomic discipline, a market economy, and openness to the world (at least in respect of trade and foreign direct investment (FDI)).”

By the 1980s, neoliberalism – both as a political philosophy and policy mix – had taken deep root and was applied both forcefully and manipulatively. For instance in New Zealand, a New Right Labor government instituted sweeping market reforms across the board against the interests of its traditional affiliated trade union party and against sustained democratic protests. During that decade, many governments around the world supported the modernizing reform thrust of neoliberalism – particularly the exposure of the State sector to competition and the opportunity to pay off large and accumulating national debts. By contrast, many developing countries had structural adjustments policies imposed upon them as loans conditions from the IMF and WB. The reforming zeal soon ideologized the public sector *per se* and ended by damaging key national services (including health, education, and telecommunications).

The dogmatism of the neoliberal right had become a serious threat to social justice, to national cohesion, and to democracy itself. Large sections of populations had become structurally disadvantaged, working and living, on the margins of the labor market; rapidly growing social inequalities had become more evident as the rich had become richer and the poor, poorer; companies were failing and underperforming; public services had been stripped down and privatized, some were unable to deliver even the most basic of services; many communities had become split and endangered by the rise of racism, crime, unemployment, and social exclusion.

Neoliberalism, Performativity, and the Culture of Performance

It is one of the uninvestigated central ironies of the new critical science driven by French theory that one of its

major sources of theoretical inspiration is British analytic philosophy and especially the linguistic philosophy of J. L. Austin and Ludwig Wittgenstein. Both Lyotard (1984) and Foucault (1978), for example, use and adapt Wittgenstein’s conception of language games to describe the fragmentary nature of the social bond, the crisis of legitimation of scientific knowledge in the postmodern condition, and the strategic and political nature of games of truth. Derrida and Lyotard – although for different purposes – draw explicitly on Austin’s (1954) notion of the performative first formulated in *How to Do Things with Words*. Derrida (2005) embraces Austin’s category and theory of the performative as the basis for the new humanities and Butler (1990, 1993) extends this use in gender studies to indicate that gender is constituted by performative acts which come to form a coherent gender identity. Lyotard (1984) appropriates Wittgenstein’s philosophy of language games as a basis for his analysis of the problem of the legitimation of knowledge and education in the postmodern condition and draws on Austin to formulate and predict a new culture of performativity for higher education.

Lyotard’s prophetic prognosis on the nature of knowledge and its management in higher education has become a theoretical springboard for educational theorists to analyze performativity as a more general condition affecting not only the whole of the education sector but also, more widely, newly consumer-driven public services across the board. At the same time, management theorists and business schools picking up on similar socioeconomic structural changes in capitalism have developed notions of performance – performance management and performance culture – in a parallel, though generally theoretically unreflexive, discourse.

Jean-François Lyotard is considered by most commentators, justly or not, as the non-Marxist philosopher of the postmodern condition (sometimes referred to as postmodernity). His *The Postmodern Condition: A Report on Knowledge* (1984), originally published in Paris in 1979, became an instant *cause célèbre*. The book crystallized – in an original interpretation – a study of the status and development of knowledge, science, and technology in advanced capitalist societies. *The Postmodern Condition* was important for a number of reasons. It developed a philosophical interpretation of the changing state of knowledge, science, and education in the most highly developed societies – reviewing and synthesizing research on contemporary science within the broader context of the sociology of postindustrial society and studies of postmodern culture. Lyotard brought together, for the first time, diverse threads and previously separate literatures in an analysis which many commentators and critics believed to signal a epoch-making break not only with the so-called modern era but also with various traditionally modern ways of viewing the world.

One way in which his analysis has been prophetic was that the postmodern condition marks the decline of

modernity's grand narratives, and, in particular, the way in which the progress of Western capitalist technoscience has been culturally embedded in deeper metaphysical fables about reason and freedom, rather than globalization, flexibility, social regulation, and performativity. The story of Western capitalist techno-science was supposed to lead to the gradual, but inevitable, unfolding of the progress of knowledge in emancipation. Lyotard, however, hypothesizes that this story became simply too incredible to believe when, in the 1960s, it was clear that the transition to the postindustrial society (or knowledge economy) was no longer a smooth, necessary, inevitable, or desirable movement. He maintained that the postmodern condition was based on the perception that "the existence of a modern era that dates from the time of the Enlightenment and that now has run its course: and this modern era was predicated on the notion of progress in knowledge, in the arts, in technology, and in human freedom as well, all of which were thought of as leading to a truly emancipated society: a society emancipated from poverty, despotism and ignorance. But all of us can see that the development continues to take place without leading to the realization of any of these dreams of emancipation" (Lyotard, 1984). In this transitional period, Lyotard argues, science and technology are falling under the sway of "another language game, in which the goal is no longer truth, but performativity – that is, the best possible input/output equation" (Lyotard, 1984). It is clear that Lyotard is referring to performance and a logic of performativity that is a cornerstone of the new techno-scientific capitalist knowledge economy.

The 'Age of Performativity'

McKenzie (2001a) has offered an explanation of performance considered as a new social attitude in his recently published book *Perform or Else: From Discipline to Performance*. He argues that the concept of performance is now widely recognized in business and the commercial world as a conceptual tool for assessing human and technological standards and that it is fast becoming the dominant social model of evaluation. According to McKenzie (2001a), traditional philosophical distinctions are becoming less influential and performance effectiveness and efficiency are growing in power as the new conventions defining the basis for the measurement of what is right, true, and good.

McKenzie (2001a) theorizes performance as a formation of power and knowledge, and in doing so, warns us of the growing objectification and alienation of human labor. He asks whether we have entered an age of global performance and remarks that performance has emerged as a crucial term in at least three different areas of social life: economics, technology, and art. For McKenzie (2001a), performance management draws upon the paradigm of cultural performance and substitutes for scientific

management or 'Taylorism', which was the dominant organizational paradigm developed in the early part of the last century for a manufacturing-based, nationally oriented, and highly industrialized economy. Performance management, in contrast to scientific management, no longer produces highly centralized bureaucracies, rigid, top-down management styles, or perceived controlling, hierarchical, and conformist organizational cultures.

Performance management does not sell itself as scientific but rather – adopting the paradigm of cultural performance – it re-describes itself as an *ars poetica* of organizational practice, which is evident in texts like *Corporate Renaissance: The Art of Re-engineering* (Cross *et al.*, 1994), *Jamming: The Art and Discipline of Business Creativity* (Kao, 1998), and *Cultural Diversity in Organizations* (Cox, 1993). This new soft power of management theory and practice recognizes performance as having acquired a normative force. McKenzie's (2001a) analysis of it as a formation of power and knowledge enables us to appreciate a theorizing of performative power that extends beyond the realm of cultural production into discourses and practices that have the normative force to structure our organization, and the institutions of work, learning, and leisure. In addition, while there are different semantic ranges involved, together with different sites of pragmatic installation, as McKenzie argues, the soft power of performance also enables us to recognize the integration of cultural, management, and technological systems.

Higher education is a crucial subsector where these types of performative power intersect, especially when framed by the policy template of the knowledge economy – for, in the knowledge economy, the cultural and the symbolic are paramount. This is the very idea behind the so-called sign economy no longer based on raw materials but rather on the transformation of ideas and symbolic resources by means of intellectual, human, and social capital. In this environment, the three spheres of the economic, technical, and cultural are increasingly brought into a close alignment as performative power combines the rational calculation of (high performance) technical systems and databases with the domain of affective management based around personal experience and social interaction. Performance management, in this context, first came to light with the development of performance-measurement systems developed by the performance-indicator movement and later under New Public Management that drew on principal-agency theory and transactional cost analysis. Performance management is an ideal system for knowledge management, especially where one of the main aims for the knowledge manager is to extract knowledge from people's heads (often tacit knowledge that is difficult to codify) and to embed it in intellectual systems or processes as soon as possible – both protecting it as intellectual property under copyright, patent, or international trade law and putting it into commercial service to make a profit. It is classically speaking concerned with the appropriation of the knowledge surplus

and often performance management utilizes the soft psychotherapeutic technologies in the affective domain, alongside traditional peer-review mechanisms and collegial exchange and in combination with simple counts and computer and/or accounting methodologies (including the weighting and the arithmetization of soft variables like ‘reputation’) to produce departmental, faculty, and institutional performance profiles and institutional, national, and international league tables.

Parents and Children's Rights

M Clayton, University of Warwick, Coventry, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Best-custodian condition – The claim that custodial rights over a child should be allocated to those interested individuals whose parenting can reasonably be expected to be in the child's best interests.

Claim right – A claim right to ϕ is an entitlement to ϕ protected by an injunction that places others under a duty to allow, or enable, one to ϕ .

Distributive justice – The study of the conditions under which everyone receives her due or in which the distribution of opportunities and resources is fair.

Dual-interest view of custody – The claim that custodial rights over a child should be allocated in a way that is sensitive to the interest of adults who hold ambitions to parent a well as the interests of children.

Equality of opportunity – The ideal that everyone enjoys equal life chances.

Liberty right – A liberty right to ϕ is a permissions to ϕ or not to ϕ as one chooses.

Parental neutrality between conceptions of the good – The claim that parental conduct should not be guided by a belief in the intrinsic merits of particular religious or ethical conceptions.

Personal autonomy – The ideal that a person's life should be guided by her own reflective view of what a successful life consists in.

Political legitimacy – The conditions under which citizens have a weighty reason to comply with the law and support their political institutions.

Political morality – The study of how we should live together in society.

Sense of justice – The motivation to comply with a conception of the requirements of justice, or what is due to individuals.

Discussions of the rights of children and parents have centered on whether children and parents have rights, how such rights are justified, the nature and content of these rights, and how to resolve conflicts between the rights of parents and children when they conflict. These discussions proceed on the basis of the Hohfeldian classification of rights into liberties (or privileges), claim-rights, powers, and immunities (Hohfeld, 1919; Sumner, 1987). One has a liberty right to perform an action, to speak for example, if one has the

option of speaking or not as one chooses. Claim-rights are entitlements that generate duties on others: the claim-right to speak involves others being duty-bound not to prevent one from speaking. Powers are permissions to change one's own or, perhaps, someone else's normative status: for example, many claim that parents ought to enjoy the power to accept or refuse a painful operation on behalf of their child. Finally, one enjoys immunity if others are duty-bound not to change one's normative status: for example, children enjoy an immunity against anyone selling them into bonded labor.

One can enjoy legal rights, which are, by definition, enshrined in a legal system or document, such as a legally recognized declaration or convention. Academic discussions of rights, however, typically discuss moral rights. There is no settled understanding of how moral rights should be understood. Some have thought that moral rights are simply the rights that should be recognized by a legal system (Sumner, 1987). However, others insist that it makes sense to assert that someone has a right even when it is impossible or undesirable to enshrine such a right in the law (Feinberg, 1992). If valid, the child's right to be free of religious schooling discussed below may be a right of this kind, a moral right that it is inappropriate to recognize legally.

Children's Rights

Are children, particularly young infants, the sorts of individual to whom moral rights can be ascribed? The answer to this question turns on how rights and, specifically, claim-rights are further specified. So-called choice theorists of rights claim that rights protect a choice on the part of the right-holder, a choice over whether the correlative duty is performed or not. So, for example, if I have the right to \$10 from you I can insist that you honor your duty to give the money to me or, alternatively, I may cancel the duty, as I choose. Yet if rights protect choices, then it is difficult to see how individuals who are incapable of exercising rational choice – neonates and infants – can be right-holders. The choice theory has been challenged by the interest theory of rights, in which rights protect the interests of individuals. Some interest theorists insist that because neonates do indeed possess rights – rights not to be harmed and to be cared for in various ways, for example – the choice theory of right must be mistaken as a general account of rights (MacCormick, 1982). Indeed, the

interest theory seems more plausible because it can accommodate the thought that is central to the choice theory, namely, that many rights protect choices, by citing the important interest we have in leading autonomous lives. However, the interest theory resists the extreme claim that rights protect only choices, for it can also justify rights for individuals who are not capable of choice, such as young children or those who are, or become, incapable of rational judgment. It is open to choice theorists to reply that children can be protected without an appeal to their rights. Indeed, few believe that an account of rights offers a complete conception of how children ought to be viewed and treated. An adequate theorization of the place of children in our moral deliberations must take into account the duty on the part of parents and others to care for children, regardless of whether those duties can be correlated with particular rights (O'Neill, 1988). Nevertheless, it would be unfortunate to eschew the language of rights when addressing issues of the place of children, for if, as many think, the rights of individuals have priority over other kinds of normative claim and should be respected even at considerable social cost, then not conferring rights on infants might place them in a vulnerable position.

If children have rights, how should we describe the rights they enjoy? This question must ultimately be answered by appealing to a conception of morality or political morality. Liberal accounts tend to assert an individual's interests in developing and deploying a sense of justice and the capacity to lead an autonomous life. With respect to the latter some defend what Feinberg (1980) calls "a right to an open future." Children have a right to an education that will equip them with the physical and mental wherewithal to deliberate rationally between different types of lifestyle or conceptions of how to lead good lives. A right to an open future is a claim-right that places others, including parents, under the duty not to school their child in ways that would hinder the child's later autonomous deliberation as an adult. The right also requires others to provide and bear the costs of this education. Furthermore, this right is one that comes without a liberty-right: a child does not enjoy the option of taking up or declining an autonomy-supporting education as she chooses – others may force her to be educated in this way should that prove necessary.

How to elaborate the rights that follow from an interest in autonomy has been the subject of considerable disagreement. The open future elaboration is practically demanding, because it depicts parents who prevent their child from exposure to what they take to be blasphemous or otherwise unworthy lifestyles as wronging their child. Nevertheless, the right to an open future does not rule out schooling that has the aim of imparting controversial religious convictions to a child if this schooling does not inhibit the child's later autonomous reflection in adulthood. A more restrictive right that is defended by some asserts that the interest in autonomy should be elaborated in a way that generates

a duty on parents and other adults not to seek to cultivate controversial religious beliefs in their children. In this alternative elaboration, parents should retain a neutral stance with respect to these matters, leaving them to be addressed by their child when she possesses the capacity for autonomous reflection (Clayton, 2006).

The question of which rights are implied by our interest in developing and deploying a sense of justice has also produced considerable debate among liberal philosophers. Some claim that the interest generates a right to an education that develops the child's sense of justice and certain associated moral and political virtues: the capacity to deliberate rationally on questions of justice, tolerance of religious difference, courage to participate in public affairs and to challenge the political views of others, and a commitment to the ideals of freedom and equality (Callan, 1997). An alternative to this view, defended by Brighouse (1998), proposes a conception of citizenship education that equips children with the knowledge, understanding, and ability to engage in politics without imparting any particular motivation or set of virtues to them. His case rests on the claim that the legitimacy of the state depends upon the free consent of the governed, which would be jeopardized by the cultivation of particular political beliefs.

Nonliberal conceptions of political morality view the rights of children differently. Communitarian or nationalist accounts, for example, view children's interests in terms of an initiation into the particular shared understandings of the community or nation and the educational rights that protect this putative interest will consequently differ from the liberal conception. However, there are certain categories of rights that are common to different conceptions. First, children have developmental rights – rights that generate duties on others to facilitate the growth of the child in terms of health and education. But second, children might have interests that do not refer to their interest in developing into adults. Some of these are rights to be free of certain kinds of treatment, such as being physically harmed, or entitlements to certain kinds of care. Some claim that children enjoy agency rights in virtue of their interest in choosing between different options and pursuing their ambitions, even when their choices lack the level of rationality or deliberation that is typical of adults.

In every society, children lack certain legal rights that are enjoyed by adults: the right to vote, for example. Can such inequalities in the enjoyment of rights be justified? Some have argued that they cannot on the grounds that age is only imperfectly correlated with the ability to vote, and it is objectionably discriminatory to deny the franchise to the competent young while enfranchising older incompetent individuals (Harris, 1982). Others find discrimination on the basis of age to be less objectionable than is discrimination on grounds of sex or race, for example (Daniels, 1988). Whereas sexism and racism produce inequalities that last a lifetime, disenfranchising

the young is a temporary loss of rights for everyone at a certain point in her life.

If age-based discrimination is, in principle, permissible, further questions must be addressed to gauge whether denying children certain rights is justifiable. In the case of the vote, for example, some argue that it is unjust to tax or conscript individuals without extending the franchise to them. Others argue that the entitlement to vote is dependent upon satisfying certain conditions, and there are further debates about the particular personal traits an age group must generally exhibit to be entitled to vote: proposals include the capacity to determine the shape of one's own life or, more demandingly, the ability and willingness to engage competently with political questions (Archard, 2004; Chan and Clayton, 2006). Similar debates attend other rights from which children are standardly excluded: the right to drive vehicles, to marry, and to various freedoms to govern one's own life.

Parents' Rights

Few deny that parents enjoy rights. These rights comprise claim-rights to do various things with, to, or for their children, which generate duties on others not to interfere, or perhaps to facilitate, these activities. Notwithstanding this consensus, the itemization of these rights and their justification have produced considerable controversy. Consider the justification of parental rights first. The central debate here is between those who claim that the rights of parents should be justified on the basis of the interests of the child alone, and those who claim that the interests of parents count independently in determining rights. This debate focuses on the issue of how to allocate custody over children, where custody is understood as constituted by a bundle of rights with respect to a child's life. The natural outcome of purely child-centered justifications of parental rights is what has been called the best custodian condition: childrearing rights with respect to a particular child should be allocated to the interested individuals whose parenting can be expected to be in that child's best interests (Vallentyne, 2003). On this view, the fact that a person begets a child does not imply that she has a right of custody over him. Of course, there might be good reasons to think that having a biological or procreative relationship with a child is generally correlated with being the best custodian, but this need not always be the case (Archard, 1995).

The alternative view, the dual interest view as it has been labeled, asserts that individuals can have a fundamental interest in being a parent, should that be one of her life choices, an interest that should be protected by the enjoyment of custodial rights over the children she begets or adopts. This view might accept that the child's interests carry considerable weight. Consequently, it might concede that parents can forfeit their custodial rights as a

consequence of neglecting or harming their child. Nevertheless, the dual interest view insists that in many cases parents may retain custody even when it is clear that other interested individuals would offer the child in question a better start in life (Brighouse and Swift, 2006; Clayton, 2006).

Both views concerning the justification of parental rights acknowledge that the interests of children and parents can conflict. Child-centered views resolve this conflict in favor of the child, arguing that our interests with respect to parenting are less weighty than our interest in having a better start in life. Yet this position might be too extreme. In other spheres of social policy, the conflict between children and adults does not always favor the former. Medical expenditure, for example, is not overwhelmingly devoted to healthcare, the principal beneficiaries of which are children. Indeed, much of the healthcare budget is devoted to treating diseases and conditions that beset people later in life, even though the health of children might be improved with a reallocation of expenditure. Similarly, the best custodian condition is best for us as children, but the price to be paid for this is that as adults we enjoy a diminished opportunity to be a parent, should that be our ambition.

Parental claim-rights generate duties for others. Most simply, custodial rights place duties on others not to interfere with parental choices with respect to where the child lives, the extent to which he may play with friends, and what kinds of books he reads at home. However, such rights might be more or less limited. For example, custodial rights might be limited by the requirement that the child is educated in an appropriate environment until he reaches a certain age, and the right of parents to choose what the child reads in the home does not necessarily extend to them enjoying a veto with respect to reading material used in school.

Within educational philosophy, disagreements about the extent of parental rights have been played out in two important debates over school choice. The first concerns the extent to which parents have a moral right to choose the content of the curriculum their child receives. Several views have been asserted within this debate. As outlined above, many liberals appeal to the child's right to autonomy. Acknowledging such a right is not sufficient to justify legal constraints on parental choice, because it is compatible with the claim that parents are the best judges of their child's interests. Nevertheless, most autonomy-affirming liberals deny the parents as best judges claim and favor legally constrained parental choice to protect children's interests in becoming autonomous and in acquiring political understanding or a sense of justice (Feinberg, 1992; Brighouse, 2000). However, those who regard initiation into any one of several conceptions of the good life, whether or not that life involves autonomy, tend to favor more extensive parental choice with respect to the school curriculum, though they might remain committed to constrained choice for the sake

of other values, such as the cultivation of various civic virtues (Galston, 2002).

A second important debate over school choice concerns distributive justice. Is it permissible for parents to purchase expensive inequality-generating schooling for their child? In this debate, the worry is not about parents acting in ways that harm their children, but about their school choices setting back the interests of other children whose prospects might be worsened, relatively or absolutely, by these decisions. There are many different considerations that must be addressed to determine whether private schooling should be legally permissible: the importance of equality of opportunity, the effects on others' education or economic prospects of private schooling, and the extent of justifiable parental partiality, for example. For present purposes, it is sufficient to note that granting parents rights of custody over their children does not imply that parents have the right to give their child the best start in life irrespective of the consequences for others of their decisions. More extensive rights of school choice require further justification and have been challenged on grounds of their incompatibility with the ideal of social justice (Swift, 2003).

Whether or not parental claim-rights are limited, they often lack associated liberties. In other words, the fact that parents have rights to make certain choices that affect their child does not imply that they may choose as they like. Claim-rights protect choices against the interference of others, but do not necessarily mean that the protected choice is unconstrained by moral considerations. A liberal view, for example, might protect against interference by others a parent's decision to shield her child from what she takes to be the dangerously anti-religious views expressed in Philip Pullman's *His Dark Materials*. Nevertheless, it would, nonetheless, insist that the parent should not exercise her right in this fashion, because to do so would diminish her child's development or autonomy.

Nevertheless, even without associated options or liberties, parental claim-rights might retain value in protecting the ambition of adults to honor the requirements of parenthood. Many hold the view that even if individuals enjoy very little discretion with respect to how they parent, it remains valuable for them to raise their children well: their ambition is not satisfied just in virtue of their children being raised well by others.

Another aspect of parental rights that has received relatively less attention within educational philosophy concerns who should bear the costs of children. Raising children is costly in terms of time, emotional commitment, and financial resources. Does the right to parent generate a duty on the part of others to bear some of these costs and, if so, should these costs be incurred by other parents or by everyone regardless of whether she parents?

One reason for thinking that the right to parent sometimes includes a right for the costs of parenting to be

shared by others arises from the fact that these costs are unequally distributed due to luck. For example, a child with a congenital disability might be more difficult or costly to bring up. Many argue that it would be unjust for this child or his parents to bear all of the burdens associated with this bad luck. Consider another case. Some individuals might be worse equipped to parent than others are, because they lack a particular set of skills that is useful in parenting or because they enjoy fewer monetary resources through no fault of their own. If they are to have an adequate opportunity to parent, parental rights must include the requirement that resources are transferred from others to enable such individuals to parent effectively. Moreover, if we value children having equal opportunities in life, we might argue for wealth transfers to ensure that differences of family wealth do not translate to inequalities in life chances. For the sake of both parents and children, then, there might be reasons to regard parental rights as justifying duties on others to pay for some of the costs of parenting. However, the extent to which parental rights justify others bearing the costs of parenting is controversial, because certain costs are ones for which individual parents might be responsible and, therefore, do not warrant compensation.

If the costs of raising children should be shared, the question remains between whom they should be shared. Some have argued that because children are a net benefit to others, because they constitute the next cohort that will pay for social services and pensions, everyone, the childless included, are duty bound to contribute to their upbringing. It is consistent with this view to claim that because parents benefit in further ways from their children, from pursuing their ambition to be parents for example, they should bear a greater share of the costs. Nevertheless, on this view parental rights justify duties on everyone to contribute to the raising of their children (George, 1987). A more skeptical view asserts that individuals without children are not required by justice to bear the costs of others' parenting. On this view, becoming a parent is typically a decision taken by individuals motivated by their own ambitions rather than a concern for the long-term welfare of everyone. Since this is the case, it is not obvious why others are duty bound to contribute to the child's upbringing, even if the child's later life has spillover benefits for everyone (Casal and Williams, 2004).

Conclusion

One general observation that might be made about the issue of the rights of parents and children is that their discussion cannot be divorced from wider questions about political morality. Certain rights might be justified by appeal to the fundamental interests we have as children and adults. As children we have fundamental interests in

being protected against various harms, and in being cared for and educated appropriately. As adults, we might have an interest in occupying the role of parent. The rights that are generated by these interests must be accommodated in any plausible theory of politics and education. However, other debates about the rights of parents and children can be resolved only by appeal to a theory of political morality or of what we owe to one another. If we are to determine whether parental rights include an element of child support financed through general taxation, or whether they favor extensive rights of school choice, it seems we have no alternative but to appeal to a theory of political legitimacy or distributive justice. This explains why certain claims concerning the rights of children and parents are so contested. That contestation reflects deeper disagreements about what we owe to one another as human beings.

Peace Education

The Uniqueness and Aims of Peace Education

Current peace education does its utmost to be considered a unique educational practice, a field of research, and a discourse that has its own philosophical, social, rhetorical, and political aspects. As an eclectic and ambiguous construction, peace education, at present, enjoys the support and appreciation of most theoretical orientations and international political establishments. Enlightened modernists and soft postmodernists, feminists, critical thinkers, conservatives, and liberals all ardently participate in celebrating peace education. The challenge of legitimizing peace education as an academic discipline or field of research and as a much-needed educational practice is quite demanding. Salomon and Nevo present here a serious question: "What is peace education? What is the core of peace education, its defining attributes? What, if anything, distinguishes its most prototypical instantiations from other, similar fields?" (Salomon and Nevo, 1999: 5–6). According to Ben-Porath "the field entitled 'peace education' is in fact so broad that authors disagree on the description of the problem they wish to address and correspondingly on the proper solution, as well as on the site in which peace education is to take place" (Ben-Porath, 2003: 525–534).

The theoretical stance of the field actually calls for questioning the very justification of peace education as a distinctive, well-defined, self-reflective field of research and as a specific, theoretically justifiable educational practice. It is worth mentioning that, analytically, the reciprocity of its two fundamental concepts – the concept of peace and the concept of education – is hardly ever philosophically analyzed while each is highly problematic, in itself, and the two, together – in their reciprocity (Gur-Ze'ev, 2001). Some attempts to conceptualize peace education have been made in recent years, even if only as very modest preliminary efforts that left the main theoretical work for future scholars to attempt afresh (Salomon, 2004: 257; Cooper, 2005: 2; Page, 2004: 4; Ben-Porath, 2003: 525, 2006). According to Maxine Cooper "there is no one clear agreed upon definition of peace education. Authors like Harris (2004), Vriens (1997), Staub (2003) and Thompson (2003) have defined peace education in a variety of ways. This multiplicity of definitions has led to theorists such as Ben-Porath (2003) and Gur-Ze'ev (2001) stating that current definitions of peace are too wide and nebulous (Cooper, 2005: 2)."

"What is peace education?" Salomon and Nevo (1999) courageously ask the right question. "What is the core of peace education, its defining attributes? What, if anything, distinguishes its most prototypical instantiations from other, similar fields?" They reply: "numerous programs are called 'peace education,' ranging from violence reduction in schools to learning about war and peace, and from democratic education to the cultivation of self-esteem. Subsuming all of these under the category of peace education tends to blur important distinctions, such as between the kind of peace education that is carried out in areas of conflict, such as northern Ireland, and programs designed for more peaceful regions. Similarly, too wide a category tends to lump together programs designed to cultivate a universal peaceful outlook with programs aimed at promoting a peaceful disposition toward a particular group, race or nation to replace collective sentiments of hatred, discrimination, and hostility" (Salomon and Nevo, 1999: 5–6).

In their 2002 paper 'The nature of peace education,' Salomon and Nevo conclude that "neither scholarly nor practical progress can take place in the absence of clear conceptions of what peace education is and what it is to serve" (Salomon and Nevo 2002: 3). It is of vital importance for peace education – as a field of research and as praxis – to enter into this unknown land. A good beginning could have been the elaboration of central categories, such as violence, structural violence, metaphysical violence, counter-violence, power, resistance, revolt, rebellion, and disobedience. Such an elaboration should be realized synchronically and diachronically to be worthy of its name.

Central Trends in Current Peace Education

The central trends in current peace education are: (1) a modern, positivistic trend; (2) a modern critical trend; (3) postmodern, multicultural, and postcolonialist trends; (4) religious (mainly Christian) trends. Some of the modern and some of the postmodern subrends are more socially and critically oriented than others. In current peace education, the social sensibility and the focus of the social context of different types of violence are articulated in different and even within conflicting philosophical, ideological, and educational agendas. While most nongovernmental organizations (NGOs) and the United Nations

Educational, Scientific and Cultural Organization (UNESCO) discussions and agencies are sensitive to the social and conflictual dimensions of the threats to peace – some modern trends that emphasize conflict-resolution skills, and some postmodern and premodern trends, do not share such hopes and sensibilities. The critical sensitivity to the social context of peace education is clearly manifested in a typical UNESCO statement that declares that “there can be no genuine peace when the most elementary human rights are violated, or while situations of injustice continue to exist; conversely, human rights for all cannot take root and achieve full growth while latent or open conflicts are rife . . . Peace is incomplete with malnutrition, extreme poverty and the refusal of the rights of people to self-determination. . . The only lasting peace is a just peace based on respect for human rights. Furthermore, a just peace calls for the establishment of an equitable international order, which will preserve future generations from the scourge of war” (Brock-Utre, 1983: 2).

Some of the modernistic-oriented trends in peace education are more Marxist-oriented than others and some are more positivist-oriented among Marxists and liberals alike. The positivistic-oriented trend manifests a strong belief in teaching conflict resolution strategies. Very little room is reserved here for peace education as an explicit set of ideals and values. Conflict-resolution skills are, in this context, conceived as a matter of objective professional knowledge, good didactics, and fully developed rational participants. In its more mature versions, this kind of peace education enhances sensitivity for the need to cultivate the conditions for the realization of the rational potential for the development and realization of conflict-resolution skills and procedures. Skills are to be taught with the quest for justice, responsibility, common good, or, at least rational utilitarianism. Some, like Chetkow-Yanoov, believe that people might be educated and taught for conflict-resolution skills in the most specific manner (Chetkow-Yanoov, 1996: 12–28). The success of such an education, some claim, is not only possible – it is even measurable in a relatively unproblematic manner (Harris, 1996). This trend is, in the practical sense even if not in principle, in conflict with another non-critical trend – the widely celebrated UNESCO peace-education ideology that emphasizes the need for education for “culture of peace” (UNESCO, 2008).

The critical trend is the one inspired by or realized within the framework of critical pedagogy. It offers peace education a special role in light of its immanent emancipatory commitment and the centrality of the voice and the interests of the victims within this educational agenda. Freire, bell hooks, Rivage-Seul, and many other critical educational theorists like McLaren and Giroux worked hard to give voice and visibility to the perspectives and interests of the marginalized. Rivage-Seul tries to develop a critical peace education based not on Western

universally humanistic-oriented hegemonic perspectives and their interests, but on the contrary – on the locality and self-evidence of the silenced, based on Freire’s concept of moral imagination, which will hopefully transcend “the bounds of technical thought” (Rivage-Seul, 1987: 160). The more modern-humanistic-oriented trends within critical peace education are attacked by postmodern-oriented critical peace educationalists who claim that the traditional (modern-oriented) Freirean framework (Freire, 1972) is universalistic and essentialist, and, ultimately, conceives hierarchical-oppressive relations between teacher and student as a precondition for educational progress (Gur-Ze’ev, 1998a: 463). These critical educational thinkers denote the educational implications of the centrality of anti-universalistic-oriented diversity, epistemology, culture, and politics. Within a deep belief in the centrality of contingency, locality, and nonlinear-never-objective epistemology and philosophy of history, they articulate their alternative peace education.

This is also an opening for a philosophical and political contradiction that challenges postmodern critical peace education. It is a contradiction between (1) the commitment to the agenda of human rights and the defense of democracy as a universally valid set of values and ideals and (2) a strong antiuniversalist and antiessentialist conviction that results in automatic identification with the values, interest and narrative of the victim as against Western/white/American cultural and political violence that allegedly imposes a kind of universalism that destroys the uniqueness and potentials of all other voices and imposes upon them self-misconception, distorted identities, and even resistance solely within the framework of the colonialist-inflicted conceptual apparatus. Philosophically, educationally, and politically, this version of peace education does not end in resistance to dogmatism and violence as such; it concludes in resistance only to one kind of dogmatism while understanding and even supporting other violences – the counter-violence of the oppressed that realizes their self-evidence, closure, and refusal for critical dialog. This commitment of postmodern critical peace educationalists stands in conflict with other trends in current postmodern emancipatory/critical/radical education which emphasize the contingent, temporary, narrativistic, and antiuniversalistic/antiobjectivistic nature of human existence, representation, self-constitution, and communication. This contradiction between modern and postmodern critical peace education and within postmodern critical peace education itself is more dramatic in some of its branches than in others. Strong manifestations of this can be found in current multicultural and post-colonialist peace education.

The multicultural trend in peace education emphasizes diversity as a precondition for peace, in contrast to the liberal agenda of enhancing shared values and a homogeneous type of reflection toward universal solidarity and

responsibility as praised by liberal (Aduan and Bar-On, 2004; Bar-Tal, 2005) and existentialist-oriented peace educators (Gordon, 2005) and by most of the theorists of civil education (Rennebohm-Franz, 1996: 266).

The postcolonialist trend in peace education directly confronts liberal trends that work for the promotion of a humanistic version of pluralism and tolerance that will be nourished by (Western-oriented, universal, liberal) shared values and ideals as a gateway to universal openness, dialogism, pluralism, responsibility, and, eventually, peace. In recent years, there has been increasing sensibility in the liberal agenda to the presence and relevance of cultural diversity and its multicultural educational implications, especially in arenas of dense conflict (Taylor, 1992). Critical education theorists in the postmodernist multicultural and postcolonialist framework – like Peter McLaren, Ward Churchill, and Ilan Pappé – not only understand, but actually support the explicit violence of the oppressed and present it as legitimate counter-violence that echoes only the original colonialist violence and that is free of moral responsibility to its actions that ultimately will build the bridge from colonialism and resistance to postcolonialism and peace. Within this framework effective violence of the oppressed is actually nothing but peace education-in-action.

Multicultural peace education bears a strong family resemblance to postcolonialist and postmodern peace education. The differentiation between these trends is not always unproblematic. Multicultural peace education (as all other members of this family) is explicitly founded on postmodernist theory as against modern national education (Pappé, 1999: 233). It is conceived as a precondition for a worthy peace education (Pappé, 1997: 221). The new, post-modern methodology – in the service of peace education – is founded here on two assumptions: (1) negating the natural sciences as a model for human sciences, and (2) doubting the objectivity of the researcher. For Pappé, “reality is a representative and interpretative issue. The historian, therefore, is allowed to represent it as he or she wishes . . . the historian should give freedom to the sole quality which gives him the power to write about the past – imagination. Not the kind of imagination which supports a reliable representation of the past as modernists understood this conception but rather imagination of the kind that will enable the historian to produce aesthetically the history, according to the known styles in comedy, tragedy and farce” (Pappé, 1999: 235).

This is to occur in the service of the silenced and oppressed voices in a multicultural society (Pappé, 1999: 236). Peace education is made possible here by means of this new methodology for giving voice to silenced ones on the road to peace, which is conditioned by the deconstruction of the hegemony and its structural violence (Pappé, 1997: 236).

The liberal trend in peace education, in its most theoretically developed version, is represented by Johan

Galtung – the prominent founder of peace education as an academic field of research. Actually, Galtung offers the most theoretically developed concept of peace education *per se*. As early as in the 1960s, Galtung challenged the then excessive weight imparted to peace as the presence of the absence of direct violence. In his peace theory, he included the concept of structural violence and offered the conceptions of “positive peace” and “negative peace” – notions that are richer and philosophically more challenging than most conceptualizations in current peace education. According to Galtung “two concepts of peace should be distinguished: negative peace, defined as the absence of organized violence between such major human groups as nations, but also between racial and ethnic groups of the magnitude that can be reached by internal wars; and positive peace, defined as a pattern of cooperation and integration between major human groups” (Galtung, 1975: 29).

In light of his understanding of positive peace, preceding the traditional positive Utopia projects, Galtung understood that he had to develop a vision of this harmonic future of humanity but also a well-defined theory of violence: to address the role of violence in furthering progress in history. An attempt to understand the nature of violence is a precondition to making possible positive peace as a realization of human potentials. Accordingly, Galtung tells us that violence is “present when human beings are being influenced so that their actual somatic and mental realizations are below their potential realization” (Galtung, 1969: 168).

While developing an historical perspective and claiming that “*the needs perspective* has been used as an instrument of the human right tradition” (Galtung, 1994: 107), Galtung includes – in peace education – the commitment to rights such as “the right to sleep,” “the right to co-existence with nature,” and “the right to be free to experiment with alternative ways of life” (Galtung, 1994: 104). He concludes that peace education should also relate to ecological challenges and cultural colonialism while challenging the invisibility of cultural violence and structural violence.

The Concept of Peace

The concept of peace that is so central to each of the various versions of peace education needs to be analyzed diachronically and synchronically, within premodern, modern, and postmodern arenas. Its philosophical, cultural, and political functions may fruitfully be distinctively elaborated in light of (1) a culture that is occupied with the presence of God, (2) in an arena occupied with the awareness of the bursting of the alternative to this rich presence, and (3) in arenas that are free of both God and

the killing of God. Gnosis and postmodernism manifest this trend in distinct ways.

Peace is a theological concept, even in its secular transformations. Within the framework of monotheism, peace obtains its meaning in light of the tension between human exile from the Garden of Eden and the open possibility of redemption within a Godly teleological history. Within the framework of a sacred history, the telos of a monotheistic-oriented progress toward redemption is different from that of (1) secular modern conceptions of progress toward peace and (2) postmodern conceptions of progress toward peace and the relations between conflicting violences and the possibility of harmonious human existence. Simultaneously, we should distinguish between monotheistic, pantheistic, Gnostic, and postmodern concepts of peace. Within the pantheistic tradition of special relevance is the Buddhist conception of peace. Nirvana, one could claim, should not be conceived as the annihilation of life but as a possible realization of peace. Classic Greek conceptions of the relations between violence and peace are also of much value for such an analysis. Within the monotheistic tradition, the Jewish vision of peace has a pivotal role as it is offered by Yeshayahu. Nirvana, one could claim, should not be conceived as annihilation of life but as a possible realization of peace. Isaiah 11:6 offers us a premodern monotheistic utopian vision of peace within which “The wolf also shall dwell with the lamb, and the leopard shall lie with the kid; and the calf and the young lion and the fatling together . . . They shall not hurt nor destroy my holy mountain: for the earth shall be full of the knowledge of the Lord, as the waters covers the sea.”

The monotheistic theological concept of history enables a collective, even cosmic Utopia, which is very different from the Homeric conception of individual *arête* (worthy life). It is important to note that pantheistic-oriented antiquity – in opposition to monotheistic-oriented antiquity – offered many different conceptions of peace, ranging from disregard to heroic refusal of the Jewish conception of peace. The Homeric hero and Greek civilization, in general, “was dominated by a conception of life which was essentially warlike. Whatever the event, whatever the change, conflict in one form or another was always close at hand. Religion often assumed violent overtones” (Zampaglione, 1973: 18). The Gnostic tradition was a significant challenge both to pantheistic and monotheistic premodern traditions and their concept of peace. Accordingly, it offered a very different view of peace education. These traditions transformed themselves in modernity and, even in the postmodern condition, they offer rival conceptions of peace and peace education.

Modern peace education and its concept of peace are settled on the act or on the process of the killing of God. Modern philosophies have secularized theology and have much in common with the premodern concept of God as

it is revealed in central concepts such as progress and peace. The presumption of the human telos as home-returning is replaced by a vision of the killing of God as an act of giving birth – known also as the act/process of critique that is part and parcel of a road leading to positive Utopia. This is a vision of a future harmonious state of affairs, which as in Marxian theory will secularize the eschatological religious vision and will offer a tiger-like leap from “prehistory” into “history” (Marx, 1977: 1) or “peace” as an earthly Garden of Eden. Positive Utopianism (Gur-Ze’ev 1996) made possible by human heroism as a feast of eating the flesh of the Leviathan/father/God and edifying the deification of humanity is a magical spectacle: it transforms natural and historical realities.

The concept of progress as the historical realization of central ideals of humanism, such as freedom, manifests the fundamentality of the home-returning project to the Western tradition – a tradition whose impetus is fear of nature, of bestiality, of thingness, of scarcity, and of meaninglessness. It is dramatically manifested in the philosophies of Condorcet, Hegel, and Marx. According to Condorcet, humanity is under eternal self-rebirth and paves the way for itself to truth and happiness, by constantly relying on human reason and the facts. This Utopia is possible, since nature has placed no limits on human self-edification (de Condorcet, 1955: 4). According to these philosophies – in its total fulfillment, within the framework of the ideal of freedom – humanity realizes peace in the form of effective total violence against external and internal nature and all forms of stagnation, borders, unchallenged power, and the various manifestations of peace/consensus/truth. The idea of freedom as an eternal journey – burning, birth giving, and overcoming – demands total control of human existence and unrestrained effective manipulation of nature. Total rational control and effectively silencing any opposition is taken as peace.

Philosophers and poets – and more so workers, women, colored people, and immigrants – have, during the last three centuries, been brutally faced with different forms and, on different occasions, with the naivety, futility, and hopelessness of the humanistic-oriented home-returning project. They have met the fruits of the various and conflicting modern attempts to re-establishing, on the Earth, the Garden of Eden in the form of replacing total naivety, intimacy, and integration with total control of nature in all its dimensions. In the case of Nietzsche, Spengler, Camus, Adorno, Levinas, and Derrida, this encounter offered an alternative to the quest for peace and to the presumptions, frameworks, and telos of the various home-returning projects in the form of Diasporic philosophy, eternal tragic heroism, and enduring nomadism (Gur-Ze’ev, 2004).

In the post-structuralist tradition, two main manifestations of conceptualizing peace are to be reconstructed. According to one, peace – as a quest, as Utopia, and as

value – is produced, reproduced, represented, distributed, and consumed as a symbol and as a cultural good that is nothing but an echo of the contingent power-relations: a productive illusion governing the stability of a specific context. Peace, in its essence, is nothing but violence that successfully defeated its enemies and was victorious enough to silence even the voices and traces of the oppression and suffering that go along with its triumph (Gur-Ze'ev 2007). According to the other, peace is an ideal worth struggling for. Post-structuralist theory should be a medium and a path for empowering a political, cultural, and educational effort for bettering our world in the face of racism, gender discrimination, colonialism, and ecological threats, as Stuart Hall, Cornel West, Gayatri Chakravorty Spivak, bell hooks, and Peter McLaren tell us. Such efforts, however, should overcome the Eurocentric, phallogocentric, and racist presumptions that made possible Whiteness, patriarchy, and colonialism – which until now have directed traditional (humanist-oriented and Christian-motivated) peace education. Some post-structuralist thinkers, like Rosi Braidotti, Homi Bhabha, and Bracha Ettinger, offer a less political, yet no less practical, practice and vision of peace within an endless heterogeneity and eternal diversity. In this light, Ettinger articulates peace within the framework of co-poiesis and asserts that “the originary event of peace is compassion” (Ettinger, 2008). Braidotti integrates the struggle for sustainability of the Earth, peace education and the possibilities for eternal nomadism in cyberspace in an original manner which is an especially fruitful challenge to current peace education (Braidotti, 2006).

Contradictions Between Explicit and Implicit Aims of Peace Education

Peace education faces a challenging contradiction. While in its various versions it is explicitly pro-life, it represents implicitly a fear of life: an escape attempt into stability and consensus, irrespective of the nature, *telos*, or meaning of the system that it is committed to stabilize. As long as peace education is focused on peace as the elimination or prevention of destabilizing the hegemonic order of things irrespective of the concrete and specific values, ideals, practices, and *telos* of the system – in its essence, it is a conservative, antilife power. Peace education in its central manifestation has neither ambitions nor yardsticks to evaluate peace in essentially different contexts and it fails to judge and resist victories as long as they practice effective violence and have the upper hand, no matter the cost, the fruits, or the *telos* of these victories. As Augustine claimed – earthly peace, actually, represents the “Earthly City” or the more effective secular violence and it is the opposite of genuine “peace” (Augustine, 1957: 415).

Peace education actually challenges the essence of dualism, dialectics, heterogeneity, and life itself (Gur-Ze'ev, 2007: 305–306). It is understood by some scholars as a rescue attempt from the spatial-time factuality of suffering and it manifests a belief in a possible human progress toward Utopia. Montaigne, Haman, Yaacoby, Schelling, Schopenhauer, and Adorno offer a powerful alternative to great modern believers in the possibility of progress toward enlightened education and the realization of peace. The very idea of realizing and sustaining positive universal law, Utopia, or homogeneity was impossible or misleading, according to these critics of universal reason and rational emancipatory powers.

The very notion of peace, one might claim, represents a quest for homogeneity, stability, or victory of Thanatus – a return to nothingness. Ontologically, peace education presupposes the preference and the possibility of the end of dialectics, the end of contradictions, and of difference that makes a difference. This is a legitimate philosophical position and Schopenhauer (1966/1969) and Mainländer (1876) were the most dramatic among the defenders of this philosophical stand.

Counter-Education for Peace?

Eternal Diasporic existence, border-crossing, and improvisation reflect their relation to Eros as an impetus to its enduring responsibility and creativity within co-poiesis that re-affirms life. It is a specific, alternative togetherness with the other, with the self, and with the cosmos. Improvisation, in this context, is a life philosophy in a postmodern era that is teachable to a certain degree and surely a worthy educational endeavor (Peretz, 2003). The realities of present globalizing capitalism and the new technoscientific horizon enable the concrete realization of improvisation in individual and public spheres. It is a way-of-life eternally open, always dangerous, and, for all time, individual. It offers neither a quest for a perfect collective or individual life nor a future of redeemed humanity. It cannot promise us a harmonious future that will realize nirvana, peace, final solutions, ultimate justice, or consensual meaning that appeases everyone and everywhere. It is precisely these philosophical, existential, and historical presumptions and visions that Diasporic counter-education must overcome when relating to peace.

Counter-education is not a mere praxis, neither is it a given theory to be faithfully realized in order to establish the genuine heavenly Jerusalem. Peace according to counter-education is the fruit of normalizing education, as are victories, fulfillment of the nations' historical mission, and other manifestations of self-forgetfulness. At the same time, it does not conceive – with Augustine – peace as an outstanding efficient realization of violence in a predeemed world nor as a future possibility awaiting

the chosen ones when they realize the true faith in its authorized interpretation. Peace as openness that streams out of love and hospitalizes responsibility to ones' self, to the Other, and to the world is of outmost importance for Diasporic counter-education. This is because Diasporic counter-education is not simply and abstractly negative, nor is it an active critique. It cannot be content with critically reconstructing the manners by which the various kinds of normalizing education work: fabricating, reproducing, policing, and edifying the conceptual apparatus, values, and yardsticks that enable and glorify the victory of explicit violence.

Counter-education – in contrast to normalizing education – does not strive for any sentimental peace. Yet, it is at peace with the Diasporic truth, so that in the absence of a nonmanipulative consensus around the final ends, and in light of creative love as the only end/home worthy of nomadism itself, improvisation becomes home. Nomadism in eternal Diaspora religiously improvises itself in love of life. Response-ability and respond-ability toward noncollective, toward presubjective and existential kinds of homelessness, and toward erotic Diasporic existence might offer here-and-now prerational and postdia-logical forms of knowledge and togetherness; it might improvise toward new beginnings and a kind of human dance that we have not yet experienced historically, yet we all share in our blessed moments: a kind of awakening toward becoming-toward-the-world (Gur-Ze'ev, 2005) as against becoming-swallowed-by-the-triumph-of-normalizing-education that is most effective in stable systems and days of tranquility, prosperity, and peace.

Philosophy and Educational Research

D Bridges, University of Cambridge, Cambridge, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Action research – Research carried out by practitioners in the sites of their practice and designed to improve that practice through a repeated cycle of reflection, research and change in the practice.

Empirical – as in ‘empirical enquiry’ – Based on observation and experience (and contrasted with more abstract thought characteristic of philosophy, mathematics, and more speculative aspects of science).

Epistemology – or theory of knowledge –

A branch of philosophy concerned with the nature and justification of belief, truth claims, etc.

Ethics – A branch of philosophy concerned with the nature and justification of beliefs about the right and the good, sometimes referred to as *moral philosophy*. But ethics is also used to refer to codes of (moral) practice governing, for example, professional lives or, as discussed in this article, the conduct of research.

Normative – Related to norms, in this case the values and principles which underpin educational policy and practice.

Phenomenography – Enquiry aimed at eliciting and describing the ways in which people experience the world – an attempt to access, for example, the learner’s or the teacher’s subjective experience of education.

Postmodern – Refers to a body of thought and literature which challenges a whole range of assumptions associated with, in particular, the aspirations of modern science and technology. It is a notion which rather eludes definition (and most of those who espouse its various forms would seek to elude definition), but the paragraph in the text seeks to explain what it means in this context.

Practitioner research – Research (usually small scale) carried out by practitioners, most commonly in this context teachers (see also *action research* above).

The Contributions of Philosophy to Educational Research

This encyclopedia will itself bear witness to the fact that the field of educational research is enormously diverse. Education is not a single form of disciplined enquiry:

rather, it is a field of enquiry which draws on a wide range of the intellectual resources of the academy as well as the accumulation of practical wisdom drawn from the experience of educational practitioners. (There are of course interesting philosophical questions about the relationship between these two sources which are commented on briefly below). Its intellectual resources and its methods of enquiry are drawn from disciplines as diverse as history and neuroscience, literary theory and philosophy, behaviorist psychology and ethnography, law and economics, and museology and the creative arts.

This (in part philosophical) picture of the nature of educational research itself points to three kinds of contribution which philosophy can and does make to this endeavor. First, philosophy is itself among the scholarly, systematic, and sustained disciplines which can – and many would argue must – be drawn upon to contribute to educational enquiry. This is philosophy as educational research. Second, the claims and limitations of all of the other forms of enquiry which offer contributions to educational research need to be examined and understood, and this is philosophical work of an epistemological character, that is, rooted in theory of knowledge. This is referred to as philosophy of educational research. Third, any research which requires engagement with human participants and the redistribution of their knowledge and of knowledge about them raises issues of an ethical and political character which have their roots in a long-standing tradition of philosophical ethics and social and political philosophy. The remainder of this article on the contribution of philosophy to educational research is organized under these three headings.

Philosophy as Educational Research

Philosophers may feel a little uncomfortable about their work being described as research, because this term is more commonly applied in contexts in which people are seeking evidence or data of one kind or another. Philosophers tend to be more comfortable with the language of scholarship or enquiry. This is not to say that philosophers have to stay removed from the grounded world of practice or empirical enquiry, though they are sometimes criticized for failure to engage directly with these worlds (Phillips, 2005). It is rather that what they do with such material – as philosophers – is to reflect upon it, analyze it, and interpret it drawing on the rich tradition of philosophical writing which is at the heart of the subject. However, they have on

the whole accepted their role as educational researchers as the price of a seat at the table of the national and international educational-research community.

Their presence in the educational-research community is an essential one, because philosophical questions are central to the theory and practice of education itself. You cannot go far in the consideration of educational policy and practice without engaging with fundamental questions about the aims of education and about the values and principles which ought to govern this policy and practice. These are themselves rooted in conceptions of human being and flourishing, about the individual and society, and about the lives we want to lead – all of which are at the core of the philosophical tradition. You cannot go far in consideration of the curriculum without engaging in these issues but also with questions about the nature and structure of knowledge itself, about what it is to know or understand something, about the relationship between knowledge and skilled performance, about the authority which can be claimed for different kinds of belief – and about the implications of all of these considerations for what we teach and how we teach it. You cannot go far in pursuit of the social-justice agenda in education without encountering contested interpretations of social justice and conflicts with other social principles and values. How far should the state intervene in the name of justice and at what price to individual freedom and responsibility? How compatible is a pursuit of equality with the pursuit of excellence? How far ought one to respect the rights of minority communities to maintain traditional practices which appear to disadvantage women? (A fuller account of the contribution of philosophy of education to educational enquiry is discussed in the BERA website and elsewhere in the encyclopedia.)

It is not that philosophy will necessarily provide simple answers to such questions: it is perhaps more likely to reveal further layers of complexity. The point is that the questions that are illustrated and many like them are questions which have been and continue to be refined, analyzed, discussed, and substantially investigated in a long tradition of philosophical writing, and if any educational practitioner or enquirer ignores this work, they are destined to rehearse simplistic responses which have long been discredited. A research community which claims to represent the highest standards of intellectual endeavor and whose authority lies precisely in its commitment to critical, systematic, and sustained enquiry cannot restrict these requirements to the empirical aspect of enquiry in a field which, as illustrated above, depends significantly upon philosophical considerations.

Philosophy of Educational Research

Philosophical considerations underpin all or most of the central debates about educational research methods and

methodology, for they are all at base about how we can best know about or understand educational policy and practice in their many shapes and forms. In this section this point is illustrated with reference to four of these debates, though this is by no means a comprehensive treatment of the field.

Research and Educational Practice

A large proportion of academic research in education seeks to inform educational practice – in schools, colleges, and universities in professional training environments like hospitals and also in nonformal settings in the workplace, the home, and the community. However, we have to ask whether all these need research as the academy understands it at all or should we have confidence in the kind of situated practical judgment (a notion derived from Aristotle) and the tacit knowledge (as Polanyi, 1966 might call it) developed by teachers and other practitioners? If some further investigation needs to be done, might this best be in the form of practitioner research or action research developed in the classroom and in intimate relationship with the sites in which change is expected to take place and under the control of those responsible for any such change? Such questions are essentially philosophical ones which require answers rooted in an understanding of the nature of practice and the ways in which it can be informed and transformed; of the extent to which general educational prescriptions can be applied to particular situations; of the relationship between theory and practice. In this last case it is not just a question of whether and how theory can inform practice but also of whether that dichotomy does not already distort a proper understanding of the nature of practical judgment. All of this is well-worn philosophical territory, which nevertheless continues to excite contemporary debate (see, e.g., Carr (1986), Elliott (2001) and the last part of Hammersley (1993)).

Research and Educational Policy

Similarly, we may ask questions about the sort of knowledge which ought to inform wider educational policy (as distinct from questions about the often bizarre considerations which do, as a matter of fact appear to inform the decisions of policymakers). If, as philosophers would certainly argue, policy is always driven by normative considerations, where does this leave us in terms of the contribution which educational research can make? (Just possibly with the conclusion that we had better build in some philosophical consideration of this normative framework.) But, clearly, policy needs to be grounded in evidence of some kind about the actual or likely effects and the consequences of doing this rather than that.

This in turn prompts the question “so to what sort of research should we look to provide such evidence?”

This is a question which has provoked enormous debate in both educational policy and educational-research communities. At one end of the spectrum, it has been answered in very restrictive terms. The What Works Clearing House in the United States has set as the gold standard for what it calls evidenced-based practice research which conforms to the standards of the double-blind controlled experiment which has achieved preeminence in medical research. In the UK, the Evidence for Policy and Practice Information (EPPI) Centre established to conduct systematic reviews of educational research operates with criteria which are not quite so restrictive, but which nevertheless exclude large swathes of the research which is carried on across the educational community. (For a fuller discussion of these issues see Bridges *et al.* (2009) and Hammersley (2007)).

At the same time, as steps are being taken to restrict the range of research which is supposed to inform policy, the wider educational-research community itself has expansively embraced a wider and wider range of intellectual resources drawn from almost every corner of the academy – not only from the social sciences (which have themselves extended and hybridized their repertoire) but from the humanities (biography and autobiography, discourse analysis) and, as Elliott Eisner encouraged in his presidential address to the American Educational Research Association, the creative arts (Eisner, 1993).

It is not proposed to enter these debates in this context. The point to be made is that such debates about what kind of knowledge can and should inform educational policy-making are essentially philosophical ones. The claim that only research which adopts successfully the experimental design of the double-blind controlled experiment and, equally, the claim that educational research can benefit from the contribution of the creative arts are both philosophical claims which require not empirical evidence but careful philosophical argumentation and critique if they are to be sustained. The irony for the What Works movement is that no double-blind experiment will ever demonstrate that the experiment should be the preferred form of educational enquiry.

The Qualitative/Quantitative Debate

A third and related area of essentially philosophical debate about educational research is closely related to this last one insofar as it is another example of argument about what kind of research can best illuminate educational policy, practice, and experience. The debate which is often couched in terms of the opposition between qualitative and quantitative research paradigms is referred to here, though most sophisticated contributors to this debate immediately point out that this is both a crude and misleading dichotomy. It is crude because both terms pick out what are in fact some very diverse forms of enquiry: both large population studies in sociology and small controlled

experiments in classrooms, for example, might come under the quantitative label, just as a long-term ethnographic study of playground rituals, a piece of autobiographical writing by a teacher, and a piece of applied critical theory might all be called qualitative. They are misleading because quantitative data might very well have a place in the sort of thick description of, for example, a school or its neighborhood provided in what are normally thought of as qualitative case studies. Equally, some researchers will subject what might otherwise be regarded as qualitative data, for example a careful transcription of a lesson or an interview, to quantitative analysis while others could apply a different, interpretative analysis to the same data.

Such disassembling of the dichotomy has not, however, ended controversy which is seen by some to have ramifications which extend far beyond the educational-research community and into the very fabric of what is presented by some as a modern(ist) world bent on reducing the social world to a technology whose functioning can be rationally managed, controlled, and (the key to all of this) measured (Smith, 2007) and by others as a postmodern world, fractured, a-rational, defeating (happily perhaps) centralized, technocratic management, a world in which notions of truth and certainty are replaced by a mixture of social relativism, nihilism, fancifulness, irony – or none of these because it refuses to be captured in any of these ways (Stronach and MacLure, 1997; Peters, 2004).

If not all researchers (nor even all philosophers) identify fully with either of these theoretical camps, this wider argument nevertheless adds an intellectual and political frisson to more modest debates – all of which are similarly philosophically rooted. To take what must surely be a central concept in any educational research agenda: “What learning is taking place in this setting?” Drawing on the contemporary range of educational research we might find at least the following illustrative range of responses.

1. An old style behaviorist psychologist interprets learning as a relatively stable change in behavior. (S)he needs to do some systematic observation of the pupils’ behavior and probably conduct a test devised to quantify the learning which has taken place.
2. A neuroscientist (and neuroscience is an increasingly influential source of educational research) will need some more sophisticated observational techniques, involving technology which will enable him or her to observe (and again probably measure) changes in the structure or activity of the brain.
3. A phenomenologist will probably want to conduct an extended interview with a selection of the pupils, exploring their experience of the lessons in questions and their own self-reporting on what they felt they may or may not have been learning, what they benefited from and why.

There may be several different reasons why someone might prefer in general to adopt one of these approaches over another. In part the preference will depend on what one means by learning, though an answer to this question will almost certainly depend on how we think of human beings: Are they reducible to their behavior? Do we want to get rid of what Gilbert Ryle referred to as the ghost in the machine (Ryle, 1973)? What is the relationship between activity of the brain and activity of the mind? How important is it to think of and to relate to human beings as experiencing beings and to understand the world through their eyes? Beyond these fundamental philosophical questions, there are some more practical ones: How useful is it to whom to know about, for example, electrical signals in the brain as compared with a child's own perception of his or her own learning? What can a teacher do with such knowledge?

Objectivity and Subjectivity in Educational Research

The contrasting styles of enquiry illustrated above also raise issues which are sometimes expressed in terms of objectivity and subjectivity (although again this dichotomy is probably too crude – at very least, we need to add the notion of intersubjectivity, of the social character of the construction of knowledge, to the spectrum). This distinction operates at two levels at least. First, we might apply it to the objects of our enquiry, so that the behaviorist and the neuroscientist might claim to be observing the objective world of human behavior and of brain activity, respectively. By contrast, the phenomenologist might be said to be investigating the subjective world of human experience. The distinction gets blurred when, for example, we attempt to describe human behavior, which is almost impossible without reference to the individual and social significance which human beings attach to different forms of behavior (Is the child who holds two fingers up to his teacher indicating a numerical quantity or something rather ruder?) and to human intentionality, both of which are embedded in the kind of perceptions which the phenomenologist seeks to describe and interpret. However, the objectivity/subjectivity distinction continues to frame a lot of educational debate and again we are dealing with matters which are essentially philosophical in character.

The language of objectivity and subjectivity also serves to distinguish the aspirations of different educational researchers and the way in which they deal with the presentation of their research to a readership. At one end of the spectrum, researchers seek to go as far as they can to eliminate through their methodology and their style of presentation the effect, the visibility, and indeed, the very presence of the researcher. This is indeed one of the

aspirations of the double-blind controlled experiment which has been referred to already. Such research goes to great lengths to reduce any impact which the presence of the researcher might have on the research site or participants; it seeks objectivity in the reporting and interpreting of the data; the hand of human authorship is concealed by stylistic devices which replace the first person (I did this and then I observed that . . .) by the third person (The researcher used a standardized test . . .), or employs the passive voice (the students were observed) rather than the active voice (I observed the students . . .).

Elsewhere on the spectrum are advocates of the view that this search after objectivity is ultimately doomed to failure: subjectivity will always enter into educational research, perhaps through the definition of the research agenda or the research questions; through the selection of research methods and methodology; subtly through what is not asked or noted as well as what is, in the collection of data; in the observation; in the analysis; and in the reporting. We deceive ourselves, it is claimed, if we imagine that we can escape such subjectivity. It is “a garment which cannot be removed” (Peshkin, 1988: 7).

This skepticism with respect to the possibility of objectivity is closely linked to a second opinion that, rather than trying to eliminate subjectivity it is better way to enable a reader of research to take account of such subjectivity by providing sufficient information about the researcher – his or her background, interests, ideological attachments, etc. (his or her biographical positioning as it is sometimes called) – and thus enable the reader to take this into account in evaluating the import of the research (see, e.g., Atkinson, 2000). This still, in a sense, represents a search after a kind of objectivity, a version of what things are really like, lying behind what is acknowledged to be one human rendering of this reality.

A third and more radical position suggests that even this kind of access to reality is illusory. All we have are people's subjective experience of the social world, people's perceptions, and people's narratives. These can enlarge our imaginative understanding of possible ways of seeing the world, and some may appeal to us more than others for a variety of reasons, but none can command special authority.

The concern here is not to offer a conclusion to a debate which continues to run through the education research community, but to point out the nature of the argument. These and other related questions about the nature of our knowledge of the social world, about the possibility of and limitations on such knowledge, about the sense in which we can (or cannot) talk about truth and falsity with respect to the claims issuing from educational research – all of these are the very stuff of philosophical writing over two millennia. The debates which rang through Socrates' chambers and the halls of medieval disputations between nominalists and realists are as alive today as they ever were. The passing

centuries may sophisticate the terms in which they are constructed, but they do not seem to resolve them in a way that conclusively sets them aside.

In this context are illustrated only some of the issues in the methodology of educational research (and in this section the focus is on epistemological questions) which invite and have received substantial philosophical attention. There are many more. Indeed lying behind any disciplined form of enquiry whose resources are drawn into educational research, there is a body of literature which relates to the philosophy of this discipline and which addresses issues to do with, for example, the kind of confidence which might be attached to findings generated by that particular form of enquiry, the extent to which one might generalize from such findings, or the extent to which one might confidently apply these findings in a single particular setting. Without making some attempt to engage with these philosophical questions in any research setting, one cannot confidently know how to interpret the research which one reads.

The Ethics and Politics of Educational Research

Educational researchers have become increasingly aware over recent decades of the ethical and, more widely, social and political significance of their interaction with research participants (some of who are of course children), research users, and research sponsors (who include powerful government and corporate organizations). This has been reflected in the establishment within professional research organizations like the American Educational Research Association and the British Educational Research Association of ethical codes to which their membership is expected to subscribe. Individual higher education and research institutions have similarly adopted ethical codes governing the conduct of research with human participants and ethics committees tasked with overseeing conformity with these codes.

Of course, this process has required considerable debate about what are the duties and rights of researchers, of participants in the research, and of sponsors of the research. Among the central issues, perhaps are the following:

- *The issue of informed consent.* To what extent does educational research require the informed consent of those who are going to participate in it? Is covert research excluded? Is the answer the same if one is doing research with vulnerable people or in the setting of powerful government or corporate organizations? Who needs to give consent? If I want to do research in a classroom, is it sufficient to have the agreement of the head teacher or do I also need the agreement of the teacher? The children? The children's parents?

- *The issue of confidentiality.* To what extent can and should the researcher guarantee confidentiality to an institution or individual involved in the research? How does one balance considerations of confidentiality with the public right to know and indeed with participants' rights to acknowledgment of their contribution?
- *The issue of control over data and its interpretation.* To what extent should researchers allow participants to, for example, amend a transcript of a recorded interview or to control the way in which their contribution is interpreted in a research report? Should researchers pay for contributions to their research? Is research a form of theft of other people's knowledge?

The issues indicated thus far generally assume a situation in which participants' rights need to be protected from an unscrupulous researcher. There are other issues framed by situations in which the researcher's own honest enquiry is threatened by the power of controlling organizations – especially, perhaps, where these organizations are paying for the research:

- The issue of the level of control and censorship which those paying for research can exercise over what is researched, how it is researched, and how and where it is reported – and hence ...
- The issue of the responsibility of higher education institutions with respect to the kinds of contract which they enter into and the support they give to their researchers.

There are two things to note, in particular, about these issues.

First, it is easy to see how what at first might be thought of as more narrowly ethical issues carry important social and political significance. Research is about the creation and redistribution of knowledge, which is itself an act with political consequences insofar as it involves a redistribution of power. Such a redistribution has even weightier consequences when, as in the field of education, you are dealing with a social practice which itself carries such a high level of public and political investment and which is itself a matter of intense political controversy. So, beyond the narrower construction of an ethics of educational research, we have to engage with the political principles which should govern such research in a democratic setting. Considerations of social justice and the requirement for informed public opinion jostle with each other and also with considerations about, for example, the right to privacy or confidentiality or at least some kind of credit for the knowledge that participants are sharing (see Griffiths, 1998; Smith, 1999).

Second, although all or most of these issues are addressed in the sort of ethical codes referred to, this does not mean that they are now settled. Many remain controversial. Others, which might appear to be agreed at the level of general principle, turn out to be much more complex when one has to operationalize them in the field – and this

experience has led to a flurry of debate around the situatedness of ethical judgment and the relationship between general principles, embodied perhaps in ethical codes and the resolution of issues in the field.

Both of these sets of considerations drive educational researchers into the philosophical territory, which is always close to the surface in ethical argument. How are we properly to understand these ethical claims? By reference to what principles can we resolve conflicts between these ethical principles? What is the relationship between general principle and situated judgment? All of this is well-worn ground in philosophy and an essential resource for educational researchers seeking to engage seriously and systematically with the sort of issues described.

Conclusion

These last two sections describe some examples of the sort of issues which arise out of the endeavor of educational research. It has been argued that these are inescapably philosophical in character and that they are indeed the sorts of questions which philosophers have engaged with and continue to engage with in their academic work. Educational researchers, like any other citizens can, of course, lead their lives without any attention to the literature which engages in a serious, sustained, and systematic way with these issues, but at enormous cost. After all, are not researchers' particular claims to authority and their claims on public attention based precisely on the expectation that their enquiry is more serious, sustained, and systematic than that which ordinary citizens or even journalists can normally afford? If philosophical questions are, then, central to the research enterprise, then these too must receive the same rigorous attention as is given to the gathering and analysis of empirical data.

However, this argument does not only place an onus of responsibility on educational researchers, but it also points to the importance of philosophers of education engaging in a practical way with the work and life of the wider educational research community – as not only researchers in their own right (as indicated in the first section above) but also as co-workers engaged in a continual conversation about the meaning, justification, and right conduct of the research.

Race, Critical Race Theory and Whiteness

B Applebaum, Syracuse University, Syracuse, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

While contemporary science confirms that our practices of racial categorization do not correspond to factual biological classifications, racism (and other forms of oppression) continues to play out in schools, educational policy, and educational research in myriad covert (but sometimes still overt) ways. Even after racial segregation has been outlawed (as in the United States' 1954 landmark case *Brown vs. Board of Education of Topeka, Kansas*), savage inequalities (Kozol, 1991) continue to endure in educational systems across the globe. Educational reforms based on ignoring race, on the one hand, and celebrating diversity, on the other, ostensibly implemented to remedy racial inequity in education, are widely criticized not only as ineffective but also as counterproductive in that they perpetuate unjust structures by inoculating the dominant order from any serious challenge. Ladson-Billings and Tate (1995) maintain that educational reforms that attempt to remedy racial inequity get sucked back into the system (p. 62) partly because the conceptual assumptions upon which such reforms are grounded fail to acknowledge that race and racism cannot be adequately assessed without an analysis of power. In order to understand how race functions in the classroom, in schools, and in educational systems and, furthermore, to appreciate what these critics of seemingly well-intended educational initiatives are pointing to, a critical theory lens of race and racism is crucial.

Critical theories of race and racism explore concepts such as race and racism from the framework of systemic oppression and the normalization of whiteness in order to imagine new possibilities in education that challenge rather than reproduce power systems. Critical theories of race and racism are to be distinguished from critical race theory (CRT). The latter is a movement developed by primarily Black, Latino/a, and Asian American legal scholars in the 1990s and advances specific aims. Space limitations preclude an examination of CRT and how it has been applied to education. For some excellent resources, the reader is directed to Ladson-Billings and Tate (1995), Dixon and Rousseau (2006), and Delgado and Stefancic (2001).

The former term, critical theories of race and racism, is more of an umbrella term that includes a broad constellation of scholarship that explores race and racism through the prism of power systems. In what follows, the concepts of race, racism, and whiteness will be addressed from a critical theory of race and racism perspective.

Race as a Social Construction

Although for many years, scientists endeavored to prove that there were innate biological differences related to people of different races, there is much consensus among scholars in such fields as evolutionary biology, anthropology, and other disciplines that biological arguments for racial difference fail to be supported by scientific evidence. Not only is there more genetic variation within than between the so-called races (Lewontin, 1972; also see Appiah (1992) for an excellent review of the scholarship), but also what little differences that have been established between such supposed groups do not reflect the social meanings that are given to racial differences. To be explicit, there is no scientific evidence that one race is superior or inferior to another. The social construction of race also receives support from the fact that the meaning of race is relative to geographical location and historical period. In the United States, the one-drop rule in which having the most minuscule black ancestry designates one as black regardless of physical appearance can result in someone who is defined as black in the United States yet also be regarded as white in other parts of the globe. That race is a fluid and contested notion also gains support with Ignatiev's (1995) historical study that charts the process by which the Irish, raced as nonwhite when they first settled in the United States in the first half of the nineteenth century, became white by embracing racism in the years surrounding the Civil War.

The concept of race is often conflated with the concept of ethnicity. Those who do research from the ethnicity paradigm often understand ethnicity as a purely descriptive concept and ignore how the white ethnic experience often becomes the normative benchmark from which all other ethnic experiences are understood. Charles Gallagher (2003) argues that the ethnicity paradigm functions to support the myth of meritocracy and encourages blaming the victim explanations for social inequality that exonerate whites and allow them to evade any consideration as to how they might be complicit in perpetuating systemic racism. Although race and ethnicity can overlap and while ethnicities often become racialized, race is conceptually a very different type of difference. While ethnicity describes "that aspect of our heritage that provides us with a mother tongue and that shapes our values, our worldview, our family structure, our rituals, the foods we eat" (Dalton, 1995: 107), races are distinctively constructed to exist only in relation to one another. Whiteness is devoid of

meaning without nonwhiteness constituting its boundaries. Blurring the distinctions between the concepts of race and ethnicity obscures how race is a “fault line along which power, prestige, and respect are distributed” (Dalton, 1995: 108). Educators who use race and ethnicity interchangeably, “confuse the positive role of culture . . . with the negative impact of racism” (Derman-Sparks and Phillips, 1997: 13).

The observation that race does not point to a fixed biological or genetic reality but rather is a socially and historically constructed concept whose meaning shifts through time to serve dominant group interests is now widely accepted in most areas of the social sciences (Lopez, 2000; McCarthy *et al.*, 1993). The aforementioned one-drop rule served to ensure that the offspring of a black slave and a white slave owner would be a slave, not free. The rule justified the raping of black slave women by white slave owners who could perceive this act of violence as a profit-making enterprise because it increased the population of black slaves (Payne, 1998). Omi and Winant (1997) explain that groups become racialized when racial meaning is extended to a “previously unclassified relationship, social practice or group” (p. 64). They coined the term racial formation to describe the reciprocal, sociohistorical process “by which social, economic, and political forces determine the content and importance of racial categories, and by which they are in turn shaped by racial meanings” (p. 61). In the United States, racial systems functioned to justify the institution of slavery.

Once these meanings are constructed, social institutions such as law, media, and education continually reify them and mask their origins. In 1977, Susie Guillory Phipps who identified as white but was designated as black on her birth certificate because her great-great-great-grandmother was a black slave in the South (Omi and Winant, 1994) sued to have her ascription as black changed to white. Yet the courts insisted she was black even though a 100% white racial purity has always been a fantasy. The law is one institution that helps to ensure that the racial system is maintained (Lopez, 2000). Education grounded as it is in the myth of meritocracy is another institution that contributes to the reproduction of a racial system in which those who benefit from the racial system as well as those constrained by it come to see it as real. Omi and Winant maintain that there is a racial etiquette in which racial ways of understanding the social world become common sense and “everyone learns some combination, some version, of the rules of racial classification . . . often without obvious teaching or conscious inculcation” (p. 62).

An essential component of understanding race as a social construction, then, is the acknowledgment of the political and ideological institutions, such as education, that maintain the system that makes race matter. Race might not be real, yet a system of privilege and oppression has been built up around the concept of race with real

material, social, economic, and psychological consequences for groups of people. Furthermore, to say that race is socially constructed is to notice that social groups, not individuals, must be the level of analysis through which race and racism are best understood. It is social groups that come into being through racialization. Peter McLaren (2000) articulates this construction thusly,

People do not discriminate against groups because they are different; rather, *the act of discrimination itself* constructs categories of difference that hierarchically locate people as ‘superior’ or ‘inferior’ and then universalizes and naturalizes these differences. (p. 148, italics added)

It is not that groups do not exist prior to language but rather that the meanings we attribute to social groups depend on discourse. Sally Haslanger (1995) refers to the discursive construction in which social groups come to have certain meanings through language. To say that race is socially constructed, however, does not merely refer to the discursive origins that constitute the meanings of social groups but also that race marks social differences that involve the relative location of groups within a system of social relations in which one group is considered the norm and other groups are evaluated by that norm (Minow, 1990).

In her discussion of the dilemma of difference (i.e., “... when does treating people differently emphasize their differences and stigmatize or hinder them on that basis? And when does treating people the same become insensitive to their difference and likely to stigmatize or hinder them on that basis?” (Minow, 1990: 20), Martha Minow analyzes the normative assumptions that constitute difference and draws attention to social structure as the source of the problem rather than the individual. Minow discusses five assumptions that remain unstated but work in powerful ways to define difference. One of these assumptions is that the norm from which difference is demarcated can be taken for granted and does not need to be made explicit. According to Minow, as long as the norm is not made explicit, how and when difference is stigmatized will not be acknowledged.

Individual people are constituted as raced based on their ascribed membership in social groups but also internalize race as identity and their lives are affected accordingly. The white norm that remains unstated in racist systems will be subsequently addressed. If race is a social construction, one must ask, as Omowale Akintunde (1999: 4) urges educational reformers to ask, “why are we still operating in such a system and to whose benefit?”

Definitions of Racism

Race as a social construction presumes that there is a system of privilege and oppression through which racial

social groups are constructed and that individuals experience oppression not as individuals but as members of an oppressed group. Yet, many people view racism strictly as a matter of prejudice and animus. To view racism solely as prejudice and/or discrimination based on race is to ignore the racist system and how white people have systemically benefiting from the system. According to Akintunde (1999), when racism is understood as something that one consciously chooses and enacts then racism can be practiced by anyone. “That is ‘non-Whites’, too, may engage in practicing racism and thus Whites themselves may be victims of racism.” (Akintunde, 1999: 2) Akintunde contends that by narrowly restricting racism to overt, intentional acts or conscious beliefs, those who benefit from the system not only ensure “that the system of White supremacy remains intact but can, in fact, successfully create smoke screens that actually implicate ‘others’ in the maintenance of such a system” (p. 2).

Similarly, in his discussion of antidiscrimination law, Alan David Freeman (1996) explains that racial discrimination can be understood from the victim’s perspective or from the perpetrator’s perspective. While the latter focuses on intent and finding who did what to whom, the former emphasizes the actual consequences including the objective conditions of life of being a member of a marginalized group. Understanding racism from the perpetrator’s perspective alone results in a strong reliance on fault and intention and, thus, serves to draw attention away from the pattern of conditions that a victim perceives to be associated with discrimination. The upshot is that if one is not the direct cause of a racist act, then one is not at fault and bears no personal responsibility for the act.

In her analysis of the concept of oppression, Marilyn Frye (1992) offers a useful metaphor to highlight these patterns of conditions and to distinguish oppression from personal suffering that anyone can experience. Frye suggests that we imagine a birdcage. The experience of oppressed people, Frye maintains, “is that the living of one’s life is confined and shaped by forces and barriers which are not accidental or occasional and hence avoidable, but are systematically related to each other in such a way as to catch one between and among them and restrict or penalize motion in any direction” (p. 4). These objective conditions are like living in a birdcage. If one were to examine the wires of the birdcage one at a time, one might not comprehend how that one wire is restrictive. It would seem that the bird could just fly around the isolated barrier to freedom. Yet, when one steps back and is able to apprehend the entire cage that surrounds the bird, “it is perfectly obvious that the bird is surrounded by a network of systematically related barriers, no one of which would be the least hindrance to its flight, but which, by their relations to each other, are as confining as the solid walls of a dungeon” (p. 5). Oppression, therefore, involves a pattern of barriers that restrict the movement of those

inside the cage. Moreover, individuals are oppressed not because they are individuals but by virtue of their membership in oppressed social groups.

As a system, racism can be understood to work on three mutually supporting levels: individual, cultural, and institutional. The individual level refers to personal attitudes and behaviors that reproduce racial power differentials. Blatant illustrations are racial epithets and jokes directed at people of color and racial discrimination in hiring practices. Personal racism, however, can work in more covert and subtle ways as will be subsequently described in the section on white privilege. Cultural racism refers to the beliefs, symbols, and ideas represented in the media, pop culture, books, standards of beauty, etc. that construct whiteness as normal, neutral, and superior while simultaneously conveying a negative message about all those who are not ascribed whiteness. It is not just a matter of inclusion of negative stereotypes because exclusion stigmatize, as well. Cultural racism and personal racism mutually reinforce each other.

Finally, institutional racism involves the network of structures and policies that sustain these structures in ways that benefit some groups and disadvantage others. The justice system, the education system, employment, housing, banks, government, and healthcare are only some examples of institutions through which racism is maintained and constantly reproduced (Schmidt, 2005). Individuals who participate in these institutions are complicit in the perpetuation of the *status quo* often without their conscious intent or volition.

If racism is a form of oppression that is systematic and involves interlocking barriers that constrain and limit the life outcomes of members of certain social groups, can the victims of racial oppression be racist? Beverly Daniel Tatum (1997) explains that while any person can have racial prejudices and engage in discriminatory actions, she rejects the use of the term racist to describe victims of racism in order to underscore the continuing power disparities between groups and how the system of oppression sustains white supremacy and systemically benefits all white people. Tatum emphasizes, “People of color are not racist because they do not systematically benefit from racism. And equally important there is not systemic, cultural and institutional support or sanction for the racial bigotry of people of color” (p. 10). Individuals, however, belong to many social groups and thus it is possible to be both oppressed and an oppressor. In order to determine when oppression is taking place, Marilyn Frye (1983) suggests looking at the barrier and asking “Who constructs and maintains it? Whose interests are served by its existence? Is it part of a structure which tends to confine, reduce and immobilize some group? Is the individual a member of the confined group?” (p. 14).

Acknowledging racism as a form of systemic oppression that limits individuals qua members of marginalized

groups is to recognize that there is also a group who benefits from the birdcage being in place. Before addressing the issue of whiteness and white privilege, some complex questions about identity must be raised.

Identity Politics, Recognition, and Essentialist Notions of Race

Multicultural education, so prominent in Western educational systems, rests upon the categorization of individuals into groups, specifically focusing on the groups that have been excluded from mainstream society. In this sense, multicultural education and identity politics have many of the same presumptions. In the latter part of the twentieth century in the United States, political movements arose around the acknowledgment that the experience of injustice was systemic and was connected to one's being identified with an oppressed group. Identity became an important tool in political discourse as the phrase identity politics indicates. Common or shared experience was the unifying force that propelled such movements. There is also the assumption that some type of authentic experience connected to group identity has been suppressed but deserves recognition and respect (Taylor, 1994) and must be reclaimed. What made identity politics so significant, Sonia Kruks (2001) explains, is that it involves a demand for recognition "on the basis of the very groups on which recognition has previously been denied: it is *qua* women, *qua* blacks, *qua* lesbians that groups demand recognition" (p. 85).

Although scientific essentialism has been discredited, from the phenomenon of identity politics it is easy to see how essentialism can arise even when race is understood to be a social construction. Essentialism involves the assumption that there is a uniquely distinguishing feature or features that all in the group share. Often, there is an assumption of a commonality of experience that constitutes and unites the group (e.g., the black experience, and the Chicano experience) that can be described independent of aspects of the particular person's life (Harris, 1990; Crenshaw, 1991). While identity politics was useful in empowering marginalized groups, at the same time the approach attracts much criticism.

Identity politics is accused of assuming essentialist notions of identity. The problems of such essentialism involve the normative consequences of commonality (Spelman, 1988). Who gets excluded any time a 'we' is constructed for the purposes of consensus and unity? In the women's movement, what it means to be a woman has been defined on the basis upon the experiences of white, middle-class, able-bodied, heterosexual women resulting in the exclusion and silencing of women of color as well as lesbian and queer women. In his 1994 film,

Black Is . . . Black Ain't, Marlon Riggs powerfully expressed how black women and black gays and lesbians have been excluded from heterosexist and patriarchal conceptions of African-American identity. In his discussion, Chicano nationalist movement, Jose-Antonio Orosco (2002) highlights how Chicano identity has been defined from a male, heterosexist point of view. He demonstrates how a focus on authentic identity does so at the expense of silencing voices that might contest the gendered and heteronormative conception of Chicano identity. In addition, the appeal to commonality of experience can operate as a disciplinary norm within a group that imposes a particular vision of identity onto members of that group. Essentialism assumes that the lives of people who experience multiple forms of oppression can be reduced to an additive model:

straight black women's experience = the experience of racism
+ the experience of sexism;

black lesbian's experience = the experience of racism
+ the experience of sexism + the experience of homophobia

Yet, for instance, the experience of women of color can be erased because they stand at the intersections of different categories. In many cases when black women face discrimination, their experience is not taken seriously because neither white women nor black men experience discrimination in this way.

Perhaps the most radical extension of the critique of identity politics and essentialism has evolved from post-structuralists such as Judith Butler (1990) and Wendy Brown (1995). Both have charged identity politics with assuming a prediscursive self over which forms of socialization impose nonessential characteristics. According to Butler, however, the subject is always already a product of discourse. Any reclamation of one side of binary categories, even a reclaiming of marginal identities, is to reify the framework from within which those categories are constituted. Wendy Brown, for example, contends that identity politics is based on a reclamation of wounded attachments that sustains victimhood continuing to carry marks of subordination instead of challenging the system from which these attachments originate and which they support. Moreover, such politics place subjects in fixed and stable categories that constrain their freedom. Instead of appealing to any type of identity category, both Butler and Brown recommend that all subject positions be decentered and given identity categories be subverted in ways that destabilize the normalizing discursive forces that create those identities.

One of the problems with the post-structuralist position is the question of agency. How is politics possible without identity categories? In addition, reclamations of racial identity can be political and serve as a way to expose

the systematicity of oppression (Taylor, 2000; Alcoff, 2005; West, 1996). According to Paula Moya (2002), some identities have epistemic status and political salience and can be politically progressive “not because they are ‘transgressive’ or ‘indeterminate’ but because they provide us with a critical perspective from which we can disclose the complicated workings of ideology and oppression” (p. 17). What is of particular interest about Moya’s account is that she acknowledges that the simple fact of being born a person of color in the United States does not in itself give one such epistemic privilege. What this claim underscores is that some people have experiences that other people who are not oppressed do not have. In fact, the systemically privileged have other experiences that protect them from even acknowledging the birdcage. When experiences of oppression are politicized, however, they have the possibility to provide information about how power systems operate and are maintained. Political identities, according to Moya, should not be jettisoned but reclaimed.

Whether or not racial identity categories should be reclaimed or eliminated has been an ongoing debate whose complex details are beyond the scope of this overview. It is clear that these debates raise crucial questions about all educational reforms that are based on social group categories. On the one hand, while multicultural education has been vigorously critiqued (Nieto, 1995), the debates around identity categories highlight the need to be vigilant about reifying categories that sustain frameworks of power and privilege rather than challenge them. However, on the other hand, there are dangers in also abandoning racial discourse. To further flesh this out, whiteness and white privilege must be addressed.

Whiteness, White Privilege, and Critical Whiteness Studies

While for generations scholars of color have argued that whiteness lies at the center of the problem of racism and that whiteness is a mutually constitutive aspect of the social construction of race, it is only relatively recent that whiteness within academe has been acknowledged to be a necessary corrective to the study of race that has been exclusively focused on the racialized other. Critical whiteness studies is focused on exposing whiteness as a taken-for-granted norm from which difference is constructed and seeks to analyze whiteness as a determinant of social power. Whiteness is intimately related to the construction of race in that its own meaning is dependent on the process of negation of what is outside its borders. The center and periphery are mutually constituent. As Frankenberg (1996) puts it, “Whiteness comes to self-name . . . simply through a triumphant ‘I am not that’” (p. 7). Quoting from Hazel Carby, Dyer (2000) argues that it is important to study whiteness, to “make visible what is rendered invisible

when viewed as the normative state of existence” (Carby as cited in Dyer, p. 3) in order to dislodge whiteness from its position of dominance. It is impossible then to gain an understanding of systemic racism without understanding how whiteness works and Dyer claims that whiteness, because it is presumed neutral and normal, can only be studied by making it strange (p. 10).

While the definition of whiteness is difficult to pin down, there is widespread agreement that whiteness is a socially constructed category that is normalized within a system of privilege so that it is taken for granted by those who benefit from it (Rodriguez, 1998; Winant, 1997; Roediger, 1991). Cheryl Harris (1993) suggests that whiteness is best understood as a form of property rights that is systemically protected by institutions such as law. Toni Morrison (1993) uses the metaphor of a fishbowl containing fish and water to elucidate the invisibility of whiteness as the condition from which meaning is made. If we focus on the water and the fish, we do not have to see how the fishbowl itself frames where and what happens within it.

... it is as if I had been looking at a fishbowl – the glide and flash of the golden scales . . . and then I saw the bowl, the structure that transparently (and invisibly) permits the ordered life it contains to exist in the larger world. (Morrison, 1993: 17)

White people’s investment in whiteness can obscure how white people even with the best of intentions are complicit in sustaining a racially unjust system.

Much of the study of whiteness focuses on exposing white privilege. White privilege, as McIntosh (1997) writes, is “an invisible package of unearned assets which I can count on cashing in each day, but about which I was ‘meant’ to remain oblivious. White privilege is like an invisible weightless knapsack of special provisions, assurances, tools, maps, guides, codebooks, passports, visas, clothes, . . .” (p. 291). Acknowledging white privilege challenges the ideology of meritocracy grounding many institutions of education in that it is privilege not only merit that results in white people getting ahead in life. The invisibility of white privilege works in conjunction with the persistent belief in meritocracy, that is, anyone can succeed with hard work and adherence to the rules of society, to constitute those who are Othered by ignoring the fact that systems based on white norms privilege white people. Disparities between the experiences of white people and people of color can be perceived as natural and normal, in other words, the fault of the individual and not the result of systematic privileging of the dominant. The marginalization of people of color, therefore, is held in place by white privilege.

White privilege must be understood as relational and also systemic (Leonardo, 2004).

The ideology of colorblindness (that a race-neutral stance is a remedy for eradicating racism) also plays into

the logic of white privilege – if one does not have to consider one's race, one does not have to consider how white norms operate. Policies and practices based on ignoring race that purport to eradicate racism actually sustain it (Lewis, 2001; Schofield, 1997). One of the privileges of whiteness is the ability to be able to ignore in the sense of remaining ignorant, denying, and dismissing the reality experienced by people of color on a daily basis. In schools, the ideology of ignoring color results in teachers and administrators disregarding the relationship between race and tracking, biased testing, discipline etc ... and protects white people from examining how white privilege hides behind normalized whiteness. Ignoring race gives its advocates the sense that they are adhering to the moral demand for egalitarianism yet in actuality this approach leaves white racial privilege and racial disparities intact and secure. White privilege is systemic in that it is connected with a network of privileges both material and psychological. It is also manifest as a way of being in the world. Marilyn Frye (1992) discusses how being whitely exhibits itself in how white people relate to others, their sense of self and their own morality.

White teachers, for example, need to study whiteness and white privilege so that they can understand how to challenge racism as it is evidenced in their classroom. (For an excellent illustration of how white dominance codes nonwhite students as behavior problems see Delpit, 1995.) But the different discursive disguises that white privilege takes on complicate this. Alice McIntyre (1997) describes white talk as “talk that serves to insulate white people from examining their/our individual and collective role(s) in the perpetuation of racism” (p. 45) Examples of white talk that McIntyre describes are “derailing the conversation, evading questions, dismissing counterarguments, withdrawing from the discussion, remaining silent, interrupting speakers and topics, and colluding with each other in creating a ‘culture of niceness’ that made it very difficult to ‘read the white world’” (p. 46). Hytten and Warren (2003) examine how whiteness gets reinscribed in classroom discursive dynamics. In both studies, the white students were trying to be good anti-racist whites yet unintentionally employed discourse that protects whiteness as the privileged center. Whiteness, therefore, can be subtly reinscribed even when it does not appear to be doing so and can be reified even when “we try to disrupt its normative influence” (Hytten and Warren, p. 65). Such white discursive moves complicate calls for dialog and are necessary to explain why separation rather than integration is often preferred by students of color (see Jones, 1999) and expose the need for a politics of listening alongside the study of whiteness and white privilege.

Critical whiteness studies have attracted much criticism. There is a serious concern with recentring whiteness, white people and white feelings and drawing attention away from the needs and interests of people of color.

In his foreward to the book, *White Reign: Deploying Whiteness in America* Michael Apple (1998) cautions,

Having Whites focus on whiteness can have contradictory effects, one of which we need to be well aware. It can enable people to acknowledge differential power and the race nature of everyone. . . . It can just as easily run the risk of lapsing into the possessive individualism that is so powerful in this society. That is, such a process can serve the chilling function of simply saying ‘but enough about you, let me tell you about me’. (p. xi)

If focused on white self-transformation, whiteness studies can result in white people being concerned about salvaging their good moral being. Dyer notes about white people, “the display of our guilt is our cavalry” (p. 11). Whiteness studies can itself become an exercise in white privilege. If critical whiteness studies are focused on white self-transformation then it fails to challenge whiteness as a norm and instead recenters whiteness, white people, and their feelings, and well-being.

An additional concern involves how categories of race are static in much of the whiteness research (Keating, 1995). On the one hand, if interrogations of whiteness require static concepts of identity, the very framework of us/them that from which racial systems are constructed are reified. On the other hand, without marking whiteness how can it be interrogated? Two approaches to the disruption of whiteness have been discussed. One approach advocates that whiteness be rearticulated while the other contends that whiteness be abolished (Giroux, 1997; Ignatiev and Garvey, 1996). A detailed analysis of both these positions is beyond the scope of this overview. The interested reader is directed to Moon and Flores (2000), Flores and Moon (2000), Warren (2001), and MacMullan (2005).

Much of the discussion in this overview has been dominated by a US focus that may or may not be usefully employed in other national contexts. What lessons can be gleaned will depend on how similar and how different race and racism plays out in other contexts. Already there is a growing body of scholarship that is responsive to the racial dynamics in the United States, Canada, United Kingdom, Australia, and New Zealand. In all these contexts, whiteness is always the invisible norm from which the other is constructed. Continued research that interrogates race and racism in education is required. While progressive initiatives in education around racial inequity are important, paying attention to the limitations of such projects is also key in making new and better possibilities imaginable.

School Choice and the Common School

G Haydon, Institute of Education, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Common school – A school open to all potential students without discrimination, where the actual student body is representative of diversity in the surrounding community, and the education provided is appropriate for all members of the wider society.

Comprehensive school – A common school within the public education system of the United Kingdom.

School choice – A system or policy that enables parents or students to exercise choice among a number of schools within a publicly funded system.

Separate school – A school that intentionally limits its student body to a certain sector or sectors of the wider community; or a school in which the student body is contingently so limited as a result of demographic factors and parental choice (a *de facto* separate school).

The topic of school choice and the common school has come to seem a natural one for inclusion in a survey of educational issues because of the way the two elements of the topic are linked. Two ideas are sometimes joined into a single topic because they are perceived as fitting together, and sometimes because they are seen as opposed. The latter is the way the pairing of school choice and the common school is often seen: either school choice or the common school. Which should be favored, and why?

Once the topic is set up in this way, it is obvious that a great many considerations, including matters for empirical research and for practical politics, will come into the debate; and many of these considerations will differ from one school system to another.

Since the present article is written within the perspective of philosophy of education, it will not engage with the detail of such considerations. That is not to say that philosophers cannot take account of empirical data and of practical politics; indeed, some of the writers who have entered the debate from a philosophical perspective do pay a good deal of attention to empirical data (e.g., Brighouse, 2000). Still less is it the position of this article that philosophy by itself can settle such a debate. But there is a contribution that philosophy is particularly well placed to make – to clarify the terms of the debate and the nature of the arguments on both sides. Though this may sound like a mere preliminary, it is important because there is a real possibility that different parties in the debate will

have different understandings of what is meant by the common school and school choice.

A logically prior question is whether it is right to set up this topic as a two-sided debate in the first place; but it is hard to answer that question without unpicking the assumptions being made about what is involved in common schools and in school choice. Only after doing that can it be seen whether the two ideas are mutually exclusive.

Even in a philosophical discussion, an abstract comparison of the two ideas, detached from any historical or political context, would barely be possible or illuminating. Where common schools have been advocated, it has been as a practical policy within certain societies; where school choice has been advocated, it has also been as a matter of practical policy, often in reaction against a system in which common schools are predominant. There is a background assumption across most of the debate over common schools and school choice – that the ways in which schooling is provided, funded, and regulated (see Tooley (2000: 9) for this distinction between logically separable forms of state intervention) are matters for political decision. Even when, as now in many societies, there are moves away from common schools and toward greater choice in schooling – and even when such moves are at the same time moves toward lesser governmental control over schooling – it is still within the powers of government to decide how far such moves are to be allowed, encouraged, or actively instituted.

Common Schools and Separate Schools

Within such a context we can give an initial characterization – needing further refinement – of what a common school is. The present discussion draws on Haydon (2007) and on other contributors' chapters in a volume on *The Common School and the Comprehensive Ideal*.

A common school is a school open to and intended to provide education to all potential students in its locality without discrimination on the basis of any differentiating characteristics, such as the ability, gender, or ethnicity of the student or the religion, class, or wealth of the student's parents. Such a statement of intention, however, is not yet sufficient to capture the idea of a common school as it has been understood by its advocates. Two things at least have to be added: (1) that the intention of nondiscrimination should be realized in the actual student body; the actual mix of students within the school should reflect at least as

much diversity as there is in the surrounding population; (2) that the nature of the education provided in such a school should itself be common, in the sense both that it is essentially the same education provided for all within the school, and that it is an education thought to be appropriate for all citizens within the wider society (McLaughlin, 2003). The following paragraphs will focus on point (1) before moving to point (2).

What is opposed to the notion of the common school, understood as one open to all students, is not the idea of school choice as such, but the idea of a school that has a limited mix of students because it does discriminate on the basis of one or more differentiating factors. The term separate schools has been widely used by philosophers of education for such schools (e.g., McLaughlin, 1992). A separate school may, for instance, take students only from a particular faith community; or only girls; or only students with certain kinds of special-educational needs.

Where there are separate schools, this fact does not by itself mean that it is within the scope of choice by students or their parents to attend or not attend a given school. In many of the southern states of the USA, prior to the Supreme Court decision in *Brown versus Board of Education* in 1954, there were separate (and allegedly equal) schools for blacks and whites. In England, for at least two decades after the Education Act of 1944, there were separate schools for students of different measured intellectual ability. In such cases, though there may sometimes have been a degree of parental choice available between different local schools in the same category, it was essentially government (sometimes local government acting within national policy) that decided which kind of school any given student attended.

The English case can serve as an illustration, not only that separate schools are not necessarily open to student or parental choice, but also that what is a common school in intention is not necessarily a common school in its actual mix of students. At a time when many local education authorities in England began to provide schools (known as comprehensive schools) open to any student without selection by ability, it was often the case that other schools which did select from the upper percentiles of the measured ability range were operating in the same geographical area. Since the most able students mostly went to those selective schools, the comprehensive schools did not in fact contain a representative range of students from the surrounding population. Another way in which a notionally common school may be far from comprehensive in the actual composition of the student body is that the demographics of the local area served may be far from representative of the demographics of the wider society. Thus there are notionally common schools in England whose students are almost entirely Asian and Muslim; and notionally common schools in the USA whose students are almost entirely black (Levinson, 2007). These schools are *de facto* separate schools.

These points illustrate that while it is possible to describe a single school as a common school, the debate between common schools and separate schools, as also between common schools and school choice, is a debate over schooling systems and policy. On the one side, the favored system is one in which the norm for the great majority of students is that they attend a common school provided for the whole community; on the other side the favored system is one in which there is a diversity of kinds of school, between which parents have a degree of choice. Exactly what degree of diversity, what level of choice, and through what mechanism choice is exercised, are factors that may depend on local or national conditions. There are also possible variations as to who actually exercises the choice; here, as is usual in this debate, we refer to parental choice (where parents include legal guardians). But it is worth noting that if there is to be choice between schools there is a strong case for students to be involved in the choice, and many parents, especially in choosing a secondary school, will put weight on their offspring's views.

Moving to point (2) above, we can say that a common school is not only one that has a mixed student body, but also one that promotes a common education, that is, an education thought to be appropriate and desirable for all students. (It is worth noting at this point that separate schools may or may not differ in this respect from common schools. A school educating only students from one faith tradition may promote an education that is not common in that it includes initiation into the doctrines of that faith; on the other hand, a school that takes only female students may believe that girls should have the same kind of education as boys.)

What counts as a common education is open to more or less minimal interpretations (Callan, 1997: ch. 7; Haydon, 2007). It might comprise no more than a list of subjects that are more or less universally accepted as essential in anyone's education: numeracy, literacy, and perhaps some basics of scientific and historical understanding. But usually the advocates of common schooling have something fuller than this in mind, for reasons that will be apparent when we consider the arguments offered in favor of common schools.

The majority of such arguments turn on one or both of two considerations: justice to individuals, and the cohesion and flourishing of the community. Separate schools may be unjust to individuals by giving different life opportunities to different individuals for reasons that are in no way dependent on the individuals' own choice or effort. It would be very widely agreed now that the separate-but-equal schools of the southern states were in fact unequal in this way; and the English system of selecting students by ability rapidly came to be seen by many as unjustly prejudicing the life chances of children by assigning them to ability categories at the age of 11 years. In the background to such arguments is a commitment that as far as possible,

all citizens should have an equally good education giving them access to equally good opportunities in life.

More positive arguments spell out more about what such an education would involve and why it is desirable. Often referring to Dewey's (1916) classic *Democracy and Education*, the positive arguments see a common education in common schools as the best if not the only way in which a cohesive democratic community can be forged within large heterogeneous societies. The background assumption here, perhaps even more inescapable a century after Dewey was writing, is that of pluralism in the cultures and traditions of the inhabitants of modern states. In the multicultural society of Britain at the beginning of the twenty-first century, there are arguments for retaining common schools that echo those of Dewey. Alongside arguments about the forging of common values within a plurality of values, there are arguments that only in common schools can the attitudes and practices of a genuinely democratic citizenry be formed (Fielding, 2007). Respect, tolerance, willingness to listen to different points of view, can all best be formed, many would claim, in common schools. Conversely, there have been fears that where parents are able to choose separate schooling for students from different cultural and religious traditions – or where parents of one social class are able to separate their children from those of another class – this will tend to undermine the cohesion of the wider society.

School Choice

Against this background, we can turn to the question of what is to be understood by school choice and what arguments can be made for it. Some simplifying assumptions will be made here. First, although one could consider within the scope of school choice the choice that a child will not attend school at all, the possibility of home schooling will not be considered here. Further, although choosing to pay for one's child to attend a private school could also clearly be counted within the scope of school choice, the debate over the legitimacy and desirability of private schooling will not be considered here (but see Tooley (2003) for an argument that the considerations brought forward in support of school choice within a state system can actually be seen to support full privatization of schooling). The school choice considered here is choice between schools within a publicly funded system of schools.

There are in fact a variety of possible systems that may be said to incorporate school choice, and correspondingly a variety of arguments that may be put forward. Here, a background assumption (not entirely beyond challenge, as we shall see) is that choice presupposes a diversity of schools between which a choice can be made. But how much diversity is one of the variable factors. We can

roughly outline a continuum from quite limited diversity to much greater diversity.

At one end of this continuum is a system in which all schools are common schools, serving a mixed population, and expected to serve certain publicly mandated educational aims, but where there are nevertheless some differences between schools. Within urban areas, it may be practically feasible for parents to choose between a number of accessible common schools.

Why in such circumstances might a policy be favored that gives to parents a choice between several alternatives? We can distinguish here (1) arguments that assume shared educational preferences across all parents and students, and (2) arguments that rest on a diversity of preferences. The two kinds of argument may be used in combination, since parental goals and preferences may coincide in some respects but not in others, but they will be treated separately here.

1. There are arguments from the alleged benefits of competition to the effect that the existence of a plurality of schools, between which a choice can be made, will have instrumental value in raising the level of provision of a good that all parents are assumed to want for their children. For instance, it may be assumed that what all parents want for their children is a good education, where this is assumed to equate to academic achievement and thus to be measurable by test results. Given such a common measure, it is argued that not all schools will be equally effective in achieving good results, while all schools need an incentive to do as well as they can. In a school choice system, where it is assumed that parents will wish their children to go to the schools with the best results, schools have to compete to attract parents and therefore will try to improve their test results. This is a version, then, of the familiar economic argument that competition drives up performance. Some states have also made arrangements by which competition between schools is intended to drive down costs, thus achieving greater efficiency in the use of public funds (see Brighouse (2000: 28–34) for a useful review of this and other arguments for school choice).
2. There are other arguments based on the assumption that preferences, or indeed conceptions of a good education, vary across parents and students. No two schools will be identical in all respects, even if they cannot be distinguished in terms of measurable results, and even indeed if they share an avowed commitment to the promotion of common values and citizenship within a plural society. Some schools are large and vibrant places; others are small and calmer. Some may have an ethos of student deference toward teachers, and others, a culture of friendly two-way relationships between students and teachers. Some may put weight on the delivery of a prearranged curriculum almost to the exclusion of other concerns, while others

allow more flexibility in following up students' interests. Some may aspire to a democratic organization while others will reflect the bureaucratic nature of the wider system, and so on. Though such differences may coexist with similar avowed goals and similar academic results, they can make a large difference to the quality of student experience. If we add the premise that different conditions may be congenial to and appropriate for different individuals, and the further premise that parents will know best what is appropriate for their own children, there are grounds for a presumption that where possible, students and their parents should be able to choose the conditions they find congenial. To this the argument can be added that encouragement to schools to develop their own characteristics gives scope for valuable innovation to emerge.

So far, then, even where a system of common schools is in place, there can be arguments for the desirability of having variation between schools within that system, though by the definitions above, the schools remain common rather than separate. It must be acknowledged that there is also a danger in combining parental choice with common schools, in that parents may take any factors they wish into account in their choice. Where parents choose to send their child to a school where most of the other students are of similar background, this can be the beginning of a slide toward *de facto* separate schools.

The move further along the continuum of diversity involves the formal recognition of separate schools, first with a shared commitment to a common education, and then with no such commitment. At the farthest end of the continuum will be a situation of maximal differences between schools with minimal attempt at government regulation of what happens within the schools. Arguments for moving along this continuum can be made in two stages: arguing for separate schools, and arguing for choice between them. The second stage is the easier, in that if there are separate schools, such as schools promoting one religion, or schools only for one gender, and so on, then in a liberal society, there must be a presumption in favor of parents – and here it is perhaps especially important to add, students too – having either free choice or at least a strong voice in determining the kind of school a child goes to. If certain children were sent to a school promoting, say, a given religion against the parents' wishes, that would be a *prima facie* overriding of liberty and of one element of Clause 26 of the Universal Declaration of Human Rights.

That point does not, however, settle whether it is right that there should be separate schools. The argument that there should be separate schools of whatever kind cannot rest on an abstract appeal to parental rights but has to counter the strong arguments for the desirability of common schools (Brighouse, 2007: 583). The argument also

needs to be made on its merits for any given kind of separation. An argument for separate schools for different ethnic groups, for instance, would be very hard to make within a liberal democratic society where battles against racial discrimination have not yet been finally won. In contrast, the desirability of separate schools for students with certain severe disabilities is a live issue in many countries. An argument for such schools may appeal to the benefits to the individuals concerned that can be provided in specialist schools, while on the other hand it is argued that the deliberate segregation of disabled students can be harming to their self-respect and deleterious to their future integration within the wider community.

An argument for separate schools for different religious communities can appeal to parents' strong interest in bringing up their children within the belief system that they (the parents) believe to be right, and can appeal also to a child's interest in being brought up within a coherent culture (Merry, 2005). On the other side (starting from liberal premises) is the right of every child not to be inducted into a specific worldview, including that of her parents, and the interest of the whole community in having citizens who are open minded and prepared to take seriously the perspectives of others. Many theorists have concluded that the two sides of this argument need not be irreconcilable. It is open to governments, while allowing and perhaps even encouraging certain kinds of separate school, to insist that such schools must subscribe to the common educational goals of the society. Where such a policy is followed, there can be room for parental choice without – in principle – undermining the pursuit of the goals that common schools are meant to promote. Nevertheless, there remains the possibility that the goals of a common education for shared citizenship will be better achieved within those schools that actually are common schools, where students from different backgrounds really do meet and mix with others across differences in beliefs and values, so that this very interaction is part of the educational experience.

Values Underlying the Arguments

If common educational goals are intended as a response to plurality of values, it is also the case that the debate over common schools and school choice reflects a plurality of values. It is not that certain values and certain traditions stand firmly on one side of the debate and others on the other side. Faith communities, for instance, contain some parents who wish their children to be educated only within their faith community, and other parents who acknowledge the desirability of their children being educated alongside those with quite different beliefs. Both sides can, to a considerable degree, recognize the force of the same values while perhaps interpreting differently the

practical consequences of these values. All within this debate can acknowledge the human value of belonging to and being able to identify with a community, though for some it will be the national citizenship community that takes precedence and for others a more specific and local community. All can acknowledge the value of respect for persons: for some, the respect that matters most is that the state respect the rights of parents to live in the ways of their own culture and to bring their children up within it; for others the emphasis is more on mutual respect between cultures that may be best nourished within a common school.

Justice, as we have seen, underpins one argument for common schools, inasmuch as they involve neither discriminating against nor giving preferential treatment to any. But proponents of parental choice can sometimes claim with plausibility that justice is on their side. As regards the schooling of students with severe special needs, as mentioned above, there are strong proponents of their integration into mainstream schooling, but some parents can argue that common schooling is unjust to their children through failing to provide sufficiently for their individual needs. There is also the more general argument, stressed by Brighouse and others that nominal common-school systems unjustly allow choices to parents who can afford to move house to be close to a well-favored school, whereas poorer parents have no such choice.

Liberal philosophical approaches to education commonly give important weight to individual autonomy as a central quality to be developed through education. For many, the common school is the best environment for developing autonomy, because it provides for the child a certain detachment from the home community (Levinson, 1999). But others will claim, putting weight in part on the importance of cultural coherence, that schooling according to the culture of the home community can be a route toward autonomy (McLaughlin, 1992).

Proponents of parental choice can appeal to a principle of liberty, against the coercive intervention of the state into the life of families (Reich, 2007; Brighouse, 2007). But advocates of common schooling may claim to be putting more weight on the potential liberty of the individual student, and also may take a more civic republican view of liberty in which the liberty of the adult within society will not be purely private but will involve engagement within public affairs.

Although what are at least nominally the same values may be appealed to by all participants in these debates, it is possible to discern an underlying difference in what might be called the predominant ethos on either side. The advocacy of school choice is at home within a social ethos in which choice itself, construed on the model of consumer choice in the market, is given high positive value. Many of the arguments that are applied in wider contexts of the marketplace are used here too – that choice

between alternatives empowers the consumer, and gives providers motives to monitor their performance, diminish inefficiency, and be transparent in their operations.

In support of common schooling, it can be said that there are other goods than those that can be chosen on an individual basis, and that the good society cannot be equated simply with a society in which the satisfaction of individual preferences is maximized. Notions of fraternity and solidarity (Fielding, 2007) are at home in the case for the common school as they cannot be in the case for school choice (as usually understood). At the same time, a positive valuation of fraternity and solidarity should not be taken to imply that choice as such is undesirable. Here we need to return to the thought that the common school itself can itself be chosen.

The Common School as an Object of Choice

Common schools can be objects of choice in several ways, differentiated by what it is in preference to which common schools are chosen. First, there is the kind of arrangement already considered, involving a choice between different common schools within a system of common schools. Here, parents choose one common school in preference to another. This has been sufficiently considered above.

Second, a common school can be an object of choice in preference to a separate school. This, of course, is only possible in practice where there is more than one school that a child could attend, including at least one common school and at least one separate school. Such contexts (some examples of which have already been noted) are potentially unstable, since if too many parents choose separate schools, the intake of students to common schools can become distorted to the point where they become only nominally common. To the extent that this happens, whether by deliberate policy or default, parents no longer have the possibility of choosing a common school even though they may have a greater range of separate schools to choose between.

Finally, there is a sense in which common schools can be an object of collective choice. Here, what is chosen is a system of common schools in preference to a system of (diverse kinds of) separate schools. This is not a choice that can be made by individuals acting alone, but is potentially an object of choice for citizens, to be chosen or rejected through democratic political processes. There is perhaps some danger that the penetration of market forces into the political thinking of liberal states will encourage a drift away from common schools that will make the collective choosing of common schooling only an in-principle possibility.

The demise of common schools would itself diminish the range of alternatives open to citizens. This would be a paradoxical outcome in any educational system that

wishes to promote the virtues of shared citizenship within a cohesive society, since it would in effect assume that citizens would only want to make their choices by reference to their private preferences for their children, rather than by any wider public-spirited motivation. The challenge for policymakers and for philosophers of education who seek to influence policy is to devise systems, realizable within the practical politics of given societies, that realize some of the benefits of choice without unduly restricting the very basis on which choices in schooling can be made.

Glossary

Amaqihikiza – A type of mentorship program among older and younger girls to ensure sexual abstinence until the latter are ready to take full control of their affairs.

Ubuntu (botho; hunhu) – Humanness.

Ukuhlolwa kwezintombi – Virginity testing in girls.

Umuntu ngumuntu nga banto (motho ke motho ka batho) – A person (a human being) is a person (is human) because of other persons (other human beings).

Education in Africa, like virtually all social interaction, was traditionally characterized by the bounds and bonds of small-scale ethnic communities. Despite their diversity and remoteness, and the sheer geographic distances between these groups, they are seen to share not only the experience of colonization but also (predating this experience) certain common educational concepts, principles, and values.

African philosophy of education is, in some important way, contingent on African philosophy. While existence of the latter is guaranteed by manifestations of the former, the possibility and plausibility of African philosophy does not necessarily imply the same for African philosophy of education. At the heart of these considerations resides the question whether there is a (set of) perspective(s), a body of thought, and/or a particular way of doing philosophy of

education, that can be called African. There are arguably two initial ways of approaching this issue:

- Are there uniquely and distinctly African ways of philosophizing about education?
- Are the component concepts, principles, and values of this philosophy sound?

Whether or not satisfactory answers to these questions are forthcoming, the possibility and plausibility of African philosophy of education might nonetheless be established in terms of its priorities. Given the different historical, geographical, cultural, and social contexts of Africans and education in Africa, it is reasonable to assume that philosophical priorities differ in accordance with these.

Introduction: Modes of African philosophy

Perhaps significantly more than philosophy elsewhere, African philosophy has been marked indelibly by the colonial experience. Historically, and for reasons of graphic illustration, it might be divided into its precolonial and postcolonial manifestations. Precolonial African philosophy had, with very few exceptions (Egypt comes to mind here), an essentially oral tradition. The written tradition came with and succeeded colonialism, exemplified *inter alia* by missionary education. Ethnic philosophy

and sage philosophy characterized the former, while political philosophy and critical (academic or professional) philosophy exemplified the latter.

Ethnic philosophy consisted of folkloric traditions, legends, stories, and myths, and survives in the postcolonial period in both oral and, importantly, written forms. So does sage philosophy, initially the spoken words and teachings of a few wise men or sages, now also documented in writing. Political and critical philosophy, on the other hand, were marked – if not determined – by the colonial experience. The writings and documented speeches of politicians, statesmen, and prominent liberation movement personalities like Kwame Nkrumah, Julius Nyerere, Léopold Senghor, Kenneth Kaunda, and Steve Biko, to name only a few, constituted political philosophy that often also had a nationalist-ideological character. A fourth trend in African philosophizing is the direction pursued by critical or professional philosophy (see Oruka, 1998, 2002). This is a direction associated, for example, with the writings and other contributions of professional philosophers and academics like Kwame Anthony Appiah, Paulin J. Hountondji, Peter Bodunrin, and Kwasi Wiredu.

Although both Henry Odera Oruka and Kwame Gyekye can be credited with recording, concurrently and independently from one another, contemporary nonacademic intellectual traditions (Löfke, 2001: 140), Oruka was the first, in 1978 (Oruka, 2002), to undertake this classification. He has recently (Oruka, 1998: 101, 102) described two additional types of philosophy, the hermeneutic trend and the artistic or literary trend – somewhat unhelpfully, because the former appears to be subsumed by critical or professional philosophy, while the latter contains elements of the other trends identified previously, ethnic philosophy, sage philosophy, and political philosophy. These different kinds of philosophy and philosophizing are illustrated in **Table 1**.

It is important to note that ethnic philosophy and sage philosophy have survived colonialism and that they continue to thrive in postcolonial Africa. Both political and critical philosophy frequently exhibit or seek to validate elements of the former kinds of philosophy. Indeed, the number of academic or professional philosophers

repudiating substantial elements of their African doxastic and conceptual heritage remains fairly small.

A further distinction might be made at this juncture between philosophy as worldview and philosophy as critical activity. Ethnic philosophy and sage philosophy essentially exemplify the former (the worldview in question being either divinely inspired, or by the ancestors, or by the tribal elders). So do – to an extent – the postcolonial visions and ideologies of political leaders and liberation movement personalities (who were/are characteristically not academic or trained philosophers). Only with professional philosophy, at least to a greater extent, has there been a noticeable trend toward critical activity, interrogation not only of the colonial intellectual heritage but also of indigenous worldviews (**Table 2**).

African Traditional Education

African traditional and/or religious worldviews are frequently cited as exemplifying characteristically African philosophy. With regard to education in particular, uniqueness and distinctness are claimed for the component principles of African traditional education: preparationism, functionalism, communalism, perennialism, and wholisticism, principles that, furthermore, yield sound philosophical foundations (Adeyemi and Adeyinka, 2003: 431). Before turning to current trends within African philosophy of education, the author examines briefly each of these traditional principles. Are they uniquely African? Are they defensible?

In customary education, children were equipped with the skills appropriate to their gender, in preparation for their distinctive roles in society. Male education thus produced farmers, warriors, blacksmiths, rulers, and other male-dominated occupations from which women were excluded, while female education was predominantly designed to produce future wives and mothers (Adeyemi and Adeyinka, 2003: 432). Learning through imitation, initiation ceremonies, work, play, oral literature, etc., people were productive as they learned and were smoothly integrated into the community (Adeyemi and Adeyinka, 2003: 432). Third, all members of the society owned things

in common and applied the communal spirit to life and work (Adeyemi and Adeyinka, 2003: 432). This was manifest not only in shared manual labor and joint savings but also in the communal upbringing and disciplining of children. The latter were also discouraged from critical interrogation and from experimenting with the unknown, with punitive measures being imposed on those who tried to do so (Adeyemi and Adeyinka, 2003: 433). Education was essentially conservative in nature, perceived as a vehicle for maintaining or preserving the cultural heritage and *status quo* (Adeyemi and Adeyinka, 2003: 433). Finally, the wholistic nature of customary education enabled young people to acquire a variety of skills. Thus, a

child, destined to become a fisherman ... learned not only to catch fish but also to preserve and market it; to make and mend nets; to manufacture canoes and to erect temporary fishing huts. ... An individual [therefore] ... could work as a builder, farmer or fisherman, while a woman was a gardener, housewife and cook, besides being a nurse to her children, etc. (Adeyemi and Adeyinka, 2003: 433)

In a sense, not only African communities but most (if not all) small-scale societies exhibit or are guided by these principles. Moreover, one might think – with all due acknowledgment of their historical and social context – that the androcentrism and gender bias exhibited by some of them, not to mention the more or less tacit endorsement of indoctrination and irrational belief, or superstition, disqualifies a number of these principles from being taken seriously within philosophical discourses in twenty-first-century African education. In fact, as will become clear later, only communalism still enjoys wide currency.

Critical, Academic, or Professional Philosophy: The Content of African Philosophy of Education

If the component principles of African traditional education are either not uniquely African or are indefensible in (post) modern Africa, then what about current philosophical trends in educational discourse on the continent? According to Kwasi Wiredu, who like Adeyemi and Adeyinka is sympathetic to the African traditional conception of education, to be educated (in Akan, as in most other African languages and cultures) means to have knowledge (wisdom and skills), to be tolerant and willing to enter into dialog, and to possess moral maturity (Wiredu, 2004: 17, 18). For Wiredu, this normative conception of education is inspired by the following: indigenous (African) knowledge systems (Wiredu, 2004: 24), traditional African faith in consensus (Wiredu, 2004: 21), and the conceptual and normative priority of community over individuality (Wiredu, 2004: 20). African philosophy of education, thus “must combine all these considerations, which ... reveal the strengths of the traditional African conception of education” (Wiredu, 2004: 24).

The substratum for decolonization of the African mind and for “creating an educational vision capable of serving the legitimate interests of Africa in the contemporary world” (Wiredu, 2004: 24) is for Africans to (learn to) think and/or philosophize in their own language.

The present section takes stock of trends and developments presented both at recent conferences and in recent publications on or within African philosophy of education (see Higgs *et al.*, 2000; Odora Hoppers, 2002; Waghid *et al.*, 2005; in April 2007, the International Society of African Philosophy and Studies (ISAPS) 15th Annual Conference was hosted by the Rhodes University Philosophy Department in Grahamstown, South Africa, and more recently (23–25 October 2007), a conference on African philosophy and the future of Africa took place at St. Augustine College of South Africa). In essence, prevalent themes have been the following:

- the educational significance of indigenous (African) knowledge systems;
- *ubuntu/botbo/hunhu* and communalism;
- the ethical responsiveness of African philosophy (of education); and
- the legacy of colonialism.

The author will discuss each of these in turn, before focusing on an approach that arguably contains the possibility of Africa’s novel contribution to philosophy of education.

Indigenous (African) knowledge systems

The motivation for a focus on indigenous (African) knowledge is fairly easy to explain, especially when one considers the denigration, suppression, and exploitation of traditional knowledge systems during and even after colonialism. The reclamation project that underlies this renewed focus is not only epistemological but also concerned with legislation and social justice. As Mogobe Ramose has put it:

The history of epistemicide in South Africa raises fundamental questions of justice such as the question of epistemological equality of all the existing paradigms of the peoples of South Africa. Epistemological equality is a vital ingredient in the construction of a truly representative South African identity expressed, among others, in the new South African philosophy of education. (Ramose, 2004: 156)

A question that remains largely unaddressed is whether the idea of indigenous knowledge makes any sense. A central problem appears to be the lack of clarity about the meaning or understanding of knowledge. Defenders of this idea distinguish between skills and knowledge – which suggests, in the absence of any definition, that at least part of the understanding concerns propositional knowledge. Insofar as knowledge in this sense includes reference to truth, this invites the perception of the latter also being

indigenous. Bluntly asserting, on more than one occasion during the recent 2007 ISAPS conference, that truth is belief, Wiredu claimed that reference to “infallible” truth is not only a bar to dialogue but that “such a claim to knowledge is also a bar to education” (Wiredu, 2004: 24).

A problem that would need to be addressed is that of relativism (about both knowledge and truth) and of the implications of taking epistemological relativism seriously. A further question concerns the basis, if there is one, for distinguishing between knowledge and superstition within indigenous African belief systems. A common perception, in this regard, is that truth is nothing more than consensus.

African communalism, ubuntu, and consensus

Consensus is seen as desirable, and dissensus as undesirable, both on epistemic and political grounds. In traditional African societies, debate characteristically continues until a compromise is attained and all participants agree with the outcome (Metz, 2007a: 324). A central feature in African philosophy is the consensus-seeking principle provided by *ubuntu*, or humanness, the African principle of mutuality and interdependence. (According to Malegapuru Makgoba, the shared values that are fundamental features of African identity and culture . . . , for example, include hospitality, friendliness, the consensus and common framework seeking principle, *ubuntu*, and the emphasis on community rather than on the individual. These features typically underpin the variations of African culture and identity everywhere (Makgoba, 1997: 198).) According to Ramose, “African philosophy in general, and *ubuntu* philosophy particularly for South Africa, must be inscribed in the research agenda aimed at the construction of a new philosophy of education in South Africa” (Ramose, 2004: 158). *Ubuntu* expresses the view that a person is a person through other persons, or “I am because we are” – *umuntu ngumuntu nga bantu* (or *motbo ke motbo ka batbo*) – and is closely associated but not identical with African communalism.

Wiredu referred to African communalism as the foundation for national reconstruction. Traditional African society, he claimed, was communalist, founded on kinship relations, a system of reciprocity. “Morality is the adjustment of one’s interests to the community under a common guiding principle, like the Golden Rule. On this model, communalism might be characterized as the adjustment of the individual’s interests to those of the community” (Wiredu, 2007). After quoting Nkrumah – “African communalism is a form of socialism” – Wiredu claimed that Western communitarianism took root in individualist systems: “Western communitarianism is compatible with certain forms of cultural individualism, which African communitarianism is not” (Wiredu, 2007). Wiredu suggested that the term communalism therefore be reserved for the latter, but not the former. Communalism, he claimed, is the basis for a good and just society.

Apart from raising the question whether this move does not define communalism into morality, rather than see it as one amongst several orientations in ethics, Wiredu’s account appears to equate individualism with egoism or selfishness. One could ask, furthermore, whether Africa’s misery (see The legacy of colonialism below) might not in part be the result of the preoccupation on the African continent with communalism – which underlies obedience to authority, ancestors, traditional leaders, etc. – and arguably also of the tyranny of consensus. (The idea here is that palaver democracy, which aims at agreement, is considerably less democratic than a system – educational or political – that encourages dissent and critical interrogation.)

Problems that have been identified, with regard to *ubuntu* and communalism, include lack of specificity and action-guiding potential (Metz, 2007b: 342), their seeming incompatibility with deontological considerations, like human rights; as well as their alliance with, and proximity to, questionable (androcentric) practices and traditions. (In the latter regard, see Pitika Ntuli, on the validity and desirability of the *amaqhibikiza* system (a type of mentorship program among older and younger girls to ensure sexual abstinence until the latter are ready to take full control of their affairs) and of *ukublobwa kwezintombi* or virginity testing in girls (that seeks to achieve the goal of purity in the context of the spread of HIV/AIDS; Ntuli, 2002: 61, 62), and Ramose, on the compatibility of *ubuntu* and polygamy: that marriage should not of necessity be monogamous is one of the ancient practices of *ubuntu* philosophy (Ramose, 2002: 329).) Important insights, on the other hand, include the modeling of humanity, and reconciliation/forgiveness, all of which are contained in *ubuntu*. Most strikingly, the following reason was given by one of the victims during the truth and reconciliation hearings as to whether and why she would consider forgiving the perpetrator after his confession: if it means he gets his humanity back (see also Tutu, 1999: 35).

The ethical responsiveness of African philosophy

Wiredu began his plenary address by quoting Nkrumah’s view, on the occasion of Ghana’s independence, that this would be “meaningless unless it involves all of Africa” (Wiredu, 2007). Wiredu took this to encapsulate a preeminent sense of the practical value or worth of philosophy. Commitment to the view that philosophy should be relevant to the transformation of African societies, that is, in the service of ordinary Africans on the continent, in terms of an ethical commitment to their upliftment also characterized the writings and presentations by (Oladipo, 1992: 7, 28), Oladele Abiodun Balogun and Ezekiel Mkhwanazi. According to Oladipo, the task of African philosophers is to be committed to fulfilling their scholarly obligations to their societies. Their primary task should be to begin to create a tradition of thinking and discourse whose main

focus would be on issues affecting the interest and aspirations of the people (Oladipo, 1992: 28; Balogun, 2007: 12).

Such a commitment is surely important, one might respond – but so much for the work of African epistemologists, logicians, philosophers of science, etc. What may be a cause for concern is not only the instrumentalization of philosophy, in other words, the implicit or explicit denial that philosophy has any inherent value, but also the fact that philosophers are presented with a specific task. They are being prescribed with regard to what their intellectual labor should amount to or have as an object. Of course, one might argue that the cognitive, critical, and creative development of ordinary Africans has an important ethical dimension. Clearly it has, but the net effect of such a move would be the dilution of ethics and ethical. Perhaps this is a concern philosophers of education are happier to live with than pure philosophers.

The legacy of colonialism

In the 1990s, with globalization, free enterprise, and unprecedented availability of information, education, knowledge, and learning capacity were identified as key factors of development in Africa. In terms of global educational development, however, Africa remains the taillight, by some distance (Hofmeier and Mehler, 2004: 36–39, *Bildung*).

According to Táíwò (2007), colonialism is to blame for Africa's predicament (and this distinguishes colonialism on the African continent from colonialism elsewhere, that is, in countries that have since become industrial, financial, and even agricultural powerhouses) insofar as it failed to prepare Africa for modernity or modernism.

In this regard, however, it may be worthwhile to consider Axelle Kabou's counter-argument (Kabou, 1991), on the blameworthiness not only of autocratic rulers, traditional leaders, and corrupt elites but also (and especially) of ordinary Africans, that it was ordinary Africans who refused development, who rejected modernity. Moreover, one might ask whether Táíwò is talking about all colonial powers. As divergent as they were, did they all commit the same crime of nonrecognition? According to Táíwò, all had Africans occupying the lowest rung of the human ontological hierarchy. His response to Kabou would presumably be: How could ordinary Africans reject what they did not have access to? Yet, what makes Kabou's account so compelling (her failure to proceed more subtly notwithstanding) is that it takes ordinary African people seriously, as individuals and agents in their own right, and not just as helpless victims, will-less instruments manipulated by the powers that be.

The Promise of African Philosophy of Education

While African philosophy of education possibly errs in postulating distinctly African knowledge (systems), truth,

and values, its uniqueness is arguably constituted by its educational priorities – priorities that exist, at best, to a lesser extent (if at all) elsewhere.

A plausible view appears to be that African philosophy of education shares a range of concerns with philosophy of education elsewhere and that there is a distinctive set of concerns in African philosophy of education, arising from particular historical and sociopolitical circumstances. Thus, it might be claimed that African philosophy of education has different priorities to philosophy of education elsewhere. If it is correct to argue that philosophical and educational priorities will emerge from life experiences and from the ways these are socially articulated, then one might assume that, given that the life experiences of Africans on the African continent are commonly different from those of educators and learners elsewhere, the philosophical and educational priorities will also differ.

Given, for example, the experience of indigenous Africans of physical and mental oppression, it stands to reason that African philosophy of education would have as priorities matters of transformation and redress in education. If philosophical and educational concerns and priorities arise from different forms of social life, then those that have emerged from a social system in which a particular race or group has been subordinate to another must be suspect (see Horsthemke and Enslin, 2009). In addition, given the (especially vicious) history of physical and psychological colonization, it is plausible that one of the educational priorities will be to educate against development of a subordinate or inferior mindset, as well as against a victim and beggar mentality despite the continuing economic crisis and low level of economic growth. Given, too, the ravages of the disease on the continent, HIV/AIDS education has special resonance in (sub-Saharan) Africa: the pandemic does not only snatch away teachers; it also leaves children infected and/or orphaned. An additional priority arises with Africa's low literacy quotients. In many countries, the language of education is the official language of administration: English, French, or Portuguese, in which the majority of children and learners are not competent. Consequently, there exist few successes in learning; quality and efficiency suffer; and high repeat and dropout rates mean a squandering of available resources. While it does not follow that particular historical and socioeconomic circumstances yield or bestow automatic validation or justification of the content and objectives of African philosophy of education, ideas like decolonization of the African mind have a particular resonance here: going back to one's language to think about thinking, to examine one's own ways of conceptualization – in short, to philosophize (Wiredu, 2007).

The promise of African philosophy of education, then, has in part to do with context and locality – but not in terms of any exclusionist, hands-off approach. Rather, it appears to be plausible that the particular historical,

geographic, and sociocultural experiences of Africans give rise to particular priorities that shape African philosophical theory and practice – and also yield conceptual tools that are likely to enrich philosophy of education elsewhere: the idea of mental decolonization, the modeling of humanity, and reconciliation/forgiveness.

Feminism

L Stone, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Education feminism – Bounds and emphasizes the interdisciplinary presence of feminist theory and activism in professional education.

Feminisms – Named in the plural, rather than feminism, this has been used to highlight, theoretical difference, diversity, distinction, and significantly, differentiation.

Feminist movement – Defined across history as entailing both activism and theory.

Introduction

If one were to ask young Western women, particularly those white and middle class, about feminism today, many would respond that they are not feminists – and that there is no longer any need. This is because many women around the world have assumed leadership positions, girls are attending and doing well in school, and both have achieved some degree of security. These marks of equality mask and indeed belie daily struggles still being fought by women and girls, by minorities, the poor, and those residing especially in the third world. Issues, for instance, fear of violence, comparable occupational worth, and conditions and responsibilities of child rearing, are based in discrimination and affect countless females.

The article serves as a reminder that, historically, feminist endeavors were necessary and remain necessary today and feminists (both women and men) know this. Activism and theory exist everywhere. The present focus is on Western, primarily North American theory, rather than activism and theory across the planet (see Goodman, 2004). Acknowledged is the limitation of the author's experience and knowledge, but alongside is the important recognition that each nation, perhaps regions and cultures, have their own feminists whose work is represented herein, albeit very inadequately. Readers are admonished to explore their own lives through those who study and write specifically about them.

The stance of this article is strongly supportive of feminism. While anti-feminist sentiment is mentioned, how could one not support this basic idea: "[Feminism names] a movement for creating a society in which women can live . . . [full self-determined lives]" (Houston, 1996: 215). Feminist theory in what follows is characterized through a

thematic of differentiation, seen as strength. The meaning of differentiation expands across the article, always difference with various formulations of complexity. Today several aspects are central: first, potential of common projects across uncommon histories, experiences, even needs; second, continuity within differences across times and theories; third, commitments not only to individual self-interests but to other interests as well (see Stone, 1995). A central premise is that contemporary politics – the aim of theory – often is engaged across difference.

Overall, this is an overview of feminist theory for philosophy of education, its scholars, teachers, students, and interested public. For this audience, education is constituted of our professional world (institutions of education, undergraduate and graduate programs, teacher training, and the like) even as we draw from sources outside. Again a key premise is that ultimately our work in education must draw sustenance largely from sources within: educators must be agents of change.

Three differentiating frameworks are presented in this article. The first section takes up 'wave feminism,' cross-disciplinary in nature tying feminist theory and philosophy to inquiries that span sciences, social sciences, humanities, and arts. Another section overviews 'feminism in philosophy,' intradisciplinary in character organizing theory relative to modern philosophical traditions. The third section on 'feminism and education' turns specifically to potential frameworks in professional education. A final substantive section is especially important for philosophy of education as it considers the current state of feminist philosophy of education. Throughout what follows examples and exemplars are incorporated; also many references and some additional readings are included to stimulate further inquiry. Finally, the article has been enhanced through contributions from Allison Anders, Ann Diller, Susan Franzoza, Barbara Houston, Nel Noddings, and James Marshall.

To begin, one more framework initiates the discussion: it is the 'history of thought,' serving as a pre or supra frame. Surely it is historically accurate to suggest that across recorded time writings by and about women have been compared to those by and about men. These binary comparisons of difference – but not differentiation – typically established a hierarchy of men over women, of any aspect of life and culture identified with the male over that of the female. Feminist responses to these comparisons have assumed two basic forms, one protesting misogyny and the other promoting equality (rarely superiority). Philosophical treatments often have focused on concepts of human

nature, woman, and rationality. Today millennial writings by women are available but obviously this has not always been so (Mahowald, 1978, 1983; Waithe, 1986–95). In a significant study of patriarchy, Lerner offers the general observation of women's exclusion from "creating symbol systems, philosophies, science, [law, indeed] theory formation" (Lerner, 1986: 5). Referencing philosophy specifically, she points to conditions needed by women scholars: economic independence, educational opportunity, and role models (Lerner 2000; also Witt, 2000/2007).

Framework One: Wave Feminisms

A now-standard cross-disciplinary framework for describing feminism is waves. The general agreement on dates that encapsulate both activism and theory are these: the first wave in the nineteenth and early twentieth centuries, the second wave in the 1960s and 1970s, and the third wave to the present. Across the waves, movement has been toward differentiation, first from sameness to difference and then to dispersion in terms of identities, societal needs, and politics both between women and men and among women.

The first wave feminist theory developed in North America and Europe as part of the movement of liberal enlightenment. Jaggar (1983) pinpoints seventeenth-century England as the birthplace of modern feminism; the term is originally French from sociologist Charles Fourier (see Houston, 1996: 216). The initiating activist emphasis was women's suffrage, at first aligned with movements in abolition, temperance, and workers rights that involved both majority and minority women. Grants of franchise before and by 1920 were recognized as successful culmination of the first wave in various sites – in Britain, the USA, Western Europe, Scandinavia, Australasia especially New Zealand, and Russia. Historic hindsight perhaps indicates a stronger bond between activism and theory in this wave than in the subsequent ones.

Two exemplars illustrate themes of the first wave: Historic bookends, writings from Mary Wollstonecraft, and Simone de Beauvoir are now part of the feminist canon. In the late eighteenth century, in *Vindication of the Rights of Women* (1792, 2006) and *Thoughts on the Education of Daughters* (1787, 1977), Wollstonecraft (1777, 1787, 1792, 2006) builds on rights theory to posit the value of women's place in the private sphere while promoting public co-education (see Richardson, 2002). In mid-twentieth century, Beauvoir locates women's subordination in gendered culture, attends to psychological and sexual normality, and moves women more into the public sphere (see Andrew, 2003). Her classic text is *The Second Sex* (1949/1952). Of note, theoretical discussion continues every today of relationships of these women writers to Locke and Sartre respectively.

The second and third wave feminism/feminisms are developments from and responses to the first wave and to each other; significantly critique has become commonplace.

Once the valuing of diversity was established, several specific trends of differentiation have been apparent: a first is to add to the conventional first wave liberal formulation of women's equality, comparing them to men in terms of deserved resources and positions as well as acknowledged contributions and competencies. A central reconsideration is of nature and capacity (Kroløkke and Sørensen, 2006: 5–6). Part of the first trend also is to radicalize theory through first offshoots. New categorizations then constitute a second trend. By the early twenty-first century, listings account for groupings drawn from activist movements and ideologies, identity and identity politics, theoretical and academic traditions, and cultural and time-bound origins. Memberships and labels, writes Tong about the latter, remain useful as they not only highlight diversity but also point to a significant idea "that, like all other time-honored modes of thinking, feminist thought has a past as well as a present and a future" (Tong, 1998: 1). Examples of labels include socialist, psychoanalytic, eco-feminist, postmodern, and global feminism. A third trend is the emergence of nonmajority feminist theorizing. For example, in the USA groupings include Black, Womanist, and African-American, Latina and Chicana, Asian-American and Native as well as multicultural, and Lesbian feminisms (Tong, 1998, Kravetz and Marecek, 2001).

Differentiation continues into the present day, first, in extensions by Third World, global, and international feminisms based in particular interplays of factor effects (e.g., of colonialism, nationalism, religion, and gender) (Enns and Sinacore, 2001). Second, distinctions are emerging from young feminists in their responses to current societal conditions that they see as different from those past. Third, a feminist backlash and desire to retain more traditional but threatened gender practices is also manifest (Sommers, 1995). Finally, related to these developments, a post-feminist stance whose use is ambiguous is named. This ranges from broad rejection to broad inclusion of feminism, from no longer seeing any need to positing contributions from the lives of women for all (see Coppock, 1995). Still another tradition is post-structuralist through a variety of theoretical particularizations primarily from postmodern, continental writers and fellow travelers (e.g., Oliver and Walsh, 2004).

Across the last several decades, wave feminists have not only written individually and contributed to and been part of commentaries, but also have been collected in general and topical texts that have defined and furthered the broad theoretical field. Two early, classic examples of the latter are *This Bridge Called My Back: Writings by Radical Women of Color* (Moraga and Anzaldúa, 1981; also Anzaldúa and Keating, 2002) and *Discovering Reality: Feminist Perspectives on Epistemology, Metaphysics, Methodology, and Philosophy of Science* (Harding and Hintikka, 1983, 2003). The first exemplar section below spotlights writers from feminist theory in 'frameworks one and two'; see also the Further Reading section.

Framework Two: Feminism in Philosophy

Locating feminism in the discipline of philosophy, framework two is the basic organizational structure employed by the *Stanford Encyclopedia of Philosophy* (hereafter *Stanford*). As Tuana points out, a contributing influence in feminist philosophy has surely been philosophical training. In this framework, the basic theoretical debate over scholarly relationships of women with men and with other women continues. However, differentiation now becomes distinction as differences in traditions establish bounded approaches to shared concepts and topics and as diversity is most often the purview of individual philosophers (see also Haslanger and Tuana, 2003, 2004). Three approaches are central: analytic, continental, and pragmatist (*Stanford* also includes two intersections, analytic and pragmatist each with continental). Philosophical considerations of method, history, context, politics and social justice, as well as such categories as woman, gender, sex, identity, and subject are distinguished.

Analytic feminism has roots in the tradition of Anglo-American analytic philosophy, in the work of such important philosophers as Frege, Russell, and the early Wittgenstein. Significantly nonpositivist, Quine, Austin, and the later Wittgenstein are important current sources. Most theoretical emphasis has been in epistemology, philosophy of science, and metaphysics and less in political and moral philosophy. Method, subareas of philosophy, and standpoints also are significant. Garry writes that out of the analytic tradition, topics taken up by feminists have been naturalized, socialized, and otherwise have modulated earlier, more abstract treatments (Garry, 2004: 2). Among well-known members are Code, Harding, and Logino.

Continental feminism has roots in the tradition of European continental philosophy developing out of Kant, Hegel, Nietzsche, Freud, and Heidegger. It is itself constituted as a set of evolving subtraditions that include phenomenology, structuralism, and deconstructionism. Like classical pragmatism to follow, each principal theorist can be understood as writing particularist social theory. Of course, epistemology has mattered but perhaps more so have ethics and politics. Cahill (2005) writes that Foucault and Derrida have had the strongest recent influence. Among its members are earlier, Arendt, and more contemporary, Kristeva and Irigaray.

Pragmatist feminism has its roots in the American classical pragmatism of Dewey, James, and Addams as well as progressives such as Gilman and Cooper. Whipps characterizes the approach thus: “For these thinkers, philosophizing was an active process, both as a way to change social realities and to use experience to modify the philosophies themselves” (Whipps, 2004: 1). In this tradition, theory and practice are especially unified; epistemology is dominant, used to further justice and democracy. Its

members include Seigfried, Minnich, and Sklar. Of the three *Stanford* approaches to feminism in philosophy, this is the least developed and known.

Recent Exemplars One

Much contemporary writing by feminist theorists, and especially philosophers, is published worldwide, making it visible and influential. In this section, the writings of three exemplars point to rich theoretical differentiation. Each feminist, in her own way, takes up issues such as race and ethnicity, sex and gender, colonial and postcolonial cultures. Each writes from a feminist orientation and also contributes to theory broadly. All reside in the USA but have strong international appeal. The three are Bell Hooks, Judith Butler, and Gayatri Chakravorty Spivak.

First, American hooks writes on feminism in the context of cultural criticism and activism. In an early work, *Feminist Theory: From Margin to Center* (hooks, 1984), she focuses on relations between black and white women. She asserts, “[privileged] feminists have largely been unable to speak to, with, and for diverse groups of women because . . . [they cannot take the interrelationships of various oppressions] seriously” (Hooks: 14). Later, generally inspired by Freire, she is more inclusive, theorizing across diverse groups for a pedagogy of hope (Hooks, 2000; 2003). Second, in more technical writings from the nineties, American Butler is very instrumental in fueling new movements such as queer and transgender politics (see (Kroløkke and Sørensen, 2006; also Salih, 2004). Writing initially on Hegel, much of her theorizing shows a debt to Foucault; the major text is *Gender Trouble: Feminism and the Subversion of Identity* (see Butler, 1990a). In an essay on pornography and feminist politics, her critical warning is this: “[The real can be understood] as a variable construction which is always and only determined in relation to its constitutive outside: fantasy, the unthinkable, the unreal” (Butler, 1990b, 2004, pp. 185–186). Third, Spivak continues interests in politics as hooks and Butler and the latter’s technical philosophy. Indian born, she was first to translate into English and has been influenced by Derrida. In her postcolonial writings, emblematic in “Can the Subaltern Speak?” she offers, “In seeking to learn to speak to (rather than listen to or speak for) . . . [this] historically muted subject . . . the postcolonial intellectual systematically ‘unlearns’ female privilege” (Spivak, 1988, 1994, p. 91, emphasis in original; also Spivak 1984, 1990; and Landry and Maclean, 1996). For each exemplary feminist, theory facilitates acceptance of provisional certainties in lives both local and global.

Framework Three: Feminist Theory and Education

Feminist theory in education generally has aligned itself with frameworks, trends, and categories in the larger

academy. The principal difference, of course, is a focus on education. Feminists have focused on public and professional activism, others on empirical gender studies, and still others on higher and adult education or pre-collegiate schooling. Writings in feminist theory span the frameworks discussed above, from histories of women's education to specific philosophical connections. Writings on education have been found across time while modern feminist theorizing was initiated by educators beginning in the 1970s. A recent statement in *Stanford*, from above, acknowledges the latter history. By the early 1980s, as Phillips puts it, "feminist philosophers of education were finding their voices" (Phillips, 2008). In this volume on philosophy of education, two potential categorizations for intersections of feminist theory and education are education feminism and feminist philosophy of education.

The category of education feminism was coined in the interdisciplinary text, *The Education Feminism Reader*, to call attention to the place of feminism in professional education (Stone, 1994; Dillabough, 2006; see also Stone, 1997). It remains today the only collection of feminist theory in professional education. To name this theoretical domain, the book's introduction makes several claims: one, a field exists in its own right; two, its scholarship is both derivative and originaive as is all scholarship; and three, professional education incorporates topics related to feminism and also to the discourses, organizations, and practices of education itself. In the text, categories include self and identity, education and schooling, knowledge, curriculum and instructional arrangements, teaching and pedagogy, and diversity and multiculturalism. Although a second volume of readings has not been published, since the mid-1990s the field has continued to develop and evolve. Differentiation not only follows the waves above but also as part of subdisciplines in education such as women's history of education, feminist pedagogy, social sciences theorizing, and research methodology. Majority and minority feminists continue to publish with the latter demonstrating significant development (see, e.g., Bernal *et al.*, 2006).

In a recent essay, Nel Noddings (2009) prefers two centers of concentration in feminist philosophy of education. Cutting through waves theory, these are women's oppression and women's agency. Within each she identifies suborganizations to retain "a kind of philosophy, not a female or feminine activity" (Noddings, citing Walker, 1995, draft p. 2). In oppression, Noddings provides useful discussion of discrimination and potential danger for feminist philosophy and its practitioners, from writings on women's experiences and traditional domains within "the world created by men" (p. 9), and in critiques of the philosophy and of science. Her feminist agency incorporates emphasis on women's cultures, specifically in attending to relation, responding to needs, facilitating familial care, and accepting social responsibility. In her own significant contribution, feminist philosophy and education come together in

connections between care theory and moral education. For this article, feminist philosophy of education might usefully be defined as a subfield of education feminism.

Recent Exemplars Two

Finding voice in feminist writings in education, three American mothers are widely known: Maxine Greene, Jane Roland Martin, and Noddings. They have led now more than one generation of feminists writing in education; indeed, writing in philosophy of education has grown exponentially into the twenty-first century (see Leach, 1991). Each writes critically about education and schooling and each remains scholarly and professionally active today.

Greene is known for her interests in the arts, multiculturalism, pedagogy, and curriculum, and to value the lived lives of all (see Greene, 1978, 1988). Her acknowledged roots are in Dewey, existentialist writings, and often literature. In a 1988 chapter promoting public lives of women, a key theme of freedom links literature, poetry, and specific histories of women leaders. She writes, "[freedom] cannot be conceived apart from a matrix of social, economic, cultural, and psychological conditions. It is within the matrix that selves . . . are created through choice of action in . . . changing situations" (Greene, 1988: 80). Culminating decades of writing, in a 2003 piece co-authored with Morwenna Griffiths, she turns to the personal: "I find myself often perplexed by what feminism signifies for me today – although I am fearfully aware of the old men of the sea, the survival of patriarchal warnings underlying and often crowding out the sound of whatever little story I have to tell" (Greene and Griffiths, 2003: 80).

Distinct from the existential, pragmatist, and phenomenological orientations of Greene and next, Noddings, Martin brings skills from analytic philosophy to women's history within philosophy of education. In addition to the education of women, her interests include broad questions of liberal education, schooling and curriculum. Martin's (1985, 1992) analysis, *Reclaiming a Conversation: The Ideal of the Educated Woman* (1985) remains today a singularly unique contribution. This was followed by an important text, *Schoolhome* (1992); recent writings concern issues of identity and culture (Martin, 2007). In the first text, she establishes a connected conversation through Plato, Rousseau, Wollstonecraft, Beecher, and Gilman. Her position is this: "If conversation about women's education is to be incorporated in the history of educational thought, the definition of that discipline's subject matter must be expanded to include the processes of society with which women's lives have . . . been intertwined" (Martin, 1985: 179).

Noddings's (1984, 1989b) feminism is best known through her career contribution to an ethics of care. Additional interests include curriculum and schooling reform, with recent attention to the potential of women's lives and

cultures. Her classic book, *Caring* (1984) is subtitled 'A feminine approach'. By her next work, *Women and Evil* (1989b), she continues to pay attention to women's experience through working along with and responding to feminist theory. In a 1989 piece republished in 2002, she offers a direct statement of her feminism, naming it social or maternal with forebears that are radical and psychoanalytic. She explains, "This perspective acknowledges that there are still substantial differences between men and women including differences in their views on moral life . . . [Many of them are traced] to centuries of different experience" (Noddings, 1989a, 2002, pp 102–103). As indicated, part of her project is to highlight significant elements of women's lives that "may help all of us lead better lives" (p. 107).

Current Considerations

At the outset of this article a present belief of Western, privileged, and largely majority women that repudiates feminism is reported. This occurs alongside the continued flourishing of feminist theory in the academy broadly and its development in education. Focusing on feminist philosophy of education, a current status check reveals three central aspects: First, feminist theorists in education read their sisters in the academy but the family is dysfunctional and there is little reciprocity. Second, the mothers largely remain emblematic although there is some recognition of progeny and of theoretical dispersion. Third, the state of feminism in philosophy of education is still relatively weak in a field in which shared recognition and governance with male colleagues is still emerging.

A focused comparison between feminist philosophy and feminist philosophy of education assists current assessment. Once again, a USA context is presented, acknowledging its limitations. Feminism in the academy is certainly here to stay even with occasional battles over Women's Studies programs. In philosophy, even minority numbers as faculty cannot obviate the sheer number of potential positions in collegiate departments. Of significance is the Society for Women in Philosophy, with active groups in all divisions of the American Philosophical Association (with a British counterpart). Other philosophical associations have a strong women's presence as well. Moreover, publication by feminist philosophers is renowned everywhere both by individuals and collectivities. Over 500 references in the *Stanford Encyclopedia of Philosophy* referenced above is itself testament. These references, publications, and faculty interests also point to field differentiation found across disciplines.

With growing numbers of publications and presentations since the late 1970s, the state of feminist philosophy of education is nonetheless much less prominent than in the discipline. Finding voice has resulted in some key placements in philosophy of education but most of the positions are filled by men. Feminist philosophers most often teach

in other education domains, particularly teacher or perhaps multicultural education. Another positive sign is leadership presence; women presidents of the Philosophy of Education Society (of North America) have become nearly commonplace. There is also a women's caucus. Many education associations are led by women where feminism appears not to matter. One arena in which feminist presence seems minimal is in specific courses or as notable inclusion. It might even be that there is less reading and studying of feminist theory today than in recent decades. Given girls' success in schooling, gender is passed over in favor of less controversial issues.

Publication presence is mixed. Most of the significant work has come from the mothers although second- and third-generation scholars are producing theoretically important work (e.g., Todd, 1997; Boler, 2003). Recent collections in philosophy of education have included a few women authors but the general pattern is one feminist piece per collection. Kohli's (1995) text, *Critical Conversations in Philosophy of Education*, is an exception (see Blake *et al.*, 2003; Curren, 2007; Siegel, 2009; also Kohli and Burbules, 2009). The most promising development is that today's feminist philosophers of education have diverse theoretical backgrounds and interests that mirror academic counterparts – feminist sisters could well learn from them! (see Li, 1993; Rice, 1999/2008; Titone and Maloney, 1999; Enslin, 2003; Stone, 2004). This seems a mark of field maturity, although one notes that there are few collections that substantiate the larger academic field.

Conclusion

Feminism, as this article attests, needs to be seen as central to intellectual and political life and to philosophy and philosophy of education. As frameworks indicate, it is characterized by various forms of historically evolving theoretical differentiation. What is significant here, of course, is that girls and women must continue to struggle both in the west and elsewhere; a world free of gender bias remains an ideal. Feminist theory in the academy and in education itself has much to contribute to its realization.

Hermeneutics

C Bingham, Simon Fraser University, Burnaby, BC, Canada

© 2010 Elsevier Ltd. All rights reserved.

Hermeneutics, in its most general meaning, is the art of interpretation. And while philosophy of education has only recently taken up hermeneutics with keen interest, it might be said that it has always been educational, in the sense that one way to become educated about something is to learn how to interpret it. That said, philosophical hermeneutics, especially as has been articulated by Hans-Georg Gadamer, has greatly enriched educational philosophy (Gadamer, 1994, 1976). Gadamer's account of hermeneutics goes far beyond the art of interpretation, offering insight into a central educational concern – human understanding. In what follows, the educational significance of Gadamer's hermeneutics will be detailed. In addition, precedents and related hermeneutic theories will be sketched.

Hermeneutic Precedents

Any educational account of hermeneutics should first take into consideration its rich history. Hermeneutics had its beginnings in, and still owes much of its educational importance to, the interpretation of texts and other symbolic messages. Those beginnings date back to ancient philosophy, with a primary example being Aristotle's work, *On Interpretation*, or *Peri Hermeneias* in Greek. The word itself derives from the Greek *hermeneuein*, meaning to interpret, translate, or express. As an example of its Greek use, one finds Plato calling poets the interpreters (*hermenes*) of the gods. In addition, hermeneutics has long been associated with religious and legal interpretation. Thus, one can place such a figure as Philo of Alexandria (ca. 20 BC–ca. AD 50), who allegorized Old Testament scriptures, in the tradition of hermeneutics. One can also place Christian thinker St. Augustine (354–430), medieval interpreters of the Torah, as well as Protestant reformer Martin Luther (1483–1546) in this tradition.

However, with the advent of modern hermeneutics, especially since the Romantic period, the scope and function of hermeneutics has widened to include elements that go beyond symbolic interpretation. German philosopher Friedrich Schleiermacher (1768–1834) was primary in establishing a system of hermeneutic thought including interpretations of all sorts – religious as well as secular – and widening hermeneutics to include psychological, social, historical as well as linguistic elements (Schleiermacher, 1998). Schleiermacher, who is an influential figure in Gadamer's central text, *Truth and Method*, lectured on

hermeneutics between 1805 and 1833. Among the many hermeneutic themes stressed by him, the following are especially significant: first, the interpretation of an author's words is both a matter of language usage and a matter of individual meaning. That is, one cannot correctly interpret the work of an author by simply knowing what the words he or she used meant at the time they were written. How the author intends words to be is as important as what the words mean in general. Second, misunderstanding a text is likely. It is not likely that the interpreter will understand a text through-and-through given historical, cultural, and psychological differences between author and reader. Third, hermeneutics can be applied to texts of all sorts – secular as well as religious, poetic as well as nonpoetic, foreign-language as well as first-language. Implicit in this third statement is that misunderstanding happens even when communicants share the same language. Fourth, the interpreter may not rely on higher principles such as divine inspiration to guide his or her interpretation, even where religious texts are concerned. These themes, and others, demonstrate how Schleiermacher made hermeneutics into a more general, holistic art of interpretation.

Generally acknowledged as the prime inheritor, and major innovator, of Schleiermacher's hermeneutics, Wilhelm Dilthey (1833–1911) contributed to the philosophical project of interpretation with a general theory of human existence (Dilthey, 2002). According to his understanding of human existence, and especially in his later works, Dilthey introduced a two-pronged description of existence in terms of *erlebnis* and *verstehen*. Regarding *erlebnis* or life, H P Rickman has noted, "The principle that we cannot go behind life is a keystone of Dilthey's whole philosophic position, which is usually described as a philosophy of life" (Rickman, 1963: 15). Whether one is undergoing a humanistic, social scientific, or physical scientific interpretation, one can never escape the horizon of life in order to study that horizon. One's entire experience of life is always implied in every act of interpretation.

A discussion of Schleiermacher and Dilthey brings us to the ontological hermeneutics of Martin Heidegger (1889–1976) (Heidegger, 1962). If Dilthey can be said to have universalized hermeneutics by giving it grounding in the totality of human experience, then Heidegger can best be described as radicalizing this grounding to the point where hermeneutic interpretation is, itself, human experience. By way of describing this radicalization, it is useful to draw on the often-used metaphor of the hermeneutic circle. For Schleiermacher and Dilthey, the hermeneutic circle is

a way of describing the interpretive method of oscillating between the part and the whole. Following this method, the reader (or any interpreter) must interpret each passage (the part) only in relation to the entire work (the whole). He or she must, in turn, interpret a work (the part) only in relation to an entire opus (the whole). And with regard to meaning, the reader (again, any interpreter) must take care to consider the author's intention (the part) as just one element of a larger social/historical context (the whole). Once this circular method has been used, one is finished with the hermeneutic circle until the next exercise in interpretation. In contrast, Heidegger claims that humans are always interpretive beings. Being, itself, gets enacted interpretively. As such, it does not make sense to say that one can step out of the hermeneutic circle since hermeneutic understanding is something human beings do even prior to employing a particular hermeneutic method. This ontological condition of already being inside the hermeneutic circle will be continued in the work of Hans-Georg Gadamer. In fact, Gadamer's entire project of philosophical hermeneutics is most indebted to the work of his teacher, Martin Heidegger.

Heidegger's hermeneutics articulates a difference between the Cartesian objectification-through-reason and a more fundamental, tacit experience of the world that typifies human understanding. Human beings, as part of what it means to be human, find themselves already thrown into a world where things, actions, and intentions are pre-understood. This is why human beings are already interpretive beings. Human beings have pre-conceptions, pre-understandings, and pre-interpretations that are not, under everyday circumstances, subject to questioning. Thus, a hammer, for example, is already pre-understood, pre-interpreted as a hammer, but as such its hammer-ness is not thrown into question. There may, however, be a point when the hammer ceases to function as a hammer. In such a situation, the hammer's hammer-ness may be thrown into question. And so it goes with interpretation of texts and human utterances. Heidegger brought to the hermeneutic project a keen awareness of the pre, of the tacitness of most human experience including the tacitness of textual interpretation. Thus, the question of interpretation is not whether to interpret or how to interpret. It is not a matter of applying some method to the object under interpretation. It is rather a matter of how to foreground, to subject to question, one's tacit interpretations.

Also central to Heidegger's contribution to philosophical hermeneutics is his concern with language itself, with its place in the landscape of human being, rather than with its supposed role as a symbol that conveys human meaning. Heidegger's famous statement that "language is the house of being" intimates this linguistic concern (Heidegger, 1999). At least since Aristotle's *Peri Hermeneias*, language had been seen as a symbol system to be interpreted in order to find an author's, or speaker's,

meaning. Especially in his later work, Heidegger turned this instrumental understanding of language around, asserting that human meaning-making dwells within language. Language is not a tool used by human beings. It is rather a way that human beings turn together to understand something. Language is thus a way of being together while paying attention to how the world presents itself to us. Language is not something to get through in order to interpret the more serious matter of an author's, or speaker's, meaning.

Related Hermeneutic Theories

Given the ancient and modern precedents of hermeneutics, it is possible to note some general hermeneutic themes. These themes will be helpful for understanding various branches of recent hermeneutic thought. First, hermeneutics has long been concerned with how the interpreter might throw a text or utterance into question and thereby problematize the received interpretations of that text or utterance. Second, hermeneutics has been concerned, to varying degrees, with how the world-historical situation of a text or utterance informs one's interpretation of that text or utterance. Third, hermeneutics has paid close attention to the role of language during the interpretive act. Fourth, hermeneutics has long been concerned with the uses and abuses of disciplinary thought. While it began as a practice of textual interpretation focusing mainly on religious, poetic, and legal texts, hermeneutics has been universalized as of late. These themes can be used to distinguish between four major branches of modern/postmodern hermeneutics: conservative, critical, radical, and moderate.

Conservative Hermeneutics

Most commonly identified with the work of E D Hirsch Jr. and Emilio Betti, conservative hermeneutics traces its lineage from the confidence of Romantic hermeneutists Schleiermacher and Dilthey, a confidence that carefully applied hermeneutic method would yield the objective truth of a text (Hirsch, 1967). With regard to hermeneutic questioning, the conservative approach asks not whether a text has a unified meaning but rather what that unified meaning is. About conservative hermeneutics, Shaun Gallagher has observed,

These theorists would maintain that through correct methodology and hard work the interpreter should be able ... to break out of her own historical epoch in order to understand the author as the author intended ... to reach ... objective truth. (Gallagher, 1992: 9)

This is to say, the world-historical situation of the object under study can be grasped given due diligence, and such a grasp will shed helpful light on the true meaning of that object. On this version of hermeneutics, language is

primarily a symbolic representation of an author's meaning. That is to say, language reveals, but does not constitute, the meaning of an author, as well as the author's historical/cultural situation. Reality is one thing; language is another. A methodically rigorous study of language yields objective knowledge of reality. And with regard to disciplinary knowledge, traditional hermeneutics, while it does not restrict the scope of hermeneutics to one or another discipline, uses disciplinary boundaries and specific disciplinary knowledge to enhance the fit between interpretive method and the object under study.

Critical Hermeneutics

Carl-Otto Apel and Jürgen Habermas typify the critical branch of modern hermeneutics. Also described as depth hermeneutics, critical hermeneutics hails from the Freudian/Marxist tradition of the Frankfurt School (Habermas, 1985). Following criticalist principles, there are always two main roadblocks standing in the way of a more accurate interpretation. The first is psychic interference and repression. The second is ideological obfuscation stemming from unjust economic practices. Both of these cloud one's understanding of the object under study to the point where it becomes falsely interpreted. In order to attain an accurate interpretation, psychic interference and ideological obfuscation must be eliminated.

Critical hermeneutics remains fairly sure about which meanings are in need of questioning. The meaning of a text or utterance is questioned, but primarily in regard to psychic and ideological obfuscations. Once these roadblocks are questioned and exposed, the text itself becomes available in all its truth, not unlike the truth revealed by conservative hermeneutics. Regarding world-historical situation, the underlying Marxist orientation of critical hermeneutics once again informs the interpreter's work. While the cultural and historical circumstances of the object under study are significant, more significant are the ways that such circumstances tend to conceal, especially through the workings of capitalist ideology, the ability of the text or utterance to speak its truth. Following the critical hermeneutics of Habermas in particular, language supplies an ideal speech situation only when it has first been purged of ideological and psychic misunderstandings. Thus, Habermas, in his debates with Gadamer, argued that it is naïve to trust language without first purging its ideological underpinnings. A critical understanding of disciplinary knowledge insists, primarily, that no discipline is more objective than another. Even the physical sciences are riddled with ideology and thus require critical, depth hermeneutics.

Radical Hermeneutics

Inspired especially by the genealogical observations of Friedrich Nietzsche, radical hermeneutics is associated

with the work of Michel Foucault and Jacques Derrida, among others. Radical hermeneutics rejects any steadfast grounding for interpretive endeavors (Foucault, 1995; Derrida, 1974). Showing neither confidence that objective truth can be obtained through sound interpretive method nor that truth lies ready to be uncovered once ideology has been unmasked, radical hermeneutics looks to interpret interpretation itself. In so doing, radical hermeneutics rejects the canonizing tendency of most interpretive endeavors, challenging the very borders of the objects it studies. Whereas traditional, moderate, and critical hermeneutics offer various ways of interpreting an object, radical hermeneutics, as it carries out its interpretations, challenges the integrity of the object itself.

This challenge to the object itself can be seen in the ways that a work is put into question. For example, Derrida is famous for stating that "*il n'y a pas d'hors text*" (Derrida, 1988). Roughly translated as "there is nothing outside of the text," this statement typifies the way that Derrida questions his objects of interpretation. Instead of accepting the integrity of an utterance or a text, Derrida often shows that a text almost always unravels precisely what it seems to mean. This is to say, a text cannot keep itself under control. It cannot keep to itself and thus has no true outside or limit. As for the world-historical situation, radical hermeneutics posits that such situations must themselves be subject to interpretation. Foucault, in his early work, posits the existence of epistemic regimes that underlie the ways that it is possible to interpret a world-historical situation. In other words, a historical situation should not be understood at face value because such an understanding does not take into account the sorts of tacit knowledge-claims underlying such a situation in the first place. There are thus clear links between Heidegger's emphasis on tacit-ness and radical hermeneutics. Where language is concerned, radical hermeneutics once again puts interpretation itself under interpretation. Foucault, for example, denounces what he calls the "reign of the signifier," where words are too easily mistaken for the things and ideas they seem to represent. For radical hermeneutics, the very link between words and ideas cannot be taken for granted as power and linguistic slippages undermine such a link at every step. As one might expect, radical hermeneutics is not a friend to disciplinary knowledge. While Foucault posits that such knowledge is no more than a ruse of power, Derrida has almost single-handedly blurred disciplinary distinctions between philosophy, theory, literature, and law, just to name a few.

Moderate Hermeneutics and Educational Thought

Moderate hermeneutics can be understood as a continuation of Heidegger's ontological hermeneutics, but without

the mistrust of the object under study that characterizes radical hermeneutics. Moderate hermeneutics has confidence that texts and utterances have something fairly unified to say to the interpreter. Paul Ricoeur and Hans-Georg Gadamer are primary thinkers along these lines, and Gadamer has been most influential with regard to education (Ricoeur, 1974, 1981; Misgeld and Nicholson, 1992). A detailed, thematic exploration of Gadamer's work indicates its educational usefulness at the same time that it illustrates central tenets of moderate hermeneutics. Though it should be understood that moderate hermeneutics in no way exhausts the scope and function of hermeneutics in its other forms (conservative, critical, and radical), the educational implications of moderate hermeneutics will be used here to illustrate the significance of hermeneutics more generally. The four themes of questioning, world-historical situation, language, and disciplinary knowledge are once again used for illustrative purposes.

Questioning

Questioning is central to any attempt at interpretation; and more specifically, hermeneutics distinguishes between two types of questions, the false and the true. When a person questions with an answer already in mind, such a question is false. Such a question already expects in advance a certain interpretation of a text or an utterance, and thus is not open to the possibility of the unknown. In contrast to the false question, a true question has the profound purpose of finding out something that is not previously known. Hermeneutics reminds us that the true question has serious, even mortal, consequences. The true question reminds one that things might be different than originally thought. That is, things might not be, at least not as they are now. Another aspect of the question is that it can never be wide open. Every question contains conditions that limit the scope of how that question might be answered. For example, when a person asks, "Why do leaves turn red in the fall?" the possible responses to such a question are not endless. The answer to such a question cannot be "There are 60 s in a minute." Every question contains the seeds of its own answer.

The educational implications of hermeneutic questioning are significant. Typically, the questions posed by teachers are not true. Teachers often have answers in mind already, answers that are set by a predetermined curriculum. It is a significant and important educational challenge to try to avoid false questions, in favor of true questions, whenever possible. The self-limiting nature of questioning also poses a significant educational challenge. Heretofore, educational questioning has generally been considered benign rather than authoritative. Hermeneutics reminds educators that questioning enacts its own particular kind of authority. When a teacher questions, he or she is steering the conversation rather than letting

the conversation be steered by the student. Questions are never posed from a blank slate. They entail predilections that are educationally significant.

World-historical situation

As the importance of the cultural backgrounds of students becomes less and less ignored in educational institutions, hermeneutics offers a way to understand the interaction between cultural and personal standpoints. Typically, the educational institution has been construed as a public space wherein students shed their cultural differences in order to engage in the personal goal of becoming educated. This liberal paradigm has the limitation of regarding the personal as an escape from the cultural. Hermeneutics, on the other hand, indicates that the part (the personal) and the whole (the cultural) cannot be separated from each other in such a fashion. When a student learns something new in the classroom, he or she does not shed his or her world-historical horizon. Instead, that larger horizon is the backdrop against which personal learning must make sense. Just as the reader can only interpret one passage of a text in light of the whole text, so too the learner can only interpret school experience in light of a larger cultural horizon.

Hermeneutics also shows that the world-historical situation of the student always orients him or her in tacit ways. These tacit understandings of the world are largely ignored in educational thinking since such thinking often considers the pre-educated mind to be a blank slate or an empty container. From the hermeneutic point of view, understanding is never at a lack, though it is for the most part tacit. Educationally, then, it is important to provoke these tacit understandings. As Gadamer has said, "All understanding is self-understanding." This means that understanding something new always entails provoking something old, something old that one's world-historical situation has tacitly conditioned. In educational terms this means provoking the tacit knowledge of students, knowledge that is informed by students' world-historical situation. Provoking tacit knowledge is a requirement for learning something new.

Language

Perhaps the most important hermeneutic contribution to education is its focus on language. In education, language is most often construed in terms of the conduit metaphor, language being the conduit that transfers thought from one mind to another. Language is taken as a medium by which human beings convey the thoughts that they have in their minds. This understanding of language has influenced teaching methods as well as curriculum construction for centuries. Following this theory of language, teachers are encouraged to make their presentations more clear and interesting because the more effective the language, the more effectively thoughts are conveyed from mind to mind. Also, it is assumed that the organization of

curriculum – through concise logical order and in concise logical language – will ensure the most efficient learning on the part of the student. Both spoken and written languages are taken as conduit for transmitting thoughts of teachers to the minds of students.

The hermeneutic project emphasizes that language cannot be taken in such a way, that educators would do well to rethink what they do along linguistic lines. Gadamer, for example, regards language as essentially conversational. Language, he maintains, is typified by the to-and-fro of partners in a conversation. Words do not start from one person and end up at another. Rather, words are partaken in. They are experienced, rather than used, by interlocutors. Because language is essentially conversational, the abstraction of facts and symbols into logically ordered progressions, indeed, the coveted progression of curricula, is of no value until it is understood and interpreted. Education informed by hermeneutic linguistics thus focuses more on the to-and-fro of dialog and less on knowledge transmission.

The hermeneutic understanding of language challenges one of the central tenets of progressive education, namely, that the authority of the speaking teacher can stultify the freedom of the student. Progressive education, at least since Dewey, has tried to move away from the student-as-listener, encouraging instead the student-as-participant. But Gadamer distinguishes between a person who speaks with authoritarianism and a person who speaks with authoritativeness. The former is harmful, while the latter enacts the laudable authority of wisdom and knowledge. The former uses his or her institutional power to dominate while the other partakes in a learned conversation. Because language is partaken in rather than transmitted, the listener is as much of an active participant as the speaker.

As language is not about understanding another person's meaning, but is about partaking in a conversation, the hermeneutic orientation also offers a very different understanding of second-language education than usually surfaces in educational discussions. Most often, the non-native speaker in a classroom is given special attention because he or she is not likely to understand the meaning of the teacher's words. Such special attention is based on the conduit model of language. If the message is not received correctly, then it is the language that is at fault. In terms of human understanding, hermeneutics reminds us that this sort of remediation puts the cart before the horse. Conversation, even if it is across languages, is always full of meaning and understanding. Education should start with a presumption of such fullness rather than a presumption of lack.

Disciplinary knowledge

Hermeneutics offers insight into disciplinary knowledge that is often overlooked in other approaches to education. Educational practices are guided by disciplinary specialization for two main reasons: because such specialization

provides an efficient way to administer curriculum, and because knowledge has historically been organized along disciplinary lines. However, along with the advantages of disciplinary specialization for curriculum delivery, it has long been acknowledged that learning is facilitated when students make connections across disciplines. Thus, educators perennially negotiate between the efficiencies of disciplinary specialization and the meaningful connections to be made between disparate bodies of thought.

Certainly, this connection between disparate but efficient disciplinary specialization, on the one hand, and making general connections among disciplines, on the other, resonates with the hermeneutic interplay between the part and the whole. But hermeneutics has even more to contribute than the part/whole metaphor. From a hermeneutic perspective, the part and the whole are not simply two entities to be negotiated. Instead, they are elements that are constitutive of all understanding in the first place. So, while educators usually describe this negotiation between the specific and the general in ways that encourage a healthy trade-off between specialization and generalization, hermeneutics reminds educators to take a much harder line. Whatever specialization or generalization characterizes curriculum administration, understanding itself only happens within the to-and-fro movement between the specific and the general.

Summary

Hermeneutics, in general terms, is the art of interpretation. As such, hermeneutics has a rich history and can now be identified with four major strands: conservative, critical, radical, and moderate. Out of these strands, the moderate hermeneutics of Hans-Georg Gadamer has proven to be the most relevant to educational thought. While many hermeneutic themes speak to educational concerns, four themes – questioning, world-historical situation, language, and disciplinary knowledge – are especially relevant. Hermeneutics remains an important, if not yet thoroughly explored, branch of educational philosophy.

Islamic Education

Y Waghid, Stellenbosch University, Matieland, South Africa

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Adl – Universal justice which implies the achievement of justice for every person irrespective of religion, culture, identity and socio-political affiliation.

Ummah – Communal engagement, generally in reference to the unity and connectedness of Muslims all over the world.

shūrā – Public deliberation which creates space for people to engage with each other on the grounds of respect for diversity of opinions.

Jihād – Just striving, including the recognition of the rights of others which is more fundamentally associated with intellectual exertion rather than the exercise of physical and emotional violence.

Ta'līm – Socialization of Muslims learners into an inherited body of Islamic concepts and practices.

Tarbiyyah – Individuation of learners into discourse of reflection and critique.

Ta'līm – Virtuous action mostly related to the achievement of social activism in communities.

Islamic Philosophy of Education and Universal Justice

The Qurān is replete with verses (*āyāt*) which emphasize the significance of achieving justice for all human beings wherever they might be. The most famous of these verses is the one which is recited every Friday when the *imām* (congregational leader) renders the compulsory *khutbah* (sermon): “Surely Allah enjoins the doing of justice and the doing of good (to others) and the giving to the kindred. And He forbids indecency and evil and rebellion; He admonishes you that you may be mindful” (The Bee, 16: 90). Again, in another verse: “O you who believe! Be upright for Allah, bearers of witness with justice, and let not hatred of people incite you to act inequitably; act equitably, that is nearer to piety, and be careful of (your duty to) Allah; surely Allah is Aware of what you do” (The Dinner Table, 5: 8). Likewise, it is stated in the Qurān: “O you who believe! Be maintainers of justice, bearers of witness for Allah’s sake, though it may be against your own selves or (your) parents or near relatives; if he [she] be rich or poor, Allah is nearer to them both in compassion;

therefore do not follow your low desires, lest you deviate; and if you swerve or turn aside, then surely Allah is aware of what you do” (The Women, 4: 135). Now considering that the Qurān is one of the primary sources of a philosophy of Islamic education – another being the Sunnah or life experiences of the Prophet Muhammad (May Allah’s peace and blessings be upon him), and the Qurān clearly emphasizes the importance of achieving justice for all, it would be plausible to claim that the rationale of Islamic education is the achievement of ‘*adl*’ (justice) in relations among people. What the aforementioned verses also foreground is an understanding that justice is not the domain or proprietorship of individuals, but that justice is done to others and in relation with others. These others, of course, might not necessarily be of the same religious, cultural, linguistic, ethnic, political, cultural, or social milieu of the individual or group enacting justice. Simply stated, justice is not reserved for a particular group, but rather for all people wherever they might live. In this sense, justice is universal or global.

The question arises: What does it mean to be treated justly? First, universal justice is conceptually linked to being nonoffensive, nonsubversive, and decent toward others. If so, then one should treat others with dignity and respect without inflicting physical and emotional harm on others. In an educative perspective, this makes sense because learning and teaching cannot take place without people (learners and educators) being made to feel that they deserve one another’s respect as dignified persons. Second, being just requires of one not to act unequally (perhaps through bigotry and resentment). In other words, people should be treated equally and not as some strangers in an unfair manner: specifically, think of the challenges that educators in universities face not to treat students from immigrant communities, for instance, as if they do not deserve our equal and symmetrical attention. Third, justice is linked to recognizing the rights of others (and not just being consumed with one’s own rights) and that their (others’) rights should be assured: think of the rights that students from all communities have to higher education and how university educators should go about ensuring that this right to education is secured. This brings us to a discussion of how treating others with decency (civility), equality, and the recognition and assurance of others’ rights can possibly be achieved through the acts of *ummah* (communal engagement), *shūrā* (public deliberation), and *jihād* (just striving, which includes the recognition of the rights of others) – all considered by the Qurān as acts of justice.

Cultivating Acts of Justice

First, the Qurān (The Chambers, 49: 13) states the following: “O humankind! Surely we have created you of a male and a female and made you tribes and families [communities] that you may know each other; surely the most honorable of you with Allah is the one most careful of his [her] duty; surely Allah is Knowing, Aware.” The point about this verse is that people ought to be recognized as not only having commonalities and differences, but they should also actually share these on the grounds of acting responsibly (with duty, that is to say, with justice). Therefore, the idea of community is aimed at getting people to share with others what they have in common and what they disagree about; that is, it is a matter of getting to know one another. In another Qurānic verse it is stated: “And people are naught but a [global] community, so they disagree; and had not a word already gone forth from your Lord, the matter would have certainly been decided between them in respect of that which they disagree” (Jonah, 10: 19). Therefore, although people are different, the sense of community which ought to exist among them is one whereby they share commonalities and disagreements. However, the fact that humanity is considered as a global community (*ummah*) means that people need to learn to live with the otherness of others, whose ways of being may be deeply threatening to our own (Benhabib, 2002: 130). Moreover, through the idea of *ummah* (community), people endeavor to find a civil space whereby they can enact what they have in common and at the same time make public their competing narratives and significations. In this way, people might develop a real opportunity to coexist. Again, in this way, they would not only establish a community of conversation and interdependence (i.e., they share commonalities), but also one of disagreement (i.e., they do not share commonalities) without holding in disrespect others’ life-worlds (Benhabib, 2002: 35 and 41). In other words, when people are engaged in a community underpinned by interdependence and disagreement, they engage in an educative process with a collective identity – they share commonalities. Besides, educating people to become members of a global community involves creating civil spaces where they can learn to share commonalities and respect the differences of others. Only then, people would be acting justly. In this regard the Qurān states: “You are the best of peoples raised up for the benefit of humanity; you enjoin what is right and forbid the wrong and believe in Allah; and if the followers of the Book had believed, it would have been better for them; of them (some) are believers and most are transgressors” (The Family of Imrān, 3: 110). In essence, when the Qurān advises people to work as a global community (*ummah*), it in fact does so on the grounds that people ought to engage communally with one another’s differences and commonalities. If they do so, their actions would be just,

because they would be for the advancement of humanity. Following such an understanding of *ummah* (communal engagement), one can claim that Islamic education aims to establish opportunities whereby people engage with one another and, in so doing, they share commonalities and differences in the interest of advancing human relations. In this way, they would act justly because participants of a global community remain respectful toward one another despite their differences and disagreements.

In other words, *ummah* (communal engagement) demands that individuals actively engage with the unending struggle and responsibility for the improvement of the economic, social, and political aspects of life (Alibasic, 1999: 234). In this sense, *ummah* is concerned with a long-term and inconclusive commitment to the improvement of human conditions. Such a community is concerned to maintain the freedom and duty of criticism and monitoring of government, to accept criticism in good spirit, to facilitate peaceful change, and to remain united through consensus and disagreement (Alibasic, 1999: 237, 240, 242, and 292) – a clear indication of such a community’s obligation to be critical, to develop self-critical attitudes, and to live peacefully. In addition, communal engagement or *ummah* is also concerned with a plurality of human ideas and not denying the rights of others (Alibasic, 1999: 249 and 271) – thus indicating its recognition of difference.

Second, the Qurān not only encourages people to act justly as a global community, but also suggests a way of *shūrā* (public deliberation) as to how people ought to engage. What does the Qurān say about *shūrā* (public deliberation)? In fact, an entire chapter (*sūrah*) of the Qurān is devoted to a discussion of *shūrā* (public deliberation). The core verse which relates specifically to *shūrā* (public deliberation) is as follows: “And those who respond to their Lord and keep up prayer, and their rule is to take counsel [*shūrā*] among themselves and spend out what we have given them” (Counsel, 42: 38). The value attached to *shūrā* (public deliberation) is so profound that Allah connects the practice to prayer (*salāh*) and almsgiving (*zakāh*). Throughout the chapter, Allah speaks about the importance of engaging others justly (Counsel, 42: 15), that is, with patience, forgiveness, and courage (Counsel, 42: 43). These constitute virtues of public deliberation which would hopefully encourage and persuade people to act justly. In the first instance, public deliberation cannot happen without the patience of listening to the viewpoints of others, albeit that they may be in conflict with one’s own. The point is that public deliberation cannot happen unless we listen attentively to others’ justifications and, in turn, give to others an account of our own justifications. Only then we can justifiably talk about deliberation.

Moreover, in the second instance, the Qurān also states: “Call [engage others] to the way of your Lord with wisdom and goodly exhortation, and have disputations with them in the best manner; surely your Lord best knows those

who go astray from his path, and He knows best those who follow the right way” (The Bee, 16: 125). Whereas public deliberation ought to involve different and contending parties listening to one another’s views, it also needs to invoke disputations. This means that people should also have the courage to take one another’s views into some kind of systematic controversy. In other words, we should not be concerned merely with listening to what others have to say and then agree with them, but also to treat one another’s truth claims critically without, of course, exceeding the limits (The Elevated Places, 7: 55). In this sense, exceeding the limits refers to insulting and demeaning people. However, it does not mean that one cannot fervently disagree with another person’s view. In this sense, disputations do not only have to be feeble; rather, arguments can be articulated ardently without alienating others, more specifically without excluding them from public deliberation. For this reason, the author is somewhat hesitant to equate courage in public deliberation with belligerence, as proposed by Eamon Callan. For Callan, people in deliberation disturb doubts about the correctness of their moral beliefs or about the importance of the differences between what they and others believe (a matter of arousing distress) accompanied by a rough process of struggle and ethical confrontation – that is, belligerence (Callan, 1997: 211). If this happens, belligerence and distress give way eventually to moments of ethical conciliation, when the truth and error in rival positions have been made clear and a fitting synthesis of factional viewpoints is achieved (Callan, 1997: 212). The problem with Callan’s view is that he assumes that all people are necessarily confrontational, which might lead to excluding others from the deliberation who might not be confrontational. One can also arrive at defensible justifications without engaging belligerently with someone else.

However, in the third instance, what is more crucial for the public deliberation to be ongoing is the virtue of forgiveness. When people deliberate, they do not have to argue for a specific point of view after others’ views have proven to be more plausible than theirs. The virtue of forgiveness can mean that a previously held view can be dismissed if implausible, and that the proponent of such a view should not be considered as intellectually slow, but rather be freed from being associated with an indefensible viewpoint. This also implies that people should not ridicule others for a previously held indefensible view. In The Chambers (49: 11) the Qurān states: “O you who believe! let not (one) people laugh at (another) people perchance they may be better than they, nor let women (laugh) at (other) women, perchance they may be better than they; and do not find fault with your own people nor call one another by nicknames; evil is a bad name after faith, and whoever does not turn, these it is that are the unjust.”

Third, this brings us to a discussion of *jibād* (just striving, including the recognition of the rights of the

others) considered as one of the most often misrepresented concepts and which can be considered as a constitutive feature of a philosophy of Islamic education. Why? The Qurān equates *jibād* with seeking closeness to Allah as stated in The Dinner Table (5: 35) as follows: “O you who believe! Be careful of (your duty to) Allah and seek means of nearness to Him and strive hard in His way that you may be successful.” Moreover, the Qurān links *jibād* to working collectively with others in the path of virtuosity: “And We have revealed to you the Book with the truth, verifying what is before it of the Book and a guardian over it, therefore judge between them by what Allah has revealed, and do not follow their low desires (to turn away) from the truth that has come to you; for every one of you did We appoint a law and a way, and if Allah had pleased He would have made you (all) a single people, but that He might try you in what He gave you, therefore strive with one another to hasten to virtuous deeds; to Allah is your return, of all (of you), so He will let you know that in which you differed” (The Dinner Table, 5: 48). If people are encouraged to strive collaboratively to attain justice, then they have to recognize one another’s rights and actually do something about ensuring that their rights are honored. Recognizing and honoring one another’s rights is important in ensuring that people are treated equally, decently, and respectfully. Therefore, the Qurān proclaims that people should be educated about their rights, whether civil, political, or social: “O people! be careful of (your duty to) your Lord, Who created you from a single being and created its mate of the same (kind) and spread from these two, many men and women; and be careful of (your duty to) Allah, by Whom you demand one of another (your rights), and (to) the ties of relationship; surely Allah ever watches over you” (Women, 4: 1). In essence, just striving (*jibād*) is aimed at drawing nearer to a higher good, developing one’s capacities to be morally upright, and respecting the rights of others.

Thus far, we have discussed how the idea of universal justice, the rationale of a philosophy of Islamic education, can be achieved through actions such as *ummah* (communal engagement), *shūrā* (public deliberation), and *jibād* (just striving which includes the recognition of the rights of others). We now move on to how these acts of justice are linked to various conceptions of Islamic education, namely, *ta’līm* (socialization), *tarbiyyah* (individuation), and *ta’dīb* (good action).

Conceptualizations of Islamic Education

Thus far, we have discussed how universal justice constitutes a philosophy of Islamic education. In turn, we have explored three different ways in which universal justice can be achieved, namely, through the acts of *ummah* (communal engagement), *shūrā* (public deliberation), and *jibād* (just striving, including the recognition of the rights of

others). We now examine how these acts of justice guide particular conceptions of Islamic education, namely, *ta'lim* (socialization), *tarbiyyah* (individuation), and *ta'dib* (good action), with reference to their implications for teaching and learning.

First, Islamic education is couched as *ta'lim* (socialization) as illustrated by the following verses in the Qurān: “And He taught (*allama*) Adam all the names, then presented them to the angels; then He said: Tell me the names of those if you are right” (The Cow, 2: 31); “They said: Glory be to Thee! We have no knowledge but that which Thou hast taught us; surely Thou art the Knowing, the Wise” (The Cow, 2: 32); and “Taught man [women] what he [she] knew not” (The Clot, 96: 5). These verses foreground a particular conception of education (*ta'lim*) whereby people learn through being socialized into an inherited body of knowledge. That is, learning takes place when people are taught what they perhaps do not know. Certainly for Muslims, this means being taught how to adhere to their faith, especially those principles associated with being a good person. For instance, being socialized means being taught what it means to believe in Allah, His Angels, His Revealed Books, His Prophets, The Last Day of Judgment, and the separation between good and evil. Likewise, being taught about Islam involves what it means to serve Allah, perform prayer, execute fasting, provide alms to the poor and destitute, and set out on a pilgrimage once in a lifetime, if Muslims have the means to do so. Socialization is also associated with learning the Qurān (including its memorization or passages from it), the Hadīth (sayings related to the life experiences of Prophet Muhammad), the Sīra (the Prophet’s life history and those of his companions), the Islamic sciences such as Shari’ah (law), Fiqh (jurisprudence), and Tawhīd (science of interpretation). Now the problem with *ta'lim* (socialization), at least so it seems, is that this form of education has often been associated with uncritical exegeses of what medieval scholars have said about Islamic knowledge. For instance, some Muslims in the Islamic world often confine their engagement (i.e., their sense of *ummah*) with the primary sources of Islam to the exegeses of past medieval scholars, which in many cases results in a stultification of knowledge and understanding. It is for this reason that claims are often made that Islamic education merely advances doctrinaire learning. This claim is supported by Bagheri and Khosravi (2006: 100), who argue that Islamic education has been used throughout the Muslim world to indoctrinate learners. In the author’s view, this limited view of Islamic education is not commensurate with the notion of *ummah* (communal engagement), whereby Muslims also need to be taught a form of education which invokes criticality. Hence, we now introduce a discussion of *tarbiyyah* (individuation).

Second, whereas *ta'lim* (socialization) aims to introduce people to an inherited body of knowledge (without being

uncritical toward such knowledge), *tarbiyyah* (individuation) specifically invites Muslims to be critical of their learning. In the first instance, the word *rabb* (literally lord, which the author has adapted to educator) occurs approximately more than 1000 times in the Qurān in relation to the provision of mercy, guidance, evidence, and clear proofs. Of concern to the author is the use of *rabb* in relation to proofs (*bayyināt*). In The Cattle (6: 57) it is said: “Say: Surely I have manifest proof from my Lord and you call it a lie; I have not with me that which you would hasten; the judgment is only Allah’s; He relates the truth and He is the best of deciders”; then, again in The Cattle (6: 104): “Indeed there have come to you clear proofs from your Lord; whoever will therefore see, it is for his own soul and whoever will be blind, it shall be against himself and I am not a keeper over you.” Likewise, in The Cattle (6: 157) “Or lest you should say: If the Book had been revealed to us, we would certainly have been better guided than they, so indeed there has come to you clear proof from your Lord, and guidance and mercy. Who then is more unjust than he who rejects Allah’s communications and turns away from them? We will reward those who turn away from Our communications with an evil chastisement because they turned away.” In a specific verse in The Cow (2: 111), Allah (as The Educator) invites people to evaluate His Guidance and that they respond critically with proof of their justifications: “And they say: None shall enter the garden (or paradise) except he who is a Jew or a Christian. These are their vain desires. Say: Bring your proof if you are truthful.” The main point about this verse is that people are invited to come up with their own proofs or justifications, which suggests that a situation or argument can be taken into controversy. Simply stated, the notion of *tarbiyyah* creates scope for critical evaluations and interpretations based on sound reasons for disagreement. The upshot of this view of Islamic education is that people can question and undermine a particular point of view, which suggests that they ought to reflect about the knowledge they receive and construct – a matter of becoming critical. Therefore, *tarbiyyah* (individuation) can be considered as another phase in Islamic learning, that is, once people have acquired knowledge and they are informed they can then begin to challenge and question prevailing understandings. No wonder the Qurān invites people to contemplate and deliberate about educational matters. Somewhere else, the author has specifically discussed how actions such as *tafukkur* (contemplation), *tadabbur* (critical reflection), *fabm* (rational understanding), and *aql* (intellectual inquiry) underscore the practice of deliberation (Waghid 1996b).

Third, with reference to my previous work (Waghid, 1996a) on the matter and in particular the seminal thoughts of Muhammad Naquib al-Attas, another form of Islamic education is under included in the term *ta'dib* (good action) (al-Attas, 1991: 23). For al-Attas, Islamic

education is guided by *adab* or the appropriate use of knowledge (*ilm*), reason (*nutq*), intellect (*aql*), and heart (*qalb*) – more specifically one's physical, intellectual, and spiritual capacities – to perform acts (*amal*) of justice (*adl*). This view of *ta'dīb* (good action) is in line with the rationale of Islamic education discussed earlier, namely that of producing a just person: "The *just* man [women] is he [she] who effects such *adab* unto his [her] self, resulting in his [her] being a *good* man [woman]" (al-Attas, 1991: 24). We concur with this approach to Islamic education on the grounds that one cannot just acquire knowledge of the Islamic sciences and then begin to critically analyze and respond to particular issues on the assumption that one's actions will then result in something worthwhile or appropriate for the global community. The author believes that *ta'dīb* (good action) has in mind actions which can lead to the improvement of the global community's situation. Therefore, one requires *jibād* (just striving which includes the recognition of the rights of others), which can invariably change distorted or improve unsatisfactory situations. For instance, we are specifically thinking of how *ta'dīb* (good action) can contribute potentially toward the eradication of racial bigotry, gender oppression, cultural imperialism, and even terrorism, because good action requires that people pursue actions which can eliminate inhumane acts perpetrated against humanity such as murder, extermination, enslavement, deportation, persecution on political, racial, or religious grounds, war crimes (mistreatment of civilians and noncombatants as well as one's enemy in combat), and genocide (through ethnic cleansing, mass executions, rape, and cruel punishment of the enemy). Simply put, *ta'dīb* (good action) has an emancipatory interest in mind, which can be made possible through a just striving which takes into account the rights of others and that others' rights ought to be assured. Here, we specifically use *jibād* as referring to just actions of the mind rather than the application brute force, which invariably leads to more violence.

In essence, we have shown that the three conceptualizations of Islamic education, namely, *ta'līm* (socialization),

tarbiyyah (individuation), and *ta'dīb* (good action), should be seen as complementary actions of the mind in the pursuit of achieving justice for every person wherever he or she might be. In turn, we have also shown how practices such as *ummah* (communal engagement), *shūrā* (public deliberation), and *jibād* (just striving, including the recognition of the rights of others) can contribute toward achieving universal justice, considered as the rationale of Islamic education.

Prehistory of Liberalism

While the seeds of moral liberalism can be found in both the Hebrew Bible and the New Testament, and especially in the appeal to individual conscience found in the reformation, political liberalism arose in response to a specific historical moment as an instrument to meliorate the religious wars that began in the middle of the sixteenth century. Thomas Hobbes's (1588–1679) attempt to re-legitimate political authority after the doctrine of the Divine Right of Kings was discredited is often seen as the foundational moment of liberalism. However, because he tried to justify the absolute power of the sovereign, Hobbes, himself, is not usually thought of as a liberal.

Hobbes's (1958) ideal was to substitute as the justification of absolute sovereignty of the Crown the rigorous principles of logic, for the will of God. He began by imagining what life was like in a state of nature before governments were formed. He conjectured that such a state would be “a war of all against all” in which life was “nasty, brutish and short” and he speculated that people, recognizing the hopelessness of this situation, eventually came together and gave all of their power over to a single sovereign who then maintained order and govern them all. This sovereign then had absolute power, except in cases where he threatened an individual's life. When this occurred then the relation of the condemned to the sovereign would be as it was in the original state of nature. Hobbes, while not a liberal, made an enormous contribution to the formation of liberalism by affirming government was a human, not a divine, product. It is dependent not on the will of God but, at least in its inception, on the will of the governed. However, for Hobbes the authority of the people, once granted, no longer existed and the authority of the government was virtually absolute. Later liberals would argue that governments continue to be accountable to the will of the people.

Types of Liberalism

The basic tenet of political liberalism is that government resides in and is accountable to the governed. As times have changed, however, this basic idea has taken a number of different and sometimes conflicting forms.

Conventional classification divides liberalism into two forms – classical and contemporary. Classical liberalism emphasizes negative political rights and the need to limit

government authority. It dominated political thought from the days of John Locke (1632–1704) until the Depression of the 1930s when philosophers and economists began to re-think the basic tenets of liberalism. Contemporary liberalism emphasizes positive rights and a more active role for government. The difference between the two can be captured by thinking of classical liberalism as a political doctrine that fears tyranny more than it loves justice, whereas contemporary liberalism may be thought of as a doctrine that loves justice more than it fears tyranny. The first seeks to keep government small; the second to assure that it is helpful. For both, however, the central principles are the same. (1) The individual is real, and society and government is a creation of the governed. (2) Government draws its legitimacy from the governed and is accountable to and can be replaced by it. (3) All individuals have certain rights independent of the government, (4) If the government violates these rights, it loses its legitimacy.

Many liberal theorists also borrow from Hobbes a mode of argumentation that roots the basic principles of liberalism in a contract that arises among people within a state of nature. As we will see, however, the use of the notion of a contract has changed over time from something that was accepted as a literal representation of the history of governments to something that carries but metaphorical and heuristic weight.

In line with political liberalism are certain other ideas; the most important one for education's purposes is that the individual is both the agent and the object of moral decision making. As the agent, the individual must accept the decision as her own if it is to be a moral one. Decisions that are manipulated or forced are not considered moral decisions. This is the root to the liberal commitment to tolerance – beliefs cannot be forced – and to the respect of individuals – persons must be respected and they must be free to choose their own way of life. That is, they must be autonomous. As the object of moral decisions the goodness or badness of any action will be judged not by how well it conforms to some external ideal or to the will of God, but by how well it serves the individual's own idea of the kind of life she should lead. Given these similarities, there is still a great deal of difference between the liberalism that fears tyranny and the liberalism that loves justice.

The real beginning of classical political liberalism is usually associated with the ideas of the British theorist, John Locke. Locke had a considerably more benign view

of the state of nature than did Hobbes. For the most part people lived peacefully with one another, committed to defend their own rights and to respect those of others. Private property arose when men (sic) mixed their labor with nature. To reach up to pick an apple is an example of the mixing of labor with nature and of the beginning of private property. If I plow up unclaimed land in order to plant an orchard, the land and the orchard become mine. Governments arise, not because there is a war of all against all, as Hobbes thought, but as a result of specific conflicts. Say, I did the reaching but you then did the planting. Governments arise when arbiters are selected to resolve the disputes. In this Locke develops the idea that the function of government was limited to protecting individual rights, such as the right to property, and to settling disputes about these rights, such as whose property does it really belong to. In contrast to Hobbes, the role of the government for Locke was not absolute. The governed could change the government, especially if it fails to protect these rights. Nevertheless, as Sabine observed: "The two men fastened on social theory the presumption that individual self-interest is clear and compelling, while a public or a social interest is thin and unsubstantial" (Sabine, 1958: 529).

Given Locke's view that government has but a very limited role – to protect the rights of individuals, rights granted by nature – classical liberals are distrustful of government authority, and often view government itself as a necessary evil. Yet there is also in Locke, as there is in liberalism in general, an implicit appeal to majority rule, and liberal thought will later divide as to whether government must be as vigilant about the possibility of the tyranny of the majority, as it must be over the tyranny of a monarch. As Robert Nozick, in his modern defense of a minimum state, argues, warning against the former, any taxation beyond that required to protect one's natural rights is theft, however good the purpose for which it might be used (Nozick, 1974), or however large the majority favoring it.

Historically, its later association with economic liberalism mitigated the tension within classical political liberalism. Economic liberals such as Adam Smith (1723–90) argued that small government is not only a protection against tyranny, but is also good for everyone. Hence in this view there is no conflict between the state that serves the majority and the state that assures freedom from tyranny. Smith (1904) argued that free commerce would allow producers to compete fairly with one another for the favor of the consumer and out of this competition would come the highest quality at the lowest possible price. The role of government then was to simply assure equal access to the market by guaranteeing that everyone had an opportunity to compete on equal grounds. Any significant government involvement beyond that point would reduce the over all productivity and wealth of the

nation. Hence, a small government was not only a moral imperative as a protection against tyranny, it was also a practical imperative that would increase the wealth and satisfaction of the nation as a whole. Consumers would get the quality they wanted at the price they were willing to pay.

Of course, it is not quite obvious that as the total wealth of a nation increases, the satisfaction of everyone increases along with it. A rising tide may not lift all boats, and the metaphor has its limitations when it comes to economic well-being. A counter example is those instances where as the wealth of a nation grows so too does the uneven concentration of that wealth leads to great inequality and an increase in poverty.

Classical economic liberalism seems unconcerned with responding to the question as to how economic progress is to be judged when there is a discrepancy between the aggregate wealth of a nation and the poverty of the different individuals who compose it. Nevertheless, classical economic liberalism added to classical political liberalism's ideas that a good government must not only protect natural rights, but also, even if only by implication, that a good society must provide its citizens with equal opportunity to compete economically. While these ideas would eventually serve as an important foundation for modern education – the one in terms of a universal right to education and the other as a significant forerunner to the idea of equal educational opportunity – at the time of their formation, politics and economics, not education, were the focus of attention. The failure to understand that an increase in the total wealth of a nation could be attained at the cost of the well-being of many of its citizens served as an important stimulus to the challenges to classical liberalism in both its economic and its political forms and to the development of contemporary liberalism.

The Rise of Contemporary Liberalism

Under classical liberalism, the absence of tyranny was equated with justice, as seen largely in procedural terms. Justice was done when one had a fair hearing or when one was allowed to compete on equal terms with others and without government favoring one producer or consumer over another. All of this would have perhaps been fine if there were not another consideration classical liberalism took seriously – the right that we all had to do what we want with our wealth, including the right to advantage our own children over others – either through inheritance, or through education, or both. This meant that for each new generation the playing field was tilted in favor of the children of the rich and powerful, who were then able to make new laws, which again favored their children. Where these favors resulted in a desperately poor working class, as they did in England and the United States in the

nineteenth and much of the twentieth centuries and where they ignored the disenfranchisement of black people and women, then the fear of destitution and the situation of powerlessness replaced the fear of state tyranny as the primary concern, and real procedural justice, that the classical idea of equal opportunity entails, was seen wanting. The very idea of a minimal government was seen as complicit with the economic tyranny that a largely uncontrolled market was allowed to produce.

Contemporary liberalism arose in response to excesses associated with classical liberalism during the nineteenth century, but it gained currency as the impact of inadequate government intervention became obvious during the Great Depression of the 1930s. While this new liberalism also feared tyranny, it did not believe that tyranny must necessarily be associated with big government. For the average worker, subject to the arbitrary will of an all powerful industrialist, economic tyranny came in the form of the masters of the free market, and the minimal state they seemed to own. In other words, unregulated big business was seen as an even greater danger than big government.

Contemporary Liberalism

Much of the ground work for contemporary liberalism was prepared by Utilitarian thinkers such as John Stuart Mill (1806–1873) who argued that the goodness of society can be measured in terms of the happiness of its members, and who extended the role of government to the performing of those essential tasks that private business would be unable or reluctant to perform. Mill (1962) was generally an advocate of free markets and limited government, as well as of free speech and tolerance. Moreover, like Adam Smith he shifted the intellectual justification for the minimal state away from a deductive argument issuing from certain premises about natural rights to an empirical argument based on the utilitarian principle of maximizing pleasure.

This change in argumentative tactics is important for should this empirical claim prove false, then the foundation of the minimal state would be wanting. As a political reformer arguing for women's rights and against slavery, Mill was aware of the discrepancy between the claims for the minimal state and the actual conditions of working people. While he was reluctant to reject the basic principles of economic liberalism, he did believe that education was the key to realizing the greatest amount of happiness. Having departed from Jeremy Bentham's (1749–1832) view that all pleasures were of equal worth, Mill's view of education would seem to require a large infusion of state involvement to insure that children of workers be exposed to pleasures that their parents did not know or have the opportunity to value. However, it remained for a new breed of liberalism to draw out the implications of this idea.

Contemporary liberalism opens up the possibility that the state and especially state-sponsored education can be instruments for unblocking potential and for advancing human flourishing. Hence, while it builds upon the concern to block tyranny, and thus carries forward a commitment to procedural justice, it also holds that the state has a positive role in enabling human potential as well as protecting rights. It thus promotes the state as both an agent of welfare and an agent of education.

Contemporary liberalism begins with what White (1957) has called the revolt against formalism or what Dewey (1929/1962) has labeled the end to the quest for certainty. It begins with a rejection of the idea that foundational political principles can be deduced by an exercise in formal logic alone, as both Hobbes and Locke seemed to believe, and substitutes probabilistic conclusions about likely consequences for conclusions about logical necessity. This more pragmatic approach provided the grounding for reform movements in many fields. In legal theory, reformers like Holmes (1920), recognizing that changing conditions required new laws, sought to balance the consideration of precedent with a consideration of the consequences of a law. The importance of this shift is difficult to exaggerate since it opened the way for lawyers and judges to seek the opinions of social scientists in a wide range of areas. The shift was also reflected as Keynes (1936/1997) and his arguments for government intervention to stimulate economic growth competed with Adam Smith and his argument for minimal government for favor in university economics departments. The shift also had a profound impact on education.

Education and Contemporary Liberalism

Because of the radical change from a rural society to an urban one as well as the changes in work that the industrial revolution brought about, education became a more significant feature of liberal theory. During the early formulation of liberal ideas when most children learned to work by sharing in the chores on the farm or by apprenticing to a master workman, formal education was but an incidental part of children's lives. For many, but not for all, rudimentary skills were all that was required for the work they were destined to perform, and higher education was important for only a small, largely cultural elite.

While classical economic liberalism advanced the idea that everyone should have an equal opportunity, the ideal was largely restricted to market exchanges. While a few, such as Jefferson, thought the ideal would be a good one to apply to education, in actual fact even high schools and certainly colleges and universities were, with a few exceptions, largely reserved for the children of the elite. The exceptions were more often bright children from marginal groups, who, it was thought, could be assimilated and could then serve as cultural exemplars for their kind.

While this began to change in the United States with the founding of land grant colleges, higher education was not the ground on which originally opportunity was supposed to be apportioned equally. In practice, of course, neither was the economic market, nor many supplementary theories about race, class, and gender, had to be added to make the vast inequalities in economic opportunity fit into the tidy theory that classical economic liberalism provided. Indeed, much of the intellectual work of the first half of the twentieth century, from racial based IQ theory to cultural deficit theory, can be seen as the latter day working through of this supplement to classical economics.

Contemporary liberals recognized that if social institutions and practice were to take advantage of and contribute to the developing technological change, education would need to play a larger role in the equation. As compulsory schooling grew so did the needs of the children in school, and a great many reforms were proposed to address these needs. These ranged from attempts on the part of efficiency experts to match the curriculum to the needs of industry, to the ideas of progressive educators like John Dewey to advance the growth of the whole child, and later to the life adjustment movement which popularized curriculum innovations such as drivers education and sex education.

In the thought of the efficiency expert equality of opportunity meant identifying (largely through IQ type tests) the capacities of individual students to fit into certain slots in the workplace and then to shape a varied curriculum in order to efficiently train students to occupy those slots. For Dewey, it meant providing students with the knowledge and inquiry skills so that they could contribute to their community and decide for themselves how to lead happy, useful, and reflective lives. Progressives like Dewey were also concerned with the psychological qualities that students need to live in liberal, democratic societies, and their pedagogical theory was guided by the implicit idea that the nature of a subject is defined in part by how it is taught, an idea that Dewey had developed more abstractly in his treatment of the concepts of ends and means. To teach a subject as a series of right and wrong answers is to teach that knowledge is fixed. To teach a subject as an area for inquiry is to teach that knowledge is open and subject to revision.

Partly as a result of (1) the war against Hitler's brand of racism, (2) the continuing struggles of women and minorities, and (3) the changing needs of the new economy, racial, gender, and class discrimination in both work and school became more visible and as it did, the principle of equal opportunity migrated from employment and markets to education and schools. In response some elite universities changed their admissions policies favoring private prep school graduates and the sons of the elite, and incorporated tests of academic aptitude, tests which

were billed as objective and impartial. The idea was to cast a wider net for talented students and to provide more opportunities for worthy public school children.

Yet the fact that over time these tests seemed to advance white students with very few spaces for students of color (often women were excluded or relegated to separate schools) led some to re-think both the fairness of the tests and the concept of equal opportunity. Partly in response to this discrepancy, a policy of affirmative action, which began as a policy about hiring, was extended to universities where race and later gender became explicit considerations in selecting faculty and students and in attempting to increase the proportion of students and faculty from different racial and gender background. Affirmative action is still controversial among liberals. Some call it reverse discrimination – implying that “two wrongs don't make a right”. Others express concern that social class is largely left out of the formula and that neither race nor gender is an adequate proxy for social class. Yet the policy also has its defenders. Some believe that diversity itself adds to the quality of education while others view it as either partial payment for a historical debt or an essential tool in breaking down debilitating stereotypes.

Milton Freedman and John Rawls

There is still a robust competition between classical and contemporary liberalism. Classical liberalism has found a persuasive voice in the late Milton Friedman (1912–2006) who argues (2002) that market solutions and small government are the solution to all economic problems. Ultimately, for Friedman all problems are economic problems. This includes education. Here Friedman advanced the idea that government should support parental choice of schools through providing all parents, rich and poor, with vouchers. Friedman seems complacent about any growth in inequality that likely would occur as a result of his policy. As his ideas have spread around the world they have been given the label neoliberalism, a term that involves both a positive and a negative connotation. On the positive side, it suggests economic growth and integration into the world economies for developing countries. On the negative side, it suggests growing inequality and an intensification of the impact of poverty and dislocation.

Contemporary liberalism is represented by the work of the philosopher John Rawls, (1921–2002). Rawls (1971) used a new version of contract theory to refine the idea of liberal justice. He proposed that we imagine that in the state of nature people must choose the principles that will govern their society but that they must do so behind a veil of ignorance where they are deprived of any knowledge of their own individual characteristics and of how they compare to others. He believes that in the absence of knowledge about our own race or religion, or about our physical

strength or intelligence and without knowledge of the wealth or historical epoch of our society, we would all choose a society that will maximize the well-being of the least advantaged person. Hence given a society in which basic individual rights and equal opportunity are secured, societies should strive to maximize the well-being of the least-advantaged person. While Rawls does not provide a lot of detail about how this is to be accomplished, a redistribution of wealth through taxation is certainly not ruled out, and would likely be required to meet the standard of social justice that he advances. While Rawls says little about education, he most likely would support policies that provide the greatest advantage for the least-advantaged child and many contemporary liberals hold that this would support redistributive educational policies.

Critics

While both classical and contemporary liberals are critical of each other, they also are vulnerable to external criticism. Communitarians like MacIntyre (1981) believe that liberalism overemphasizes individual rights and neglects communal connectivity while many Marxist and some feminists critics hold that liberalism fails to address structural inequalities and does not understand the ways in which racist, sexist, and classist institutions both reinforce and are reinforced by racist, sexist, and classist attitudes.

One liberal response to the first criticism is that liberals do not underestimate the significance of communal relations. They are only concerned that adults have the opportunity to develop their own conception of the good. While the cultural group to which the individual belongs may influence this conception, liberals insist that individuals must be free to formulate their own idea of the good life. For educators this means that children must be provided the skills and perspectives needed to lead autonomous lives as adults. Some contemporary liberals argue that liberal states may have an indirect obligation to advance certain cultural formations because of the importance cultures have in the development of individuals. Some, like Kymlicka (1991), believe that this is especially the case with regards to cultural groups that have been involuntarily incorporated into a larger polity with a different cultural orientation. Those educators who believe that it is important for schools to help children maintain their cultural connections through bilingual and bicultural education can find support in this version of liberalism.

Perhaps the most prominent criticism of liberalism today comes from postmodern theory and it comes not in the form of a sustained critique but with an ironic distance that rejects the optimism that it associates with liberalism. What is rejected is not the idea that individuals have certain rights but rather naive optimism sometimes

associated with liberalism that with modernity comes progress. Postmodern theorist remind us of the many voices that have been left out of the political discourse as the norms of liberalism were being shaped. To a large extent this would include women, people of color, as well as gay, lesbian, and bisexual people. This is less a rejection of liberalism as such as it is a reminder of the work that needs to be continued and the people who need to be included in the conversation.

Conclusion

Liberalism has provided a rich and somewhat flexible educational ideal. On the one hand, education is viewed as a means to inform people about and to help secure their basic individual rights while providing them with the skills and attitudes required to earn a living in the modern world. On the other hand, many critics hold that in actual fact schooling has become largely an instrument to reproduce an oppressive unjust social order. The latter view has considerable credibility, especially in countries like the United States and Great Britain where intergenerational mobility, especially among certain minority groups, has been inadequate by most standards of human flourishing. There is also concern that education has lost its public forming mission and has become largely a vocational enterprise. To the extent that liberal theory is used to cover up these concerns, say by insisting that individuals are free to choose their own fate, it is rightly seen as culpable. However, this seems to be a misuse of liberal ideas and certainly there are likely enough intellectual resources within liberalism itself to help us shape a new and more just educational project.

Glossary

Civil disobedience – Revolutionary attitude as opposed to the government to be found in existentialism.

Embodiment – The phenomenological answer to the mind–body problem. The human body is as well object as subject. (Merleau-Ponty).

Essence – The objective of philosophy before phenomenology.

Existence – The human way of being (Heidegger).

Freedom (absolute) – The core of Sartre's early philosophy. Human freedom pushed to the extreme.

Life-world – The human world where all meanings stem from (Husserl).

Natural attitude – Common but wrong conviction in philosophy and science that there is something like a reality behind reality (Husserl).

Pedagogy – Continental view on (philosophy of) education, not restricted to what happens in the school, but focused on upbringing in general.

Responsibility – The important consequence of Sartre's view on human freedom. In the view of Levinas, pedagogical responsibility is not intentional but being held hostage by the helplessness of the child.

Transcendental idealism – The world as – in the view of Husserl – constituted by human consciousness.

Visibility – The property of the world that the invisible can in principle be made visible (Merleau-Ponty).

Visuality – The capacity of human beings to see more of the world than what is caught by the eye (Merleau-Ponty).

“There is no reality behind the reality.” In both philosophy and science, we have to do with reality as we encounter it through our ordinary experience. That is the position of the father of phenomenology, Edmund Husserl (1859–1938). From an epistemological perspective, phenomenology has to be seen as a radical response to the viewpoint of Kant. Precisely what Husserl had in mind is, curiously, not so easy to grasp. The idea that there is a genuine reality concealed behind the reality of phenomena, the so-called natural attitude, is far more familiar to us in one form or another. It is a view that has been

drummed into us since Plato. Husserl's creed *Zu den Sachen Selbst* should not, therefore, be understood as a form of objectivism; more than anything it means “back to the original experience.” However, the structure of this ordinary, everyday experience is anything but easy to reconstruct.

In *Die Krise der Europäischen Wissenschaften und die Transcendentale Phänomenologie*, Husserl (1954) demonstrates very clearly that the idea of a reality behind the reality arises from doubts about the veracity of the reality as we encounter it through our ordinary experience. But on what grounds could we doubt the truth of everyday experience? The idea of the true reality is a fabrication, the result of substruction, as Husserl called it. All meanings originate in the life-world, the concrete human world. With this conclusion and taking this as his starting point, Husserl really set off in a different direction.

At first, Husserl had not completely given up the ambition to get through to objective reality. At that stage, he still regarded phenomenological reduction as putting the question of the relationship between phenomena and genuine reality on hold for the time being. In his later transcendental idealism, Husserl assumed that the world is constituted in the consciousness. A more radical rejection of the natural attitude is not possible. Be that as it may, phenomenological analysis is not concerned with the relationship between phenomena and a true reality behind them, but with the relationship between phenomena themselves. One of the most important lessons that phenomenology can teach us, therefore, is that we have to stop searching everywhere for something behind things. That is a theme that we will encounter again in various different forms.

The triumphal procession of the natural sciences that followed the scientific revolution of the late Middle Ages was based on a concentration on epistemological questions. For the first time in history, epistemological questions were being asked separately from ontological questions. In the classical era, it was customary first to determine the nature of reality in order to then look for adequate ways to acquire knowledge. Now, it became the custom to abandon speculations about the nature of the cosmos and to formulate rules which had to be drawn up based on scientific methods, come what may. Such rules, the primacy of formal logic and the method of doubt, led with René Descartes, for instance, to a strict division between subject and object.

Descartes' method generated interesting problems. The epistemological subject–object division was associated with a strict mind–body division. The epistemological question

"How is knowledge possible?" manifested itself at that level as the question "How can a nonspatial mind have knowledge of a spatial body?" A consequence of Descartes' methodical rules was in fact that mind and body do not resemble each other in any respect. Everything that the mind was, the body was not: immaterial/thinking versus material/nonthinking. How and where would they interact with each other? As we will see later, phenomenology, for the first time in history, came up with a solution for the mind-body problem that had been formulated as long ago as Aristotle. Phenomenologists prefer not to speak in terms of subject and object, but in terms of I and the world. I and the world are not separate but are related to each other, since it is simply impossible to separate I and the world. There is no world without I, because the world we want to talk about exists by the grace of the meaning humans give to it.

The I-world relationship is about unity in diversity. I and the world do not coincide. The world is not in my head. Consciousness is always consciousness of something, but I experience the things that I see or hear, not here but there. Intentionality is called the intelligibility moment of phenomenology. That is to say that the idea of giving meaning lies at the basis of the ability to know the world. This is a two-way matter. Besides giving meaning, there is also borrowing meaning. I give things meaning, but the world also forces its meanings upon me.

It is self-evident that language plays a very important role in the relationship between I and the world. Language allows me to name the things in the world, to indicate what the things in the world mean to me, but the world that I come across does not need me to name it from top to bottom. The things already had names before I was born. Intersubjectivity seems to precede subjectivity, as we will soon see.

All the same, language is the crowning glory as far as the meanings in and of the world are concerned, rather than the most fundamental connection between I and the world. It is human corporeality that creates the original bond between I and the world. Corporeality, particularly as developed by Merleau-Ponty (1945), has little to do with the body as in Descartes, from which the relationship with the mind remained entirely unclear. The body in Merleau-Ponty is not an object, it is object and subject. I can look at my hand and describe it, then it is an object. But I can also grasp objects with my hand, then it is a subject. Because the human body is both subject and object, corporeality solves the epistemological subject-object problem.

The body is indeed, to paraphrase Brand (1971), the pre-eminent concrete *a priori*. Kant was still treating space and time as abstract categories of consciousness. According to phenomenology, people proportion their world in a concrete sense starting from their corporeality. Before the day that a metal bar was laid down in Paris as the metal

standard meter, and much later the meter was defined as the distance traveled by light during an infinitesimal time interval, people had used their thumbs, elbows, and feet to measure things and 5 km was expressed as the walk for 5 h, the time you needed to move your body over that distance. Even when it comes to psychological traits, from time immemorial, these have been expressed in terms which made reference to the body. Before abstract scientific terms like extrovert and authoritarian came into everyday use, we talked, for instance, about people being headstrong and pigheaded when we wanted to describe the psychological traits of others.

In the philosophy of Maurice Merleau-Ponty (1908–61), the relationship between I and the world falls nicely into place by describing the phenomenology of observation in terms of corporeality. We generally only see the things and people around us partially and we never see the front and back sides at the same time. That does not make us nervous; it would be absurd to doubt that things have a reverse side. Our own corporeality completes the things. We really do not need to see it for ourselves, although it is still possible to check whether things have a reverse side. Merleau-Ponty (1964) speaks of *visuality* and *visibility*. We still see the things that are outside our field of view in a certain sense and the things are visible even though there is, in fact, no image on our retina. To put it in everyday terms: our corporeality allows us to look round the corner, as it were.

Visuality and visibility come to play not only in the concrete observation of people and things around us. Our observation of the state of mind of other people is also like being able to look round a corner. After all, we can never directly observe the inner self of another person, we do not know what the inner self is or even whether such a thing as an inner self exists. We observe that a person is not feeling at ease by comparing his or her facial expressions and the circumstances, because of the fact that we know that the person has looked happier on other occasions. Our knowledge of another person's inner self is based on interpretation at the phenomenal level.

Memory and thinking back to earlier times can also be conceived as looking round a corner. When I think about the past, I can still conjure up certain events vividly in my mind, so vividly in fact that they do not seem any less intense that they did at the time they were actually happening. But the past is not really present. Anyone watching me while I am musing on the past will most probably feel that I am absent minded, and, despite the vividness of my recollections, I know that they are memories. Just as I have knowledge of the physical distance to things that I observe from a greater distance, even looking at them can bring me very close to them, as if I were there and not here, so I am aware of the distance in time when I remember, but my thoughts can bring me so close to events in the past that it is as if I have actually spanned the years.

That brings phenomenology into the realm of anthropology. In addressing the epistemological question, we have already said a lot about the specifically human way of knowing, and by doing so about the human condition. The relationship with the world takes us back from an epistemological relationship to a being relationship and that entails a rehabilitation of ontology. If it had been left to Martin Heidegger (1889–1976), we would have started from the other side. Existence, according to Heidegger, precedes essence. We can only fathom the world when we approach it from the human awareness of being there. At the end of his principal work, *Sein und Zeit*, Heidegger connects being with the typically human awareness of time. With the new anthropology comes a new ontology. The new ontology is, however, very different from what the Greeks understood by that term.

Time did not exist for the Greeks, time was a nonbeing. However, human existence is more than a sequence of moments in time that are irrelevant in themselves, human existence is not a continuous present. The human being is a unity of the past, present, and future. That becomes unmistakably clear when we try to understand the meaning of fundamental concrete human experiences like fear, guilt, and regret. To exist is to endure through time. In the case of regret, it is an unpleasant feeling that I have now, that relates to an event in the past, and which forces me to make a resolution for the future. Regret is not a self-chosen recollection of the past or noncommittal contemplation of the future. Regret is a feeling that happens to you at a particular moment, that you cannot prevent, and which connects you unavoidably to your past and your present. Where Husserl was still speaking about consciousness, Heidegger spoke about existence. In Husserl's transcendental idealism, the human being constituted reality; in Heidegger's analysis, the relationship with the world is affective as much as it is cognitive.

From Epistemology to Method and Upbringing

Phenomenology has two general epistemological principles, which not only serve as the starting point for its method, but are also significant for the way the process of education and upbringing takes shape.

The two general epistemological principles of phenomenology are subjectivity and intersubjectivity. There is personal sense-making, which means that every individual human being has his or her own outlook on reality. That personal perspective is bound up with preconceptions and preferences that we have acquired in our own personal past. In addition to this subjectivity, there is intersubjectivity, the body of communal sense-making. These shared meanings are tied up in social rituals and

customs and the communal meanings that are embodied in a language and which are specific to their time and culture.

Subjectivity creates a methodical problem. The phenomenologist bases his analyses on his own experience but the issue is that he is trying to say something about the reality. Phenomenological reduction ought to mean that he will give up his personal prejudices. Those analyzing upbringing do not report on their own personal experiences, even though having been brought up themselves does offer a sure way into the phenomenon. Phenomenological reduction is more of an attitude of wanting to observe things in an unbiased way, rather than a written-up methodical procedure. On close analysis, phenomenological reduction is also actually an impossible operation. After all, if one were to really renounce the meaning one personally gives to reality, that would make reality disappear.

The process known as eidetic reduction dovetails with the epistemological principle of intersubjectivity. It attempts to circumscribe the meaning of the phenomenon to be described through systematic variation. Eidetic reduction can take place by means of concrete comparison or through imaginary manipulation. This allows one to clarify which characteristics must be counted as belonging to a particular phenomenon and which must not. Some say that eidetic reduction cannot actually produce any new knowledge, as it rests on the meanings we already have and is partially embodied in the language that we have acquired in a specific cultural circle. However, if we make the pre-reflexive reflexive, put into words something that has never been put into words before, then we have to ask ourselves whether we can really sustain the view that we knew it all along.

The way the upbringing process takes shape can indeed be described very well in terms of two general epistemological principles of phenomenology. Bringing up children and educating them is always about transferring the culture, introducing them to intersubjective meanings. This means that the child is treated from the outset as a person who is also making sense of the world subjectively, in that process.

Existentialism: How to Live?

Jean Paul Sartre (1905–80), one of the two existentialists whose work and life we want to focus on first here, developed his phenomenology in an intensive exposition of the work of Husserl and Heidegger. In discussing the work of the phenomenologists up to now, their lives have not been addressed. With existentialists such as Sartre and Camus – neither of whom incidentally wanted to be called existentialist – that would be inconceivable. Work and life are so profoundly interwoven that a wrong impression

could be created if one were to pay no attention at all to their lives. Furthermore, in the case of both Sartre and Camus, their literary work formed an excellent introduction to their philosophy. That is why it used to be recommended that people start with the novels to gain a good understanding of these philosophers. For the contemporary reader though, the extreme individualism in the novels has probably become just as abstract as the philosophy, so one may as well start with the epistemology and ontology.

Sartre's philosophical development is marked by his two principal works *L'Être et le Néant* (Sartre, 1943) and the unfinished *Critique de la raison dialectique* (Sartre, 1960). He started the first book that was given the subtitle *Essay d'ontologie phénoménologie* (*Essay on Phenomenological Ontology*) in the early 1930s, before he became acquainted with phenomenology. His second book reveals his turn to Marxism, in particular historical materialism. In *L'Être et le Néant* (*Being and Nothingness*) Sartre substantiates his idea of absolute freedom that is so characteristic of his early philosophy. That absolute freedom is extreme, not only because it does not allow human beings any relativism or any excuse at all for their actions on the grounds of restrictive social conditions. Sartre takes the idea of absolute freedom much further. The man being burned at the stake dies, according to Sartre, not because the fire consumes his body but because he chooses to die. The importance of Sartre's concept of absolute freedom is probably ultimately not the concept itself, but the ethical dimension of human existence that is its consequence: absolute individual responsibility. Sartre aptly expressed the human condition with the words: "man is condemned to freedom." The power of this statement is obvious in that when people are convicted in court, their freedom is generally what they are deprived of, but a human being cannot do anything other than take responsibility.

The title *Being and Nothingness* is readily open to misinterpretation. In that title Sartre is not thinking of being human, his ultimate concern, when he uses the term *Being*; on the contrary, he is thinking of the being of things. The being of things is inherent in itself, it is *en soi*. Nothingness, *le Néant*, is the logical opposite of that being a thing, absolutely nothing. *Nothingness* is consciousness, is *pour soi*: it is geared to being and, for Sartre, that is typically human. This means that human consciousness is purely negative. Sartre coined a new term for this negation: *néantiser*. That is indeed the essence of being human: the freedom, the fundamental indeterminateness. The fact is that people are bound by the consequences of their own decisions: what Sartre called *facticité*. The term existentialism is not found in *Being and Nothingness*. Sartre became especially associated with the term existentialism following his 1946 lecture entitled *L'Existentialisme est un humanisme*, in which he attempted to defend his views against attacks from Catholic and communist quarters. However,

the authenticity that he focused on in that lecture appeared already at the end of his main work.

Sartre does not, however, have his philosophical work to thank for his immense popularity. That was simply too difficult for the ordinary reader and the student. The general public in the 1950s could, however, acquaint themselves with his ideas through his plays and novels, in which the meaning of absolute freedom is insinuated into the consciousness of the reader. In *Huis clos* (*No Exit*) (Sartre, 1938), a play that was later filmed under his direction, three people are condemned to be together for eternity: an army deserter who had cheated on his wife, a woman who had committed infanticide and a lesbian. They conceal their original identities from each other but have all chosen to be what they are. They cannot avoid accepting that what they are is the result of their own choices. In his novel *La nausée* (*Nausea*) (1938) and stories such as *La chambre* (*The Room*) and *Le mur* (*The Wall*), (in *Le mur*, Sartre, 1939), Sartre clarifies philosophical themes such as consciousness, absolute freedom, and responsibility for the ordinary reader.

Sartre is also an outstanding example of the intellectual who for 40 years made no secret of his anti-bourgeois opinions. Throughout all those years he expressed his views on collaboration, the Cold War, colonialism and the exploitation of the Third World, the Vietnam war, Russian prison camps in Siberia, female emancipation, and so on. When he tries to understand people in their social and historical context, the key concepts of his early philosophy, absolute freedom and responsibility, turn out to have shortcomings. He was reluctant to admit to wrong choices that he made and the truth behind political ideologies generally only dawned upon him slowly. When studying phenomenology in Berlin in the early 1930s, he was blind to the emerging fascism. In 1950 he was still reluctant to acknowledge the reality of the Soviet gulags. However, President de Gaulle expressed a judgment of him in no uncertain terms when he said "You don't arrest Voltaire" when Sartre the activist was about to be arrested.

The second existentialist to be discussed here is less a philosopher than the first. Albert Camus (1913–60) only wrote two books that can be broadly termed philosophical books, *Le mythe de Sisyphe*, 1942, and *L'homme révolté* (*The Rebel*), 1951. Both, Camus in 1957 and Sartre in 1964, were awarded the Nobel prize for literature. Sartre turned it down. In the late 1930s, Camus wrote with admiration, but also with detachment, about *La nausée* and *Le mur*. They met in 1944, the beginning of what Sartre called a difficult friendship. Camus never considered Sartre to be his friend. Whatever the relationship was, it ended in 1952 when the periodical *Les Temps modernes*, which Sartre edited, published a scathing criticism of *L'homme révolté* penned by Francis Jeanson.

Camus himself admits that three mythological themes operate in his literary work, those of Sisyphus, Prometheus,

and Nemesis. Sisyphus is for Camus the symbol of the human condition. By the human condition it is not so much about the conditions themselves, but about how people deal with those conditions. In the classical theme of Sisyphean labor – it is the lot of the first king of Ephyra to be punished in the underworld for his wiliness and greed by being made to push a block of marble up a steep hill over and over again for all eternity – the human condition gets its special meaning of absurdity. Absurdity does not exist for the cricket or the ant, only for humanity. However, acknowledging that life is absurd is only the beginning. Camus formulated a number of rules for human behavior. Whatever you do you should not lie and take refuge from the absurdity in religion; that is philosophical suicide. Life is worth the effort because there is a logic of the heart that is stronger than that of the intellect. No lies, no violence, no idealism either, because that costs human lives, but nor can you look on as a disinterested observer. There is a need for *bonnêteté*, which means decency rather than honesty, and tenderness.

It is thanks to French existentialists like Camus and Sartre that civil disobedience came to be part of the thinking about citizenship in the late 1960s. That was something on which they agreed. Where they disagreed was on the limits of protest and especially on the admissibility of violence. Camus set the different positions on violence against each other in his play *Les justes*. Camus was no unconditional pacifist, but he said he would rather be right by not killing anyone than be right standing on the rim of a mass grave. He also said that one can only kill on condition that one is also killed. Because Camus ultimately based resistance to terror on respect for life, he was reproached for having a Red Cross morality. Sartre, who had the last word in the *Les temps modernes* debate, accused Camus of lack of philosophical depth. When it came to the admissibility of violence, Sartre was indeed far more radical as the years passed, but he had his limits. He scathingly described Andreas Baader, a member of the German terrorist Baader-Meinhof group, after visiting him at Baader's request in 1974 in prison, as incredibly stupid.

Freedom and Responsibility in Upbringing and Education

In the continental European pedagogic tradition, in which phenomenology and existentialism play an important role, the term education (German: *Erziehung*, Dutch: *opvoeding*) is emphatically not confined, as it tends to be in the English-speaking world, to what takes place in school. The term pedagogy has been used in Western Europe (and South Africa) from time immemorial to refer to the branch of learning that is concerned with what happens to children on their long journey to adulthood, so this also includes what happens in the family. Not only the relationship

between parents and children, but also the relationship between teacher and pupil are primarily seen as pedagogic relationships. The modern formulation of the purpose of upbringing and education stems from the concept of autonomy, as developed in the work of the philosopher Immanuel Kant. The idea of autonomy, that we encounter again in a radicalised form in the absolute freedom concept of early Sartre, had become untenable by the end of the 1970s, as criticism from postmodernist circles made clear. Absolute freedom is not only restricted by outside forces – social conditions – it is also restricted internally due to internal flaws and inadequacies. For human beings, autonomy is unachievable in the real world. However, autonomy remains essential as a positive fiction for the process of bringing up children. Child-rearing and education continue to aim for autonomy, because human society in general, and especially human society in a democracy, assumes individual autonomy.

On the question of the responsibility that parents and teachers take in the pedagogic relationship, Sartre's interpretation of the concept also falls short. In general one can indeed assume, as Sartre does, that responsibility presumes freedom. In the case of the pedagogic relationship, however, responsibility is not based on freedom but on the lack of freedom, more specifically: the child's lack of freedom. The parent does not have the option whether or not to accept the parenting role. In the terms of the French phenomenologist, Emanuel Levinas (1906–95), the parent is held hostage by the helplessness of the child. Parents cannot do anything other than take this responsibility upon themselves.

Glossary

Community of inquirers – Peirce's term for those who are most educated in the subject of inquiry, their coming together to share their knowledge with each other in order to advance our understanding to the next generation of scholars.

Critical thinking – Synonymous with reflective thinking for Dewey.

Experience – James defines experience not just in terms of things or events, but also the relationships between things. It involves a doing and an undoing, a trying and undergoing, and recognizes no division between act and thing in its primary integrity, as described by Dewey.

Fallibilism – Peirce's term for the limitations and situatedness of philosophers who cannot make truth claims that are certain.

Habits – James's concept that links the body and mind.

Pluralism – James's term that emphasizes the valuing of diverse cultural perspectives and the possibility that there are multiple ways to describe our world and what we take to be truths.

Radical empiricism – James's term for his theory that the only things debatable among philosophers are those definable in terms of experience. The world we experience is more than we can describe.

Reflective thinking – Dewey's term for the inquiry process that begins with doubt, a felt need, which triggers the thinker to seek a solution by gathering information and making observations and testing out the ideas by application, similar to the scientific method.

Relativism – The view that truth is a function of human practice, and that reality is a function of human belief.

Social behaviorism – Mead's term for his theory, that argues we become individuals out of our social relations with others.

Vicious intellectualism – James's term for philosopher's efforts to describe our experiences in terms of concepts, which are helpful but also limiting. Concepts help us avoid context.

Warranted assertability – Dewey's term for knowledge that focuses on the agreement process that we use to try to establish epistemic claims, emphasizing that the testing of truth claims is a social practice.

Introduction

Euro-Western philosophy has a long history that stretches back to ancient Greece with the contributions of Plato's dialogues and Aristotle's university lectures. American (USA) philosophy owes much to continental philosophy, and its influence is strongly felt in American universities. We cannot lay claim to contributing significantly to philosophical discussion until more recent times, for America is a young country in comparison to other countries, although we do have indigenous views that have developed over a long period of time in the Americas (North, Central, and South), which we are just beginning to appreciate and consider as possible contributors to philosophical thinking. Even though American philosophy is still young, there is a philosophical approach that Americans have developed that continues to contribute to the larger philosophical world, and that is pragmatism. In fact, it can be argued that because of America's youth, pragmatism took root there. However, this youthful suggestion about pragmatism is not meant to suggest that it lacks philosophical depth.

This article describes key ideas that pragmatism contributes to current philosophical discussions, by sketching some of the important contributions made by the founders of pragmatism. Through this discussion it is shown how pragmatism has an influence on philosophers today with neo-pragmatism/postmodernism (Rorty and Foucault), critical race theory (West), and feminism (Seigfried), as well as an influence on philosophy of education (Biesta, Bredo, Garrison, and Thayer-Bacon).

Classic Pragmatism

Charles Sanders Pierce (1839–1914) was credited with coining the term pragmatism by his friend, William James (1842–1910), while they were in graduate school at Harvard University in the 1870s. Peirce later renamed his philosophical views as pragmaticism, in an effort to distinguish himself from James and others. John Dewey (1859–1952) called himself an instrumentalist, or experimentalist, not a pragmatist. Dewey's good friend and colleague, George Mead (1863–1931), called himself a social behaviorist; however, history has brought them together and describes them as the classic pragmatists.

Peirce, a logician, mathematician, and scientist by background, is now known as one of the most original

and versatile American philosophers, the father of not only pragmatism but also of semiotics. Much of his work was unpublished at his death, for he was not able to attain a permanent position at any university and retired while still in his 40s. It was his friend, William James, who not only brought Peirce's work to people's attention, and helped in getting them get published, but also had Peirce's writings housed at Harvard University, where James had a long, successful career. James (1890, 1950) went on to become a well-known professor of philosophy and psychology, and is known as a father of psychology in the United States.

What were Peirce's key ideas that launched pragmatism in the Metaphysics Club that the Harvard graduate students formed? Peirce argued that we cannot separate our ideas from our experiences for there is an inseparable connection between rational cognition and rational purpose, between thought and action, and between thinking and doing. For Peirce: "A belief is that upon which a man [*sic*] is prepared to act" ("The fixation of belief"). Put in the form of his famous maxim, he said, "consider what effects, which might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object" ("How to make our ideas clear"). He contrasted his view of modern philosophy with that of continental philosophy through his devastating criticism of Descartes' doubting method, arguing that we cannot universally doubt, as Descartes attempted to do, for, doubting presupposes something to doubt, therefore we must have prior beliefs. We also cannot find the answer to our doubts in our own individual consciousness, as Descartes attempted to do, for this will lead us to subjectivism, with no way out of our ideas to reality. Peirce showed that Descartes relied on God, in the end, to account for the self and the world. Peirce suggested instead that we determine how clear our concepts are by running them through a functional test, grounding them to experience.

Charles Darwin's *Origin of the Species* had a profound impact on the thinking of the classical pragmatists, and his influence can be found in all of their work. For Peirce, this evolutionary view of science is expressed in terms of wanting philosophy to act like science and be open to critique, not taking anything as given, but instead viewing philosophy as a field of study that is in process, relying on criteria to make judgments that are corrigible. Darwin's evolutionary influence can also be found in Peirce's theory of Truth. Peirce's theory of fallibilism describes philosophers as limited, situated knowers in need of each other to help us find ever-elusive truth(s). Peirce defeated the idea that philosophers could claim to know universal Truth, individually, on their own, with certainty. He made the case for the need of a community of inquirers, those most educated in the subject of inquiry, to work together

and share their knowledge in the hopes of getting clearer in their ideas, and then passing on their knowledge to the next generation of scholars to work on further. For Peirce, Truth is something we are moving closer and closer toward; it is objectively real and in the end of time we will all agree on what it is. However, it is an elusive, regulatory ideal, always in the future, for there is always more we can learn that will help us understand better the world in which we live.

Most philosophers today embrace Peirce's idea of fallibilism, and the need for us to work together to solve our problems, instead of thinking that any of us have a God's eye view of Truth and can discover it on our own. Most philosophers have given up the search for certainty, a clear sign of Peirce's influence. However, concerns have been raised about Peirce's community of inquirers in terms of fears of elitism (who gets to count as a scholar?), his progressivism (that Truth is something we are moving closer to), that at the end of time we will all agree on what Truth is (a consensual, universal view of Truth), and his commitment to realism (that there is a world out there separate from us and what we think about it). Contemporary feminist philosophers (Seigfried, 1996; Thayer-Bacon, 2000, 2003), critical race theorists (West, 1989), and postmodernists (Foucault, 1980; Rorty, 1982, 1989) critique Peirce on these concerns. However, we find disagreements concerning these ideas even with the classic pragmatists.

Peirce's idea of Truth as an emerging absolute, that demands of us endless investigating, changes in the hands of his friend, William James, which is one of the reasons why Peirce tried later to disassociate his pragmatism with James'. James follows Peirce's radical lead of incorporating contingency and revision into a theory of truth, yet he unties his theory of truth from Peirce's assumption that Truths are objectively real. James postulates with Peirce an end of Truth but knows that this is just a belief. "Meanwhile, we have to live to-day by what truth we can get to-day, and be ready tomorrow to call it falsehood" (*Pragmatism*). For James a belief is true if it yields sensibly satisfactory results in experience when acted upon. As James defines truth in *Pragmatism*: "True ideas are those we can assimilate, validate, corroborate, and verify. False ideas are those that we cannot." True ideas are ones we have resolved and no longer doubt. "Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process; the process namely of its verifying itself, its *veri-fication*." James took the notion of absolute Truth to be dogmatic, a foreshadowing of feminist and postmodern concerns (Foucault, 1980; Rorty, 1982, 1989; Seigfried, 1990, 1996; Thayer-Bacon, 2000, 2003).

The postulation of a mind-independent reality is how Peirce escapes the charge of relativism often leveled against pragmatism, that pragmatism is relativistic due to its relying on a view of reality as a function of human

belief and a view of truth as a function of human practice. One of James's contributions to pragmatism is his willingness to let go of realism. James soundly critiques the epistemological/metaphysical split that worried Peirce and himself as graduate students by critiquing a false metaphysics, that separates experience from existence, and dissolving the absolute/relativist distinction with his theory of radical empiricism and pluralism.

James' (1909, 1975) radical empiricism starts with the postulate that "the only things that shall be debatable among philosophers shall be definable in terms of experience," and goes on to define experience not just in terms of things or events, but "the relations between things, conjunctive as well as disjunctive" (*The Meaning of Truth*). For James (1912, 1976), experience has no inner duplicity; it just is, in its pure thatness. Experience is subjective and objective, it is private and public, it is internal and external, it is thought and thing. What we do with pure experience, when we categorize and separate it and create lines of order for it, is by way of addition, not subtraction to pure experience (*Essays in Radical Empiricism*). Experience can serve different functions and may be different kinds. In different contexts, it plays different parts. With James's radical empiricism, it is not contradictory to say that experience is both absolute and relative; it is both particular and universal.

James (1909, 1977) argues in *A Pluralistic Universe*, that the world we experience is more than we can describe. He describes reality as genuinely continuous and active, it is not a closed system but ontologically open. Our theories are incomplete and imperfect, for our concepts, as valuable as they are, stay on the surface of things. They are not capable of capturing reality's continuously changing nature. James shows over and over again how philosophy is guilty of vicious intellectualism due to its reliance on the use of concepts that are unable to penetrate and capture the flux and depth of concrete reality and experience. It is not that certain concepts are limiting, but that all concepts are. James describes how first we have immediate experience, his radical empiricism, the mere thatness of experiences. Then we frame our experiences, we name them, with concepts. However, our immediate experiences always overflow concepts and logic, conjunctions and disjunctions. Concepts start as a method for us; then they become a habit, and finally a tyranny. Concepts fix things and try to tie them down, and by doing so they help us avoid context. Whenever we try to describe our experiences something always escapes, our logic always omits something.

James represents America's live-and-let-live individualistic approach, in that he argues for the sacredness of individuality. He embraces the value of pluralism in terms of valuing diverse cultural perspectives, thus avoiding the charge of elitism others have made against Peirce. James's individualism caused him to be accused of relativism in his

lifetime; however present-day feminist scholars have demonstrated how he avoids this charge through his dissolution of the absolutism/relativism bifurcation with his theory of radical empiricism and pluralism (Seigfried, 1990). Yet, his individualism leaves him vulnerable to present-day concerns about his blatant sexism and racism that are evident in his writings, both of which are representative of his historical and cultural embedding (Seigfried, 1996). James critiques himself on some of his biases in various essays such as 'On a certain blindness in human beings,' but misses other important limitations, thus confirming Pierce's theory of fallibilism (see Garrison *et al.*, 2002 for present-day essays concerns James).

Along with James' (1899, 1958, 1890, 1950) concept of experience, another key concept of his is habit (See *Talks to Teachers on Psychology*, and *The Principles of Psychology*). James looks at habit in terms of individual habits, how these develop over time and form the basis of learning, how they link the body and the mind, how they help to economize and coordinate our actions, and how an understanding of habit can be used by teachers to not only help manage their classrooms, in terms of students' behaviors, and avoid problems such as students' balky wills, but also help teachers establish helpful habits of inquiry for their students. Children learn to ask questions and to pay attention to their doubts because they are taught to do so and have the chance to practice inquiry skills. Dewey (1910, 1938, 1965) further developed James's habits in terms of habits of thinking (*How We Think*) as well as with his two principles of interaction and continuity (*Experience and Education*). However, before diving into some of John Dewey's key ideas, we turn to his colleague, friend, and neighbor, George Herbert Mead, as Mead's social turn influenced Dewey's thinking as well.

Mead was a philosopher and a scientist, a psychologist and a sociologist during a time when those fields of study had fuzzy boundaries. Mead (1934) describes his theory as social behaviorism in his famous social psychology course (*Mind, Self, and Society*). Mead argues that we become individual selves with minds out of our social relations with others, thus turning upside-down psychology's focus on individuals *qua* individuals as well as classical liberalism's view of the individual as separate and autonomous from society. Mead argues we are first of all social beings who then become individuals. His fundamental approach to understanding human behavior is from the point of view of conduct, particularly conduct as it is observable by others. Again, we find a theory that focuses on action as its fundamental datum.

Mead tries to go back to the early stages of social acts preceding symbols and deliberative communication, apart from some form of consciousness, in order to understand how we develop a mind and self. He looks historically at early human beings' conduct as well as studying infants' experiences, both as they are prior to language. Mead

argues that we must assume that individuals are brought into essential relation with the social process before communication so that contact with the minds of others is possible, in order to avoid solipsism. First, we have experiences within a context – we have the conduct of the individual in the environment. This environment is a social one. It is through communication by a conversation of gestures in a social process that our consciousness develops, our mind arises, and we develop a self. For Mead, gestures are our first means of communicating, the beginnings of social acts. When a gesture means an idea and it arouses that idea in the other, then we have a significant symbol. A significant symbol signifies a certain meaning, and we call this language. When our gestures have shared meaning and become significant symbols, then we are able to think. Mead defines thinking as “simply an internalized or implicit conversation of the individual with himself by means of gestures” (p. 47).

Mead explains that in order for an individual to become conscious of the meaning of her own gestures, she must be able to take the attitude of the second individual toward that gesture, and respond to it in the same way. As we are able to take the attitude of the other toward our own gestures, our consciousness evolves. So that the mind, or intelligence, is defined by Mead as “the taking of the attitude of the other toward one’s self, or towards one’s own behavior” (p. 48). When a gesture indicates to another the same that it indicates to the individual, then it has meaning. This is why Mead says that meaning is a social act. When our gestures call out the same response in the other as ourselves, then we are unconsciously seeing ourselves as others see us. For Mead, the most important gesture we have is the vocal gesture, as vocal gestures allow us reflexivity, the ability to turn back our own experiences upon ourselves. The conversation of gestures is the beginning of communication.

Mead’s theory of self-development is that the self is not there at birth, but develops in the process of social experience and activity by becoming an object to itself. Psychology’s essential problem, according to Mead, is explaining self-consciousness: how can the self get outside of itself to become an object to itself? Mead’s answer to this problem is that the self becomes an object to itself by taking the attitude of others toward her within the social environment. The language process is essential for the development of the self, for communication provides a form of behavior in which the individual may become an object to oneself. As Mead’s theory of self-development is based on social construction, he must address concerns of social determinism. He does this by describing our subjective experiences, our memory, and imagination, as being accessible only to the individual, the I, while the social side of us, the me, stands for the self I am aware of, the conventional self based on the organized attitudes of others. The I is unpredictable and uncertain and exists in

the now; it is unknowable. It is the self’s action over and against the social situation. The me acts like a censor, setting the limits of the self through social control. Together they form a self, which adjusts to others’ attitudes and at the same time changes others’ attitudes.

There are several issues with Mead’s theory with which present-day scholars wrestle with (see Biesta, 1999; Thayer-Bacon, 2003). In the effort to heal splits, Mead continues to assume splits, for example, between the mind/body in his discussion of the mind and self, between reason/emotions in his discussion of thinking and self-reflection, and between the public/private in his discussion of the social me and the qualitatively unique I. However, we find Dewey seeks to heal these splits in his own work as well.

John Dewey and George Mead were good friends and colleagues, and also neighbors living next to each other in Chicago. They greatly influenced each other, as they both were developing their individual theories during the time they worked together. Like Mead, Dewey holds a social behaviorist view of meaning. Dewey, with Mead, recognizes that individuals start out as members of communities. However, Mead’s individual tends to be subsumed by the generalized other, the social me disciplines and censors the I, while Dewey’s individual, even in its state of immaturity as a young child, interacts with and changes general society. Dewey distinguishes his views from Mead’s when he creates a transactional model that describes social groups affecting individuals and individuals affecting social groups (Dewey and Bentley, 1949, 1960). Dewey (1916, 1996) starts his famous *Democracy and Education* with a description of communities and self-development that is very much in agreement with Mead. However, for Dewey, while children are physically helpless and dependent on others, they are socially powerful. They are gifted at getting the cooperative attention of others and of attending with interest to the doings of others. The young, immature, affect the mature and the mature affect the young. Dewey’s significant contribution to democratic theory is based on his recognition of the interactive, interrelational, and interdependent qualities of individuals in relation to others (Thayer-Bacon, 2008). The way we measure the worth of any given mode of social life is by how much the interests of the group are shared by all of its members, and how full and free the group’s interactions are with other groups. For Dewey, democracy is defined as more than a form of government: “it is primarily a mode of associated living, of conjoint, communicated experience.”

In Dewey’s (1922) *Human Nature and Conduct*, he describes his psychology with a social emphasis (habits) based on an evolutionary framework (impulses), where habits constitute the self and mind and serve the regulatory role that the generalized other serves for Mead. Yet, Dewey allows for a greater potential for flux and

adjustability due to impulses. Habits are enforced upon us from the day we are born, by the very fact that we are social beings. Habits are imposed upon us through social custom. Yet, habits are acquired and secondary, not native to us as impulses are. In agreement with James, Dewey argues that impulses are what give us flexibility and diversity and habits are what give our impulses direction and shape.

Not only does James's concept of habit contribute significantly to Dewey's psychological theory, but James's concept of experience is also further developed by Dewey. In *Democracy and Education*, Dewey (1916, 1996) describes experience as having an active and passive element, trying and undergoing. "We do something to the thing and then it does something to us in return; such is the peculiar combination." In *Experience and Nature*, Dewey (1939) describes experience as "a double-barrelled word ... it includes *what* men do and suffer, *what* they strive for, love, believe and endure, and also *how* men act and are acted upon, the ways in which they do and suffer, desire and enjoy, see, believe, imagine ... It is 'double-barrelled' in that it recognizes in its primary integrity no division between act and material, subject and object, but contains both in an unanalyzed totality."

We find this trying and undergoing description of experience in Dewey's educational theory as well. In *Experience and Education* Dewey (1938, 1965) describes two principles, continuity and interaction, that we can use to interpret an experience for its educational significance and value. The principle of continuity emphasizes how every experience "both takes up something from those which have gone before and modifies in some way the quality of those which come after." The principle of interaction "assigns equal rights to both factors in experience – objective and internal conditions. Any normal experience is an interplay of these two sets of conditions." Dewey tells us, "every experience enacted and undergone modifies the one who acts and undergoes, while this modification affects, whether we wish it or not, the quality of subsequent experiences." An experience that has educational value is one that encourages further growth by arousing curiosity, strengthening initiative, and stimulating desires and purposes for effecting change in the environment.

Dewey developed further Peirce's idea of fallibilism and James' radical empiricism with his concept of warranted assertability. Dewey (1938, 1955) tells us in *Logic* that Peirce is the source of his ideas concerning logic. As he takes seriously Peirce's claim that we will never know this Reality, that it is a futuristic Ideal, Dewey distinguishes between ontological Truth (the nature of truth) and epistemic validity (the test of truth). For Dewey, logic is not separate from inquiry; logic is embedded in the contextuality of inquiry. He shows that interpretations of logical forms vary with underlying metaphysical and epistemological assumptions.

As knowledge has come to mean a fixed eternal end, rather than that which satisfactorily terminates inquiry, Dewey adopts the concept warranted assertability to stand for knowledge as a general abstract term related to inquiry in the abstract. Dewey argues that we need to focus on the agreement process that we use to try to establish epistemic claims – inquiry, for this helps us understand that the testing of truth is a social practice. Certainly today's postmodern, feminist, and critical theory work, all support Dewey's argument, and in fact turn to Dewey to help them make the case for the importance of addressing power issues in discussions of truth. Dewey argues that as fallible, contextual human beings, we have access only to truths derived from our own error-prone yet self-correcting procedures. Even our logical forms are developed within our own contextuality. Therefore, our truth claims are forced to be tentative and revisable, and any argument for Truth as corresponding to reality or as coherence must fall back on warranted assertability in practice.

As Dewey's (1938, 1955) central argument is that all inquiry (and logic itself) is affected by philosophical assumptions that are culturally bound, he recommends a view of inquiry that embraces the self-developing and self-correcting nature of scientific inquiry (*Logic*). The scientific model reminds us that individual conclusions are only hypotheses until agreement can be reached. Again we find science's influence on pragmatism. Dewey (1916, 1996) describes his recommended scientific approach to inquiry as reflective thinking in *How We Think* and *Democracy and Education*. As a pragmatist, Dewey shows us that thinking begins with a situation of experience, then a problem develops within this situation (felt need); this triggers the person to seek a solution (hypothesis) by gathering information and making observations (reasoning/solutions), and testing out the ideas by application (testing hypothesis/ideas). His model for reflective thinking is like the scientific method and it has greatly influenced more recent debates concerning critical thinking.

Dewey (1900, 1902) sought to connect his philosophical theory to educational practice, and can be credited as a father to philosophy of education in America. While working at the University of Chicago, he started a lab school that became famous and still exists, a place where educational theories could be tested out in the daily practice of teaching children (see *The School and Society* (1900), and *The Child and the Curriculum* (1902)). His own children attended this school and his wife, Alice, served as principal (Seigfried, 1996). One cannot go to an educational conference in the USA without hearing Dewey's name being referred to, and often his name is in the title of the presenting papers. It is impossible to overstate his influence on American education. However, one will find varying interpretations of Dewey's work, and he is often critiqued for crimes that others argue he never

committed. It is easy to misread Dewey, for he uses common language in unique ways, and one must look carefully for his definitions and examples to make sure the meaning is correctly understood (Biesta and Burbules, 2003; Garrison, 1995, 1997).

Conclusion

It makes sense that pragmatism developed in the USA, for the roots of pragmatism are in the developing culture of the country as well. Pragmatism is about connecting theory to action, showing what the result of that idea is. Pragmatists seek to connect thinking to doing, experience to the outcome of directed action, so that philosophy is not just about abstract ideas, but is also about trying to have an impact, make change, and solve real-life problems that people have. Pragmatists seek to get philosophy out of the ivory tower of the university and out in the community with the philosophers' task viewed as one of social activism. They are dreamers of what should be ideally – poets, prophets, and soothsayers who seek to improve people's everyday lives. Pragmatists take on classical philosophers from the past and offer strong criticisms of their work, rejecting central problems and dichotomies such as mind/body, reason/will, reason/emotion, thought/purpose, facts/values, self/others, appearance/reality, and theory/practice as they seek to heal splits and dualisms that others have created and offer a unifying description of the world. In the healing of dichotomies that have developed over time, pragmatists bring together various fields of study to help them. They turn to history, psychology, sociology, anthropology, for example, to help them in their ameliorative efforts, thus making their work interdisciplinary. They are also pluralists, not only in terms of recognizing the value of diverse perspectives, experiences, values, and meaning, but also in terms of recognizing that there are multiple possible answers or solutions – multiple truths. They seek to work in collaboration with others and create a community of inquirers as they do not think that on their own they are as likely to be able to solve the problems with which they wrestle. Pragmatists want philosophy to act like science in terms of being able to question one's theory at a deep level, all the way down to one's criteria, methodology, and basic assumptions, as well as one's situatedness.

Psychoanalysis and Education

Reconsidering Psychoanalysis

The entire enterprise of education has become colored by means–end rationality. The other, with whom the teacher is confronted, is treated first and foremost as a recipient for knowledge or training whose content has already been set out in advance. Some have, therefore, turned to psychoanalysis as a model for a very different way of relating to the learner. It can be understood as a nontechnical enterprise in which issues of language are in the foreground, where the educational and the ethical no longer go separate ways, and where the encounter with the other precedes understanding. At its core are susceptibility, vulnerability, and openness rather than any kind of knowledge as may be conventionally conceived. The climate of opinion has moved fairly conclusively against psychoanalysis – especially concerning its scientific standing. Yet, Freud often laid claim to being a scientist. It is familiar, for instance, that he is inclined to see the mind in terms of fluid mechanics – as if psychic energy swirls around the system, gaining in pressure the more it is repressed and sublimated, and emerges in dreams, slips of the tongue, and so on like puffs of steam; or, to take another example, that the meaning of dream symbols is fixed as if they were mathematical constants. Freud's followers and translators, generally, perpetuated this picture. Of course – given the prestige of science in Freud's time, as well as in ours – this is unsurprising. Is there a way to understand psychoanalysis, if not as some kind of science?

The views of philosopher Ludwig Wittgenstein are illuminating on this question. He disparages Freud for “constantly claiming to be scientific” (Wittgenstein, 1966: 44) yet is reported (*ibid.*, p. 41) as saying: “I happened to read something by Freud, and I sat up in surprise. Here was someone who had something to say.” The mistake, according to Wittgenstein, is to take physics as our ideal science when studying psychology (Wittgenstein, 1966: 42): “We think of formulating laws as in physics.” We should rather think of Freud as offering us a new mythology to live by:

Freud refers to various ancient myths . . . and claims that his researches have now explained how it came about that anybody should think or propound a myth of that sort . . .

Whereas in fact Freud has done something different. He has not given a scientific explanation of the ancient myth. What he has done is to propound a new myth.

The attractiveness of the suggestion, for instance, that all anxiety is a repetition of the anxiety of the birth trauma, is just the attractiveness of a mythology. (Wittgenstein, 1966: 41)

Freud

In giving us a story about the unconscious, repression, and so on, Freud is doing the same kind of thing as when he reminds us of the story of Oedipus. In both cases, he tells us “life's like this.” Wittgenstein declared approvingly of Freud's work that “It's all excellent similes” (Monk, 1990: 357). On this account, the value of the myth of Oedipus is not that it prefigures or dramatizes the Oedipus complex – the latter being seen as a piece of psychopathology, independently and scientifically knowable, which bears the Greek name for the sake of vividness. To make the acquaintance of the myth is rather, in itself, to learn something helpful – in that the myth depicts a pattern in which aspects of our lives fit and make sense. It is – Wittgenstein says – speculation rather than insight (e.g., into the timeless human condition). “It is something which people are inclined to accept and which makes it easier for them to go certain ways: it makes certain ways of behaving and thinking natural for them. They have given up one way of thinking and adopted another” (1966: 44–45). Mythological explanations have the attraction that they say “this is all a repetition of something that has happened before. And when people do accept or adopt this, then certain things seem much clearer and easier for them. So it is with the notion of the unconscious also” (Wittgenstein, 1966: 43).

Myth supplies a new language, a new framework for looking at the world. It offers both the patient and the analyst an alternative to languages and frameworks which seem necessary, written in the stars, even obsessive; meanings that appear fixed and determinate. An example may help here. A young woman found it difficult to resist her parents' blandishments to return to the family home which she alleged had been a place of abuse during her childhood, and visits back to which correlated accurately with what her psychiatrist diagnosed as subsequent psychotic episodes. She was, on one level, well aware of the damage these visits did her, but repeated that “mum was only trying to be kind,” that it was nice to be in a house that was well decorated (compared to her student accommodation), even if rather fussy, with everything color-coordinated

and ubiquitous potpourri; and that “there was always food available” and that mother constantly joked about “fattening her up.” At one point, the young woman’s counselor commented that home sounded like the gingerbread house (from the fairy tale of Hansel and Gretel: the children are lured there by a witch who only wants to fatten them up to eat them). This apparently gave the young woman a metaphor she found helpful: a way of acknowledging that home was both sweet and threatening, potentially fatal. It appears it released her from the fantasy that home is home after all (this one is, indeed, home, sweet home) and from the difficulty of acknowledging its threats. Wittgenstein says that “it may then be an immense relief if it can be shown that one’s life has the pattern rather of a tragedy—the tragic working out and repetition of a pattern . . .” (Wittgenstein, 1966: 51): or, we might say, the pattern here of a fairy story.

To summarize: in its focus on language, psychoanalysis reminds us that we live in and through language: language is not a neutral instrument. It offers us a new myth in the form of its own characteristic frameworks of understanding (the anal stage, the oral stage, and so on). The technical jargon that it generates is both liberating and dangerous. It is one of the best insights we owe to Freudian psychoanalysis that language is not an indifferent medium through which we conduct our value-neutral scientific interventions. An individual might reflect that the development of a richer and more responsive framework of language (to replace fixed concepts with absolutely determinate meanings) is clearly as much a task for the teacher, at every level, as it is for the psychoanalyst. Moreover – as a major task for the therapist is to see through, and help patients to see through – there is also another interesting parallel. The analyst is not concerned to hand over solutions – readymade or otherwise – but to help the patient learn to find his or her own way to solutions, and this not as a matter of acquiring techniques but of the reorientation of self to the world. What is worth taking seriously in psychoanalysis is, thus, parallel to what is worth taking seriously about some aspects of education.

Lacan

Children’s lives are, to a large extent, led according to rules fixed by adults. Perhaps, this situation is not to be deplored – they are, after all, not yet adults, not yet held responsible in the full-blown sense. Yet, it remains hard to deny that their freedom is limited. People – and children as well – desire particular things, and what comes in the way of fulfilling these is experienced as restraint. In the relationships between teachers and parents – and teachers and children – desire works in different ways. There is, first, what they want for themselves and for this matter from each other, but there is also what they want the other

to desire. In addition, last but not least, there are cases where it is not clear what exactly one wants from the other, where this can only, generally, be indicated as recognition for one’s own desires. The French philosopher and psychoanalyst Jacques Lacan (for a more elaborate general introduction to Lacan, see Benvenuto and Kennedy (1986)) developed a theoretical position in which a number of these matters are dealt with in a highly sophisticated manner. This position sheds light on how others are necessarily always there, and on how their expectations are – for the subject, at the same time – both unavoidable and liberating, that is, they enable her desire to find a pathway for expression. Lacan’s subject is not the subject of the *cogito*, that is, the subject that consciously assures itself of itself in its representations. It is split – separating itself from itself in the very act of self-representation and disappearing into the gap between the *cogito*’s enunciation and its statement: in Lacan’s words, the subject thinks where she is not, therefore, she is where she does not think. Lacan radicalizes Freud’s epistemological and psychoanalytical position – interpreting it not so much as a matter of surging energy or a hydraulic metaphor of the instincts, but rather in terms of particular representations that will recur and recur. Psychoanalysis is itself – in his opinion – above all, based on a fundamental split between the subject and the knowledge she has of herself. Lacan looks at the turning points of the discourse not from a purely linguistic point, but as the effect of a meaning which escapes its own signification. The order of language replaces the subject’s lack of being – from which the desire for the missing object arises. There are always other desires and other objects which present themselves as being able to fill up the lack of being. The formation of the subject (of the one who says ‘I’) is explicated by Lacan through what he calls the mirror phase. The helpless infant – not yet objectively in control of her movements – jubilantly perceives in the mirror the mastery of her bodily unity, which objectively she still lacks. She becomes aware – through seeing her image – of her own body as a totality, as a total form or *Gestalt*. The subject’s identification with her own body as other than herself structures herself as a rival to herself, and the separateness and the rivalry generate aggression. This structure remains present throughout human life and characterizes all human interactions. In dealings with the Oedipus complex, Lacan emphasizes the function of the lack of the object and lack in general. The end of the original unity of mother and child is precisely what leads to the subject’s possibility of becoming a subject of desire. Without the law – which deals with relations with others – the mother can autonomously, in a sense arbitrarily, deal with the child’s wants. In the unmediated realm, the other is not bound by any law and the child is a possible toy of her changing answers. The presence of a third person – one could say (literally or figuratively) the father – breaks this fusion-like unity open. He is also the

one she desires. In this sense, the child cannot be everything for her mother and she is not only there for her. The relationship between mother and child is mediated by a third who represents the symbolic law of the culture.

The separateness already indicated in the mirror stage is further affirmed when the child enters the symbolic – the social order of language and culture. Before the subject can act as a self, it is projected and absorbed in the universal order of language and culture. The child has to settle herself in this order. The symbolic order does not consist only of a system of different meanings (differences), but also of a complex network of discourse, conversations of the Other. The term discourse refers to what is said, to the conversation, to its content, to what is regarded as important. Because of that network, the subject is not only subjected to the formal system of signifiers, but also to the way in which these are organized in the discourses of others, and in other words subjected to a historically determined meaning. The child is absorbed as a part of a network of tales (discourse) told by others about him, some of them even before he was born: “It is a boy. Doesn’t he take after his father?” This network consists of a number of prohibitions and commandments, desires, anticipations, obligations, and value-judgments to which the child has to accommodate herself. These discourses are contradictory and do not give a coherent image of herself. As a consequence, the subject can never satisfy their demands.

The unconscious images – the discourses of the Other that cannot inscribe themselves in the subject and that cannot be accommodated by the subject – stay active in the mind and come to the surface in all kinds of symptoms unavoidable for the subject. They cannot be accommodated – are at war with the already existing images in the subject. The subject, the ‘I’ who speaks of herself, is not the same as the ‘I’ that is spoken of: the meaning surpasses her. The subject (the one who says ‘I’) is not master of herself, but subject of the symbolic order: “*Je est un autre [I is another]*” (Lacan, 1966: 118). The subject arises in relation to desire that is unknown to her. The Other is the real witness and guarantor of the subject’s existence, as it is she who can recognize the subject. In the perception of the subject, the Other is not affected by the same lack, and can be identified with the mother’s original role in relation to the infant. The Other is where the subject is born, not only as a biological entity, but as a subject with a human existence.

From the moment of initiation into the symbolic order, the subject can never reach anymore what she, in the end, desires. That is what keeps the desire going. However, it is also the symbolic law of the language and culture that makes it possible for the child to withdraw herself from the suffocating omnipotence of the Other. There is always the desire of the Other – who recognizes or does not recognize her desire, who approves or rejects, and allows or punishes. To develop in a meaningful way, the desire

needs the recognition of the Other. Thus, the desire of a human being becomes the desire of the Other – “*le désir de l’homme, est le désir de l’autre*” (Lacan, 1966: 693). Unlike Freud’s version in the chain of conscious reasons, the Lacanian unconscious will not provide the answer one cannot find on a conscious level that leaves no gaps. The unconscious reminds the subject that reasons will never really do, it marks the ineliminable impossibility of understanding human desire in a definitive way. The truth of the unconscious – that human desire is not limited to what is good for herself – is something that the subject does not want to know. Because the Other is (necessarily) deceiving her, the psychoanalyst’s function is not to answer the subject’s appeals and demands, but, instead, to act so that the answer comes back to the subject from the analyst as a question: What do you want from me? What the subject lacks or has lost is not present in the Other.

Implications for Education

The message for education may go back to something basic: the importance of being surrounded by people who care and, indeed, demand a lot of those whom they care for. Nothing is, indeed, more violent than being left out, not desired at all by the Other – at the extreme, not being able to enter the symbolic order. Lacan’s position hints at a new ideal of personhood – interpreting what one does and does not do to understand better how and why one desires what one particularly longs for. Maybe all that in order to be able to accept (at last, and each time anew) who one is, to find at least for a moment one’s peace, and one’s truth.

Turning to the context of formal education, one can see that the thoughts and actions of teachers and students are influenced by the imaginary, symbolic world of the school. Even if the student thinks and speaks to herself, the Other exists, choosing the words in language that can best be understood by her. The Other becomes a central concern, ‘it’ controls the infant’s first associations with her parents and forces her to attend to the world, teaching her to see it in terms of logic, rules, and orderliness. Schools make an important contribution to society by reproducing the *status quo* – both in its intellectual and cultural variants. Despite this, they have been able to maintain the fiction of neutrality and autonomy – providing significant ideological services to a capitalist society. In this instance, the culture of the school is conceived as transmitted through pedagogic practices, validated by the political power of the state. These practices, in combination, provide students with a language that defines them and their place in the social system, definitions of what is important for youth growing up in the inner city, for instance. In reality, a litany of traditional values and beliefs are recited to them which seek to define what is good and

bad, who is intelligent and stupid, and what good manners ought to be in the classroom. Good taste and the norms of educational decorum are placed in front of children as a constant reproach: this is how you should act if you wish to be considered an intelligent and worthy person. Thus, the socially correct attitudes and behaviors of classroom life are taught. Children are not to chew, fight, or throw things. They are not to leave their desks or talk without permission. The teacher has the right and duty to control their bodily movements and gestures, can force them to sit still and be silent, and can punish and humiliate them with a word. Rothstein (1993) argues that schools have always been tied to other agencies of capitalism, even as they denied such links. They have arisen from social and political customs and from the functional needs and beliefs of those who funded them. In addition, in pursuing their own purposes, "they [have] developed a special history and practice, borrowing methods from mental hospitals, military and penal institutions, and the charity schools of the early nineteenth century" (Rothstein, 1993: 80). The organization of education systems seems to be opposed to change, insisting on a return to basics and a simpler past.

The insistent demands of Otherness are taught in the classroom, a world of words sustained by teachers where the primary Other is the teacher. It is the teacher who has the power to decide, who is the one pupils must attend to, who speaks where they listen. A collective voice of the Other is constructed – reflecting the background and levels of attainment of the children. Only internalization of the mores, moral understandings, and language of the classroom permits students and teachers to speak and to be understood. It is, however, not something they consciously plan or execute. Early in their schooling, children become aware of the Otherness that teachers and other students represent. The Other, in these instances, is never an actual person, but always an unconscious construct in which the word is located and used by children and teachers alike. With their servile silence and submissive gestures, students seek to soften the coerciveness and authority of the all-powerful adult, summoning up and transferring behaviors and identifications from previous experiences with all-powerful parents. Mostly students seek recognition and acceptance as worthwhile and competent persons, and some measure of assurance and predictability in their relationship with the demanding teacher. 'A very good answer' is not only an encouragement and praise, but also creates the dangers of dependency and submissiveness. As long as the teacher ignores her role as a state-employed worker – as long as she is ignorant of the social functions of schooling in modern life, she cannot understand her true relationship to her students, Rothstein (1993) argues.

In this case, the unconscious is that part of an educational system's history that is marked by mythology, folklore,

and amnesia. It is the proscribed past that has forgotten its own roots and social functions. It can be uncovered in the words and phrases that teachers and students use when they speak to one another. It can be discerned in the traditions and folklore of schooling, and in the normative and ethical structures used to validate pedagogic practices. Every experience of failure and rejection in classrooms leaves personal scars. The humiliations of student experiences are, often, repressed and unavailable for conscious retrieval. But what has been forgotten still exists and affects the way students and teachers act. As the context of education reveals itself as serious and important, the child represses her social needs and desires. She accepts her subordinacy and regimentation because all of her own kith and kin have advised her to do so, and because of her own dependent status in her family and communal relations.

When small children are doing well in mathematics, they might, sometimes, become fearful if confronted with more complicated problems. The child needs to be disturbed out of this kind of complacency and needs to be made to confront the mathematics problem. Instead of giving the correct answer, the teacher might try to help them to feel more secure, that they are up to this – thus not taking this task away from them. At the other extreme, in the writing of a PhD thesis, the adult student – while also working at a full-time job – frequently struggles with the question of where it all leads to. Such a student will go through periods where the whole thing seems impossible – she thinks she is not able, she does not have the time to do the topic justice. However, perhaps, the struggle is internally related to the quality of the learning and to what is produced; a student's PhD work can come too easily. This may also more broadly be true of education. It points to the inappropriateness of separating what is learned and the learning involved from the person of the learner in a broad sense, although not of all learning, of course – for example, learning to type. Here, the supervisor should not try to answer but return the question and its difficulties to the student. Although she might try to re-channel the candidate's energy when she goes through a difficult time, it would be wrong for her to offer answers. Constantly available and maintaining that there are ways forward, she should refrain from giving one – instead, creating the opportunities for the student to find one for herself. It would be a betrayal to her real interests if the student were not frustrated, comforted but not confronted with real learning itself. Another case is the youth who fantasizes about a future career. There is an incredible range of choice in higher education and there is a tendency with the rapidly improving information and guidance on these matters to treat the decision in an excessively rational way. Again, the student ought to become frustrated. The careers counselor should acknowledge her desire and indicate alternatives, but she should stay away from indicating the

answer. Her project ought to be a negative one, as, again, it is the student who has to find for herself what she wants to do. As for the pilgrim of earlier days, it is most important to travel. Here, as elsewhere, there is the message that you cannot know what you really want unless you are confronted with something. In addition – as in sport – frustration and failure are, sometimes, desirable in teaching. This is at odds with finding the correct answer as suggested by the technological spirit in education; rather, it points to the idea of self-realization in progressive education.

The Lacanian position and psychoanalysis, more generally, thus challenge several pictures that held us captive – not the least of which is that we know what we really want. In stressing the third-person perspective and the way the infant is fixed into this order, Lacan finds a subtle balance. He reminds us over and over again that there are many rooms in the house of being and that transgressing this border by trying to delimit them is dangerous. An estrangement from herself will destroy the subject and put humanity itself at risk. (For an elaboration see Blake *et al.*, (1998, 2000) and Smeyers *et al.* (2007) on which this article is based.)

Social and Cultural Capital in Education

M Print, University of Sydney, Sydney, NSW, Australia

Glossary

Cultural capital – A broad theory to explain differences in societies such as class differences.

Formal curriculum – The formally planned and organized set of learnings for students which usually takes the form of the subjects that compose the school curriculum.

Informal curriculum – The nonschool subject learning in schools that includes activities such as participation in meetings, clubs, student governance, and fundraising which are largely unplanned by the school compared with the formal curriculum.

Social capital – This refers to connections among individuals that facilitate collective action and includes trust, norms, and networks of association representing any group which gathers consistently for a common purpose.

Many forms of capital – economic, human, cultural, and social – have been identified by social scientists. These are mostly seen as input measures to explain variations in phenomena in society. For example, differential amounts of capital may explain differences between classes, or why some students perform better at school than others and so forth. This article examines the relationships that social and cultural capital have with education in general and schools in particular. In these contexts education is usually considered as an input variable that affects the level of social and cultural capital. Consequently, increasing levels of education, it could be predicted, should produce higher levels of social and cultural capital. While this is an intriguing possibility this article will concentrate upon the nature of the relationship between social capital and education and particularly on the potential of the school in facilitating the accumulation of social capital by individuals and society.

Social Capital

Social capital is a seductive concept. It offers much, tantalizing researchers and policy makers with a procedural solution to unsolvable problems. As Portes commented "... social capital has evolved into something of a cure-all for the maladies affecting society at home and abroad." (1998, p. 2) Its ability to deliver solutions, however, has

been seriously questioned (Portes, 1998; Baron *et al.*, 2002; Dika and Singh, 2002). In the 1990s social capital burst upon the academic scene driven by the popular work of Robert Putnam and its appeal to major intergovernmental agencies such as the World Bank and the Organization for Economic Cooperation and Development (OECD) as it addressed major issues of civil society, economic development, and poverty (World Bank, 1999; Woolcock, 2001). For the World Bank social capital is a useful organizing concept to explain levels of social cohesion which, in turn, is critical for economic development and sustainability (World Bank, 1999).

It was soon realized, however, that the construct was neither new nor without controversy. Some have traced its roots to even the late nineteenth century, though most researchers attribute the work of Bourdieu (1986) and Coleman (1988) as the meaningful beginnings. While most writers treat social capital as highly positive, it can also have a dark side (Bourdieu, 1986; Print and Coleman, 2003). Interestingly, in recent years social capital has, to a limited extent, consolidated its presence in a diversity of applied areas (such as welfare, urban planning, engineering, health, economics, organizational behavior, sociology, natural resources management) and yet waned academically as it appears to have failed to live up to its high expectations as a research panacea for explaining social phenomena. So what is this construct and why is it seductive?

Defining Social Capital

How one defines social capital depends in large measure which position one takes relative to the three key theorists – Bourdieu, Coleman, and Putnam. From a socialist perspective Bourdieu saw social capital as elitist, helping to explain the process of social reproduction. He envisioned social capital as a critical tool, with an analytical function that would contribute to a deeper understanding of the way different forms of capital interacted. Coleman argued that nonelites could also benefit from acquiring social capital, taking a more nuanced, sociological perspective to the construct. Putnam, however, took a political science perspective and used social capital to help explain political systems, especially democracy and how people might gain from increasing their stock of social capital.

Putnam's view that social capital refers to connections among individuals that facilitate collective action has received wide, though equivocal, support. These resources include trust, norms, and networks of association

representing any group which gathers consistently for a common purpose. In a political sense social capital is often seen as the glue that keeps democracy together. It is essentially about trust, cooperation, and networking. As Putnam argues, social capital enables people to resolve collective problems more easily, facilitates trust and interactions in communities, enhances interconnectedness amongst people, and facilitates the flow of information.

Many researchers have argued that healthy democracies are characterized by high levels of social capital. For example a norm of a society high in social capital is reciprocity, which encourages bargaining, compromise, and pluralistic political outcomes. Another norm is belief in the equality of citizens, which encourages the formation of groups that transcend traditional societal groupings such as class.

In a more pragmatic sense the World Bank (1999) refers to the norms and networks that enable collective action. It encompasses institutions, relationships, and customs that shape the quality and quantity of a society's social interactions. For the World Bank social capital consists of five dimensions – groups and networks; trust and solidarity; collective action and cooperation; social cohesion and inclusion; and information and communication.

A common theme amongst these definitions is that social capital facilitates social functioning. As such it consists of four main components – it resides within groups; it involves civic virtues such as trust, cooperation, and civility; it requires of participants that they be actively engaged; and it is mutually beneficial for members and the group (Print and Coleman, 2003).

However, to suggest that there is unanimity in definition or even conceptualization, let alone whether the construct is meaningful, is far from reality. Contested definitions abound (Portes, 1998; Newton, 1999; Lin, 2001) usually arising from a different perspective or the argument that earlier definitions are incomplete or inadequate.

Types of Social Capital

The literature, and particularly the extensive work of Putnam (1993, 2000), Woolcock (2001), and Field (2003), identifies at least three types of social capital and one could argue for a fourth:

1. Bonding social capital is more exclusive. This includes social networks amongst homogeneous groups of people such as family, friends, and neighbors. Bonding is referred to as dense, tight-knit, homogeneous social networks. For Putnam (2000) the best metaphor was sociological superglue. While envisaged as a positive form of social capital, bonding can also include negative social capital as in the case of criminal gangs.
2. Bridging social capital is more inclusive and includes social networks between socially heterogeneous groups

such as close friendships, workmates, and formal groups. These are more access oriented to enable access to valuable resources and information outside immediate networks. Putnam (2000) saw this as a form of sociological lubricant. This form of social capital is more positive as it builds bridges between different groups and so contributes towards more effective functioning of society, governments, and communities.

3. Linking social capital is where unlike people, in dissimilar situations, join together for mutual advantage (Woolcock, 2001). This refers to vertical associations that provide upward links to more powerful groups, agencies, and people. For example, a community might link with valuable outside members to build a wider pool of resources.
4. These are not discrete forms of social capital and more commonly societies would experience various combinations of the above.

Appeal of Social Capital

Why is social capital so alluring? Why is it sufficiently important to be adopted by intergovernmental agencies such as the World Bank? Social capital has wide appeal in the social sciences, and other disciplines, as a means of explaining differences between individuals and groups. In particular social scientists seek to understand and predict relationships, hopefully causal relationships, between social capital and other aspects of society. For example the following hypotheses suggest the appeal of social capital, especially to policy makers, although many social scientists would be tentative in applying them:

- The greater the social capital, the greater the confidence in government (and other institutions) which enable societies to function more effectively and prosper.
- The greater the social capital, the easier to organize support to resolve collective problems. People will be better able to solve collective problems if they cooperate, trust each other, and build networks together. They may perceive advantages in not cooperating but this is short-sighted. Addressing global warming is an example.
- The greater the social capital, the higher the percentage of problem-solving outside the governmental sector, while less social capital requires greater reliance upon authoritative controls. When people join together they tend to be more tolerant, more empathic to others' problems, and less cynical, and consequently, require less government persuasion to live harmoniously together.
- The greater the social capital, the more prevalent the norm of reciprocity (bargaining, compromise, pluralism) amongst people. This enables them to resolve problems more effectively.
- Similarly, the more social capital is present in society the higher the priority of the norm of equality. In high

social capital areas public space is friendlier, safer, cleaner, and has less crime.

- The greater the social capital the more it will assist those in disadvantaged areas and will lead to an improvement in the quality of their life and mitigate the insidious effects of socioeconomic disadvantage.
- In general, being involved in groups is beneficial to people and associational life (and its quality) builds social networks, enhances society, strengthens democracy, and can improve health and happiness.

The application of social capital has particular interests in providing explanation for a current phenomenon plaguing western democracies – declining political support and increasing political disengagement. Many social scientists have explored this approach in some depth (Putnam, 1993, 2000; Woolcock, 2001; Print and Coleman, 2003; Jennings and Stoker, 2004), as they search to explain why, particularly in western societies over the past few decades, social ties and political engagement have diminished. As Putnam argues, decline in social capital erodes political participation, interpersonal trust, as well as political trust, all of which have become abundantly evident more so in the United States, Canada, and Britain but also in varying degrees in Western Europe as well.

Education and Social Capital

Putnam (2000) and more recently his associates (Helliwell and Putnam, 2007) contend that education and social capital are closely linked. Education they believe is the best predictor of many forms of social and political engagement. They also note that while education levels have risen dramatically within the United States over the past half century, levels of social and political participation have not risen accordingly and on many measures have declined.

This paradoxical puzzle has concerned political scientists for some time though recent research reinforces the argument that as education levels rise so do key measures of social capital. The conundrum remains, partly because Putnam and others use gross indicators of education such as years of completed schooling and partly because there is little evidence of understanding what happens within schools (Print and Coleman, 2003). Greater insight into the contribution and impact of civics and citizenship education subjects and noncurricula aspects of schools would enable a deeper understanding of how schools may affect social capital development (Print and Coleman, 2003; Print, 2007).

Schools and Social Capital

As social capital can be acquired and expanded, schools could, and arguably should, play an important role in

building social capital especially in terms of affecting citizenship and democracy. For example, Print and Coleman contend that “Schools offer a potentially powerful opportunity for both learning about the elements of social capital and enacting components of social capital through related activities. [including] some form of civics and citizenship education” (2005, p. 129). The contribution of schools can occur through three sources – the formal curriculum, the informal curriculum, and the extra curriculum. The hidden curriculum may also contribute but given its nature it is not considered here.

Formal Curriculum

When Putnam suggests that schools may contribute substantially to building social capital through enhancing trust, networking, and participation, he, and others, are thinking about social capital in relation to the formal curriculum, that is, the subjects that compose the school curriculum (Croniger and Lee, 1991; Dika and Singh, 2002; Print and Coleman, 2003). That is, schools can contribute to social capital through teaching certain subjects (such as civics, citizenship, service learning) which builds knowledge, skills, and values within students. Citizenship education, for example, contributes to knowledge of society and government, building skills of cooperation and networking as well as facilitating values such as trust and civic virtues (Print and Coleman, 2003). In this way teachers facilitate the growth of bridging, bonding, and linking forms of social capital. This of course, assumes that schools and teachers understand social capital, how it works and why they should purposively facilitate it.

Putnam (2000) also addresses the relationship between social capital and schools from the other direction. He contends that children will have more positive academic and nonacademic outcomes (lower drop-out, higher academic performance, less truancy) if social capital is strong at home and parents engage with schools. Similarly, Croniger and Lee (2001) found that teachers are an important source of social capital for students. Where these teachers help students personally, influencing the quality of the student’s social networking, students are significantly less likely to drop out of school.

A group of Scottish researchers in the Applied Educational Research Scheme are investigating social capital in the context of school outcomes. They are exploring how teachers and schools may utilize social capital to enhance student school outcomes. A current study is investigating how students may build their personal stock of social capital, particularly to use in overcoming backgrounds of disadvantage.

Informal Curriculum

Within the school, social capital may be generated substantially in ways other than through formal curriculum.

The informal curriculum refers to the non-school subject learning in schools that includes activities such as participation in meetings, clubs, student governance, and raising funds for charities (Print and Coleman, 2003). These activities, largely unplanned compared with the formal curriculum, are ways of building social capital for, as these authors argue “It is specifically through the informal curriculum that students may acquire participatory skills and values, as well as knowledge, from engaging in activities such as conducting student councils, running school parliaments, raising funds on special days, interacting with the community through service learning and the like” (2003, p. 134).

Extra curricular activities may also contribute to building social capital through individual and group activities which are beyond the confines of the school curriculum. These activities are conducted outside of school hours and retain only minimal contact with the school, such as debating, charity fundraising and, in many countries, many forms of community service.

Issues in Social Capital

Social capital is far from unproblematic, both as a social science tool and as an explanation of social phenomena. Further theoretical work and empirical research is required to enhance the value of this construct. Meanwhile several issues can be raised about its effectiveness.

In terms of schools, building social capital should be seen as an important, integral task of education. This occurs, though not as much as expected and certainly less than many may like. Many parts of the formal school curriculum are undervalued in this role including school subjects such as civics and citizenship education.

Similarly, the informal school curriculum could play an even more important role in generating social capital within schools. Yet, as Print and Coleman note, this is problematic given the low status of the informal curriculum and “Significant further research is required in this area to gauge the impact of the informal curriculum on student potential to build social capital” (2003, p. 134).

There are also, more generally, potential problems with social capital should the capital component be excessively emphasized. Within social phenomena there are clearly many factors that cannot be economically isolated or expressed in terms of capital. Human behavior does not necessarily follow a logical path, such as the maximization of capital, so that accumulating social capital may not occur even though it might be logical to do so. For example, many people do or will not join associations or social networks, for a variety of reasons, and thereby restrict their bonding and bridging social capital.

Finally, social capital is inevitably treated as a positive asset and is portrayed in a positive light. Yet the acquisition of social capital may also occur amongst gangs and criminal groups or in societies which are fundamentally

divided such as Northern Ireland or the Balkans or in countries dominated by malevolent leadership such as Nazi Germany or the Khmer Rouge in Cambodia. Thus the potential for a dark side of social capital needs further consideration.

Cultural Capital

Cultural capital is a very general theory, somewhat elusive, and employed largely by sociologists to explain culturally generated differences in societies. As a theory, cultural capital recognizes that a multicausal approach is required to understand the complexity of a social phenomenon, thereby making it more valuable as a realistic explanation of society. The concept of cultural capital is perceived as a useful means for researchers to explore phenomena such as how social inequalities are organized in culture-drenched societies. It has been particularly influential in sociology to explain the ways the middle classes distinguish themselves from the working classes through their distinctive cultural tastes, knowledge, and competencies.

For example, cultural capital may be anything in one's personal/social background that contributes to or diminishes one during one's life. It could be something like family background or educational qualifications or wealth/income. These attributes help explain differences between people in a multicausal way. There is, in effect, no limit to what can or cannot be considered cultural capital as it really depends on the context being studied. However, as a theory it has a weakness in that it is frequently difficult to identify the relative influence of particular cultural factors and so explain social phenomena effectively.

Bourdieu (1986) referred to three types of capital in his seminal work – economic, social, and cultural capital. The last he saw as forms of knowledge, education, skills, or similar advantages that persons might have which gives them a higher status within society. As such, cultural capital helps explain why classes exist within societies and why they are essentially sustained. The capital element of the construct is applied because, as with other forms of capital, cultural capital may be accumulated, built, or diminished.

Types of Cultural Capital

Bourdieu (1986) identified three subtypes of cultural capital: embodied, objectified, and institutionalized:

Embodied. Cultural capital may be embodied within the individual, such as the inherited and acquired properties of one's self. Inherited cultural capital would be the cultural traditions from one's family and social class. This is acquired over time and is strongly linked to one's personal character and way of thinking.

Objectified. Cultural objects which are owned, such as artworks, may be transmitted symbolically as cultural capital as well as the more common transmission physically or by sale. Bourdieu claimed that while one can own objectified cultural capital through possession, those objects can only be utilized if people have the correct type of embodied cultural capital.

Institutionalized. Institutional recognition of cultural capital is mainly understood in relation to the labor market in the form of academic credentials or qualifications. Institutionalized cultural capital allows easier conversion to economic capital by assigning a monetary value for a certain institutional level of achievement.

Cultural Capital and Education

From an ideological perspective Bourdieu's thesis is that the role of education is mainly one of social reproduction that enables the dominant social class to reproduce its power, wealth, and privilege in a legitimate manner. Consequently, schools, as part of the political/ideological superstructure in capitalist society, help to perpetuate social and economic inequalities across the generations.

Using cultural capital Bourdieu demonstrated how the working classes were systematically blamed for their relative failure within the education system. He argued that access to resources and information as found in schools is a form of cultural capital restricting the working classes. If an equal opportunity to schooling was available to all, then success or failure must be a consequence of the individual rather than the way in which the system is structured to favor one class over another.

Further, Bourdieu argued that children are not simply socialized into societal values as a whole, but rather, they are socialized into the culture that corresponds to their class. This becomes their set of values, beliefs, norms, attitudes, experiences, and so forth that equip people for their life in society and represents their cultural capital.

More recently in terms of education, cultural capital may theoretically explain differential student achievement utilizing a wide range of influences. The past two decades have witnessed an increasing emphasis upon formal, systemic assessment of student achievement in many countries. The outcomes of these assessments reveal, unsurprisingly, that students from disadvantaged backgrounds perform at lower levels than other students. Cultural capital can provide a theoretical framework for explaining this phenomenon by addressing questions of power and ideology which authors contend are central to the differential achievement debate. For example, in the context of differential student achievement the explanation is traditionally linked to individual ability and some school effects rather than by cultural resources reflecting family influences and in the process the transmission of privilege is legitimized and not perceived as handicapping the disadvantaged child. Social capital

refers to connections among individuals that facilitate collective action and has received wide, though equivocal, support. These resources include trust, norms, and networks of association representing any group which gathers consistently for a common purpose. In her study of cultural capital on English school students Sullivan (2001) found strong evidence that cultural capital was transmitted from parents to their children which helps explain differential performance.

Issues in Cultural Capital

Multiple problems have been identified in both the theoretical understanding and practical application of cultural capital to explain social phenomena. Foremost there are conceptual difficulties concerning how cultural capital is to be identified and measured given that most measures are proxies. For example, which cultural activities constitute cultural capital? If reading books and newspapers as well as television viewing habits are included as Sullivan (2001) suggests, what of music habits, both listening and playing or participation in sport?

Similarly, technical difficulties abound concerning how cultural capital can be applied practically to address sociological problems. Will reading more books, for example, enhance cultural capital? Or is some measure of quality in books important in contributing to an individual's stock of cultural capital?

The impact of cultural capital is valuable as an explanatory concept but is more problematic when considered as a major theory of cultural reproduction. As Sullivan found, when disaggregating the effects of cultural capital and social class on student attainment, cultural capital provided only a partial explanation of social class differences in the educational achievement of students. As with social capital, cultural capital appears more useful at first blush and both were initially welcomed by social scientists with acclaim. But subsequent exploration, both theoretically and empirically, has found both concepts wanting as broad based explanation of social phenomena.

The Aims of Education

R Marples, Roehampton University, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Anyone with any serious concern about the aims of education during the past 50 years will have been influenced by the work of Peters (1973), who, during his tenure as professor of philosophy of education at the University of London, had a profound influence in devising courses on which teachers were forced to come to grips with the question of whether or not education, or even schooling, had any overall aim or purpose. In an article concerned with the question “what is the aim of education?”, he suggested that an appropriate answer would be the same as the answer to the question “what is the aim of life?” namely, that it has not got one, while at the same time acknowledging that in the case of education, a longer story needs to be told if only to satisfy the taxpayer. Both here, and in his hugely influential *Ethics and Education*, Peters (1966: 28) argues that questions about the aims of education are “... a way of getting people to get clear about and focus attention on what is worth while achieving. It is not to ask for the production of ends extrinsic to education which might explain their activities as educators.” Education, he insists, is logically connected to what is thought to be worthwhile; its value is intrinsic, and not contingent upon something else to which education is a means.

Such a claim certainly has a *prima facie* plausibility in virtue of the fact that instrumental reasoning is forced to end somewhere; some things just are, as it were, of ultimate significance. Whatever it is to be educated, it is not necessarily a state which derives its value from any instrumental purposes it might serve. Nevertheless, it would be invalid to conclude from this warrantable premise that education serves no instrumental purposes whatsoever. There are countless reasons why society might want to invest in education. Probably more than any other institutions, schools exert a profound influence in shaping people's belief systems and characters, which in turn have an incalculable impact on the kind of society in which we conduct our lives. It is therefore incumbent upon those with responsibility for curriculum construction and delivery to try and ensure that pupils are equipped with the wherewithal to make the sort of contribution to society that a liberal democracy has a right to expect.

If asked to specify the aims and purposes of schooling, many a hard-nosed Victorian would have had few qualms about the desirability of two different kinds of schooling, with radically different aims. Working-class children should learn to read, write, and count, with the patronizing

aim of teaching them to appreciate their position, while their middle-class counterparts required little more than an unrelieved diet of Latin and Greek, with the very different aim of preparing them for positions of leadership throughout the Empire. It is now generally accepted that something more is required from a system of publicly funded education, and it is the concern of what follows to spell out what this might entail. We shall, of necessity, be forced to restrict the discussion to three possible candidates. These are: knowledge for knowledge's sake, preparation for work, and education for well-being.

Knowledge for Knowledge's Sake

According to Peters, education is the process of initiation into intrinsically worthwhile activities, or those activities which one might engage in for their own sake. These include things such as history, science, mathematics, religion, and esthetic awareness. Those who are successfully initiated into such forms of thought, and in some sense make it their own, find, according to Peters, “the contours of the public world... transformed. The process of initiation into such modes of thought and awareness is” he says, “the process of education” (Peters, 1966: 51). He went on to develop this idea in collaboration with Hirst (1965, 1973), who had earlier argued that the principal aim of education should be the development of mind for its own sake, through a liberal education conceived as an initiation into such forms of knowledge and understanding.

As fine-sounding as this is, there are enormous problems associated with determining what is to count as intrinsically worthwhile. What some might take to be a valuable activity appears boring or pointless to others. In *Ethics and Education*, Peters goes to considerable lengths to articulate the notion of worthwhile activity, relying on a transcendental argument reminiscent of Hirst's attempt to justify the importance of knowledge and understanding as the bedrock of a liberal education. According to Hirst, “to ask for the justification of any form of activity is significant only if one is committed already to seeking rational knowledge. To ask for a justification of the pursuit of knowledge therefore presupposes some commitment to what one is seeking to justify” (Hirst, 1965: 126). In an educational context, transcendental arguments are notoriously problematic. But were we able to demonstrate the worth of particular activities or forms of understanding by this or any other means, it remains to be seen whether or

not rational curriculum planning should include such activities at all, or whether there is more to the notion of a liberal education than the pursuit of knowledge. Propositional knowledge (knowing that) is, after all, only one way of knowing. It is also possible to know how to do things – communicate in Mandarin, drive a car, use PowerPoint, re-wire a house, and countless other things. It might well be argued that schools have for too long concentrated on knowledge for knowledge's sake at the expense of equipping children with the skills they are likely to require in adult life. In reality, however, the problem is one of emphasis only, because most skills are impossible to master without knowing that certain things are true or false, and even if the teaching of skills of various kinds could be justified as part of a liberal education, it is inconceivable that one could live a fulfilling life in a society such as ours, without a great deal of factual knowledge and understanding. According to Bailey (1984: 29), a liberal education is characterized by its capacity to liberate a person from the here and now, by involving pupils in what is fundamental and general, and this, he argues, requires an education firmly within the framework as articulated by Peters and Hirst.

As indisputable as the value of knowledge undoubtedly is, the fact remains that until we are clear as to what there is about such knowledge that makes it indispensable to a person's long-term interests, we should not just assume that it is the only thing of any value in a child's education, or indeed that it should be regarded as having supreme importance. Again, if we are to take seriously the aims underpinning the current English National Curriculum, which include the transmission of enduring values, with the intention of promoting pupils' integrity and autonomy, helping them become responsible and caring citizens committed to sustainable development, promoting their self-esteem, emotional well-being, their ability to form satisfying relationships, to relate to others for the common good, and to be able to make informed choices throughout their lives (DfEE/QCA, 1999), it is unclear how a knowledge or subject-based curriculum is expected to realize such aims.

A number of philosophers, in recent years, have not only expressed reservations about Hirst's analysis of knowledge (subsuming it as he does, under a number of different forms such as mathematics, physical sciences, knowledge of persons, literature and the fine arts, morals, religion and philosophy, with each form distinguishable from the other by reference to its own unique set of concepts, logical structure, and tests for truth), but have questioned the desirability of restricting the idea of a liberal education to the pursuit of truth, on the grounds that such an obsession with the intellectual ignores other equally important aspects of personhood, such as the emotional and the practical, with which education must have an equally legitimate concern (see, e.g., Martin, 1981).

People do not exist in ivory towers, pursuing arguments wherever they may lead in the manner of the proverbial professor. Ignoring such a truism would have dire consequences, especially for those students who fail the initiation test and are left floundering at the gate with other barbarians. There may well be a place for the pursuit of knowledge for its own sake within a school setting, but unless those who advocate its having priority over other possible aims are to avoid the charge of elitism, they will need to demonstrate to both individual learners and the society of which they are members, the benefits that knowledge is likely to bestow.

We must now address other claims as to what the aims of education might be. After addressing the competing merits of vocational versus liberal education, we shall return to the question of what constitutes an appropriate education for a whole person.

Education and Preparation for Work

Discussions relating to the aims of education are all too frequently plagued by the assumption that criteria of relevance should be determined by reference to the extent to which school leavers are prepared for the world of work, or the real world. The whole point of schooling, and the investment in education in general, is often seen as a means to the obtaining of qualifications leading to paid employment. Knowledge, (or book-learning, as it is often disparagingly called) is all very well, but can the billions we spend on education be restricted to its pursuit?

Some of the advocates of what is generally known as vocational education see it as having relevance for all pupils, especially those in the latter stages of secondary education, while others would like to see some kind of educational divide at around the age of 14, whereby the academic sheep are separated from the vocational goats, on the grounds that some children are unmotivated in the quest for prestigious academic qualifications and need something else to show for all their years in compulsory schooling. While it is no doubt true that many pupils would relish the idea of opting out of academic courses, and would no doubt perceive the vocational alternative to have greater relevance, such a solution to the problem of the disenchanting underachiever or disgruntled student is both facile and fraught with dangers.

First, there is the problem of identifying the vocational goats. The fact that a pupil hates her history or science lessons does nothing to undermine the claim that she has needs and interests in common with the rest of us to which, as a person, she has a right, and for which those charged with her education have an obligation to provide. Second, there are complex issues relating to the kind of work for which she might be expected to be trained. Many jobs are not only boring, they are useless in the sense that

they require people to produce things for which nobody has any real need, as well as have adverse consequences for the environment or for opportunities to exercise individual judgment or imagination or the possibility of enjoying a fulfilling family life and a host of other activities for which someone may have talents or enthusiasms. A great many people have very little choice about working for others who are privileged and wealthy, and for very low wages. The injustices associated with writing off people at an absurdly young age, before they are fully aware of the range of significant alternatives before them, and while their critical powers of evaluation are insufficiently developed, are obvious. Unless we conceive of vocational education in more liberal terms than that associated with vocational training, teachers should refuse to conspire in the process of selling children short by refusing to alert them to the nonegalitarian, oppressive, and all too frequently unrewarding features associated with so many jobs in a modern industrial society.

The problems associated with how to identify those children who might be thought most suitable for vocational training notwithstanding, it has long been thought to be the case that meaningful work is indispensable to a flourishing life and that schools are under a moral obligation to prepare people for it in some, as yet, unspecified way. However, as White (1997) has persuasively argued, there are reasons for doubting this. In a wide-ranging discussion on the role of education in relation to work, he makes a number of important distinctions, including that between: (1) autonomous work (where it is one of one's major goals to produce something) and heteronomous work (where it is not), (2) work in which one willingly engages, from that done unwillingly, and (3) paid work and voluntary work. He goes on to question the assumption that work (of any kind – meaningful, autonomous, or whatever) must, of necessity, find a place in a fulfilling life, given the plethora of alternative possibilities in which one might enthusiastically engage, such as gardening, spending time with friends, cooking, playing the piano, or just thinking. Given the all-absorbing nature of such pursuits, it is unclear why one needs to find time for work. Persuasive or not, the fact remains that an unacceptably large number of young people end up working in tediously repetitive jobs from which they would almost certainly quit upon winning the lottery.

Teachers might well respond in a number of ways. They could ignore the facts, ostrich-like, and concentrate on trying to initiate pupils into the forms of knowledge, or they could face up to the fact that work is so much a part of most people's lives after leaving school that they had better give serious thought to what counts as preparation for it, even if they find themselves in the uncomfortable position of having to subscribe to the values to which so many employers are attached, such as deference and obedience; values which they themselves may abhor.

Alternatively, they could acknowledge the truth in something to which Dewey (1916) drew attention almost a century ago, and that is the absurdity of the hard-line distinction between the theoretical and the practical.

Pring (1995) is one philosopher among many who is highly critical of vocational training, on the grounds that its prime concern is with mere competence, as opposed to the liberal ideal of the educated person having something to do with what it is to be fully human. While there is nothing wrong in preparing people for the world of work, such preparation may be conceived as genuinely educational only if it helps people to make sense of the social and economic context in which they find themselves. Pring is at pains to demonstrate that vocational education can not only be liberating, but can also provide opportunities for people to gain access to all kinds of knowledge and ways of seeing the world. Through work, such as building or motor mechanics, one may come to appreciate something from an esthetic, scientific, or even moral point of view, which, if true, serves to dispel the false dichotomy between liberal and vocational education.

In trying to specify the aims of education, we have had reason to be skeptical about two widely held views; that education, or schooling, should aim at nothing more than producing knowledgeable people, and that criteria of relevance can be seen in purely vocational terms. As we have seen, the authors of the English National Curriculum believed that schools had other functions than that of merely producing knowledgeable or employable people. They were only too well aware that there was more to human well-being than this, and that education should make significant inroads in trying to help young people flourish as people. In what follows, we shall explore what this might entail, by reference to which notions such as self-esteem, the ability to make rational choices between competing alternatives, and concern for others, gain application.

Education for Well-Being

The idea of what it is to flourish as a person has occupied the attention of philosophers since Plato and, as might be expected, there is considerable disagreement as to what it amounts to. There are at least three aspects under which it might be conceived; as happiness, desire-satisfaction, and having the capacity and opportunity to live autonomously as a moral being. This latter notion is both complex and troublesome, but it is hoped that a proper understanding of what it involves will provide a morally acceptable basis for those concerned with preparing young people for life in the twenty-first century.

Utilitarianism is the theory according to which well-being is seen in terms of happiness. Unfortunately, happiness is a notoriously subjective phenomenon. Nothing

better illustrates this than a thought experiment postulated by Nozick (1974), who asks us to imagine what it would be like to be connected to a machine capable of providing us with any experience whatever. While plugged in, one could believe that one was loved or famous or popular; one could satisfy more or less any fantasy that one had and remain blissfully happy throughout. But how can it possibly be the case, Nozick asks, that one can flourish if, in actual fact, one is friendless, ignorant, despised, exploited or in any other state manifestly incompatible with personal well-being. The principal objection to any such mental-state account of well-being is that it fails to distinguish between believing that one is flourishing and actually flourishing; in other words, there is more to flourishing than simply feeling happy. Moreover, as an aim of education, the pursuit of happiness is a nonstarter. It is precisely because of its subjective status that it is impossible for teachers to gear what they do toward its promotion. In so far as it is attainable, it is the result of a subjective judgment that one's life is, for the most part, going well.

A variety of desire-satisfaction accounts of well-being have been constructed in order to meet the difficulties associated with the simplistic reductionism associated with mental-state accounts. One such theory construes well-being in terms of getting whatever it is that one happens to want, the initial plausibility of which rests firmly within liberal democratic theory whereby we should remain unconstrained in the pursuit of our own version of the good life, however idiosyncratic that might be, with the proviso that in so doing, we avoid preventing others from pursuing theirs. Such a view is problematic in several respects. Even if it were possible to structure one's numerous and all too frequently conflicting desires into some kind of order of priority, the theory has counterintuitive implications. It would be compatible with such a view that my well-being could be promoted without my knowing it if, say, as a result of my charitable work other people, the fate of whom was unknown to me, thrived in ways not possible without my contributions. Having satisfied my desire to improve the quality of other people's lives albeit unknowingly, it is questionable whether such beneficence on my part could be said to have any positive impact whatsoever on my own well-being. Again, having successfully obtained some of the things I happened to want, I might well end up feeling indifferent or ashamed, while other (satisfied) desires may be based on such false beliefs that my actions have no rational foundation, providing a sufficient reason for doubting that my welfare might possibly be enhanced in trying to satisfy it in the first place.

In response to such objections, a number of philosophers have attempted to construe well-being in terms of the satisfaction of those desires about which one could be said to be fully informed, in the sense that one is cognizant of both her origins as well as the consequences

of satisfying them. Unfortunately, there is no guarantee that such a ploy will work. However informed one might be about a particular desire, satisfying it might well be incompatible with one's flourishing. Knowing all there is to know about the lethal consequences of smoking, one may well continue to satisfy the desire to smoke. Those wishing to defend the view that well-being can be cashed out in terms of the satisfaction of informed desires are wont to restrict the notion to only those desires a person would have, were she to fully appreciate what is at stake, while all too frequently failing to provide an account of what it is to appreciate such information that is not circular (see Thomson, 1987).

If this were not enough to undermine desire-satisfaction accounts of well-being, we have to acknowledge that desires do not appear from nowhere; for the most part, they arise as a result of the aspect under which their objects are seen or evaluated. Our preference for *x* as opposed to *y* is, as often as not, a direct result of acknowledging the desirability of *y*, which itself depends on something other than merely wanting it. On the assumption that not just anything merits the epithet desirable, teachers have a major role in helping young people appreciate the significance of what Taylor (1985) calls the language of contrastive evaluation, in accordance with which values, in areas of life as diverse as the political, the esthetic, and the moral, acquire their import. We attribute qualities of character to someone by reference to moral idioms such as courage, integrity, loyalty, and kindness on the one hand, and malicious, depraved, pusillanimous, and cruel on the other, and it is foolish to pretend that we could employ them in any way we choose. Rational choice and decision making, as well as the evaluations upon which they are based, must rely on more objective foundations than the extent to which we happen to want something. There is a fundamental disagreement between philosophers on this matter however. Those who are inclined to see values as essentially subjective, tend to argue that the order of explanation is from desire to value, while those who believe that values are, in some sense of that term, objective, are inclined to believe that desire, as an indispensable element in attributing value to something, is unnecessary. The issues are complex, however, and cannot be pursued here. (For a full discussion of the issues involved, see Griffin, 1986.)

The history of philosophy is replete with accounts of human flourishing in terms of a single *summum bonum*, and it is all too easy to assume that the only alternative to desire-satisfaction accounts of well-being is some form of perfectionism and the associated specter of authoritarianism. Nevertheless, there are limits to what can possibly amount to a flourishing life; limits, for the most part, determined by a life that is recognizably human, with its legitimate concern for harm-avoidance. A person may be said to have been harmed if her needs remain unmet, but not necessarily when her desires are merely frustrated.

What a person needs in order to flourish will undoubtedly vary from one social context to another, but as Raz (1986) has argued, in a society such as our own, whereby enormous value is attached to being able to make choices in significant areas of one's life such as with whom one might live, whether or not to subscribe to a religious faith, choice of career and such like, it is inconceivable that one could do so without a measure of autonomy in such matters. Teachers thus have a particularly important role to play in promoting the autonomy, both intellectual and emotional, of their pupils.

A person may be said to be autonomous to the extent that she is in a position to appreciate the degree to which her beliefs and actions have been shaped by the forces of socialization, as well as having the courage and strength of will to reject them if necessary. She must also be able to provide some coherence to her choices over time, in accordance with which her life may be distinguished from the episodic and infantile. An autonomous person must also have the ability and opportunity to make choices from a significant array of options. Anyone who is deficient in these respects is more likely to fall victim to the will of others and her life will be largely inauthentic.

Important as personal autonomy undoubtedly is within contemporary accounts of well-being, it would be wrong to assume that people could flourish as autonomous egoists. As Benn (1988: 259) says: "We are species-beings in the sense that our enterprises are necessarily embedded in some continuing tradition, in terms of which we discover what is worth doing. . .". Our interests are rarely entirely self-interested; there are countless respects in which they might be said to be bound up with those of others, including those to whom we are intimately related as well as to things as distant as the ecological balance of the rain forests. As Lear (1984) has demonstrated, a significant form of human flourishing partly consists in promoting flourishing generally, whereby morality provides its own motivation and the distinction between altruism and egoism is less-sharply defined than might otherwise appear.

The implications for education are legion, with teachers confronted with the daunting task of trying to promote sensitive perception within children as well as getting them to care about the needs of others as well as themselves. In this respect, moral education is more complex than that proposed/promoted by those wedded to the teaching of knowledge and understanding for its own sake, whereby a morally educated person is little more than someone able to understand the meaning of moral concepts or, at best, as someone trying to regulate her actions by reference to a set of principles. As Anthony O'Hear (1981: 129–130) says: "Moral behaviour is not so much a matter of an isolated rational agent acting on freely chosen principles, as a development of one's sense of a shared humanity." While the promotion of autonomous

agency is undoubtedly one of the principal aims of education, it cannot suffice in the absence of a moral and social education appropriate to the fostering of the skills and dispositions associated with participatory democracy (see, e.g., Gutmann, 1987). All this, of course, presupposes a considerable amount of knowledge and understanding, but the purpose of instilling this into children derives its legitimacy from the perspective of the altogether deeper underlying values associated with human flourishing, with the implications for rational curriculum planning being recognized accordingly.

The Analytical Tradition

The Analytical Tradition in Philosophy

From an analytical perspective, although we may attach some sense to the idea that there is a separate and distinct analytical approach to philosophy, there is equally – as we shall shortly indicate – much confusion in this notion. To be sure, going back to the person who might well be considered the founding father of analytical philosophy – the Athenian philosopher Socrates – it would appear that Socratic philosophizing was of a rather different order from that which characterized what has come to be called (significantly enough) pre-Socratic philosophy. By and large, the various pre-Socratic philosophers – Anaxagoras, Anaximander, Thales, Heraclitus, Parmenides, Zeno (as well as such sophists as Gorgias and Protagoras with whom Socrates so often took issue) – were concerned with the construction of grandiose speculations on the nature of the cosmos or human society that might nowadays appear rather closer to the theories of modern natural or social scientists. Of course, Socrates' own great pupil, Plato, was not himself averse to ambitious cosmological speculations and political theorizing; but even Plato generally follows the rather different view of his mentor, Socrates, of the fundamental role of philosophical reflection in the construction of such theories. For while Socrates agrees with previous thinkers that it is a key aim of any human enquiry to get to the truth of things, he also thinks that it is crucial to the achievement of such truth that the terms in which such enquiry is conducted are rationally clear and coherent. For Socrates, the chief impediments to truth are conceptual confusion and invalid argument and for him it is the major task of the philosopher to clear such impediments from the path of knowledge.

The key philosophical task, as Socrates sees it (and as most subsequent analytical philosophers have come to view it), is the clarification of concepts – or, as it might also be nowadays said – the precise definition of terms. Before we can begin to talk or speculate clearly about anything, we must make sure that we are using the basic terms of debate or discussion in a clear and unambiguous way. Indeed, Socrates is perhaps the first great philosopher to realize (though he clearly learned much in this respect from the Eleatics) the intimate connection between such conceptual clarity and valid inference. Socratic elenchus, for example, seems to be largely directed to exposure of the general fallacy that later philosophical logicians have come to call *reductio ad absurdum*. In Plato's *Republic*

(Hamilton and Cairns, 1961), for example, Socrates adopts his usual strategy of asking interlocutors to define a given philosophically problematic term – in this case, justice – and a respondent offers a particular definition, *p*, of justice (in this case, telling the truth and paying one's debts). Briefly, Socrates then proceeds to describe a circumstance, *q*, in which doing what is indicated in *p* would not (by common agreement) be just. Since *q* therefore entails not *p* and not *p* is inconsistent with *p*, *p* cannot be a conceptually coherent concept of justice, and in so far as arguments or inferences based upon such a concept of justice are liable to inconsistency, they must therefore be invalid.

At all events, such close Socratic attention to the logical form of argument and to clarification of the terms in which such argument is conducted might well be considered the backbone of the analytical approach. From this viewpoint (and for present purposes), one might identify three key moments in the subsequent post-Socratic development of this approach. The first of these would seem to be the earliest systematic attempt by Plato's pupil, Aristotle, to develop a formal theory of inference, based on certain fundamental laws of thought (of identity, non-contradiction, and excluded middle), according to which any and all valid reasoning would need to proceed. In the works collectively known as the *Organon* (see McKeon, 1941), containing his theory of the syllogism (the basic form of deduction), Aristotle set out to identify the rules governing valid inference from separate premises *A* and *B* to some further distinct conclusion *C*, such as would thereby block inference of true conclusions from false premises. Aristotle's theory of syllogism (despite some ancient rivals and/or variants) was widely regarded as the last word on logical theory until virtually the late nineteenth century. However, in what might for present purposes be considered as the second key moment of analytical method, the great German logician and mathematician, Gottlob Frege, devised revolutionary techniques for the logical analysis of complex statements of mathematics, science, and natural language – the logic of quantification of so-called predicate calculus – that virtually replaced Aristotelian syllogistic (see Frege, 1978; Geach and Black, 1960). From this viewpoint, Frege – particularly along with the British philosopher and logician, Bertrand Russell (Russell, 1956), who showed how Fregean quantification theory could be used to illuminate hitherto intractable metaphysical and ontological problems – may be considered the main founder of modern philosophical analysis.

However, among the important twentieth-century philosophers influenced by Frege – including the Anglo-American and Germanic logical positivists – was the Austrian philosopher, Ludwig Wittgenstein. Wittgenstein's early *Tractatus Logico-Philosophicus* (Wittgenstein, 1961) was deeply influenced by both Frege and logical positivism, but his later *Philosophical Investigations* (Wittgenstein, 1953), seeks to develop a key idea of Frege in a way that effectively demolishes positivism. For generally, the logical positivists inherited from such earlier British empiricists as David Hume, an idea – also, as we have seen, to be found in Socrates and Plato – that the philosophical search for meaning is basically a search for definitions: in short, that one needed to fix the unique and invariant sense of a given term, before one could meaningfully use it. In the introduction to his important work, *The Foundations of Arithmetic*, however, Frege had said that the meaning of a term could only be grasped “in the context of a proposition” (Frege 1978, Introduction p. xe). In a nutshell, Wittgenstein's revolutionary application of this point in his later philosophy consists in showing that one cannot generally understand a (philosophically problematic or other) term by deciding its meaning in advance of usage – precisely because one needs to know how a term is used in order to understand its meaning: hence, the slogan, usually associated with Wittgenstein's philosophy – “Do not look for the meaning, look for the use.” Wittgenstein perceived, as previous ancient and modern philosophers had not (though this insight is arguably foreshadowed in Aristotle), that philosophically intractable terms seldom have a single univocal use. From this viewpoint, it seems philosophically mistaken to look (as previous philosophers had) for a single unitary definition of good given the rather different uses of the term in the utterances, “That's a good thermometer” and “Good morning!”

During his long association with Cambridge, first as a student and later as professor of philosophy, Wittgenstein had a profound influence on the development of Anglophone philosophy, although the extent to which he directly influenced such leading Oxford philosophers of the time as Gilbert Ryle and J. L. Austin (or whether these other philosophers were independently moving in the same broad direction as Wittgenstein) is a moot point. But generally (and despite differences), all three of these philosophers came to be regarded as leading lights of the particular philosophical movement known (by way of some contrast with the logical analysis of Russell, logical positivists, and many American pragmatists) as ordinary-language philosophy. Broadly, ordinary-language philosophers shared with more formal approaches the basic analytical view that the key philosophical task of conceptual analysis is primarily that of understanding the logical workings of the forms of discourse through which human beings have tried to understand their world. However, whereas the latter were inclined to regard forms of human discourse that could

not be precisely regimented (broadly in terms of Frege's predicate calculus) for scientific purposes as unworthy of serious philosophical attention, ordinary-language philosophers were wont to consider such looser forms of discourse (e.g., the languages of ethics, esthetics, and religion) of considerable philosophical interest. Indeed, it is noteworthy that the later Wittgenstein tended to dispense with the term logic (with all its connotations of formal precision) in his characterization of philosophical work, in favor of the term grammar. The job of the philosopher is precisely to investigate the particular grammatical complexities of large areas of usage that – despite being resistant to precise scientific regimentation – may, for all that, express matters of the very highest human value and concern.

Analytical Philosophy of Education

There can also be little doubt that by the middle of the twentieth century, a broadly ordinary-language approach to conceptual analysis had yielded impressive philosophical results in such traditionally problematic (and often less systematically codifiable) fields of philosophy as ethics, esthetics, and philosophical theology, and – in the wake of widespread postwar political, social, and educational trends and reforms in Britain, America, and elsewhere – it was only a matter of time before the techniques of philosophical analysis came to be applied to the discourse of education. The philosopher most readily credited with developing analytical philosophy in Britain was Richard Stanley Peters who already had an established reputation in mainstream philosophy (for extensive work in philosophical psychology, ethics, and political philosophy) prior to his appointment as Professor of Philosophy of Education at the London Institute of Education in 1962. At the Institute, however, Peters quickly gathered around him a group of younger philosophically minded educational theorists – including, notably, Paul Hirst, Robert Dearden, and John White – with a view to the fairly radical overhaul of educational philosophy in particular, and of educational theorizing in general, in Britain and elsewhere. Indeed, Peters' pioneering analytical approach to educational reflection – strongly influenced by the largely ordinary-language drift of Oxbridge philosophy in which he had himself been schooled – had a much wider influence in the English speaking world, not least in such British Commonwealth countries as Canada, Australia, and South Africa. However, this Oxbridge approach was less favored in USA, where Peters' American counterpart, Israel Scheffler, drew more on a pragmatist tradition inspired by the late-nineteenth- and early-twentieth-century work of such home-grown philosophers as Charles Sanders Peirce, William James, and John Dewey. Still, although the influence of Wittgenstein (despite some important American disciples) and other Oxbridge philosophers was not so extensive in

USA, and much mainstream pragmatism inclined to the formal extremes of analytical philosophy, there was considerable agreement between Peters and Scheffler and their respective followers on what was broadly appropriate for postwar educational philosophy in terms of analytical aims and methods.

In this regard, one of the past academic trends that the analytical approach of Peters in Britain sought to overturn was the doctrines of the great educators approach (as Peters called it) to professional educational theorizing in general, and philosophy of education in particular, characteristic of professional teacher education in the British colleges of education. This approach largely consisted of a mixed and uncritical diet (taught mainly by ex-practitioners with occasional professional masters' degrees) of educationally relevant history, philosophy, and social science, in which Plato, Rousseau, and Dewey rubbed rather promiscuous theoretical shoulders with Pavlov, Piaget, and Basil Bernstein. To whatever extent such perspectives were taken seriously by professional teacher trainers as theoretically relevant to past or present educational policy, they were almost certainly regarded as quite irrelevant to actual classroom practice by the vast majority of teacher trainees. However, although Peters certainly regarded Plato, Rousseau, Dewey, and other such past great educators as educationally relevant – writing insightfully on many of them (Peters, 1981) – he envisaged a quite different analytical role for educational philosophy in the professional armory of teachers. In short, for the new analytical philosophers, the key role of philosophy was not to learn the views of past philosophers, but to acquire the skills of critical analysis of past or present theory, policy, and practice in the interests of greater conceptual clarification of the professional task. The early leaders of this analytic movement also set the highest possible standards of such work in a wide range of pioneering studies. In Britain, in addition to Peters' (1973) own pioneering conceptual and normative work on the aims of education – among many other topics – his colleagues Paul Hirst, R. F. Dearden, and John White produced seminal work on (more or less, respectively) knowledge and the curriculum, primary education, and on issues regarding the psychology of learning (e.g., intelligence and indoctrination) and, in USA and elsewhere, there was equally important work by Scheffler and others on reason, teaching, and a host of other educationally central issues and topics.

Once again, the key point in all of these was not to learn about philosophies of education but to develop a set or repertoire of professionally relevant skills that would enable reflective teachers and policymakers to come to a clearer and more coherent view of the point and purpose of their practice. Indeed, one important brainchild of the London Institute revolution in philosophy of education was the development of a whole new discipline-based

conception of professional teacher education for the new post-Robbins Bachelor of Education degrees in Britain. On this view, first sketched by Peters (1966) in *Ethics and Education* and more fully developed by Paul Hirst in various papers (e.g., Hirst, 1983), the new professional degree ought to be grounded in the systematic specialist-taught study of such key educationally relevant academic disciplines of history, psychology, sociology, and (of course) philosophy of education. However, the point above all was that philosophy of education should be practically useful to educational practitioners in clarifying both their rational understanding and intelligent conduct of education and teaching. Moreover, the reason why the new analytical philosophers considered some such facility for philosophizing to be indispensable to teachers was precisely because education and teaching would seem, on the face of it, to be problematically unclear – or at least conceptually and normatively complex – enterprises. Thus, while some of the expertise needed by teachers (such as the craft skills of classroom practice) might be of a more straightforward technical kind, the kinds of professional decisions in which they were likely to be daily implicated would also be such as to require quite ethically complex reflection and judgment on a variety of normative and evaluative issues. Although philosophical analysis could not, of course, relieve practitioners of the burdens of professional judgment, it was held that such burdens might be considerably eased by the clarity of thought and argument that analytical techniques of philosophical analysis could afford.

The three key tasks of analytical philosophy of education were also arguably well exemplified by works published by well-known mainstream philosophers within a few years of each other. The first and most fundamental of these tasks – that of straight conceptual analysis of basic educational concepts, of distinguishing between different senses of terms, and teasing out the logical or conceptual implications of a given expression – was well represented by a work of the distinguished Australian philosopher, John Passmore (1980), published under the title *The Philosophy of Teaching*. Indeed, this work might still be considered an evergreen philosophical treatment of this important educational topic. However, the second time-honored task of analytical philosophy – on which latter-day educational philosophers have long been (perhaps from Socrates on) profitably engaged – is that of the critique of received theories of education and learning. This task had been an early concern of Peters (1958) as a pure philosopher in his trenchant demolition of psychological theory in an influential work entitled *The Concept of Motivation*, but related points against psychological theory were given explicit educational application by Peters' erstwhile Birkbeck colleague, David Hamlyn (1978), in his penetrating critique of Piaget and others in *Experience and the Growth of Understanding*. However, the third central task of analytical philosophers in general, and of educational philosophers in particular, might be characterized as the

clarification of normative perspectives on education and the exploration and/or critique of the (practical) reasons for holding this rather than that position. Just as it has always been considered part of the mainstream moral philosopher's job to evaluate arguments for and against capital punishment, euthanasia, or abortion, so one might expect educational philosophers to be interested in the reasons offered for educational selection, separate schooling, or the use of corporal or other punishment in schools. From this viewpoint, the British philosopher, David Cooper's (1980) defense of selective education in his publication, *Illusions of Equality*, could be considered (whether or not one disagreed with it) a philosophically clear example of this sort of work.

Criticisms of Conceptual Analysis and of Analytical Philosophy of Education

Still, there can be little doubt that the early 1980s saw the beginnings of a shift away from analytical philosophy of education in the style of Peters, Passmore, Hamlyn, and Cooper. While it is not easy to identify and/or account for all sources of this shift, it may suffice for the moment to highlight two key dimensions of it. The first involved widespread growing interest in philosophers and theorists who had not been traditionally associated with mainstream analytical traditions – and who, indeed, it had been common for early- and mid-twentieth-century Oxbridge analytical philosophers to discount as any sort of philosophers at all. To be sure, such (diverse) thinkers as Hegel, Kierkegaard, Marx, Nietzsche, Heidegger, Sartre, Levi-Strauss, Lacan (and later), Derrida, Foucault, Lyotard, and Levinas were linked with such largely continental European currents of thought as Marxism, phenomenology, existentialism, structuralism, post-structuralism, and postmodernism that had ever been prone to unfavorable contrast with Anglo-American conceptual analysis. Indeed, it was partly such contrasts that were to lend weight to the widespread notion that there are different traditions of, or approaches to, philosophy. At the same time, however, it was becoming fashionable in some educational quarters to hold that there was something profoundly mistaken about conceptual analysis as a philosophical method an idea that gained ground not only under the influence of post-structuralism and postmodernism but also with increased educational attention to latter-day historicist trends in the philosophy of science and (from the early 1980s onward) to more neo-idealist or post-analytical social ethics.

Briefly, the dominant idea in this connection was the view – owing most perhaps to nineteenth-century German idealism and its Marxist and pragmatist progeny – that since human knowledge and truth are socially constructed in the light of rather diverse local circumstances, the absolute and/or universal meaning and truth which bygone philosophers had sought could be only illusion. There can also be no

doubt that this idea has in various recent guises had a fairly intoxicating effect on contemporary philosophers. It is no less clear that, new garments notwithstanding, it is almost as old as the hills. Indeed, a highly subjective form of this essentially relativist view – according to which all truth is perspectival – was both defended by the ancient Greek sophist Protagoras and (according to Plato in his *Theaetetus*) opposed by Socrates. Moreover, of the numerous modern educationally influential forms and versions of this idea, one might mention three. The first is that of the French post-structuralist philosopher, Michel Foucault, who characterizes the task of philosophy in terms of what he calls (borrowing from Nietzsche) genealogy (Foucault, 1980, 2004). This is essentially a form of historical sociology that seeks to recognize – in, so far as one can tell, a fairly neutral and nonjudgmental way – the diverse ways in which key social concepts of madness, punishment, and sexuality have been conceptualized from past to the present. A second is associated with the postmodern anti-theorist, J-F Lyotard, who – on much the same sociological grounds – urges us to accept that there are no grand recits or overarching meta-narratives (Lyotard, 1984). The third (albeit a good deal nearer to analytical philosophy than these other two) is the moral and social theory of the British philosopher, Alasdair MacIntyre, who has lately defended a unique brand of neo-idealist Aristotelianism (or perhaps, more accurately, Thomism), that denies the possibility of any external moral adjudication between diverse rival social traditions of moral enquiry (MacIntyre, 1981, 1987, 1992).

In the interests of avoiding some confusion, however, there are pressing questions to be asked about the extent to which such views are inconsistent with either an analytical approach to philosophy or (for that matter) the idea of absolute or universal truth. Thus, to begin with, is analytical philosophy at all at odds with the view of Foucault and others, that key social and other concepts are sociohistorically constructed? The answer is, of course, that it is surely not. In fact, it is probably safe to say that all serious modern (if not also many past) philosophers subscribe to what the British analytical philosopher, Michael Dummett (1978), has called the thesis of “the social character of meaning” – precisely the idea that human ideas have complex and philosophically interesting social histories. Indeed, after Wittgenstein, one might well expect those modern analytical philosophers of usage who influenced the postwar revolution in philosophy of education to be sensitive to such linguistic developments – which, indeed, this author thinks they have generally been. However, does this mean that modern analytical philosophers would have to deny any and all possibilities of universal, analytical, or necessary truth? Again it clearly does not, and any such denial would in any case be spectacularly foolish. Indeed, the first effective attempt to refute subjectivist or social constructivist denials of absolute or universal truth was made (in Plato's *Theaetetus*) by Socrates who pointed

out that such denials are themselves absolute claims (to the effect that there is no absolute truth). Likewise, a philosopher such as MacIntyre who claims that there can be no single cross-cultural conception of morality or moral education, presumably holds that this universally – rather than just occasionally – holds.

It is also worth asking how Socrates might have responded to the postmodern claim of Lyotard – often paraded by educational theorists as a self-evident truth – that there are no overarching meta-narratives. It is likely that Socrates might first have asked Lyotard to clarify the precise sense in which he intended this claim to be taken. Could the denial of meta-narrative mean that no one today can possibly believe in any grand theory? (which is, more than likely, a false empirical claim); could it mean that no single theory can be taken to explain everything? (a claim that, while true, would seem virtually trivial – for who would ever have supposed this to be so?); could it mean that no theory could be regarded as successfully or effectively explaining what it sets out to explain? (which would also seem implausible – since many theories appear to explain things rather well); could it mean that any and all explanations are final, so that there is nothing left to say on this or that matter? (which may well be a false claim – but also one that is unlikely to have been widely endorsed); and so on for other possible interpretations. However, the key point for a Socrates would be that such general skeptical sloganizing about the nature and status of theories or explanations can be taken at its face value only at the price of much muddle and confusion of different issues requiring careful articulation and distinction (and that once these have been so distinguished such generalities may cease to be at all coherent or plausible). Indeed, an analytical philosopher's trouble with the sweeping claims of a Lyotard (apart from the fact that they look suspiciously like meta-narratives themselves) is much the same trouble that Socrates discovered in the no-less-sweeping skeptical claims of various sophists and pre-Socratic philosophers: that, once carefully examined, they lack any clear or coherent sense.

However, in this light, the widely held claim that there are traditions of or approaches to philosophy or philosophy of education – such as Marxism, phenomenology, existentialism, critical theory, post-structuralism, postmodernism – that offer viable alternatives to conceptual analysis begins to look less plausible. Indeed, this view is prey to the dilemma that either Marxists, critical theorists, or post-structuralists are engaging in the critical analysis of concepts and arguments or they are not; if they are, then it is difficult to see how they might constitute different forms of or approaches to philosophy; if they are not, then it is difficult to see why one should want to describe what they are doing as philosophy. From this perspective, moreover, the short answer may well be that sometimes they are and sometimes they are not. In so far as Marxists,

phenomenologists, and post-structuralists do sometimes seem to have been in the business of making sweeping quasi-empirical claims about the social provenance of concepts and knowledge, there would seem to be something to the received analytical suspicion that all of this is not so much philosophy as bad speculative sociology. On the other hand, there are evidently moments at which such non-analytical philosophers seem to be quite clearly involved in the clarification of concepts and arguments – which rather undermines any claim that such work rests on an alternative approach to that found in the analytical tradition. On this view, indeed, while it seems clear enough that much nineteenth-, twentieth-, and twenty-first-century pragmatism is about as analytical as it gets – and is therefore of considerable philosophical interest – it may also be that some Marxism, existentialism, and post-structuralism is not (whatever its sociological or other interest) really philosophy as such at all.

Recent Philosophy of Education

In so far as all this is so, it would seem that there is at least some confusion in any alleged repudiation of the analytical tradition: for, if this means a rejection of the hard-won analytical techniques bequeathed to us by the likes of Plato, Aristotle, Aquinas, Descartes, Kant, Russell, Quine, Wittgenstein, Ryle, Austin, and others – or, yet worse, some kind of denial of the laws of thought and logic themselves – then it is difficult to see how anyone might subscribe to this and still claim that what they are doing is philosophy. To be sure, some feminists have come close to claiming that the laws of logic are to be regarded as mere expressions of the power and control of males by males – but how might we either agree or disagree with those who refuse to recognize the basic rules of argument? What is true, of course, is that some of the above philosophers who have evidently contributed to the development of analytical philosophical techniques are also philosophers who philosophized in the light of particular metaphysical, epistemic, and moral perspectives or commitments. Thus, for example, Thomists are Roman Catholics who are committed to a certain perspective on Catholic theology and moral teaching deriving from Aquinas, and Quineans are pragmatists committed to no less distinctive perspectives on knowledge and truth. That said, many modern Thomists have been avowedly analytical in their philosophical approach and few pragmatists would regard themselves as departing from the overall analytical drift of philosophical method. It is also not hard to see how there might well be analytical Marxists or existentialists – and some phenomenologists and critical theorists seem to have been analytical enough.

However, it is also possible that what those philosophers who would want to regard themselves as opposed to

analytic method or the analytic tradition have wanted to deny is just the idea that there can be a rationally neutral or value-free conception of, or approach to, philosophy that does not presuppose metaphysical, epistemic, or moral commitments. This is certainly a hard claim to evaluate – not least because, from an analytical viewpoint, it is again not altogether clear what it means. On the one hand, one wants to ask who exactly is supposed to have denied this – since it is generally as clear to analytical philosophers as anyone else that although arguments may be more or less valid, the basic premises on which arguments are based may not in turn have been arrived at by any further argument (although they may be supported by better or worse intuition or evidence). On the other hand, it seems equally clear that philosophers (and other people) have been driven to change their minds or commitments precisely on the grounds that they no longer found the arguments for such commitments entirely compelling: thus, for example, there are well-documented instances of philosophers rejecting their Catholic or Christian faith because they no longer regard the arguments commonly advanced for such faith to be compelling – as well as of atheists becoming theists under the same compulsion. In short, a (relatively) detached analytical view of a matter and an appreciation that our arguments may not be as strong as we formerly took them to be can help us to see more clearly and to correct our views – which would be precisely a major analytical claim.

It is in precisely this spirit that many contemporary philosophers of education have persisted in deploying analytical methods in the interests of further clarifying a range of key educational concepts, questions, or arguments that are often no doubt prone to ambiguity, conflation, and other sorts of unclarity. Some of these philosophers are Christians, others are Marxists or socialists, others are secular liberals (or even neoliberals) and few of these would see these different commitments as impediments to serious intellectual engagement with those of other commitments. What is of concern to such educational philosophers is the more dogmatic adherence to Marxism, feminism, or post-structuralism which might claim that no argument can be anything other than bourgeois or patriarchal hegemony, or more radical interpretations of Nietzsche or existentialism that deny that there is anything to human value beyond arbitrary personal

choice. For, if we are forced to conclude that any and all aspiration to unbiased and/or objective argument and truth is in vain, this surely spells not only the end of philosophy but of anything much worth calling education.

Experience and Andragogy

If a single concept marks out the learning of adults from the learning of children, it is experience. The pursuit and accumulation of learning, and its refinement, by adults, is usually underpinned by some assumptions about the integrity and persistence of experience. If an individual has lived longer (i.e., has passed through childhood), they are regarded, initially, as more adept at identifying what they have learned, in the past, and what they want to learn in the future. Moreover, adult individuals are also assumed to have insights into how they learn best now, and in the past, and expect to learn, in the future.

Experience, closely connected to the life span of individuals, is therefore a fruitful way into a review of the main philosophical issues involved in adults' learning. There are clearly, also, intimate conceptual links from this singular life span across into the parallel area of lifelong learning, which will emerge below. The immediate task is to set out how the fruitfulness of a single concept (experience) should be distinguished from the singularity of its manifestation, that is, in individuals, all of whom experience experience differently. As Candy puts it, the assumption that experiences are only located in individuals is "so deeply entrenched in the ethos of adult

education as to be thought 'obvious' or 'self-evident' and to thus be beyond question" (1987: cited in Usher *et al.*, 1997: 93).

What is so special about adults' experiences, as adults? Distinguishing between children's and adults' learning was crisply and famously done by Knowles (1970), who was not a philosopher but gave significant shape to the field of practice called adult education, at least in North America. His andragogy (not androgogy) theorized adults' learning through the explicit utilization of experience. Adults learn best, according to Knowles, when they

learn how to take responsibility for their own learning through self-directed inquiry, how to learn collaboratively with the help of colleagues rather than compete with them, and, especially, how to learn by analyzing one's own experience. ...[This] is the essence of the human relations laboratory. (Knowles, 1970: 45)

By contrast, Knowles' pedagogy marked out children's learning, in which instruction continued to be central, due to the limited and naive nature of youthful experience. Later, Knowles modified this crisp distinction in favor of more experientially inclusive learning for individuals of any age.

So if we take experience as the point of entry to theorizations of adult learning, we can readily locate it

within humanist scholarship, more generally. Knowles quite explicitly drew upon the psychologists, Carl Rogers and Abraham Maslow, but philosophers can agree that advocating experience as the bedrock concept for adult learning immediately looks Deweyan, and educators in general have been drawing on his vast publications well before andragogy surfaced in the 1970s and 1980s (Dewey, 1938). Of course, Dewey mainly had school-based education in his sights, but his advocacy of organic, holistic learning (and teaching) has attracted many adult educators.

However, before we go on, getting some idea of where nonschool education occurs is important in understanding the impact of Deweyan (and Knowlesian) experience. There is no single sector of the education industry in which one could find adults' learning (unlike schooling, where children mainly and compulsorily learn). We can immediately identify formal organizations and institutions, such as vocational colleges and universities, but adult learning occurs informally, in daily life: at paid work (in employment), unpaid work (in the home and in community settings), public discourse (mass media including infotainment), and political advocacy (e.g., the green agenda). There is, then, an amorphous and distributional quality about adult learning, which a simple reliance on experience under-recognizes. We will return to that inherent contextual messiness shortly.

Shaping Foundations

Giving shape to the messiness of theorizations of adult learning has been splendidly done by Elias and Merriam (2005) over the past three decades. They list and describe various main philosophical foundations of adult education: liberal, progressive, behaviorist, humanistic, radical and critical, analytic, and postmodern. It is worth noting that Knowles provided the foreword to the first edition in 1980, beginning with the claim that "[d]uring the entire time I have been in the field of adult education, which is almost half a century, I have heard it being criticized for not having a philosophical foundation (xi)." Elias and Merriam do not attempt to provide such a foundation, but instead provide an accessible overview of several main writers in the various approaches which are frequently drawn upon to underpin policies and practices in adult education. As expected, these various approaches are generically educational, so giving shape to the messiness of adults' education is assumed, rightly, to be a subset of these.

Experience – that is to say, how adult learning is best conceptualized – fares differently within each of these foundations or approaches, as Elias and Merriam (2005) show. Liberal writers draw upon the classical Greeks, the values of medieval schooling, and the character formation

thought to evolve from the contemplative study of an intellectual canon: literally the classics. By contrast, progressivists, such as William James and John Dewey, engage the relationship of subjective experience to the worlds of work, democracy, and of sociality, generally, with change as the driving force.

Behaviorism is well known through the work of Pavlov, Watson, and Skinner, where experiences are manifest as modified behavior, achievements of outcomes, and reinforcement (or not) of these. Humanism has been already introduced, above, through the Knowlesian contribution to adult education, but its heritage is much broader and deeper: Heidegger, Sartre, Camus, Marcel, and Buber, in European scholarship, and Dewey, in North America, for example. In adult education specifically, Brookfield, Mezirow, and Jarvis have each shaped richer contributions to theory, policy, and practices from within this tradition (yet none would claim to be philosophers).

Radical or critical adult education takes sociopolitical stances on learning, and advances it in the spirit of ideologues such as Marxism, some feminisms, anarchism, critical theory, environmentalism, and so on. Holt, Goodman, Illich, and mainly Freire are significant contributors here.

Analytic philosophy is represented by Lawson and Paterson, who have made influential early contributions in the United Kingdom (about the same time as Knowles, in the USA) drawing upon the London School of philosophy of education, well known through the work of R.S. Peters and Paul Hirst, for example (Curran *et al.*, 2003).

Elias and Merriam (2005), draw attention, finally, to postmodern approaches, which "offer... a trenchant critique of the entire enterprise of adult education," (p. 14) in that a host of scholars in a vast range of fields, across the arts and social sciences, have interrogated the modernist assumptions of unilateral and monocultural progress, in human affairs in general. Postmodern perspectives in adult education were evidenced in the second paragraph of this article you are now reading: Usher *et al.* (1997: ch 5 *passim*) refuse to take experience as a given (bedrock) phenomenon. We may ask, in the spirit of postmodernity: Whose experience? In what contexts? By whom is it perceived? These are three interrogations of the modernist experiential narrative which was our point of entry, and in asking these sorts of questions, postmodernists seek to expose the various constructions of learning, learners, and of teachers, from which adult education can, itself, be interrogated.

Experience is, then, manifest diversely and intersubjectively (among, not merely between, each other). It follows that all constructions are relational: they build upon, and between, varieties of subjectivities. Postmodernity works the relationality of experiences even harder than that. Identities and practices are themselves

constituted in and by the networks and nodes by which humans associate. We live, move, and have our being through such associations; and postmodern perspectives in philosophy of education, and in adult learning, in particular, are serious about diverse and locally devised interrogations of problems, issues, and challenges.

Embracing Diversity

So Elias and Merriam do us a fine service in mapping the main foundations of adult education, and introducing persisting and influential bodies of scholarship to practitioners and other theoreticians. Overall, we can agree that there is no one-size-fits-all philosophy of adult education, nor is there one best approach to adult learning. In their chapter in a well-received book covering all of adult education and training, Fenwick and Tennant (2004: ch 5), set out to understand adult learning, by making three assumptions:

First, no one theory of learning or of facilitating learning trumps the others. There is no generic essentialised “adult learner”. . . . Second, learning is not a mental process occurring in a vacuum. The context of a person’s life – with its unique cultural, political, physical, and social dynamics – influences what learning experiences are encountered and how they are engaged. Furthermore, “context”. . . is active and dynamic. Third, the “learner” is not an object separable from the “educator” in teaching-learning situations. The positionality of the educator (whether the expert, coach, liberator, observer, arbiter, commentator, guide, decoder) affects how learners perceive, feel, behave, and remember. (Fenwick and Tennant, 2004: 55.)

Drilling down even more sensitively into adults’ experiences often requires a phenomenological approach. Here, bringing one’s awareness of one’s consciousness to the surface, and articulating it, is essential to the realization of a sense of personhood (Stanage, 1987). This Husserlian approach holds much potential for adult education in, for example, nurses’ leadership of antenatal classes, where utterly personal expectations, and real experiences, of pain, can be trawled.

When faced with the messiness of theories, we can conclude so far that a postmodern spirit, rather than embrace a singular postmodernism, enables an eclectic and particularistic approach to central philosophical issues (subjectivities and their construction in and around sociopolitical associations), that themselves revolve around adult learning’s traditional focus on the integrity and persistence of experience.

Now we return to the messiness of contexts. Sensitivity to diversity of contexts of adult learning is essential, but is difficult when formal and informal adult learning

may well work against each other, and frequently do. An apprenticeship requires on-the-job assimilation of masterful skill (the informal) and typically also 1 or 2 days a week in a vocational college (the formal), over several years. Yet these experiences may not dovetail. Similarly, one of the main criticisms of traditional university teaching (formalized learning) at least in the West has been its disdain for those experiences brought to the lecture hall and tutorials, not just by school leavers, but also by mature age or further education students (informal learning).

Know-How at Work

The formality of what philosophers call propositional knowledge – necessary though it is for a worthwhile education – is now regarded as insufficient for genuinely lifelong learning, in particular, for enhancing a graduate’s employability across the life span beyond the compulsory years of schooling. How, for example, a university or a vocational college, engages students’ informal learning, which is inevitably and desirably experiential, raises fundamental issues of teaching, program design, and assessment for that institution. Ryle’s (1949) important distinction between knowing that X (where X is a proposition) and knowing how X (where X is an experience) has become problematic for many educators as lifelong-learning policy discourses traverse experience as a human phenomenon, trawling it for meaning.

Know-how is emerging as a fruitful site of analysis in its own right. For example, Polanyi (1966) picked up the tacit (inarticulable) significance of knowing how: we know more than we can say. Decades on, we are now more willing to acknowledge that powerful adult learning resides in what have hitherto been low-status experiences, often called intuition, common sense, women’s ways of knowing, and nous. The epistemological significance of these is now under evaluation, especially in the light of Deweyan accounts of how learning processes, such as reflection, both enhance, and are constitutive, of action. This is in the global context of adult learning at and for work, which has emerged as a major new component in the new world of free trade, rampant consumerism, and market-driven organizational changes, with the collapse of Communism in the 1980s. As Boud and Garrick (1999) put it:

Learning at work has become one of the most exciting areas of development in the dual field of management and education. . . . Modern [sic] organisations ignore learning at the cost of their present and future success. . . . learning has moved from the periphery. . . to the lifeblood that sustains them. (Boud and Garrick, 1999: 1)

Significant philosophical issues are raised by the vocationalization of adult learning, to which we now turn.

Livelihoods, Competencies, and the New Model Worker

Adults learning at and from work undergo experiences only some of which are educative, and only some of which are of enterprise, or strategic, significance. So what, then, is worthwhile workplace learning? And how can it be recognized? A good deal of attention has been given to the calibration of such learning, in various competence structures in most developed economies, and in many developing economies. The extent to which any vocational or workplace competencies can capture the really worthwhile is highly debatable, but so also is the debate – what is really worthwhile? Making a livelihood is essential: how does learning contribute to that? Only in the past couple of decades has this question achieved such prominence. After all, any educational significance that learning at and for work may have has often not been the main motive governments and organizations have in embracing competencies. Learning is not the main activity of most organizations and enterprises. Industrial, labor market, and productivity considerations are important motivators to be weighed among the educational and philosophical, here.

What helps to shape such debates is the acknowledgment of an epistemological and ethical tension. At one polarity, is a reliance on behaviorism issues in low-level checklisting of skills performed, without regard for the rich practical judgments often implied by such performances, and invites reductive, outcomes-driven accounts of human learning. Teaching and training, on this behavioral approach, consist of modifying behavior by repetition, motivators, and incentives which may have little to do with intrinsic satisfactions. An organization, or national government, can run entire learning programs on this approach.

The other polarity is humanist, which assumes the whole person is the worker, not merely a set of hands, but ascribes to the workplace the expectations of fulfillment attributable to human life in general, accompanied by the vocational self-direction to achieve these fulfillments. Again, an entire organization or national government can run entire learning programs on this approach. National generic or key competencies can be identified, often without regard for contextual sensitivities, against which varieties of more or less reductive performance evidence can be assembled, and, in some more enlightened case, some Aristotelian-influenced practical judgments can be inferred.

More commonly, controversies accrue around the fluidity and admixture of behavioral and humanist assumptions in particular contexts. Does the so-called new model worker (ideally self-directedly flexible, well-rounded, creative) get caught up in the ideology of individual success to the detriment of her or his integrity as a person? Usher and Edwards (1994) argue, following Foucault, that “the exercise of modern disciplinary power is exemplified

in the panopticon” (p. 101), which was the nineteenth-century circular prison designed as cells radiating spoke-like, from a hub, with the guards in the hub, such that surveillance was always assumed, by the prisoners, even if the hub was unstaffed.

Usher and Edwards critique the new model workplace, and the competencies that calibrate the work, if workers are learning to be complicit in their own organizational or professional surveillance. This raises substantial ethical and epistemological issues for adult learning, provoked by the very shape and structure of accountabilities for worthwhile vocational learning. Although these issues arise at national, organizational, and enterprise level, they are best resolved locally and in particular cases, with due recognition of contextual sensitivities from those with the experiences that matter most. In this way, a postmodern spirit is played out in judgments of worthwhile adult learning.

Knowing That, Knowing How . . . , and Knowing Why

Epistemology and ethics are only part of the adult learning story. The already amorphous and distributional quality of adult learning is exacerbated by the immediacy of the self-direction which Knowles’ traditional andragogy highlights. Adults learn best when they see the point of it.

Vocationalization within adult learning (as part of a globalizing lifelong-learning policy scenario), such as has just been discussed, impels us to consider the extent to which adults learn best when they can see its direction: this is to know why X. . . (where X is a reason, purpose, or goal).

As we have seen above, translating this across formal and informal contexts is complex: individuals will have a variety of motivations, often in any one day, and often derived from sociocultural allegiances. Through work, home, community, and national institutions, individual adults locate their sense of what is worth achieving – not only for themselves as individuals, but also for their sense of their shared self-hood. What kind of worker, partner, parent, or citizen do I, or rather, we, want to be? Once the arena for learning is broadened out, we can locate ourselves as distributed among and between diverse allegiances. This lateral dimension complements the linear dimension – the journey of the individual across the life span.

In this way, we can add to the traditional Rylean analysis, a teleological perspective: we learn, from each other, what it is to know why we have particular goals and motives. These might come from our employment (such as a corporate vision or strategy), or from our home or community allegiances (such as spiritual or activist values), or from national imperatives (policy discourses which attract or repel).

On this tripartite analysis, worthwhile adult learning is constituted, coextensively, by know-what, know-how, and

know-why. This adds to propositional knowledge the significance of sensitivity to our own learning experiences (knowing how X...), and also adds the directionality of this learning, or the teleological dimension (knowing why X...). This analysis locates the individual as an intersubjectivity among not only other individuals, but also as relationships of associations and allegiances, in groups of diverse sociocultural significance.

Adult learning, analyzed this way, is a wide and deep phenomenon, with astonishingly diverse manifestations, only some of which fit with traditional assumptions of the learner as an individual, or subjective self, enrolled in formal studies in an educational institution. On the contrary, this analysis requires philosophical enquiry into diverse contexts where, almost case by case, particularistic approaches can be tailored to prospects of successful learning. So we need to look closely at educative practices, from which adults can learn.

Practices and Identities

The practice turn in education has taken much attention in recent years (Hogan, 2008), and not just with adults. However, here we are advancing an experiential analysis of adults' learning in particular contexts of practice, so it is important to bear in mind some actual learning activities which could be and often are assembled into programs and practices for groups of adults, both formally and informally:

- problem solving/workshopping; learning-to-learn/double-loop questioning; critical thinking/evaluation exercises;
- negotiation/collaboration/interactivity/interpersonal skill formation via groupwork;
- literacy and numeracy through real-life excursions/reporting;
- case studies/informal presentations;
- simulations/role playing;
- journaling;
- work placements – real on-the-job learning/training with episodes of expert instruction/guidance (coaching);
- peer-group instruction/guidance (debriefing/consulting/mentoring);
- audio-visual presentations and resultant groupwork;
- project-based team activities.

Diversity is not self-justifying. Here, the purposes in assembling diverse activities within particular contexts expose adults to diverse ways of learning – experiences – from which they build their own capacity for self-direction.

Implicit in this very Deweyan concept of organic growth is both self-direction and self-identity. Identities, or subjectivities, are constructed and reconstructed, in

practices – such as in classrooms, anywhere in the world. The way, then, to clarify important aspects of experience for adult learning, given the amorphous and distributed nature of those experiences, is to pay close attention to the practical – even as a philosophy. In the policy context of lifelong learning, Leicester *et al.* (2007) argues for practical diversity in this way:

Our notion of “practical philosophy,” in encouraging attention to the diversity of voices and experiences in the real world, also has this political tendency [that is, to be more inclusive of the interests of all people]. Postmodernist epistemology recognises that knowledge is validly constructed from the intersubjective agreement in the experiences of oppressed groups and not just from that of the educated group (the group which writes papers) which has tended to exclude these voices hitherto. However...we are also suggesting that practical philosophy, recognising that meaning is rooted in the (complex and context-dependent) uses of a word, has implications for conceptual analysis regardless of any political commitments or implications. (Leicester, 2007: 263)

Both Leicester's constructive practical philosophy and the author's listing of a range of learning activities (listed at the beginning of this section) have in common an experientially diverse approach to the practice turn. Most important in this is that both imply a richer and hitherto model of agency. Adult learning is underpinned by assumptions of the integrity and persistence of human experience, as we noted at the outset, but in this era of lifelong learning, individuals are assumed, and indeed required to exercise, in their very self-direction, and to advance their self-identity, sophisticated autonomy, which assumes agency. It is in this sense that Schon's (1987) reflective practitioner gets a new lease of life: socially located, amidst the intersubjective messiness of daily work life, and fully agentive. The revitalization of Aristotle's *phronesis* in clinical medical practice is a case in point (Montgomery, 2006).

The Project of the Self: Always Work In Progress

If, as has been argued above, and building upon a Rylean analysis, a tripartite, more intersubjective, more social notion of adult experience is required, then agency itself needs to be rethought. If adults – and, indeed, all humans – learn not just individually, but powerfully from each other, then agency as expressed in what can be called the project of the self, needs recasting. Self-direction becomes self-management, but less of me, and more of us.

The vocationalization of higher education has been rightly criticized if it merely reduces adults' learning to employability. Such reduction of the head to the hands

preserves a Cartesian dualism at the very time adult and lifelong learning is taking the organic and holistic approach that was argued by Dewey and many others in adult education across the twentieth century. Reductive attempts to produce the new model worker – utterly flexible, compliant, and creative – deserve criticism when, as often occurs, competencies and shallow skill-talk drive the educational and policy discourse. It may be that a character-driven capabilities approach (following Nussbaum) is a more defensible formulation of the project of the self.

However, what is interesting beneath all this is the need to revitalize agentive practices: these are opportunities for adult learners to make decisions and judgments in particular contexts which meet the particular purposes of those contexts. Practice-based learning activities immerse participants in intersubjective relationships with various forms of association (e.g., a team, mentorship). Moreover, they can take skill acquisition seriously – beyond behavioristic training, and often meld with broad organizational development initiatives, and can do this inclusively – with the respect for constructively diverse experiences, which Leicester claims for them, above.

In addition, the embodied nature of adult learning is crucial. Rather than leave materiality of the learning to the doing of the hands (which preserves a Cartesian dualism), some current research is bringing to prominence the whole person with a due regard for how what we find ourselves doing expresses not merely our learning, but our identities as well (O'Loughlin, 2006).

Thus, agency and identity are intertwined in deliberately providing a (strategic, purposeful) diversity of learning activities for particular formal and informal contexts. Intersubjectivity requires the selection of social, reflective (both public and private), and personal experiences of the most profound kind. In this way, the practice turn demonstrates what a new approach to agency might look like when adults gather to learn. Over time, and explicitly heading toward assessment tasks, or some other agreed outcomes, the intention is to grow self-direction and self-identity. Choices – decisions – are negotiated, and in these ways, human decision-making capacity is shown to be valued.

Beckett and Hager (2002), argued for the centrality of practical judgments, as a relational way of advancing a new epistemology of practice, one which decenters the traditional Cartesian and even Platonic epistemology. Educators have traditionally assumed that coming to know something is to arrive at a state of the mind as evidenced in accounts of what is cognitively the case – this is about whether the propositions are in place there. Yet adults learn best when their experiences are taken seriously, so a tripartite Rylean epistemology should supplement the traditional account. The low status of the tacit, intuitive, reflective, phenomenological, embodied, and the socially efficacious leaves much human

experience out of the educational vision, wherever it is, but especially for adults.

By taking seriously the holistic nature of particular everyday experiences, such as those of the workplace and the pedagogically diverse classroom, adult educators, whether they are practitioners (who have real expertise in inclusive learning strategies) or researchers (who have interests in relational practices), can find philosophically rich ways through the messiness of adult learning.

Autonomy

The Concept of Autonomy

Autonomy was originally a political term meaning sovereign or self-governing, as applied by the Greeks to independent city-states, and it is still used today when we speak of autonomous regions in such countries as China or Spain. In the context of present-day moral and educational philosophy, however, it is usually ascribed to individuals whose conduct, way of life, and belief systems are determined by their own choices and in the light of their own judgment.

Although Kant (1785) is normally credited with popularizing our modern usage, the notion of rational autonomy and its justification, though not the term itself, was already an important part of Enlightenment thinking in political and other writing that sought liberation from the authority of the ancients and tradition in matters of belief and conduct. The faculty of rationality or reason was widely held to be equally available to all in matters of factual or religious belief (Hobbes, 1642) and if political obligation was to be considered valid, it had to take a form under which individuals in a state of nature, or guided by reason alone, would voluntarily agree to put themselves (Hobbes, 1642; Locke, 1689). Human beings were held to enter the world with no prior indication of their authority or subordination (Locke, 1689) and all were said to be the best judges of their own best interests. Such thinking remains central to our understanding, not only of liberal democracy but also of our social norms, social policies; health education and health promotion (Heathcote, 2000); medical ethics; as well as our freedoms of religion, speech, the press, enquiry, research, teaching, and learning.

The state of not being autonomous is termed heteronomy, controlled by others or, importantly in the moral field, by one's whims, inclinations, and instincts. These, Kant held, represented the part of ourselves that belongs to our material being and is subject to the material laws of nature rather than our rational humanity which is capable of exercising moral freedom by prescribing laws for itself. According to Kant, one's autonomy is one's power to follow a self-chosen moral law arrived at in the light of reason alone.

Autonomy may be distinguished from the wider concept of freedom, which in its so-called negative form usually refers to the mere absence of external constraint or coercion. The term positive freedom, may be used with unfavorable connotations by liberal writers (Berlin, 1969) to imply that the person concerned has been liberated

from illusion, error, or false consciousness in order to pursue or adopt a particular cause or belief system, but with the help of some fairly robust guidance or re-education, not to say brainwashing or coercion. The dependence of autonomy on rationality distinguishes it from authenticity, which may likewise be cited as an educational aim (Bonnett and Cuypers, 2003). Proponents of authenticity may, indeed, point to the arguments of rationality as barriers to the genuinely individual will. Truly authentic choices, it may be held, may be essentially criterionless and attempts to make them according to canons of reason or even consistency may be seen as a form of bad faith.

Moral autonomy is an essentially mental quality enabling the rational agent to overcome such nonrational influences as emotion, obsession, addiction, and weakness of the will, as well as error and falsehood or indoctrination, both in making individual judgments and in choosing, pursuing, and amending his or her conception of the good life.

Autonomy as an Educational Aim

In certain respects, the concern of post-1960s philosophers of education with autonomy goes some way to provide a systematic rationale for the earlier writings of progressive educators who attacked not only the coerciveness and rigid assumptions of transmission-based traditional education but also aspired to enable their pupils to think and act independently for themselves (Dewey, 1916; Neill, 1962). Crucially, however, the child-centered assumptions of many progressive educators that the unconstrained and virtually uninstructed child would naturally develop both moral and intellectual qualities, is fundamentally rejected by philosophers of education from the 1960s onward (Peters, 1969; Hirst and Peters, 1970; Dearden, 1972). Both the virtue of autonomy and the rationality that underpins it were seen by them as sophisticated social achievements, which have taken many generations to develop and must be systematically taught rather than simply allowed to unfold.

Promoting the learner's autonomy and by implication his or her powers of reasoning came to be seen as one of the central aims of education during the largely Kantian era of philosophy of education in the 1960s and 1970s (Aviram, 1986). For many it was, and for some indeed it may remain, part of the very definition of education itself. Learning processes, which promote belief and compliance

without ensuring the learner's autonomy in respect of belief and action tend to be termed, at best training or socialization, at worst indoctrination (White, 1970). The tight connection between the concepts of education and autonomy has led many writers to adopt the supposedly neutral term schooling in relation to a process that may be seen as enslaving rather than empowering and leaves unanswered the question of whether critical scrutiny is encouraged, or even possible (Illich, 1971; Barrow, 1981). The disparaging use of the term socialization, when contrasted with education, goes even further with its Marxian implications of engendering false consciousness and subordination of the true interest which the autonomous learner would rationally choose to follow, to that of others.

The concept of autonomy has been fundamental to much thinking about both the justification and the curriculum of education (White, 1982, 1990, 2007). In one key text it is proposed that, given the nature of the human predicament, we unlike other creatures, are constantly obliged to make choices for ourselves (Peters, 1973). Often these will be choices with moral implications and, given the view of moral judgment then widely prevailing, good moral choices were seen as a matter of applying higher-order moral principles to the dilemma with which one was confronted (Hirst, 1972). Various writings on moral education and moral development take it as axiomatic that maturity of moral development and success in moral education are achieved when young people are able to do this without hindrance from the various forms of heteronomy by which human beings are beset (Kohlberg, 1968).

The necessity upon human beings of making choices and the related goal of promoting autonomy of the individuals who are to make and be affected by them, is also taken as a justification for the knowledge curriculum of education. If we are to make valid choices about our lives we need to know both about the range of options available to us and the implications of our choices in the real world: what satisfactions, valuable pursuits, and worthwhile ways of life are open to us; what will be the effects of our choices and what significance may be attributed to them. In the modern world, it has been argued that this need is particularly strong in view of the greatly increased scope for personal and vocational freedom available to individuals, as well as the range of leisure pursuits and other satisfactions which the modern world presents (White, 2007).

We cannot here discuss in detail how the various so-called forms of knowledge, or forms of human sensibility and understanding, contribute in their various ways to the meeting of this need. Of significance, however, is the degree of importance attached, in the educational discussion of the forms of knowledge or disciplines, to the supposed tests for truth or validity central to each.

Autonomous choosers not only need a great deal of content knowledge about the world, but they also need to be in a position to subject what they are told to rational criticism and, if necessary, generate new knowledge and understandings for themselves (Hirst, 1965; Dearden, 1975). This has obvious implications, not only for the curriculum content to be selected but also for the manner in which it is to be communicated, for relations between teachers and learners, and for the organization and management of educational institutions (Hirst and Peters, 1970).

Although the development of moral autonomy and intellectual autonomy in the pursuit of individual disciplines may be important in all areas of study, both have a particular place in the field of citizenship education in a liberal democratic society. Central to the conception of such a polity is the right of individual citizens to choose, pursue, and amend their own ways of life. Though there is no absolute obligation to participate actively in the political life of one's community, all have the right to do so and those who do participate actively may be regarded as responsible citizens making a positive contribution to their community's life. All may contribute to the direction of society's affairs by the formal act of voting and through their expressed attitudes regarding their national and local governments' policies. Such contributions can only be made by morally and intellectually autonomous citizens capable of judging the moral validity of outcomes that are proposed and criticizing the factual and ideological premises by which they are supported (Bridges, 1997; Smith, 1997; Wringe, 1992, 2006).

A brief mention must finally be made of the way in which, in the context of higher and further education, autonomous learning may refer to the manner and organization of learning rather than its larger aims. By this stage it may, rightly or wrongly, be supposed that the essential core elements of a liberal education are in place and that what is studied will relate more or less closely to the diverse life choices of particular students. These may reasonably expect to be free to prepare themselves to follow this or that vocation or way of life and, in view of their various aspirations, resources, and commitments, may need to arrange their studies with a degree of flexibility. At this level too, it may often be an efficient use of time, expertise, and other resources for teachers to guide their students in the pursuit of their own learning rather than act as direct transmitters of educational content. In a world in which knowledge needs may be more diverse than can be served by the resources of individual institutions and the availability of new knowledge may advance rapidly, the ability to continue to learn outside periods and places of formal study is important. In this situation, however, the ability to continue to apply autonomous intellectual and, in some cases, moral scrutiny remains crucial.

Some Reservations Regarding Rational Autonomy and its Place in Education

Neither the view that reason alone can or should provide the motivating grounds for the actions of individuals, nor the central place ascribed to it in education have escaped criticism. Attention may be drawn to the view of Hume (1739) regarding the relationship of reason, emotion, and action. Far from being an essentially heteronomous element which should play no part in our practical reflections, Hume argues that it is the passions which determine our goals while the function of reason is merely to choose the most efficient means of achieving them. More recent writers have also drawn attention to the difficulty of bridging the gap between so-called grounding reasons which may indicate in rational terms what we ought to do and motivating reasons which ultimately lead us to act (Bond, 1983). One attempt to overcome this problem has been to posit a hierarchical model of autonomy according to which our first-order or everyday desires may be restrained by so-called second-order desires when these conflict with some other, to us, more important if less immediate desire (Frankfurt, 1971, 1999). Typically we come to recognize our second-order desires as a result of rational reflection. Critics of this view have, however, asked where the authority of second-order desires comes from and pointed out that recourse to a level of third-order desires would, of course, prefigure an infinite regress. It has also been suggested that so-called second-order desires, insofar as they are desires at all, are logically indistinguishable from those of the first order (Cuypers, 1992; Bonnett and Cuypers, 2003).

One of the problems in defending rational autonomy is that, at least in its pure Kantian form, it may seem to suggest that one course of action or way of life is indisputably rational and that others must therefore be less so, if not actually irrational. This, far from promoting individual freedom, would seem to leave the agent with very little scope for choice of action and suggest that an agent taking an alternative view was in need of restraint. It may even seem to open the way to a measure of coercion or moral bullying, if not to the excesses of so-called positive freedom referred to above. Critics of this interpretation of rational autonomy may point to the observation of Mill (1859) that as no one size or style of footwear fits all, it is even less likely that all will be suited by a single way of life.

In recent years postmodernists, communitarians, feminists, and virtue ethicists have all expressed reservations about the central role attributed to rational autonomy or its equivalent in political and moral as well as educational philosophy. The grand narratives of progress, justice and democracy, truth, and even reason itself no longer command the unquestioned acceptance they did from the philosophers of the Enlightenment. We no longer think that the problems of moral and political philosophy can be

solved by a single overriding theory analogous to the newtonian law of gravity, as Kant (1785), Hobbes (1642), and no doubt many other Enlightenment philosophers supposed. Access to the facts behind any general theory about the social or political world is difficult to obtain (Baudrillard, 1989; Fish, 1989) and these are, in any case, subject to interpretations, which may owe more to contingent relations of power than to reality if, indeed, it is meaningful to speak of reality at all. Bodies of argument or justification relying on such Enlightenment foundations as reason, truth, justice, and individual identity may be dismissed with such deconstructive terms as rationales, rhetorics, discourses, or phrase regimes (Foucault, 1978; Lyotard, 1979; Rorty, 1989).

Communitarians have also denied the very coherence of an intellectually and socially unencumbered individual autonomously developing, choosing, and evaluating a personal way of life, or even making important moral choices independently of the established values, practices, and traditions of his or her community (MacIntyre, 1981; Sandel, 1982). With this in mind one writer (Allen, 1982) goes so far as to claim that, far from securing a person's freedom, attempts to instill the practice of rational autonomy along the lines envisaged by some philosophers of education would risk entirely destroying it.

Many philosophers, including philosophers of education, no longer think of moral conduct as being arrived at by the application of moral rules deduced from certain higher-order principles which are themselves subject to rational scrutiny and validation. Good conduct may now often be seen as that which embodies certain virtues whose appropriateness or the appropriate manner of whose exercise will vary according to contexts of time, place, and tradition, the role of the agent in relation to particular others or more generally within his or her society (Slote, 1992; Carr, 1991). The view that inclination should have no place in our moral reflections may be unfavorably contrasted with the Aristotelian view (Aristotle *Nicomachean Ethics*) that the virtuous person is one who loves virtue and pursues it precisely because he or she is aware of its attractions.

The virtues of independence and rational decision making, especially where this is conceived of as the application of impersonal rules and principles, have also been identified as predominantly masculine traits (Griffiths and Smith, 1989). The Piagetian/Kohlbergian (and essentially Kantian) account of moral development according to which all individuals potentially develop through successively rational, or supposedly rational stages, culminating in the ability to make moral judgments in the light of principles which, at the highest level, are themselves subject to rational scrutiny, has been challenged by Gilligan (1982) among others. These writers argue that the mature stages of moral development in many women may take an alternative course leading to the different and equally

estimable, if not superior virtues of flexibility, cooperativeness, and the preservation of caring interpersonal relations. On this view, an education which accords supreme importance to predominantly masculine forms of development shows undue gender bias and undervalues women and their contribution to social, professional, and everyday life.

In Defense of Rational Autonomy as an Educational Aim

The hesitations considered in the previous section are valuable in problematizing the Enlightenment assumptions that reason alone can find unitary solutions to moral as well as scientific questions. It should be said, however, that they tend to focus on an extreme version of the notion of rational autonomy and may not be universally accepted as conclusive. Nor should it be thought that they provide convincing reasons to abandon the aim of encouraging and, as far as possible enabling, young people to become morally and intellectually independent. It may be felt that the theoretical assumptions which these criticisms presuppose are themselves vulnerable when taken to their logical conclusions. The following remarks, however, can do no more than indicate some of the more obvious counterarguments that may be advanced.

A life totally without inclinations, desires, and even passions, in which everyone's actions and words expressed nothing but the purest rationality would certainly be impoverished. As Kant recognized, we are in part emotional and physical beings. Unlike Kant, however, we recognize that this part of ourselves may enrich rather than damage the flourishing life. We also have more reason than Kant to be aware of the harm that may be wrought by the injudicious repression of this part of ourselves. Equally, however, we can scarcely deny the baleful effects both socially and upon individual lives if all yielded to their immediate desires and passions or fecklessly followed their passing inclinations. Little needs be said of the ills of over-ready acquiescence in the promptings of others or the uncritical acceptance of the beliefs it may suit others to foist upon us. It is not obvious that the disjunction between reason and desire is quite as clear as Hume and others have suggested or that the gap between grounding and motivating reasons is quite as unbridgeable as more recent writers have supposed unless, that is, the two terms are defined so tightly that reason cannot, in the nature of the case, give rise to action. Certainly, reasoned judgment can enable us to choose between conflicting desires and may sometimes equip us to see that a particular goal is more or less desirable than we previously supposed. It is also possible to speak of rational passion, as when we are strongly motivated to do something precisely because it seems

the right, proper, or most worthwhile thing to do. Of course, if it is then said that once we want to do something which has these properties, this then automatically becomes exclusively definable as a desire and therefore no longer a reason, then the conclusion that reason and desire are irremediably distinct is demonstrated, but vacuous.

The criticism that higher-order desires are logically indistinguishable from first-order ones appears to be based on a misunderstanding. Second-order desires do not provide the grounds for first-order ones in the way that higher-order principles are sometimes said to justify individual moral injunctions. Their function is, rather, to coordinate our various desires and enable us to choose between them, giving reasons to prefer some to others in particular contexts of time and place. Once again, of course, it is always possible, but vacuous, to claim that since so-called higher-order desires determine action they must necessarily be of a kind with other desires of the more immediate kind.

Hesitations arising from Mill's claim to see freedom as the ability to follow the promptings of our own nature, and to some extent also those suggested by the communitarians, are less troublesome to counter. It must be acknowledged that even if our essentially human nature resides in our rationality, it is nevertheless irrefutably the case that we inhabit different bodies, are possessed of different capacities, have different past histories, are in different situations, and have differing material resources. These are the givens of individual human lives which we may to some extent challenge as we challenge the uncritical assumption that they debar us from doing what we think is right or desirable to do, but in the end they must be taken into account when individuals decide how to conduct their lives. To fail to do so would not indicate autonomy but heteronymous perversity. Autonomy does not demand that we perform the impossible and what is possible will depend on circumstances.

We may readily accept the communitarian view that society, rather than pure reason, is the source of values in the light of which our moral decisions and lifestyle choices are made. The pluralistic modern world, however, offers us a vast range of values and possibilities of fulfillment. There is no predetermined fixity in the matter of who we choose to be or, to adopt MacIntyre's (1981) terminology, of what narrative our life forms a part, or to which tradition the life we live will eventually be seen to belong. Autonomy is the ability to critically assess the possibilities our society offers and to choose judiciously between them.

Postmodernist criticism of the disreputable origins of some of our values and assumptions and the problematizing of Enlightenment narratives are helpful in alerting us to the dangers of moral and political complacency. Some courses of action may nevertheless appear more

satisfactory than others, even if it is always possible that our major choices will later come to be seen as having been based on illusion. Insofar as this is the inevitable lot of humankind (if that is indeed the case) this would seem to be all the more reason for helping individuals to create or choose their own destinies and, as far as possible, to do so in the light of plausible, if provisional, justification. Though virtues are perhaps not to be identified by the application of universal rules and must owe much to one's community and local traditions and practices, they are, as Aristotle recognized, far from making the use of reason and rational choice entirely redundant. This is particularly evident when undoubted virtues appear to clash as when, for example, the virtue of personal loyalty appears to clash with those of truthfulness or public spirit. The autonomous individual may also have recourse to reason in order to distinguish the virtuous mean from the vices of deficiency or excess as his or her community defines them.

It may also be the case that in some societies including our own, the making of decisions and the application of rules and principles happen to be associated with individuals of one gender while, for whatever reason, flexibility, cooperativeness, and the preservation of caring interpersonal relations are more associated with those of the other. These capacities, however, are desirable in all human beings, irrespective of gender and courses of action involving flexibility, cooperativeness, and the preservation of good interpersonal relations may be as freely chosen in the light of reasoned reflection as decisiveness or the rigorous following of rules. It is at least questionable whether these two sets of qualities are to be regarded as innately different in persons of different genders rather than the result of differential socialization which as a society we may quite rationally determine to abandon.

The modern world is one which offers many lifestyles and is subject to rapid change; individuals may receive little guidance from the practices and traditions of earlier generations and are bombarded with information and persuasive claims, which they must critically assess in their own interests and as responsible citizens. Despite the various reservations mentioned above and others which may be advanced in the future, it is difficult, in such a world, to envisage reputable programs of upbringing and education in which developing a measure of moral and intellectual autonomy does not play a central role.

Bildung

J Masschelein and N Ricken, Katholieke Universiteit Leuven, Leuven, Belgium; Universität Bremen, Bremen, Germany

© 2010 Elsevier Ltd. All rights reserved.

Bildung could be regarded as one of the most central as well as controversial concepts in (German) educational and cultural discourse. Although there is no single notion of Bildung, it functions as a particularly modern paradigm that conditions specific theoretical perspectives as well as practical strategies, which differ strongly from Greek-antique *paideia* and Christian-medieval *imitatio* (but are not without parallels to liberal education). Considering this paradigm, we first indicate some general features of the concept of Bildung and its complicated history. However, we want to concentrate on the way in which the concept was part of various discourses. Starting from the question of which space of experience and thought is opened up by the notion of Bildung, we want to investigate the way in which the notion allows for educational phenomena to be shaped and to appear. Precisely because Bildung implies a certain relationship between the individual and itself, others and the world, and a certain idea about the dynamics of this relationship, we intend to ask how and in what way Bildung asks us to look at ourselves, to look at ourselves in relation with others and with the world, that is, how we have to think about ourselves. Concretely, we will elaborate the question about the strategic function of the notion of Bildung in five steps. We will first (1) give a historical and (2) semantic clarification, before we (3) sketch the space of experience and thought that is opened up by Bildung and indicate (4) briefly the use of the concept in present discourse. We conclude (5) by asking whether we should look at Bildung itself as being part of a particular power formation, whether the anthropological matrix offered by Bildung is obfuscating our radical vulnerability, and, finally, whether the space of experience it opened up is still ours.

The History of Bildung

Seen from a historical perspective, the concept of Bildung has had a remarkable and unique career. The concept was still very rarely used in the first third of the eighteenth century and when used, it was done so exclusively in relation to questions regarding origin and generation in the context of discussions on the issue of creation. However – albeit within a very different meaning and relatively late compared to the cultural and esthetic discourse (Horlacher, 2004) – by the middle of the eighteenth century, it was already very evident in educational discourse. By the end

of eighteenth century, it had turned into one of the key concepts of (educational) Enlightenment (Assmann, 1993). Originally coming out of a theological-mythical context and strongly connected to the notions of Bild (image), Gebilde (building, structure), Imago, and Forma (see Meyer-Drawe, 1999), the early notion of Bildung referred to the process of a becoming-in-time, of growing, and decay of creatures in the context of basic assumptions concerning creation. In the middle of the eighteenth century, the concept becomes more and more secularized and becomes related to the “allgemeine Emporbildung der inneren Kräfte der Menschennatur zu reiner Menschenweisheit” (“the general raising of the inner forces of human nature towards pure human wisdom”) as a still normative concept of development (Pestalozzi, 1780/2001: 32).

At the end of the eighteenth century, the concept of Bildung was developed as a central category for thinking about human beings (about what was called then: the destination of mankind – *die Bestimmung des Menschen*) which was, in particular, introduced through the work of Johann Gottfried Herder and Wilhelm von Humboldt. Based on the theoretical conception of *perfectibilité* as it was developed by Rousseau (1762/1969) in contrast to and as a transformation of the idea of perfection, Bildung was formulated as a critical principle of education to refuse specific and determining expectations of the old and new civil society. It indicated an epigenetic (cultural) structure, in contrast to a genetic conception in which the origin is linked with man's development: human beings are not determined by their own nature or their metaphysical and religious origin as creatures, but by their own practices. Consequently, it is not possible to specify any definite aim of human development. In fact, Bildung was given the endless task of developing, unfolding, and enlightening the human mind and making real the independence of human will and action from natural and social determinations, coercion, and constraints.

Within Wilhelm von Humboldt's conception of the “true meaning of men” as the “highest and most proportional edification of his (cf. human) forces into a whole” (“höchste und proportionierlichste Bildung seiner Kräfte zu einem Ganzen”) (Humboldt, 1792: 131), Bildung becomes a process of self-production through self-activated dealing with the world, implying that the process in which the individual gets his or her form can be understood above all as a work of myself (*Werk meiner selbst*) (Fichte) and is no longer to be seen as the realization of a pre-given

(innate) structure. From this perspective, *Bildung* is an intransitive term and has to be spelled as *Sich-Bilden* (self-construction and self-education) – with the consequence that each world appropriation (*Weltaneignung*) has to be reconsidered as a specific way of producing oneself (*Selbstervorbringung*) and vice versa. This double relation of the self and the world (*Wechselwirkung*) could be described as the task of involving oneself in the world (*Einarbeitung in Welt*) as a production of world (*Ausarbeitung von Welt*) by self-production (*Selbstervorbringung in Welt*), which means both to encompass the world in oneself (*die Welt in sich einzubilden*) and to establish and express oneself in the world (*sich in die Welt auszubilden*) (Humboldt, 1793/1960). In this way of conceiving *Bildung* as *Selbstbildung*, which, however, still needs the outer action through education that is itself bound to public state institutions in the concept of *Bildsamkeit* (Herbart, 1841/1997: 186), we get a clear rupture in the representations of development, in the sense that the human being is not any more just becoming what s/he was (as was still the idea with Goethe), but now became, through *Bildung*, what s/he made of her/himself. However, the horizon on which this rupture came about was, of course, still one in which the issue of who s/he should (ought to) be remained evident (cf. Hegel, 1807/1970).

It was precisely the enormous integrative and synthesizing force of the concept of *Bildung* which expressed itself in the reconciliations between opposites, which it allowed for and which had been inconceivable before – such as the opposition between *Eigentümlichkeit und Brauchbarkeit* (“the individual distinctiveness or identity and the social or economical usefulness”) (Niethammer, 1808/1968: 118), *Entwicklung und Bestimmung* (“development and destination”) (Pestalozzi, 1780/2001: 32), *Vernunft und Natur* (“reason and nature”) (Kant, 1803/1964: 697), *Wissen und Glauben* (“knowledge and belief”) (Schleiermacher, 1822/1988: 324ff.), *Individuellem und Allgemeinen* (“the individual and the general”) (Humboldt, 1960/1793: 235), and, finally, *Freiheit und Ordnung* (“freedom and order”) (Hegel, 1807/1970: 359ff.) – that makes clear why this concept could become one of the central concepts of Enlightenment and Modernity. In the Brothers Grimm’s classic *Deutsches Wörterbuch* (1854–1960), the word *Bildung* takes four meanings indicated by the Latin expressions: (1) *imago* (image), (2) *forma* (form), (3) *cultus anima, humanitas* (cultivation of the soul), and (4) *formatio, institutio* (edification or formation).

To understand the really spectacular process through which the *Bildung* discourse managed to establish itself as the main intellectual discourse in the late eighteenth century, we have to refer to three different contexts in which it played the role of guiding concept and of program draft (see Koselleck, 1990). In all three contexts, we can discern a process of destruction of the traditional order and – hand in hand – an increase and generalization of an experience of uncertainty and insecurity so that we

could say that increasing awareness of (radical) contingency as well as its possible compensation in the idea of progress constitutes the central characteristic of upcoming modernity.

First, in the context of a radical change in the generational constellation and relation between generations, and in contrast to the traditional (Christian) *imitatio* and the (Greek antique) *paideia*, *Bildung* replaces the traditional circle of life (in which the younger follow the elder) and establishes a new order of life (Rousseau) in which the elder generation is superseded in an endless process of higher development (*Höherentwicklung*, Humboldt) of the younger generation. According to this new dynamism and the general idea of progress, *Bildung* became the exclusive educational goal, which was articulated in the European wide establishment of the school system and marked a more or less paradoxical cultural and pedagogical orientation to facilitate self-determination by a disciplinary logic.

Second, in the context of a radical change in the political constellation, initiated by the French revolution and leading toward a new order in Europe based on nation states, *Bildung* was considered to be the royal road to the construction and reconstruction of the nation and of national culture. This was a complicated matter since *Bildung* was originally conceived as a critical and emancipatory enterprise, that is, as a process in which human beings became truly free and emancipated themselves from all kinds of power including the power of the actual given State. This is also true for Humboldt even though he believed for a time that this process could be organized by the State if it held back from intervening in the actual content of the process and even when, in fact, the process of *Bildung* was leading toward the establishment of a new (national-German) culture and a new (nation) State (Bollenbeck, 1994).

Third, in the context of a radical change in the cultural and religious constellation, in which not only traditional Christian representations of order lost their overall meaning but also (scientific) knowledge about the world gained increasing importance, *Bildung* became the notion under which the appropriation of knowledge was promoted and legitimized by the same token.

Although, as we have seen, the concept was introduced at the end of the eighteenth century, it was only toward the end of the nineteenth century that it became articulated as the ‘specific structure of education.’ Since Dilthey (cf. Dilthey, 1884/1986), it has occupied a central place in educational practice and thought, referring to the incorporation of human beings into society through their individual self-production and spiritual self-formation.

Semantic Field

The enormous range of meaning covered by the concept of *Bildung* has meanwhile given way to its tremendous

broadening (some say dissolving), although this did not lead to a totally different use or to its actual disappearance. On the contrary, the concept of Bildung seems to be omnipresent as much in daily language as in professional educational discourse, certainly in Germany, and now also increasingly in other countries and regions. Indeed, notwithstanding the fact that one of the decisive roots of Bildung has to be traced back to the English moral philosopher Shaftesbury (1671–1713) and his concept of ‘inner’ or ‘inward form’ which was translated by Herder into German as Bildung (Horlacher, 2004), it seemed that the notion was tied very strongly to the particular history of Germany, both as the history of the formation and development of the nation and as the history of the German thought and language (including the broader sphere of its influence in Western and Eastern Europe), and that there was no point to it outside Germany. However, in the last decade – and although there had been sporadic interest in the notion (and history) of Bildung – we witness increasing attention to Bildung in the Anglo-Saxon philosophy of education (e.g., special issues on Bildung in the *Journal of Philosophy of Education and in Educational Philosophy and Theory*). Strikingly in this context, Bildung, which some propose to translate as edification, as cultivation or ‘formation,’ has been related to various conceptions of liberal education (Løvlie and Standish, 2002) in an attempt to recover, strengthen, or renew its critical force with regard to actual developments in educational policy at all levels (as also discussion below). However, before going into this critical ambition, which has been associated with Bildung for a long time, let us return to its field of meaning.

Roughly stated, the notion of Bildung refers as much to the process in which the individual acquires its form as to the product of this process of formation of soul and spirit. If we have a closer look at both process and product, we can distinguish between six typological areas of meaning. (1) Bildung can refer to the body of knowledge which is generally mandatory (binding) in a certain time (the canon), including reflective knowledge. (2) The notion is also used to refer to qualifications and certificates obtained through a process of knowledge appropriation and acquisition. These are commonly seen as measures of Bildung and regulate very concrete opportunities of access to and participation in social, economic, and cultural life (educational privileges, so to say). (3) In addition to these two notions and as their necessary transformation, Bildung can indicate the disposition or attitude of the Gebildete (the educated), which is the product of this process and which has to be clearly distinguished from simply being an expert or somebody who disposes of a lot of knowledge. In this sense, Bildung could be spelled out as a habitus or an inner horizon of references, which remains when all objects of knowledge are forgotten. In the same direction, Adorno explains Bildung as the subjective inside

of the objective outside of culture (Adorno, 1959/1972). (4) The process character of Bildung itself, which has no end and is a process of continuous higher development (without a final destination) and permanent self-transformation. (5) The self-referentiality of this process, so that knowledge is not (and has not to be) appropriated for its own sake but for the sake of self-improvement and self-perfection – a process which can be measured by the increase of the individual degree of freedom. As a result, Bildung is sometimes reduced to a plea for a humanistic individualism and used as critically opposed to social and especially economic needs. (6) Finally, the hope that this appropriation of knowledge with regard to producing an increase of freedom also implies a raising of morality and ethics, so that Bildung is often related also to respect, prudence, and caution. How this hope, at least regarding its assumption of automaticity, has proved to be an illusion is shown by the developments of German fascism and its experiences of human destruction. Indeed, since World War II and taking into account that an important part of the leadership of Nazi-Germany could be called ‘Hoch-Gebildete’ (highly educated) in all of the meanings just mentioned, it seems that Bildung should be approached with suspicion (see Adorno, 1959/1972).

The Anthropological Matrix

Taking up the issue of the strategic function of the discourse of Bildung and asking how the figure of Bildung asks us to think about ourselves, our relations to others and the world, we can see how it offers a kind of matrix in which these relations are configured and prefigured. Two things have to be remembered here. (1) Bildung refers neither to a process of unfolding out of a prefigured inner self nor to a development process which would be directed by actions from outside. The term Bildung is used only when the intended process can be understood as a relational process – a process of self-production through appropriation of the world. This fits the meaning of Bildung as the inner part of culture, that is, the part of appropriation and acquisition of culture (Adorno, 1959/1972) and it echoes Herder’s translation of Shaftesbury’s concept of inward form. (2) Moreover, and very importantly, Bildung opens up a different experience of time in as much as it has largely contributed, in the historical context of the dissolving of foundational, timeless substances and essences, to a particular consciousness of our temporary existence. Indeed, on the one hand it increasingly opened up the forward side of the time axis – time became, seen and experienced in terms of progress without, however, a clear identifiable end of history. On the other hand, it carried, on the reverse side of the time axis, so to say, a historical consciousness which sorted out traditions and structured time experiences. In this it

bounded the openness of the future (as progress) back to the handed down history (as tradition). Indeed, this historical consciousness or self-understanding, implying an experience of being part of a historical process, with its promise of emancipation and progress (and of reconciliation of mankind) – notwithstanding that this process has its own obstacles and possible relapses, its own contingency, is one of the main features of the space of experience and thought opened up by the notion of *Bildung*.

Returning to the way in which *Bildung* makes up human beings or creates a way for people to be, we can understand *Bildung* as an anthropological matrix in a threefold way (Ricken, 2006): (1) As the formation of the self in relation to itself, in as far as the self sees itself to be set in a relation which it has to think and construct as to be constantly overcome or transcended. (2) As the formation of the social, that is, as a particular formation of the self in relation to others, in as far as the relationship to others is to be thought of in terms of neither commonality nor species, but on the horizon of the General (*Das Allgemeine*). (3) As being in relation to the world, which is not so much to be understood as the sustaining ground and the encompassing and endless transcending world, but as something which offers itself as an object, something which is before us, to be appropriated in view of our own ends – and which for educational reasons can be partitioned in disciplines and (teaching) subjects.

Therefore, the particular space of experience and thought opened up by the concept of *Bildung* can be sketched as a particular configuration of a power–knowledge complex (Foucault, 1975), which at once defines the self and produces it.

The Present Use of the Concept

Against this background, the contemporary use of the concept of *Bildung* is quite ambivalent. On the one hand, the notion of *Bildung* is still in wide use, especially in the public discourse on the meaning and function of education and the education system (including the educational sciences) within the currently emerging large-scale transformations of societies that are often described under the key term ‘globalization process’ and increasingly associated with the establishment of ‘learning societies.’ In this perspective, *Bildung* has become a key term in politics representing the different competences which seem to be required for survival in such a learning society. It is used and invoked by administrators and politicians to accompany and legitimate the deep transformation processes of (national) educational systems. On the other hand, the concept of *Bildung* is often neglected and refused as an antique and no longer regarded as a fitting idea because we seem to be moving in different spaces of experiences and thought. In particular, its supposed

normativity provokes distance and permanently leads to different concepts such as majority (*Mündigkeit*), identity, competence, or capability.

Additionally, in educational discourse, the meaning of the concept of *Bildung*, its utility, and its adequacy is increasingly contested (see Thompson, 2008). On the one hand, there are still traditional interpretations of *Bildung*, for example, firstly indicating the cultural content of education formulated as a specific canon or secondly sketching *Bildung* as a specific sort of self-experience and self-development summarized in the phrasing of *Sich-Bilden* or self-education. Although *Bildung* has become in some sense the key term of the educational sciences, there are many theorists in educational sciences who question its semantic and theoretical consistency and its practical as well as its political function.

According to Lenzen, for example, the concept has become superfluous and useless because, due to its dependency on the practical educational context in which it appears, it no longer allows us to create clarity or meaningful differentiation within the discipline and its theoretical discourse. He therefore argues that we should abandon the concept of *Bildung* and introduce the concept of autopoiesis or self-organization (Lenzen, 2000). In contrast to Lenzen, Tenorth pleads for maintaining the concept, since it would be the only concept which is sufficiently poly-referential and multivalent to locate the different disciplinary and nondisciplinary, and practical and professional pedagogical domains in relation to each other and since it could function as a leading concept for the sciences of culture in a broad sense (Tenorth, 2000). However, both Lenzen and Tenorth seem to forget that academic disciplines are themselves very specific projects whose interpretations penetrate deeply into our lives, that is, they seem to neglect the role of disciplines and their concepts in the development of power.

In fact, the concept of *Bildung* now occupies a lasting and prominent but ambivalent critical role. Gruschka’s article in one of the leading journals of the German educational scene, the *Zeitschrift für Pädagogik*, is an indication of this ambivalent role which is also present in the title: ‘*Bildung*: Unvermeidbar und überholt, ohnmächtig und rettend’ (‘*Bildung*: unavoidable and outdated, powerless and redeeming,’ Gruschka, 2001). Although Gruschka admits that the old idea of *Bildung* and of the *Gebildete* (the educated woman or man) has become actually outdated and dysfunctional, the same idea remains a central means for analyzing and criticizing what he diagnoses, following Adorno (cf. Adorno, 1972) and Heydorn (cf. Heydorn, 1979), as *Halbbildung* (half-edification) or *Unbildung* (un-edification). In this context, the concept of *Bildung* is used, for example, to criticize the concepts of learning present in the discourse on the learning society and also in criticism of many didactic and constructivist theories, accusing them of forgetting or misunderstanding the relationship

of knowledge to the world and the own rights and exigencies of that world, which are recognized in Bildung (this critical use parallels the way in which the notion 'liberal education' is often used for similar aims; see Løvlie and Standish (2002)). In fact, Gruschka's article is illustrative of a very common argument. The idea of Bildung here remains related to a kind of forgotten, negated, neglected, reduced, distorted, unfulfilled, or even not yet articulated promise which is, however, misused by some writers as a license for introducing differentiations of rank and distinction into education. Even though as Ruhloff (cf. Ruhloff, 1996) states, Bildung can be retained only as a nonnormative concept since absolute foundations and teleological ambitions have to be rejected, this does not show that we can conceive of Bildung without any normative connotation. The concept of Bildung always contains an understanding of what is human (an understanding of humanity) and how we can attain this. Bildung always implies an idea of humanity and a knowledge or representation of that which is unsatisfactory or insufficient. This idea of humanity which is contained in Bildung remains fundamentally oriented toward the choice of one's own form of life as an independent, emancipated, and self-directed life. It remains related to the Enlightenment ideas of autonomy and consensus (as the agreement between autonomous persons) since educated men, the *Gebildete*, are essentially autonomous persons. The ideal of Bildung can serve then as a point of resistance or a critical orientation which can be invoked against all kinds of distortion and negation of this independence and autonomy (in thinking and acting).

Against this background, and taking into account that Bildung meanwhile constitutes an omnipresent and culturally rooted interpretation scheme, it is not so surprising that the more recent reflections on Bildung neither want to simply revive traditional approaches nor to replace or abandon the concept. Rather they try to take up the tradition using its contradictions and ambivalences as an opportunity to problematize the paradoxical figure of learning and development processes (Schäfer, 1996; Meyer-Drawe, 1999; Thompson, 2008).

Some Questions

Even if it is not convincing to question the usefulness of the concept of Bildung in general, it could be productive to reflect on three questions. One could ask (1) whether we should look at Bildung itself as being part of particular power formation (rather than being the opposite of power), (2) whether the anthropological matrix offered by Bildung is obfuscating our vulnerability, dispossession, and deliveredness, and finally, (3) whether the space of experience it opened up is still ours or whether we are meanwhile part of a totally different space in which the

notion of Bildung is still present, but no longer effective with regard to our experience and thought.

1. Because the educational sciences in the broadest sense can be analyzed as truth games involved in the formation of actual power relations, we have suggested elsewhere that, starting from the analytical framework offered by Foucault, it is possible to analyze Bildung as a specific matrix of power and to reveal and unravel a complicity between Bildung (in practice and theory) and the birth of the modern subject (Masschelein and Ricken, 2003; Ricken, 2006). We could look indeed at both the history of Bildung and the history of educational discourse in which it is as central as being part of the history of the ways in which human beings conduct and govern themselves and others in the light of specific truth games. Here the notion of Bildung is regarded as connected to a certain kind of knowledge about and relation toward ourselves and others. The idea of Bildung then implies a very specific kind of interpellation, that is, a very specific way in which we are addressed as social beings and in which we are supposed to address ourselves and others. Bildung, with its epigenetical (cultural) and social connotation, appears as a social program formulated in a specific historical and social context in which it becomes the key term of bourgeois society. This program articulates itself as a transformation from the anthropological perspective (what kind of beings are we), from the social perspective (how, through which techniques and strategies are we related to the others), and both linked together in a transformation of the epistemological perspective (what kind of knowledge is possible and expected).
2. In line with this first analysis of Bildung as a specific modern matrix of subjectivation, it could be interesting to reconstruct the character of experience in the concept of Bildung. In contrast to the widespread conviction that Bildung is strongly linked with the idea of self-determination and self-assertion, there are some elements allowing a description of Bildung as a paradoxical process of individuation as self-consciousness on the one hand and self-alienation as a specific dispossession or exposition on the other hand. Following Foucault's explanation of experience as a paradoxical process of subjectivation and desubjectivation, Bildung could be reconstructed as a performative concept of transformation and transgression – including the existential problem of human vulnerability and deliveredness to others. In this perspective, Bildung means the fragile situation of being exposed to others, of experiencing one's own dispossession and of becoming different to oneself (see Thompson, 2008).
3. Finally, a totally different question is whether today the notion of Bildung is still able to give way to what we called the experience of a historical consciousness

(Simons and Masschelein, 2008). One might wonder whether today our space of experience and thought is first of all characterized by an environmental, that is, a spatial, consciousness (moving in networks) which means that Bildung now appears in terms of a resource or a (always temporary) competitive advantage in dealing with the demands of ever changing environments, rather than as an operation that situates us in history, that is, in relation to a tradition and in view of a future emancipation.

Critical Theory and Pedagogy

M Mason, Hong Kong Institute of Education, Hong Kong, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

In at least one sense it might be argued that any pedagogy worth its name is necessarily critical, for if it were not, it would be especially vulnerable to accusations of indoctrination, or it would, at best, be a form of pedagogy that intended pupils merely to become well versed or well drilled in the propositional claims or procedural skills identified with the subject being taught. However, the association of critical pedagogy with critical theory implies a particular understanding of the term critical, one associated most strongly with the Frankfurt School.

At the same time, it should be noted that not all critical pedagogy, critical practice, critical research, or critical discourse in education is associated with the critical theory of the Frankfurt School. The term critical is widely used (and abused) in the discourse of education, not least in examining why and how education fails, how education reproduces unjust economic relationships, how education reproduces state power and other unequal power relationships in society, and the role education plays in social and cultural reproduction. Comparatively little of this discourse, however, has much to do with the Frankfurt School, other than in the loosest sense or at a rather general level. Kincheloe (2008: 5 ff.), for example, includes the following as among the central characteristics of critical pedagogy, none of which could be claimed as necessarily derived from the Frankfurt School: it is “grounded on a social and educational vision of justice and equality, ... constructed on the belief that education is inherently political, ... dedicated to the alleviation of human suffering, ... [and is] a pedagogy that prevents students from being hurt.”

Some strands of this critical discourse may share Marxian roots with the Frankfurt School; others may claim a shared paradigm of conflict theory. Those that draw explicitly on the critical theory of the Frankfurt School constitute the major focus of this article.

Critical Theory and the Frankfurt School

The Institute of Social Research, from which the Frankfurt School developed, was founded at the University of Frankfurt in 1923. Its most active years, from 1930 (when Max Horkheimer assumed the directorship) to 1944, coincided with the rise to power and prominence of Nazism and Fascism: the Institute was accordingly moved to Geneva in 1933, and to Columbia University in New York in 1935. It was not until 1953 that it was properly

reestablished in Frankfurt. Horkheimer, Theodor Adorno, Herbert Marcuse, and Jürgen Habermas are perhaps its most notable members, but the importance of the contributions of the likes of Walter Benjamin, Erich Fromm, Leo Löwenthal, Franz Neumann, Friedrich Pollock, and Albrecht Wellmer should not be missed. The most influential early members of the Frankfurt School, Horkheimer, Adorno, and Marcuse, developed a form of Marxist theory known as critical theory, which, following Bottomore (1984), exerted a substantial influence in social theory on the study of class, politics, culture, and ideology. Critical theory also, following Held (1980), engaged with Marx's critique of political economy, Freudian psychoanalysis, esthetics, and the philosophy of history; contributed to the analysis of capitalism, the family, and the individual; and pursued new directions in epistemology and research methodology – their aim being “to lay the foundation for an exploration, in an interdisciplinary research context, of questions concerning the conditions which make possible the reproduction and transformation of society, the meaning of culture, and the relation between the individual, society and nature” (Held, 1980: 16). For Geuss (1981), the Frankfurt School's critique of ideology was central to these concerns, a question which will be considered shortly.

The Frankfurt School's primary intellectual sources lay in Kant, Hegel, Marx, Weber, Lukács, and Freud, although Habermas looked also at particular strands of Anglo-American thought, especially linguistic philosophy and the more recent philosophy of science. Kant and Hegel, and German idealism (and its critics) more generally, provided them with a better understanding of the philosophical foundations of Marx's work. Weber's work on the processes associated with rationalization and bureaucratization was important for their theorization of contemporary society. Freud's writings informed their investigations of human subjectivity. Importantly, it was Marx's early writing, especially the 1844 *Manuscripts*, to which they turned for an understanding of the critical grounds and orientation of his ideas. In Lukács and Korsch they found critiques of strongly determinist and positivist interpretations of historical materialism and its emphasis on the inevitability of historical development as the inexorable and logical expression of an apparently autonomous economic base of society. As Held (1980: 21), in this regard, puts it, the Frankfurt School maintained that “the traditional standpoint of orthodox Marxism ... fails to grasp the significance of examining both the objective conditions of action and the ways in which

these conditions are understood and interpreted. By underplaying human subjectivity and consciousness Marxists missed the very factors which were so central in preventing the emergence of a revolutionary agent.”

The point should not be missed, however, that the Frankfurt School were, while rejecting dialectical materialism, also critical of an overly humanist interpretation of Marx. As Horkheimer (1968: 202) wrote, “There can be no formula which lays down once and for all the relationship between the individual, society and nature. Though history cannot be seen as a uniform unfolding of human nature, the opposite fatalistic formula that the course of events is dominated by necessity independent of Man is equally naive.”

The Frankfurt School drew extensively on Lukács’s argument that the process of reification posed a substantial impediment to the development of revolutionary consciousness. Lukács had in turn drawn on Marx’s account of the fetishism of commodities in *Capital*, on Simmel’s analysis of the commodification of culture, and on Weber’s description of the process of rationalization to define a process of reification, in terms of which work becomes meaningless: the process and products of people’s labor or productive activity are construed as alien to them – as, in other words, existentially worthless. This definition of reification is closely related to the more common understanding of the term – the process whereby that which is socially constructed is perceived as natural, and therefore as objective, inevitable, permanent, and immutable – which would have been equally important to the Frankfurt School in understanding the ossifying processes contributing to the reproduction of the *status quo*.

The members of the Frankfurt School anticipated that the outcomes of their research would contribute “to the making of history with will and consciousness,” intending their findings “to become a material force in the struggle against domination in all its forms” (Held, 1980: 35). It is worth noting in this regard that Horkheimer, Adorno, and Marcuse viewed the exploitation typical of capitalist relations of production as only one, specific form of domination. The history of civilization reveals a history of domination in all its forms: “First, domination over one’s self, over one’s own nature. . . ; second, domination of the labour achieved by such disciplined and controlled individuals; and third, domination of outward nature, science and technology” (Marcuse, 1970: 12). This theme underlies and permeates many of the Frankfurt School’s main research projects, which, following Held (1980: 35), included questions such as: why European labor movements had not produced a united workers’ struggle; how the political and the economic were related in capitalist societies; why authoritarianism and bureaucracy were increasingly prevalent in society; how Nazism and Fascism had come to dominate Central and Southern

Europe with such apparently large-scale support; how social relationships and individual development appeared to be changing, possibly along with the development of a new type of ideology in the cultural sphere, which appeared increasingly open to direct manipulation (in this, a foreshadowing of a society dominated by consumerism); and whether, given the fate of orthodox Marxism, there existed a social agent capable of initiating progressive change toward an equitable socialist society.

These and other key research foci of the Frankfurt School were generated by their concern with instrumental rationality, a form of rationality focused more on technical than on normative questions, on the limitation of practical problems to technical questions. In its analysis they drew substantially, as indicated above, on Weber’s concept of rationalization. Enlightenment notions of reason had in their view become distorted in a modernity steeped in rationalization and bureaucratization into a form of rationality obsessed with means, with method and efficiency, rather than with ends and purposes. Important normative questions, such as “Why should?,” with their implicit humanist orientation, are in this process displaced by questions of procedure and technique such as “How to?”. Questions about values and interests are thus unacceptably, in the view of the Frankfurt School, separated from the production of the so-called objective fact. It is this view that underlies the Frankfurt School’s rejection of correspondence theories of truth and their critique of positivism and its associated belief that true knowledge is scientific and consists only of those statements which are objectively and empirically verifiable. Their concerns about the shaping of research practice in the human and social sciences according to a positivist model of the natural sciences widened to a critique of the ways in which scientific rationality had been extended to the conduct of life itself (Weber, 1972: 293), where a means–end rationality becomes a form of domination in itself, with means becoming ends in themselves, and with the consequent predominance of a rule-oriented disposition vitiating the possibility of critique. As Geuss puts it, a key aim of the Frankfurt School involved “the criticism of positivism and the rehabilitation of ‘reflection’ as a category of valid knowledge” (Geuss, 1981: 2).

Challenges to the critical theory of the Frankfurt School have been numerous, but frequently start from, or are related to, the criticism that critical theory remained too steeped in German idealism and engaged insufficiently with Marx’s materialist critique of political economy. Related to this is the charge that members of the Frankfurt School were more concerned with philosophical and theoretical problems and questions than they were with practical and political issues, and that they failed to connect in any integrated way their studies of individual and social psychology with material political economy and

societal critique. Closely connected is the criticism, from a harder Marxist perspective, that the Frankfurt School was too attentive to phenomena in the superstructure of society – culture and esthetics, for example – and insufficiently focused on factors associated with the economic base. What was almost worse is that Horkheimer and his colleagues were seen to be remote and far-removed from working-class politics, from the daily life experiences of ordinary people. These perceived shortcomings probably led to the visceral challenge Adorno suffered at the hands of his students at the University of Frankfurt in April 1969. Shortly after starting his lecture before almost 1000 students, he was challenged to engage in self-criticism, accused of defending capitalism, and confronted by three female students who bared their breasts, showered him with roses and tulips, and tried to embrace him. He left the theater in humiliation; within 4 months he had died of a heart attack. The event came to be known as the Busenaktion, or breast action, and typified the challenges offered by the increasingly praxis-oriented German New Left to the intellectuals whose theories lay behind their movement, but who were now perceived as too theoretically removed. It should be noted, however, that Marcuse, who did not return to Frankfurt when the Institute was reestablished there in the early 1950s but remained in the USA, continued to enjoy the confidence of the New Left in the 1960s and into the early 1970s. His sustained commitment to social and political struggle contributed to the esteem in which his *One-Dimensional Man* was held by the left.

Once a research assistant of Adorno's, Habermas has, since he first began extending and further developing the concepts of critical theory in the late 1950s, become the Frankfurt School's leading exponent. He himself understands his project to include: the development of a theory of society motivated by the normative purpose of the self-emancipation of its members from domination; a reinvigoration of the possibility of making history, in the words of one of his collaborators, Wellmer, "with will and consciousness" (Wellmer, 1974: 53); and the development of a critical theory that all but collapses the epistemological/axiological divide in its recognition of the inseparability of truth and virtue, of facts and values, and of theory and practice. In Wellmer's words, it is a project defined in terms of a "struggle for the critical soul of science" and "the scientific soul of criticism" (Wellmer, 1974: 53).

As intimated earlier by reference to Geuss (1981), the Frankfurt School's critique of ideology is central to these concerns, and it is at this point that consideration of their notion of *Ideologiekritik* most appropriately provides a context in which to understand a central strand of Habermas's thought. Perhaps the Frankfurt School's greatest interest in Marx's theory of society lay in its epistemological

implications, which underlie their critical theory, the essential distinguishing features of which are summarized by Geuss as follows:

1. Critical theories have special standing as guides for human action in that:
 - a. they are aimed at producing enlightenment in the agents who hold them, i.e. at enabling those agents to determine what their true interests are;
 - b. they are inherently emancipatory, i.e. they free agents from a kind of coercion which is at least partly self-imposed, from self-frustration of conscious human action.
2. Critical theories have cognitive content, i.e. they are forms of knowledge.
3. Critical theories differ epistemologically in essential ways from theories in the natural sciences. Theories in natural science are 'objectifying'; critical theories are 'reflective'.

A critical theory, then, is a reflective theory which gives agents a kind of knowledge inherently productive of enlightenment and emancipation. . . . The very heart of the critical theory of society is its criticism of ideology. Their ideology is what prevents agents in the society from correctly perceiving their true situation and real interests; if they are to free themselves from social repression, the agents must rid themselves of ideological delusion. (Geuss, 1981: 1–3)

The implications of this epistemology become clearer when contrasted with positivism's (a major target of critical theory, as indicated earlier) denial that theories could be both reflective and cognitive. While positivism may be useful in the natural sciences, its expansion into the human and social sciences could only, from the Frankfurt School's perspective, have a deleterious effect on that major vehicle of human emancipation, a critical theory of society and its potential to enable *Ideologiekritik* to that end. With this in mind, we can consider a central aspect of Habermas's thought – the relationship between knowledge and human interests.

In his major exposition of this theme in *Knowledge and Human Interests* (1971), Habermas suggests that "knowledge is neither a mere instrument of an organism's adaptation to a changing environment nor the act of a pure rational being removed from the context of life in contemplation" (Habermas, 1971: 197). Knowledge is constituted by our cognitive interests, because these orientations "shape and determine what counts as the objects and types of knowledge: they determine the categories relevant to what we take to be knowledge, as well as the procedures for discovering and warranting knowledge claims" (Bernstein, 1976: 192). Habermas's concern, in other words, is not merely epistemological: it is with the cognitive interests,

more broadly conceived than as in the interests of private individuals or those of politically motivated groups, which ultimately influence the constitution of knowledge. He identifies three primary cognitive interests: the technical, the practical, and the emancipatory, to which correspond three types of disciplinary fields: “The approach of the empirical-analytic sciences incorporates a *technical* cognitive interest; that of the historical-hermeneutic sciences incorporates a *practical* one; and the approach of the critically oriented sciences incorporates the *emancipatory* cognitive interest” (Habermas, 1971: 308). As Bernstein clarifies, “each of these cognitive interests is grounded in one dimension of human social existence: work, interaction, or power. Work corresponds to the technical interest which guides the empirical-analytic sciences; interaction, to the practical interest which guides the historical-hermeneutic disciplines; [and] power, to the emancipatory interest which guides the critical disciplines – the critical social sciences” (Bernstein, 1976: 193).

The empirical-analytic sciences, and the historical-hermeneutic sciences (which Habermas also describes as the “systematic *sciences of social action*, that is economics, sociology and political science” (1971: 310)) have, in Habermas’ view, the goal of producing nomological knowledge, the laws of nature. However, he asserts, “a critical social science . . . is concerned with going beyond this goal to determine (not only) when theoretical statements grasp invariant regularities of social action, . . . (but also, more importantly) when they express ideologically frozen relations of dependence *that can in principle be transformed* (emphasis added)” (1971: 310). A critical theory of society is then, according to Habermas, able to criticize a set of beliefs or worldview as ideological by showing, as summarized by Geuss:

- a. that the agents in the society have a set of epistemic principles which contains a provision to the effect that beliefs which are to be sources of legitimation in the society are acceptable *only* if they could have been acquired by the agents under conditions of free and uncoerced discussion;
- b. that the *only* reason the agents accept a particular repressive social institution is that they think this institution is legitimized by a set of beliefs embedded in their world-picture;
- c. that those beliefs could have been acquired by these agents *only* under conditions of coercion. (Geuss, 1981: 68)

Of key importance here are these conditions of free and uncoerced discussion. Habermas describes these conditions as the ideal speech situation, a transcendental position, based in his views about the preconditions for language use, that refers to a situation of “absolutely uncoerced and unlimited discussion between completely free and equal human agents” (translated by Geuss (1981: 65)

from Habermas and Luhmann (1971: 101ff., 113ff., 135ff.) and Habermas (1973: 252ff.)):

To be a human agent is to participate at least potentially in a speech community. . . . But no agent can be even potentially a member of a speech community who cannot recognize the difference between true and false statements. . . . But what it means for a statement to be true is that it would be the one on which all agents would agree if they were to discuss all of human experience in absolutely free and uncoerced circumstances for an indefinite period of time.

This ideal speech situation serves Habermas (translated by Geuss (1981: 66) from Habermas and Luhmann (1971: 139, 224))

as a transcendental criterion of truth, freedom and rationality. Beliefs agents would agree on in the ideal speech situation are *ipso facto* true beliefs, preferences they would agree on are rational preferences, interests they would agree on are real interests. The agents are free if their real situation is one which satisfies the conditions of the ideal speech situation.

The ideal speech situation is, according to Habermas, “neither an empirical phenomenon nor simply a construct, but a reciprocal supposition unavoidable in discourse, . . . a critical standard against which every actually realized consensus can be called into question and tested” (translated by Held (1980: 344) from Habermas (1973: 258)). It is the conditions of the ideal speech situation that critical pedagogs are frequently concerned to replicate as far as possible in their classrooms.

Critical Pedagogy

In Habermasian terms, the study of education is probably quite commonly understood as a historical-hermeneutic science incorporating a practical interest corresponding to the field of human interaction. However, from the perspective of critical theory, the study of education is conceptualized as a critical social science, incorporating an emancipatory interest focused on the distribution of power and its associated attributes: economic wealth, political influence, cultural capital, social prestige and privilege, and the like. Critical theory and pedagogy, in other words, are premised on the normative commitments associated with the exposure and transformation of, and the emancipation of humans from, oppressive economic, political, social and cultural formations, and the associated inequalities and injustices that are ubiquitous and pervasive in all domains of human interaction. Critical pedagogy is a term commonly used to describe the theorization and operationalization of the pedagogical challenges grounded in opposition to these formations.

Following Ellsworth (1989: 298), other terms used in the field include pedagogy of critique and possibility, pedagogy of student voice, pedagogy of empowerment, radical pedagogy, pedagogy for radical democracy, and pedagogy of possibility. Ellsworth's (1989: 300, 307) review of the literature reveals that critical pedagogy supports classroom analysis and rejection of oppression, injustice, inequality, the silencing of marginalized voices, and authoritarian social structures (see Fine, 1987; Giroux, 1986; Simon, 1987). Radical educators committed to critical pedagogy recognize and, in turn, help students to recognize and name injustice; they empower students to act against their own and others' oppressions (including oppressive school structures); and they criticize and transform their own conceptualizations in response to those of their students (see Giroux and McLaren, 1986; Shor and Freire, 1987). The goals of critical pedagogy include a critical democracy, individual freedom, social justice, and social change, realized not least through a revitalized public sphere which is characterized by citizens capable of confronting public issues critically through ongoing forms of public debate and social action (see Shor and Freire, 1987; Giroux, 1988). Students would thus be empowered by social identities that affirmed their race, class, and gender positions, and that provided the basis for moral deliberation and social action (see Liston and Zeichner, 1987). Such empowerment would be for human betterment (Parker, 1986: 227), for expanding "the range of possible social identities people may become" (Simon, 1987: 372), and for "making one's self present as part of a moral and political project that links production of meaning to the possibility for human agency, democratic community, and transformative social action" (Giroux, 1988: 68–69).

This review of the literature reveals the key role that Henry Giroux has played in the development of critical pedagogy. His *Theory and Resistance in Education: A Pedagogy for the Opposition* (Giroux (1983) is a key text in the field, not least in its solidification of the concept of a radical (theory of) pedagogy in the discourse in North America and more widely afield.

A key figure prior to Giroux in the emergence of critical pedagogy in the 1960s and 1970s is Paulo Freire (Freire 1970, 1973). His *Pedagogy of the Oppressed*, originally published in Portuguese in 1968 and in English in 1970, and his *Education for Critical Consciousness*, published in English in 1973, parts of which were originally published in Portuguese in 1969 as *Education as the Practice of Freedom*, are landmarks in the field of critical pedagogy. Freire shares the Frankfurt School's focus on the early Marx and the role of human consciousness and agency in contributing to social change; in addition, his work is influenced by existential and phenomenological themes, and by Catholic liberation theology. Freire was a Brazilian literacy educator who worked with rural peasants until the military dictatorship that took power of that country

in 1964, seeing him as a threat to wealthy landowners and to themselves, imprisoned and subsequently deported him. Well known for its critique of conventional forms of education as akin to banking, where teachers deposit knowledge into the passive minds of students only to withdraw it subsequently in examinations, Freirean pedagogy – problem posing and dialogical in nature – is probably synonymous with education as a process of conscientization, whereby unjust economic, political, social, and cultural relations, reified into a state of perceived permanence, as natural and inevitable, are raised to a level of conscious critical questioning in a process in which students learn to name their world and the factors contributing to their oppression. For Freire, literacy means both reading the word and reading the world. As Kincheloe (2008: 74) has drawn on Freire, through such a process of learning, students "read their reality and write their [own] lives." Freirean pedagogy is thus thoroughly political and inextricably engaged with the students' world, with their being in it, with the injustices, both explicit and implicit, which they suffer, and against which they learn to act. Freire's influence on the field has been such that McLaren (2000: 1) has referred to him as the inaugural philosopher of critical pedagogy.

Critical pedagogs, as indicated above, have frequently been concerned to replicate as far as possible in their classrooms the conditions of the ideal speech situation, where "all members have equal opportunity to speak, all members respect other members' rights to speak and feel safe to speak, and all ideas are tolerated and subjected to rational critical assessment against fundamental judgments and moral principles" (Ellsworth, 1989: 314). This commitment to dialog is a basic assumption of critical pedagogy, and has been posited as a necessary condition of democratic education and, in turn, a democratic society. In Giroux's words, in order for genuine dialog to be possible, students and teachers must show "trust, sharing, and commitment to improving the quality of human life" (Giroux, 1988: 72). Giroux and McLaren describe the critical educator's classroom as a form of public sphere in which "students and teachers can engage in a process of deliberation and discussion aimed at advancing the public welfare in accordance with fundamental moral judgments and principles School and classroom practices should, in some manner, be organized around forms of learning which serve to prepare students for responsible roles as transformative intellectuals, as community members, and as critically active citizens outside of schools" (Giroux and McLaren, 1986: 237).

Recent developments in the theory of critical pedagogy offer a description, following Kincheloe (2007: 21–24, and 2008: 50–59), of some of its current concerns and indicate subtle refinements in some of its key concepts. The notion of critical emancipation, for example, tends latterly to be used rather cautiously, following recent

acknowledgments that no one is ever completely emancipated from his or her context; the term is also frequently used with a skeptical orientation to the claim that this involves access to what some theorists refer to as Western reason. There have, in particular, been refinements in the conceptualization of power in the theory of critical pedagogy. Given that in contemporary society institutions such as the media and the architects of political ‘spin’ play an increasingly important role in widening acquiescence to inequitable distributions of power, wealth, and opportunity through the legitimation of socially constructed economic, political, social, and cultural relations by their depiction as natural and inevitable, critical pedagogy has become more cognizant of the importance of Gramsci’s (1971) notion of hegemonic power, associated with rule by consent of the ruled rather than by physical force. Contemporary theory of critical pedagogy has also become increasingly convinced of the accuracy of Foucault’s conceptualization of power: that, in its capillary-like nature, it is a fundamental and ubiquitous constituent of social relations, with both oppressive and productive capacity and consequences. Critical pedagogs are, further, all the more aware of the nuanced role that ideology plays in the establishment of hegemonic power relations. Far from understanding ideology as blunt, monolithic, and unidirectional propaganda, they realize that “ideological hegemony involves [at least] the cultural forms, the meanings, the rituals, and the representations that produce consent to the *status quo*” (Kincheloe, 2007: 23, 2008: 55). Also in a related vein, linguistic and discursive theories of power have become more prominent following the influence of post-structuralism: critical theory and pedagogy are now less convinced of the Habermasian position that language is, at least potentially, a vehicle for transcending ideologies and engaging in a free and equal exchange of communicative reason in an ideal speech situation, and more convinced by the positions of discourse theory that language is a socially shaped resource, steeped in culturally and historically sedimented values and assumptions, whose distillations of social meaning comprise multiple discourses, which in turn, produce, or become constitutive of, social reality, and legitimate particular discourses of power while excluding others.

As critical theory and pedagogy have become increasingly concerned with discourse and the analysis of discursive practices, so has their concern with critical hermeneutical analysis and interpretation, which are focused on revealing the dynamics of power and the normative hermeneutics – prescriptive norms of meaning and their legitimation – that constitute social and cultural texts. Critical hermeneutics might, for example, be concerned to understand why the attributes associated with a particular form of cultural capital, or with a particular form of symbolic violence (see Bourdieu, 1977a, 1977b; Bourdieu and Passeron, 1990), would carry the

meanings that they do. Related to Bourdieu’s concept of cultural capital, and following and further developing the Frankfurt School’s exploration of high culture, popular culture, youth culture, and the relationship of human culture to the natural environment (a theme of increasing importance in critical pedagogy, albeit very recently, thanks in most part to the work of Bowers, 1987; Bowers and Apffel-Marglin, 2004), the domain of culture is perceived in contemporary critical theory and pedagogy to be particularly important in understanding relationships of power and domination. The field of cultural studies has played an important role in this domain, which has taken on new levels of importance in media-saturated societies dominated by consumerism, the latter not least because of the contemporary ubiquity of consumer goods made possible over the last two decades in particular by the globalization of production (in turn made possible by huge differentials in costs across continents, by cheap containerization and transportation, and by the proliferation of information and communications technology). Culture is hence viewed as a domain of struggle over the production and dissemination of knowledge, since “dominant and subordinate cultures deploy differing systems of meaning based on the forms of knowledge produced in their cultural domain” (Kincheloe, 2007: 23, 2008: 56). Cultural pedagogy has accordingly come to play an increasingly important role in critical pedagogy. As cultural production disseminates particular forms of knowledge, socializes, and constructs identities (and contributes to both domestication – through the legitimation of particular hegemonic ideologies – and the potential for emancipation), so it is understood as a form of pedagogy. Cultural pedagogy refers here to the ways in which “dominant cultural agents produce particular hegemonic ways of seeing [in a] . . . corporate-dominated, media-based pedagogical process” (Kincheloe, 2007:24, 2008: 59). Hence, and again, in media-saturated societies dominated by consumerism, such cultural pedagogies have, of late, received increasing attention from critical educators.

This ongoing and lively debate in the field notwithstanding, the term critical remains, as indicated in the opening paragraphs of this article, widely used and abused in the discourse of education. Blake and Masschelein (2003) warn that the way in which the somewhat vague aim of critical competence, for example, has become a standard educational end and even a “standard prerequisite of operating and functioning within the given order” risks robbing critique of its “element of transcendence of the given order.” It has substituted a “positivist ameliorism for a critical awareness of the ‘intolerable’ experience of injustice” (Blake and Masschelein, 2003: 55). What is clear in the rather widespread trivialization and domestication of the terms critical and critique is that as long as what Blake and Masschelein refer to as “society’s anaesthetization to injustice” (2003: 54) remains an unfortunate

hallmark of contemporary social interaction, critical theory and critical pedagogy will remain important in education.

Critical Thinking

H Siegel, University of Miami, Coral Gables, FL, USA

© 2010 Elsevier Ltd. All rights reserved.

This article draws extensively upon Siegel 2003 and Bailin and Siegel 2003.

Critical thinking enjoys a preeminent position among the many educational aims and ideals advocated by educators and educational theorists today. It has enjoyed this status since the earliest days of philosophical thinking about education, at least in the Western tradition originating in Greece nearly 2500 years ago. Although the expression 'critical thinking' is relatively new, the underlying ideal it names – often expressed in terms of the cultivation of reason or the fostering of rationality – has been regarded as a fundamental educational ideal by most of the historically significant philosophers of that tradition who turned their attention to education. No other proposed aim of education – caring, civic-mindedness, community, creativity, happiness, knowledge, obedience to authority, social solidarity, spiritual fulfillment, the fulfillment of potential, etc. – has enjoyed the virtually unanimous endorsement of historically important philosophers of education that critical thinking, reason, and rationality have (Siegel, 2003).

In contemporary discussions (e.g., Nussbaum, 1997; Siegel, 1988, 1997), critical thinking continues to be defended by many as an important educational aim or ideal. Unlike some historical predecessors, contemporary advocates of the ideal do not understand reason as a special psychological faculty; in defending rationality, they do not align themselves with the historical movement known as continental rationalism, according to which knowledge is based on the perception or intuition afforded by such a faculty. What then, exactly, is that underlying ideal? How is the ideal of critical thinking to be understood?

Critical Thinking: What Is It?

Key aspects of critical thinking, as currently advocated by contemporary theorists, include (1) the claim that the notion is essentially normative in character and (2) the claim that critical thinking involves two distinct components: both (a) skills or abilities of reason assessment and (b) the dispositions to engage in and be guided by such assessments. These are discussed in turn next.

Normativity

Advocates of efforts to foster critical thinking in schools sometimes conceive it narrowly, in terms of imparting

skills which will enable students to function adequately in their jobs, and in so doing to be economically productive. More often, however, proponents of the educational aim of critical thinking have in mind a broader view of critical thinking as more or less equivalent to the ideal of rationality.

So understood, critical thinking is a sort of good thinking. Therefore, the notion of critical thinking is fundamentally a normative one, thus distinguishing this understanding of critical thinking from those, common in psychology, which treat the notion as descriptive, identifying particular psychological processes (Bailin *et al.*, 1999). To characterize a given episode of thinking as critical is to judge that it meets relevant standards or criteria of acceptability, and is thus appropriately thought of as good. Most extant philosophical accounts of critical thinking, in addition to the account by Bailin *et al.*, emphasize such criteria. Robert H. Ennis, for example, defines critical thinking as "reasonable reflective thinking that is focused on deciding what to believe and do" (Ennis, 1987: 10), and offers a detailed list of abilities, skills, and dispositions which thinking (and thinkers) must manifest if it is (they are) to qualify as critical. Matthew Lipman defines critical thinking as thinking that facilitates judgment because it relies on criteria, is self-correcting and is sensitive to context (Lipman, 1991). Richard Paul analyses critical thinking in terms of the ability and disposition to critically evaluate beliefs, their underlying assumptions, and the worldviews in which they are embedded (Paul, 1990). Harvey Siegel characterizes the critical thinker as one who is "appropriately moved by reasons" (Siegel, 1988: 23), and emphasizes the critical thinker's mastery of epistemic criteria which reasons must meet in order to be rightly judged to be good reasons, that is, reasons that justify beliefs, claims, judgments, and actions. Other authors, including John McPeck (1981, 1990), similarly emphasize this normative dimension of the concept. While these authors' accounts of critical thinking differ in many respects, and have their own emphases, they are nevertheless agreed on its essentially normative character (Bailin and Siegel, 2003).

Skills/Abilities and Dispositions

While some early treatments of critical thinking defined it only in terms of particular skills – for example, Ennis' early

definition of it as “the correct assessing of statements” (Ennis, 1962: 83) – almost all more recent philosophical discussion of it (including Ennis’ more recent discussions) regards critical thinking as involving both (1) skills or abilities of reason assessment and (2) a cluster of dispositions, habits of mind, and character traits, sometimes referred to collectively as the critical spirit (Siegel, 1988). According to the advocates of this broader conception of critical thinking, education should have as a fundamental aim the fostering in students of (1) the ability to reason well, that is, to construct and evaluate the various arguments, and the reasons/premises and inferences of which they are composed, which have been or can be offered in support or criticism of candidate beliefs, judgments, and actions; and (2) the disposition or inclination to be guided by reasons so evaluated, that is, actually to believe, judge, and act in accordance with the results of such reasoned evaluations. Students (and people generally) are rational, or reasonable, or critical thinkers, to the extent that they believe, judge, and act on the basis of (competently evaluated) reasons. Thus, being a critical thinker is a matter of degree. To regard critical thinking as a fundamental educational aim or ideal is to hold that the fostering in students of the ability to reason well and the disposition to be guided by reasons is of central educational importance. These two aspects of the ideal deserve further comment.

The reason assessment component

Thinking is critical just to the extent that it manifests and reflects due attention to, concern for, and competence in assessing the probative strength of relevant reasons. In this respect, critical thinking can be understood as the educational cognate (Siegel, 1988: 32) of rationality, since both rational thinking and critical thinking are coextensive with the relevance of reasons (Scheffler, 1965: 107). Beliefs, judgments, and actions are rational just to the extent that the believer/actor has good reasons for so believing, judging, or acting; consequently, being able to think critically involves the ability to ascertain the epistemic or evidential goodness of candidate reasons. Consequently, a central task involved in educating for critical thinking is that of fostering in students the ability to assess the probative strength of reasons.

Any such account of critical thinking needs to be supplemented by an account of the constitution of good reasons which the proponent of the ideal is obliged to provide. How do we determine the degree to which a proposed reason for some belief, judgment, or action is a good or forceful one? What are the guidelines, or principles, in accordance with which the goodness of candidate reasons are to be ascertained? What is the nature of such principles? How are they themselves justified? Related questions arise concerning the criteria by which the goodness of candidate reasons is determined. How are these criteria chosen, and

who chooses them? How are they themselves justified – and indeed, can they be justified, even in principle, in a non-circular or question-begging way? What is the source of their epistemic authority? Are they absolute or relative? Are they really epistemic or rather political, constituting tools of power and oppression? These questions and others like them are epistemological in nature; they call for a general account of the relationship between a putative reason and the belief, judgment, or action for which it is a reason. Such an epistemological account will have to grapple with deep questions concerning the nature of epistemic justification, the relationship between justification and truth (and so the nature of truth), the relativity (or absoluteness) of principles of reason evaluation, and so forth. In this sense, the educational ideals of reason and rationality depend, for their own articulation and justification, on an adequately articulated and defended underlying epistemology. (For further discussion see Bailin, 1992, 1995, 1998; Siegel, 1988, 1989, 1997, 1998.) This also supplies a reason for thinking that epistemology should itself be taught in schools (Siegel, 2008).

The critical spirit

Having the ability to determine the goodness, or probative force, of candidate reasons for belief, judgment, or action may be necessary, but cannot be sufficient, for critical thinking, since a given thinker may have the ability but not (or not systematically or routinely) use it. Accordingly, most theorists of critical thinking argue that, along with the skill or ability to assess the probative force of reasons, critical thinkers must also have relevant dispositions. The primary dispositions are those of valuing good reasoning and its fruits, and of seeking reasons, assessing them, and governing beliefs and actions in accordance with the results of such assessment. In addition, most theorists outline a subset of dispositions or traits which are also necessary for critical thinking, including open-mindedness, fair-mindedness, independent-mindedness, intellectual modesty and humility, an inquiring attitude, and respect for others in group inquiry and deliberation (Bailin *et al.*, 1999; Hare, 1979, 1985). This two-component conception of critical thinking – according to which critical thinking encompasses both a reason-assessment component and a dispositional, critical-spirit component – is endorsed by most theorists.

The second aspect of the ideal – the disposition or inclination actually to be guided by the results of the reasoned evaluation of reasons – has broader philosophical implications. Here, the ideal recommends not simply the fostering of skills or abilities of reason assessment, but also the fostering of a wide range of attitudes, habits of mind, and character traits, thought to be characteristic of the rational or reasonable person (Scheffler, 1989; Siegel, 1988). This extends the ideal beyond the bounds of the

cognitive, for, so understood, the ideal is one of a certain sort of person. In advocating the fostering of particular dispositions, attitudes, and character traits, as well as of particular skills and abilities, the proponent of this educational aim denies the legitimacy, or at least the educational relevance, of any sharp distinction between the cognitive and the affective, or the rational and the emotional. The ideal calls for the fostering of certain skills and abilities, and for the fostering of a certain sort of character. It is thus a general ideal of a certain sort of person, which sort of person it is the task of education to help to create. This aspect of the educational ideal of rationality aligns it with the complementary ideal of autonomy, since a rational person will – at least ideally – also be an autonomous one, capable of judging for himself/herself the justifiedness of candidate beliefs and the legitimacy of candidate values.

Critical Thinking as a Fundamental Educational Ideal

As noted above, the cultivation of reason has been regarded by many philosophers of education in the Western tradition as a fundamental aim, and overriding ideal, of education. Today, the fostering of critical thinking (and so rationality) is often regarded in the same way. To so regard it is to hold that educational activities ought to be designed and conducted in such a way that the construction and evaluation of reasons (in accordance with relevant criteria) are paramount, throughout the curriculum. As Israel Scheffler puts the point:

Critical thought is of the first importance in the conception and organization of educational activities (Scheffler, 1989: 1).

Rationality . . . is a matter of *reasons*, and to take it as a fundamental educational ideal is to make as pervasive as possible the free and critical quest for reasons, in all realms of study (Scheffler, 1989: 62, emphasis in original).

The fundamental trait to be encouraged is that of reasonableness. . . . In training our students to reason we train them to be critical (1989: 142, 143).

To so take it is to regard the fostering of the abilities and dispositions of critical thinking in students as the prime educational directive, of central importance to the design and implementation of curriculum and educational policy. It is to hold that educational activities should be designed and conducted in such a way that the construction and evaluation of reasons (in accordance with relevant criteria) are paramount, throughout the curriculum. This is not to say that other aims and ideals might not also be of serious importance, but that none outranks the

primary obligation of educational efforts and institutions to foster critical thinking (Siegel, 1988: 136–137).

Justification of the Ideal

Why should the fostering of critical thinking be thought to be so important? There are at least four reasons for thinking so. First, and most importantly, striving to foster critical thinking in students is the only way in which students are treated with respect as persons. The moral requirement to treat students with respect as persons requires that we strive to enable them to think for themselves, competently and well, rather than to deny them the fundamental ability to determine for themselves, to the greatest extent possible, the contours of their own minds and lives. Acknowledging them as persons of equal moral worth requires that we treat students as independent centers of consciousness, with needs and interests not less important than our own, who are at least in principle capable of determining for themselves how best to live and who to be. As educators, treating them with respect involves striving to enable them to judge such matters for themselves. Doing so competently requires judging in accordance with the criteria governing critical thinking. Consequently, treating students with respect requires fostering in them the abilities and dispositions of critical thinking.

A second reason for regarding critical thinking as a fundamental educational ideal involves education's generally recognized task of preparing students for adulthood. Such preparation cannot properly be conceived in terms of preparing students for preconceived roles; rather, it must be understood to involve student self-sufficiency and self-direction. In this, the place of critical thinking is manifest. A third reason for regarding the fostering of critical thinking as a central aim of education is the role it plays in the rational traditions, which have always been at the center of educational activities and efforts – mathematics, science, literature, art, history, etc. All these traditions incorporate and rely upon critical thinking; mastering or becoming initiated into the former both requires, and is basic to the fostering and enhancement of, the latter. A fourth reason involves the place of careful analysis, good thinking, and reasoned deliberation in democratic life. To the extent that we value democracy, we must be committed to the fostering of the abilities and dispositions of critical thinking, for democracy can flourish just to the extent that its citizenry is sufficiently critical (Siegel, 1988, ch. 3).

These four reasons have been spelled out at greater length by several authors (e.g., Bailin, 1998; Robertson, 1995, 1999). They are sufficiently powerful to justify regarding critical thinking as a fundamental educational

ideal. Efforts to foster critical thinking aim at the promotion of independent thinking, personal autonomy, and reasoned judgment in thought and action; these particular aims are themselves in keeping with broader conceptions of knowledge, reasons, and persons: for example, that all knowledge is fallible, that it is possible to objectively evaluate the goodness of reasons, and that personal autonomy is an important value (Bailin, 1998: 204). These aims, and the broader conceptions in terms of which they are grounded, are philosophically contentious; it is no surprise, then, that they – and the educational ideal of critical thinking itself – have been challenged.

Criticisms of the Ideal

There are many extant criticisms and thoughtful critics of the ideal of critical thinking. Critics charge that critical thinking:

1. privileges the values and practices of dominant groups in society and devalues those of groups traditionally lacking in power;
2. privileges rational, linear thought over intuition;
3. is aggressive and confrontational rather than collegial and collaborative;
4. neglects or downplays emotions;
5. deals in abstraction and devalues lived experience and concrete particularity;
6. is individualistic and privileges personal autonomy over community and relationship; and
7. presupposes the possibility of objectivity and thus does not recognize an individual's situatedness (for details, discussion and references, see Bailin, 1995; Bailin and Siegel, 2003).

These criticisms, often made from feminist and/or post-modernist perspectives, must in the end be considered on their own merits. However, it is of considerable comfort to friends of the ideal that there is a general reply available to all attempts to reject the ideal, one that appears to be effective against them all, and which is manifested in the discussions of each of the specific critiques considered above. This reply, if successful, establishes the impossibility of rationally rejecting reason – and so preserves the legitimacy of regarding its cultivation as an educational ideal. This discussion concludes by rehearsing the reply and assessing its effectiveness.

Suppose that one wishes to reject the ideal of reason. One can reject it without thought or argument – indeed, one can reject it without ever recognizing or addressing the question of whether it should be rejected – or one can reject it on the basis of some reasoned challenge to it (e.g., that it fosters patriarchy, aids and abets oppression, depends upon a problematic individualism, rests on an inadequate conception of objectivity, or whatever). In the

former case, one's rejection does not threaten the legitimacy of the ideal, since no challenge is made. It is the latter, philosophical sort of rejection that genuinely challenges the ideal's cogency.

However, if such a challenge is made, it will be forceful, and successful, just to the extent that it is based upon good reasons for rejecting the ideal. The challenger is arguing, in effect, that there is good reason to reject the ideal of reason. Any such argument against reason, if successful, will itself be an instance of its successful application or execution. That is, the reasoned rejection of the ideal is itself an instance of being guided by it. In this sense, the ideal appears to be safe from successful challenge: any successful challenge will have to rely upon it; any challenge which does not cannot succeed. While challenges to the ideal might succeed in refining our understanding of it, none can succeed in overthrowing it. Thus, the ideal cannot be successfully challenged.

Transcendental arguments like this one are notoriously controversial philosophically; I cannot provide a general defense of them here. However, I should note that the argument does not prove too much. It does not suggest that other ideals are not important. Nor does it suggest that people cannot live contrary to it – although that they can (and do) does nothing to challenge the legitimacy of the ideal, or the claim that they ought to be guided by it. The argument obviously will not be persuasive to one who rejects reason, but offers no argument against it. But such an argument-less rejection fails as a critique, since it offers no criticism of the ideal or argument in favor of its rejection.

The proponent of rationality and its cultivation must, to be consistent, regard challenges to it as centrally important, and must regard the obligation to take such challenges seriously as integral to rationality itself. Insofar, deep criticisms of the ideal, and reasoned consideration of both its praiseworthy characteristics and its indefensible ones, are exactly what the ideal itself recommends. Whether the ideal survives extant criticisms will always be, in some sense, an open question; such criticisms may well succeed in altering our understanding of it. Nevertheless, there is a limit beyond which any proposed criticism of rationality cannot go without undermining itself. In so far, the ideal of rationality (at least in some formulation of it) cannot be coherently rejected (Siegel, 1996, 1997, ch. 5, Epilogue; 2003).

This self-justifying feature of rationality might itself be thought to provide some reason for regarding its cultivation as desirable. However, the main purpose served by the fundamental reply just rehearsed is not that of justifying the ideal directly – that task is more directly performed by the four reasons (respect, preparation for adulthood, initiation into the rational traditions, and democratic life) offered in favor of the ideal above. Rather, the main purpose is to make plain just how difficult it is to challenge the

ideal. Once the unchallengability of reason is clear, the desirability of its cultivation – on the basis of those four reasons (and quite possibly others as well) – is manifest.

Environmental Education

Introduction

While environmental education has been recognized as an important aspect of education for some time (the term itself perhaps dating back to a meeting of the International Union for Conservation of Nature and Natural Resources in Paris 1948), it is only comparatively recently that it has received sustained philosophical scrutiny. This is now establishing itself as an area of growing interest.

There are a number of reasons why the topic is attractive to philosophers of education. The first, shared by philosopher and non-philosopher alike, is the growing extent and urgency of what are perceived to be serious environmental problems affecting humanity both locally and globally. It is clear that these are becoming acute for citizens of the early twenty-first century and that education has a responsibility to address them. The goals, assumptions, and general approach of educational programs designed to do this therefore are of more than purely academic interest to philosophers. Second, some of the central ideas and assumptions that inform and orientate much current educational policy and debate regarding the environment are rapidly rendered problematic by philosophical examination. This is illustrated by reference to what is currently one of the most powerful orientating ideas in the arena of environmental education: sustainable development. Third, there is a very extensive and rich literature (including philosophical) on the environment to be examined and sifted for its educational significance. This is a major task. Fourth, the issues that are raised by environmental concern and environmental education are profound; they invite us to review a range of ideas and assumptions about the nature of knowledge, learning, and human well-being that have implications not simply for some discrete curriculum area or theme, but for the content and ethos of education as a whole. Indeed, many who have taken a strong interest in environmental education have wished to explore its potential as a vehicle for innovation in education, sometimes linking it with other reform movements such as school democratization and action research. Hence the clarification of key concepts and frameworks used in underpinning research, their relationship with learning theory more generally, and the adequacy of the measures to be employed in assessing the success of environmental education is also an important task (see Meyer, 2006).

The following sections identify some of the main ideas, strands of argument, and – most important – questions that characterize a growing field of educational debate.

General Issues Concerning the Aims of Environmental Education

Orr (1994) was perhaps one of the most influential in making the point that environmental concern raises not simply problems in education, but the problem of education – that is, conventional Western education that increasingly focuses on producing students who are effective operators in a global market economy premised on perpetual growth. For Orr, students so equipped, lacking ecological literacy, would perpetuate – indeed, render ever more rapacious – an economic system that is a heavy contributor to our current environmental predicament in terms of the strain being placed on our planetary ecosystem. This then raises a general point concerning the character of the aims of environmental education: they are not necessarily such as to sit comfortably within or alongside existing taken-for-granted practice.

A further issue arises from a practical impulse underlying environmental education: a tension between a desire on the part of many educational policymakers to achieve certain tangible behavioral outcomes that are taken to be environmentally friendly and a commitment to educate in the sense of developing a critical understanding of issues and possibilities. It is not merely that these demands will lead to different emphases in what is taught and expected, but that the independence of mind developed by the latter approach might lead to a questioning – and possible rejection – of the behaviors specified as desirable by the former. In environmental education, the issues are highly value-laden and not infrequently highly controversial. For example, not only are there serious tensions between environmental concern and capitalism as indicated above, but also what have been offered as environmental imperatives can conflict with key principles of liberal democracy, such as freedom and non-specification of the good life. (See Bell (2004) for some discussion of this.) Again, it becomes important for the philosophy of environmental education to address the issue of the general character of its aspirations. For example, should its focus be to convey information, to clarify competing ideas, to modify attitudes, or perhaps to inculcate some environmental ethic that parallels a widely accepted basic human ethic? In turn, such alternatives make wider assumptions about whether the solutions to environmental problems are to be achieved through technocratic authority or democratic participation.

They also raise questions about intergenerational learning and the role that children should play in addressing the

environmental situation. For example, should pupils be prepared to act as initiators of environmental education at home and in the community? This is an issue that environmental education raises in a particularly cogent form: social action is desperately needed, but should education be regarded as a vehicle for producing this? – as, indeed, arguably it has been on, say, the problems of racism, inequality, and economic competitiveness. By way of counter, it has been argued that not only is it unjust to transpose the responsibility for solving environmental problems from the generations that produced them to the generations that inherit them, but also that school activities must be evaluated on the basis of their educational value and thus according to educational criteria.

A school does not become 'green' by conserving energy, collecting batteries or sorting waste. The crucial factor must be what the students learn from participating in such activities, or from deciding something else

(Jensen and Schnack, 1997).

Finally, while education unavoidably needs to address the question of what our response should be to perceived environmental problems, it has been argued that at the most fundamental (and educative) level this means not merely addressing how we deal with discrete problems, but considering the underlying issue of what should be our relationship with nature. For this, it is held, pervades and conditions what we perceive as problems and sets the parameters for what can count as satisfactory solutions. Such views arise in the context of analyses that problematize ideas of nature and of the environment.

The Idea of the Environment

The term environment signifies a relational context: that in which something is located or embedded, the surrounding conditions in which it operates or has its being. Hence, for humans, it embodies the issue of our place in the world and the quality of our relationship with it. On such an account, our engagement with the environment necessarily will be manifold: sensuous as well as intellectual, esthetic as well as moral, involving affect and conation as well as pure cognition. Thus, environmental education would seem to refer to gaining some embodied understanding of ourselves in our surroundings, our world. Cooper (1992) has suggested that in many ways the idea of the environment is best understood as one's intentional field of significance: that web of entities and phenomena with which one has an intimate familiarity – the world in which one lives. This may be contrasted with the global environment and even one's geographically local environment – with which one might have scant familiarity. It might be argued that as necessarily the context in which personal understanding and action are

grounded, this lifeworld is where education has to start – and in a certain sense end – education must seek to enlarge and refine it if rather myopic and too partial environmental responses are to be avoided.

Some have seen this to raise afresh and in a forceful way the issue of place: the importance of locale to the significance of action, our sense of identity, and our sense of responsibility toward the environment. It is noted by environmental psychology that nothing we do is unplaced; hence, humans are always and already geographical beings. If place is an interactive environment that influences and responds to whatever is within it, places themselves can be understood as nodes in a nested holarchy. Our interactions with nature and place (our emplaced contingent existence) condition our worldview. Here again the importance of the lifeworld of the individual as the space where environmental phenomena are encountered and interpreted is emphasized.

In parallel with this, often a distinction is drawn between the built and the natural environment, and while the former may be an important educational topic – and itself inter-relates with the latter – ultimately, it is the issue of our relationship with the natural environment that is foregrounded by aspects of environmental concern that are currently experienced as most pressing, for it is the impact of human behavior on natural systems as evidenced by our concerns over things such as resource depletion, pollution, climate change, and wilderness and species extinction that motivates our present sense of a looming environmental crisis. Of course, addressing such issues has extensive implications for the built environment – especially if we were to include under this our social/political/economic environment – but the fundamental locus lies in our attitudes toward, and the impact of our behavior upon, the ecological systems that constitute our natural environment. Thus when we encounter educational talk of learning through, for, and in the environment, usually the implicit reference is to the natural environment.

But even if this delimitation is accepted we must be aware of the plurality of the natural world. Clearly, there are significant differences in the entities that compose it, both in terms of level (is the concern with the biosphere, an ecosystem, a species, a population, an individual, or a particular habitat or landscape?) and in terms of quality (such as human, conative, sentient, biotic, material), such that there would be corresponding differences in the way that each category is to be valued and treated.

Some of these issues have been taken up through the widely encountered idea of environmental or ecological literacy. Drawing on the broader literacy debate, Andrew Stables (1998) has identified three senses of environmental literacy: (1) a functional awareness of the scientific facts of nature (equivalent to decoding–encoding of text, understanding of literal meaning); (2) a received awareness of cultural significances and inputs regarding ideas and aspects

of nature and environmental issues; and (3) a capacity for critically evaluating personal meaning and underlying social/ideological determinants of issues in ways that can be translated into action.

As with a number of other views, this approach emphasizes the fact that environmental issues are human issues (or issues viewed from a human perspective) and therefore not only matters for natural science but for the arts and humanities. Its implicit suggestion that the environment can be regarded as a text that can be read has also been seen as opening the way to a full-blooded semiotic approach that problematizes the human–nonhuman boundary and leads to a questioning of aspects of the special position that humans frequently attribute to themselves.

To what extent is it appropriate to regard nature as a text? The question of the reality of nature goes to the heart of environmental education and is clearly highly philosophical in character. Is nature (merely) a social construct, redolent with ideological bias and therefore having no foundational reality? In an attempt to address this question, the point has been made that while of course, our concept(s) of nature are socially produced, we experience nature as precisely not socially produced. Its essential independence of human intention is central to its meaning, such that indeed its fundamental experiential quality is that of being self-arising (Bonnett, 2004: ch 5). It has been claimed that this experience of the autonomy – and hence the mystery – of nature is so deeply embedded in, and orientating of, our engagement with the world at large that it can in no way be regarded as optional or disposable as some postmodern views have suggested (Rorty, 1994: ch 8). Nature therefore can serve in a foundational role, though of course there is a constant need to be alert for the way in which naturalizing certain categories (such as man, woman, child) has the potential to authenticate, for example, questionable power relationships (Haraway, 1991, ch 8). Debate on such issues continues and is again illustrative of the very wide significance of the questions that are invited by a philosophical examination of the grounds of environmental education.

Furthermore, in emphasizing the central importance of our relationship with nature, the view both argues for seeking a systemic wisdom that transcends systematic scientific knowledge and alerts against naturalising environmental problems that lie not in nature (which has no problems) but in the character of our relationship with it. It therefore seeks to reveal the deep motives (such as mastery) that inform human practices in the modern and late modern era.

Education for Sustainable Development

In addition to frequently being taken to encapsulate what our response to the environment should be, the idea of sustainable development provides rich illustration of the

philosophical issues that are opened up for education. The notion first came to prominence with the publication in 1987 of the report of the World Commission on Environment and Development, *Our Common Future*. Here sustainable development was defined as a development that meets the needs of the present generation without jeopardizing the ability of future generations to meet their needs. This definition was widely taken up and was consolidated as an educational matter at the Earth Summit Conference held in Rio de Janeiro in 1992 attended by delegates from over 170 countries and whose centerpiece agreement was Agenda 21 which included the proposal to introduce sustainable development into the educational programs of signatory nations. Thus, it has found its way into the core curriculum of many nations.

Now the question is: how adequate a notion is sustainable development, so defined, as a basis for environmental education? Advocates make clear that it has the benefit both of a positive focus – on what we can do, rather than overweening gloom of ever-burgeoning problems – and in its recognition that human economic and material aspirations must be included in any proposed solutions. From the perspective of philosophy of education the question is in part modulated through three further questions: first, what does sustainable development mean?; second, how defensible are the values and assumptions it expresses?; and third, what are its educational implications? For some, pursuit of these questions has proved to reveal an approach to environmental education that is itself highly problematic and perhaps open to the objection that it risks undermining what should be at the very heart of any education that takes environmental concern seriously. In addition to problems concerning identifying non-paternalistic criteria for judging human needs both present and future in the context of a world population that is highly diverse geographically, culturally, and economically, there is the issue of an overweening anthropocentric stance. While some argue that allying concern for the environment with human self-interest is its best protection, others, fearing that the idea of development in sustainable development will inevitably be interpreted in accordance with Western market models (Shiva, 1992), point out its compatibility with economic and epistemological postures that may be at the very heart of current environmental problems – making sustainable development, so interpreted, a net contributor to them. Again, such arguments have led attention to the importance of our underlying attitude toward nature as an issue for environmental education, the educational focus moving from sustainable development as a policy to sustainability as a frame of mind (Bonnett, 2004: ch 9). Here, in somewhat Heideggerian vein, arguments have been mounted to suggest that understood as the place where things show up – are let be – authentic human consciousness is intrinsically involved in sustainability and that education

should be concerned to promote and nurture this by disrupting the metaphysics of mastery that currently holds sway in Western-style culture.

Knowledge, Behavior, and Action

One of the central questions facing environmental education is the kind of knowledge that it requires. Often, the philosophies underlying different approaches have emphasized qualities of knowledge that challenge much conventional educational practice.

The long-running OECD Environment in Schools Initiative (ENSI) is a good example of this. Its movement toward an ecologization of schools by placing environmental issues at the heart of the curriculum and its development of the notion of action competence, which involves students identifying and addressing environmental problems as a member of the school and wider community, requires that pupils not only acquire relevant factual knowledge, but that they personally evaluate issues and the relevance of knowledge, and learn the practical ability to work effectively with others in a way that respects the views of all concerned. Here, the aim is not the acquisition of pre-specified subject organized knowledge, but critically reflective environmental action framed in the context of students' own lifeworlds and understandings. In such a context, they are as likely to be the generators of knowledge as the recipients. This approach has been viewed by those involved as radically transgressive in the way it disrupts many boundaries that structure conventional education such as those between childhood dependency and adult responsibility, knowledge users and knowledge producers, knowing and acting, and facts and values. It is argued that the inherently complex, contextualized, frequently controversial, and often piecemeal occurrence of environmental issues in real-life situations precludes a traditional school curriculum and requires students to participate in shaping the social and economic conditions of their existence in society (Elliot, 1999).

This highly dynamic model of environmental education is clearly removed from the traditional model that seeks to transmit from above pre-decided environmentally good attitudes and behavior. It provides a powerful example of the extent to which environmental education might impact upon conventional views of pupils, teachers, and educational institutions. There is clearly much philosophical work to be undertaken in reviewing such possibilities, including the adequacy of a student rationality tacitly conditioned by the current motivational climate to identify key issues. This leads to two further points concerning the kind of knowledge to be valorized by environmental education.

The first of these is the importance and interpretation of systemic wisdom as an educational concern. A strong theme underlying much environmental debate

is that we must regard ourselves as thoroughly (though perhaps not exclusively) embedded in nature conceived as an ecological whole and hence that our actions reverberate throughout this whole having unlimited and often unintended consequences. Not infrequently, the whole visits us with unanticipated repercussions. On such an account, there is a strong need to think in a way that embraces this greater whole – and is open to it in a way that transcends our self-orientated purposiveness. But human consciousness is always selective. How is the greater whole to be understood? What are the appropriate metaphors? A variety of candidates are current: a causal system, an information flow and feedback (i.e., cybernetic) system, a realm governed by abstract laws, a domain of dialogical encounters attended by mystery. The helpfulness of any or all of these relates to the second point.

There has been an extensive debate in the literature concerning the traditional assumption that science offers the most authentic insight into the reality of nature. The central elements of this debate concern the aggressive and manipulative motives taken by some to be inherent in modern experimental science and the possibility that these are antipathetic to revealing the manifoldness of nature properly understood, such that other portals must be sought – a further argument for broad curricular involvement. Recognition of the need for more receptive-responsive, dialogical, forms of knowing reveals wide-ranging implications for knowledge transformation, curriculum, pedagogy, and the culture of the school. This has been interpreted as providing an entrée into educational debate for indigenous perspectives, romantic philosophy, as well as the more measured views of early environmentalists such as Thoreau, Emerson, Leopold, Muir, and ecofeminist points concerning *inter alia* knowing dominated by a masculine rationality (Plumwood, 1995).

In a different but not unrelated vein, the so-called co-evolutionary approach sees the relationship between society and nonhuman nature as one of ongoing reciprocal change, each impacting on the other in ways that can never be fully anticipated. Drawing on economic theory, Gough (2002) suggests that this perspective in which uncertainty is systemic invites a real-options approach to environmental planning. Here one attempts to calculate the option value of some aspect of the environment at different decision points over a given time period – the impetus being to think in a way that tends toward increasing the future option value of the environment and that is permanently prepared to be surprised by the way that things turn out. Education would need to develop the ability to conceive, recognize, and manage an ever-increasing range of possibilities and change perceptions so that future options that are systematically discounted in a political context that characteristically focuses on the short term can become more highly valued. It would need

to prepare all to contribute to this in their decision-making in the different fields and institutions in which they work.

Interestingly, such an approach invites a heuristic rather than economist interpretation of the much-vaunted learning society in which we allow the sense-giving frameworks that we employ in understanding the world to be open to change, “surrendering ourselves to the inescapable creativity and open-endedness of our grapple with the emergent” (Foster, 2002). In thus being radically open to life it will be radically precautionary in order to leave room for our fallibility and accommodation to the unexpected. These are some of the deep structural conditions for sustainability conceived as living with the grain of nature, recognized as a well-spring of surprises as much as an object of prediction.

The Social/Political Dimension

In addition to bringing pupils to an understanding of the sociopolitical values and practices that have been heavy contributors to the current environmental situation, it has been argued that there is an equally pressing need to address the sociopolitical consequences of these values and practices. An important cluster of these and their educational implications has been foregrounded through the notion of an eco-justice pedagogy. On the account developed by Bowers (2002), this has three main foci: (1) to develop an awareness of the environmental racism and class discrimination involved in the way that the deleterious environmental impacts fall disproportionately on ethnically and economically marginalized groups; (2) the recovery of non-commodified aspects of community through a reversal of an ever-increasing dependency on meeting life's daily needs through consumerism rather than through self-reliance within the family and within networks of mutual support within communities; and (3) to develop a sense of responsibility toward future generations and a corresponding self-limitation by an expansion of nonconsumptive relationships and opportunities to develop personal talents that enrich the community. Key to achieving these aims, for Bowers, is a recognition of the root metaphors embedded in language that shape the way that we understand the world. He argues that currently, the metaphors that hold sway are those that underlay the industrial revolution such as individual and linear progress and that these systematically undermine the value of tradition and therefore of intergenerational knowledge and continuity; they are in conflict with the root metaphor underlying an eco-justice pedagogy which is ecology and which foregrounds the relational and independent nature of our existence as cultural and biological beings.

On such a view, the educational aim that would have greatest impact would be to get students to see how language carries forward culturally specific ways of thinking

(orchestrated by root metaphors) and to reflect upon how the cultural and environmental patterns connect. In this way, a cultural space could be created for criticizing the language patterns of different Western cultures that create the individual psychology that accepts consumer dependency and environmental degradation as a necessary trade-off for achieving personal conveniences and material success.

Finally, there is a further important social cultural element to be addressed. Plausibly, it has been argued that politically sustainability has become exhausted. In the late-modern context – and two decades after *Our Common Future* – the pervasive dominance of liberal democratic consumer capitalism has left it as a piece of hollow rhetoric, and that in fact we now live in a post-ecologist paradigm of the politics of unsustainability (Bluhdorn, 2007). A hyper-environmentalism conceals the fact that the emphasis has shifted from life reform aiming to bring social practices into line with categorical, that is, non-negotiable, eco-imperatives to adapting these imperatives to systemic needs and lifestyle preferences which have themselves acquired the status of non-negotiability. Insofar as today, environmental education has been shaped largely as a response to concerns over environmental degradation and seeks an understanding that focuses on the sociopolitical sources of this situation, such an analysis of sociopolitical reality is of considerable relevance to its enterprise and the framing of its agenda.

Summary

In all there are many ways in which environmental concern leads to a questioning of the general anthropocentrism and Enlightenment humanism that dominates education, suggesting a need to consider the possibilities of post-humanist approaches. In this and in cognate ways considered above, a philosophical examination of environmental education prompts us to address the metaphysics of education as a whole.

Identity

M S Merry, University of Amsterdam, Amsterdam, The Netherlands; Nieuwe Prinsengracht 130, 1018 VZ, Amsterdam, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Published research and theory on identity far exceeds reasonable expectation. Thousands of articles and books have been written on the subject, yet navigating this topic continues to be something of a conceptual minefield. Like diversity, the term identity has been used in so many contexts, many of them polemical and political, that it is difficult to find any common understanding on which scholars agree. Culture typically has been the way that anthropologists have talked about identity, yet critics charge that anthropological models of identity too often proffer essentialist interpretations of their object, masquerading as objective description. Sociological models of identity, notwithstanding their bold structural claims and attention to environmental and institutional forces, are thought by some to have a thin empirical basis. Doubtless psychology has dominated the field of identity (and self) studies, yet psychological models, for all of their personal and interpersonal promise, are believed by many to have a weak theoretical foundation.

Meanwhile, identity in the philosophical literature has until recently been confined mostly to ruminations on the self: as soul in Plato; rationality connected to, but not coterminous with, the body in Descartes; uninterrupted consciousness in Locke; a stream of experiences which a thing has in relation to itself in Hume; an emotive life in Rousseau; as noumenal self about which we can know little in Kant; as will in Schopenhauer; as an elusive but nonspecific something in Wittgenstein; and as the continuous, purposive struggle of creative power against an historically contingent concatenation of social, political, and cultural forces in Nietzsche and Foucault (Glover, 1988; Perry, 1975; Marshall, 2001).

Yet what follows is not a summary of metaphysics or philosophy of mind. There also is not sufficient space here to examine identity in each of the separate disciplines. Instead, what follows are some prefatory discursive remarks about identity; then, owing to the dominance of psychological theories on identity, a brief overview of some of its salient themes will be adumbrated; this will be followed by a discussion on identity formation and maintenance both in political philosophy and philosophy of education.

Contemporary interpretations of identity run the gamut, ranging from essentialist readings found in the many varieties of culturalist discourse (e.g., aboriginal and indigenous studies), to postmodern dismissals of the term itself. Thus from the one end, essentialists ascribe inherent, lucid meanings to identity which lay beneath

social or political particularities. While essentialists appreciate that circumstances and historical contexts vary, they nevertheless insist that persons know, experience, and relate to something constant about themselves beyond or beneath the linguistic constructions or cultural narratives to which these merely give expression. Essentialist readings of identity, then, are reductionist inasmuch as some particular aspect of identity is believed to be irrevocably and timelessly true. This interpretation of identity assumes that there is something inalterable and determined about who one is on the basis of genealogy, culture, race, gender, or sexual orientation; as such, this interpretation risks erring on the side of identity politics.

Identity politics describes the fact that persons of various minority groups may feel trapped within an identity constructed by others, leading to the expectation that one must represent a particular set of ideals, interests, and behaviors in order to be authentic (see Merry and New, 2008). Essentialism is amply on display in the fields of psychology, sociology, and, perhaps most especially, in anthropology, which gave birth to the notion of cultural identity and difference. Yet the notion that one must identify exclusively with a specific identity marker (e.g., gender) – with all sorts of concomitant purposes and meanings in tow – usually comes at the expense of creating or exploring alternatives, or of critically examining how one's identity is both historically and continuously constructed. Here, Appiah (2005: 113) astutely observes that while the “contours of identity are profoundly real, [they are] no more imperishable, unchanging, or transcendent than other things that men and women make.”

Conversely, postmodernists argue that no such thing as a self exists; identity only describes indeterminate, mutable narratives of persons located within the social or cultural roles they are called upon to play. Subjectivities (in the preferred parlance) are contingent, malleable, hybrid assemblages that never cease evolving and adapting to any number of contexts. As Hall and du Gay (1997: 6) write:

Identities are, as it were, the positions which the subject is obliged to take up while always knowing (the language of consciousness here betrays us) that they are representations, that representation is always constructed across a lack, across a division, from the place of the Other, and thus can never be adequate – identical – to the subject processes which are invested in them.

For postmoderns, then, identity names little more than ephemeral positions and attachments we assume within

the various discourses that circumscribe who we are at any given moment. On this view, all identities – whether historical or cultural – are manufactured, disseminated, and politically deployed (Anderson, 2006; Hollinger, 1994). However, this approach renders insignificant the ways in which persons actually experience their identities, underneath it all, as substantive and real. That is, persons can sense that something about them exists beneath or outside of their cultural or social narratives; that it is they who are the authors of such stories; and that they can sense themselves as being in time and social space.

Indeed, however socially constructed identities are, one nevertheless feels herself to be Jewish, transsexual, black, or whatever. Of course there are myriad ways in which one is Jewish, transsexual, or black, and these markers of identity do not describe all that we are (the blunder of identity politics), but this point is frequently missed by critics of identity: how we see ourselves, and how we are seen by others, matters, and perhaps especially to those whose (constructed) identities enjoy little if any public recognition. The politics of recognition makes this very point: everyone should have the right to be acknowledged publicly for the identities that matter to them. Recognition is central to social anthropology in the context of ascribed and assumed identity. One is what one is seen to be, and one is as one believes oneself to be.

Both personal and social aspects shape identity but most theorists on the subject generally agree that identities do not evolve from pristine cultures; rather, identities are products of multiple, oftentimes conflicting, attachments. Indeed, the stable and fixed identity so favorable to earlier psychologists is increasingly being challenged by others who argue that our identities, far from being fixed and secure, are constantly evolving, adopting new meanings, and appropriating habits, customs, and beliefs according to contextual circumstance and need. Indeed, all persons possess hybrid identities that combine, mix, and separate identity components to adapt to different environments. Hybrid identities – what Salman Rushdie called the mongrel self – reflect the plural cultures and societies we live in, and we do not so much discard one identity for another so much as we interchange multiple, not entirely consonant, identities (Benhabib, 2002; Holland *et al.*, 1998).

In industrialized, Western societies, identities are understood as intensely personal and individual, stressing uniqueness and the independent self. Accordingly, the aim of exploring and questioning inherited values, opinions, and habits generally is encouraged. Conversely, identity in more traditional cultures – including, in East Asia, those which are highly industrialized – is typically circumscribed by one's age, caste, gender, or status. Accordingly, what some have called the interdependent self inclines toward similarity, conformity, and group harmony (Gross and Gore, 2003; Markus and Kitayama, 1991).

Of course, even describing these differences is a symptom of essentialism, and increasingly these cultural dichotomies are being challenged. It is likely that various levels of individual, relational, and collective identity are to be found in most persons irrespective of where they were born and how they were raised. Yet whether one is an independent or an interdependent self, Hogg (2003: 462) observes that group membership plays a crucial role in identity development:

Groups [influence] the type of people we are, the things we do, the attitudes and values we hold, and the way we perceive and react to people around us. Groups furnish us with an identity, a way of locating ourselves in relation to other people. Indeed, our sense of self derives from the groups and categories we belong to, and in many ways individuality may merely be the unique combination of distinct groups and categories that define who we are.

Identity Defined

Granting its manifold nuances, meanings, and applications, identity normally refers to the complex and ever-evolving expressions of self-understanding that describe how persons relate, and form attachments, to their historical–social–cultural environment over a lifetime and consciously or unconsciously arrange their priorities and commitments to reflect those, sometimes conflicting, attachments. Attachments are formed with other persons as well as one's environment (hence the attachment to one's homeland, for instance).

Identity denotes an understanding of who we are, as individuals, and not merely as products of history, culture, or caste. Josselson (1987: 12–13) describes identity as a “dynamic fitting together of parts of the personality with the realities of the social world so that a person has a sense both of internal coherence and meaningful relatedness to the real world.” One's identity is invariably multifaceted and may involve tension; identities, too, may be ranked (and reordered) in importance, some aspects being discarded or constructed in light of new and changing circumstances and experience. Sen (2006: 19) concurs:

Identities are robustly plural, and [one] identity need not obliterate the importance of others [...] a person [also] has to make choices – explicitly and by implication – about what relative importance to attach, in a particular context, to the divergent loyalties and priorities that may compete for precedence.

Some identities may be temporary, while others endure. Any number of different selves may be salient depending on the persons or environment with whom/which a person may be relating. Which aspects of identity one consciously or unconsciously summons will largely be determined by her context and circumstances, but also her temperament and emotional needs.

Yet, while identity is rarely settled or fixed, it vaguely describes how persons see themselves and how they express what is important to them. However variable one's self-concept is there remains a very particular sense in which persons understand themselves, and others, as specific, historical persons in space and time. Who one thinks she is, is unavoidably connected to the self that she was, is becoming, and will be, however little she remembers, understands, or is able to predict about those distinct phases of growth and development. This is consistent with what some psychoanalysts believe to be true of a healthy ego identity, namely, there must be a "subjective sense of continuity of being the same person over time and in different situations" (Côté and Levine, 2002: 121). This means that personal identity will manifest characteristics of having a past, a present, and a future, even if the present or future self no longer identifies as the same person she once was. This, then, is one of the great paradoxes of identity: experience changes who we are, and thus how we see the world as well as how we are seen by others.

Identity Formation

Identity formation has been studied from a number of perspectives. For example, there are models of racial identity formation (Cross, 1971), sexual identity formation (Cass, 1979), and minority identity formation (Atkinson *et al.*, 1983). Whatever the case, identity formation describes the conscious process of (re)examining one's feelings, thoughts, behaviors, and ways of relating to others who may or may not share similar commitments and habits. It is to reflect upon "our place in the universe, the meaning of life and death, and our purpose for being here" (Chickering and Reisser, 1993: 207). Identity formation also describes the way in which individuals deal with uncertainty and ambiguity.

Notwithstanding a variety of disciplinary approaches, contemporary studies on identity formation continue to assume a psychological cast, and none has towered over the field like Erik Erikson. Identity formation, for Erikson, names a process at the core of the individual and at the core of her communal culture, a process which establishes a single identity that links them together. "Identity grows and is nurtured or frustrated in a complex bonding of self and society" (Hoover *et al.*, 1997: 21). The formation of identity involves both competence and integrity. Competence is achieved by one's efforts and is validated by the recognition of others, while integrity is a state of mind about who one is in relation to oneself and others.

Identity for Erikson is both a personal and social construction, for there is a strong interplay between the psychic self and the social self. It is personal inasmuch as identity is

developed through the integration of various identifications with significant others and reference groups, and it is social inasmuch as it is developed through the internalized roles and appraisals of others. Central components of identity include: (1) a sense of personal continuity over time and across situations; (2) a sense of inner agency; (3) a commitment to certain self-representations as self-defining; (4) a commitment to certain roles as self-defining; (5) an acknowledgment of one's role commitments and views of self by significant others; (6) a commitment to a set of core values and ideal self-standards, and (7) a commitment to a worldview that gives life meaning (Erikson, 1959, 1968).

For Erikson, identity begins long before there is self-awareness, for it is in the nascent bonds of intimate relations (primarily with one's parents) that identity assumes its earliest expression. Intimate relationships, particularly the maternal bond with children, supply the mutual trust and recognition necessary for security and trust. Over time, and with consistent care and attention, it is within these trusting bonds that one comes to identify in a particular way with a set of attachments, habits, and thought patterns. This also describes the manner in which persons are enculturated, which is to say that most persons gradually come to identify with a way-of-being as natural, self-evident, and correct. The foundations of trust give rise to greater possibilities for personal well-being; well-being in this sense describes the experience of being accepted by others as well as a sense of security, satisfaction, and confidence about one's being-in-the-world. A healthy self-concept describes those who are comfortable with their self-image, with how others see them, with the roles they have chosen for themselves, or even which others have chosen for them. (Erikson's notions also supply the foundations for many sociological and anthropological understandings of what makes groups of individuals cohere.)

Yet an absence, or shattering, of foundational trust, for Erikson, portends a looming identity crisis. This crisis (which in late adolescence he describes as identity diffusion) frequently results from persistent doubts about one's ethnic, gender, religious, sexual, or racial identity, and describes the inability to resolve a profound personal challenge when faced with it. On the other hand, another type of crisis known as moratorium, is one that persons must navigate in order to achieve identity at each stage of development. Either way, identity crises arise when the acceptance of one's identity is questioned or rejected by oneself or others. Young persons are particularly susceptible to peer pressure; anxious to be accepted as a group member, intolerance may be expressed towards non-members, that is, outsiders. In Erikson's words:

It is difficult to be tolerant if deep down you are not quite sure that you are a man (or a woman), that you will ever [be] attractive, that you will be able to master your drives,

that you really know who you are, that you know what you want to be, that you know what you look like to others, and that you will know how to make the right decisions without, once for all, committing yourself to the wrong friend, sexual partner, leader, or career (Erikson, 1959: 93).

If the crisis proves too difficult to overcome, some kind of identity pathology may set in (e.g., narcissistic personality disorder), these normally being the “result of impaired ego functioning caused by a functional or organic disorder” (Côté and Levine, 2002: 154). The result, for psychoanalysts, is that a failure to thrive at any level represents a failure to successfully navigate a much earlier conflict (e.g., trust vs. mistrust, autonomy vs. doubt) so that a personality disorder is the result of a more primary problem with attachment that is manifested in that period when intimacy is the primary demand for growth, that is, adolescence and early adulthood.

Marcia (1966) extended the work of Erikson by examining the various ways in which identity formation occurred in adolescence. Marcia, however, was less certain that identities were either resolved or confused. The crisis that Erikson described was not, for Marcia, an emergency but rather a stimulus for overcoming challenges and therefore leading to growth. The result would be greater individualization and differentiation. Marcia also concurred with most psychologists on this point: identity arises from any number of competing – and not necessarily conflicting – influences. Though not an exhaustive list of identity-forming effects, birth order, peer group, gender assignment, sexual orientation, religion, occupation, and culture all influence, to one degree or another, how one comes to understand her relationship to others, including the way in which one shares a set of communally based commitments or practices.

Needless to say, identities will not arise within, or map onto, neatly prescribed categories. Côté and Levine (2002: 46) observe:

[In] order to understand an individual's personal identity, one needs to know more about a person than his or her ego constructions and sociohistoric location and opportunities – one needs to know about the emergent interpersonal circumstances affecting his or her behavior, including others' perceptions of past personal-identity displays, labels that might have been affixed to him or her by others, prejudices faced, gossip relevant to the person, multiple and contradictory pressures to conform, and so forth.

Perhaps one truism seldom noted by psychological identity theorists is that many identities also are formed in resistance to peer or parental expectations, as well as to one's inherited group identity or membership. Further, preferring an interdependent and relational model of

identity formation, some feminist critics (Gilligan, 1982) of Erikson – and moral development theorist Lawrence Kohlberg – have objected to their purported androcentric preference for autonomy and independence as signs of identity achievement.

Philosophical Trends

In political philosophy, communitarians have long argued that personal identity is entirely dependent on one's inherited cultural context. Parekh (2000: 159) expresses this well:

[C]ulture gives coherence to our lives, gives us the resources to make sense of the world, stabilizes our personality, and so on. Its values and ideals inspire us, act as our moral compass, and guide us through life; its arts, rituals, songs, stories and literature fill us with joy and add colour and beauty to our lives; and its moral and spiritual wisdom comforts and helps us cope with the inevitable tragedies of life.

Some cultural identities are recognized and protected by dominant beliefs and practices and enjoy a level of identity capital that those in minority groups do not. Identity capital describes the various investments that persons make about who they are, but the term also expresses a series of transactions and exchanges with others that validate or invalidate one's personal or social identity. Yet where identities appear to be under threat owing to a weakened cultural base, well-being itself appears threatened to some, thus leading to efforts to protect and maintain (fixed) cultural identities. Some have even argued that the state ought to underwrite the protection of certain imperiled cultures in order that the identities of their members may remain intact (Margalit and Halbertal, 1994). Meanwhile, postmodern critics, such as Appadurai (1996), argue that minorities in many parts of the world are at least as artificial as the majorities they seem to threaten, while liberal critics have noted that the problem with cultural rights is that it seeks to uncritically protect groups and not the individuals within them. More will be said about this in the following text.

Kymlicka's (1989) *Liberalism, Community and Culture* marked a watershed. By far his most interesting and controversial claim has been that culture – and by extension, cultural identity – is, in Rawlsian terms, a primary good. That is, like income, basic liberties, opportunities, and a social basis for self-respect, culture is necessary in order to flourish as a human being. This is because cultures supply us with our most basic identities, facilitate trust between ourselves and others, and promote general well-being among others who share our way of life. Cultures also supply persons with the context for choice, and thus enable freedom and autonomy.

The implications for identity are clear: identities arise from within a given cultural context. To be sure, many choices are already made for us, inasmuch as our cultures provide a limited range of options. Importantly, however, while our cultural identities may be given, for Kymlicka it remains for persons to form, pursue, and revise their conceptions of the good life, and this includes how we see ourselves as individuals and in relation to others. Interestingly, Kymlicka argues that some groups, owing to past and present discrimination, are not effectively able to choose or to act unless corrective measures are taken by the state (e.g., affirmative action) to level the playing field. These corrective measures also may require considerable cultural protection of indigenous (though not immigrant) groups. Yet, as a philosophical liberal, Kymlicka is ultimately concerned with individual freedom and autonomy, and therefore argues that persons need to be free to revise or even cast off their cultural identity if they are unable to live it well from the inside. As such, one's identity is not fixed or determined by cultural membership.

Kymlicka's views have been strongly criticized from several directions. First, communitarians argue that culture provides such depth of meaning and direction that one's identity is both circumscribed and bound by it. In Sandel's (1982) terms, the self is irrevocably encumbered. Additionally, there is resistance to what some interpret as a liberalizing agenda in Kymlicka's insistence that persons ought to autonomously subscribe to their cultural identities, that is, rationally and critically reflect upon who they are. Most cultural identities, they argue, are not open to revision, nor should they be.

Liberal critics of Kymlicka mostly target two areas. Some (e.g., Barry, 2001) argue that Kymlicka's cultural defense assumes too unspoiled a notion of how cultures actually are formed and operate, and further, ignores the fact that identities are unavoidably hybrid and complex. Arguing against the one person-one culture model, Waldron (1996) insists that while a person needs cultural attachments for a meaningful identity to develop, a homogeneous, stable, or unaltered culture is not required, nor is one likely to find it. Further, cultural characteristics do not tell us all we need to know about individuals. Rather, positing the one person-many fragments substitute, Waldron argues that in this postmodern, post-Fordist, globalized world the idea of absorbing only one culture – let alone the idea that any univocal culture exists – is implausible.

Concerning Kymlicka's claim that some vulnerable cultures may need state protection in order to help preserve threatened identities, critics note that cultures are not static entities that can be preserved by state intervention except in the most artificial way. Indeed, state protection will only sanction contestable expressions favored by a minority group's leadership. Further, state intervention in order to protect the identity of a minority population

suggests that persons are unable (or unlikely) to adapt, and thus need assistance in order to weather the storm of cultural change. Indeed, Waldron suggests that there is something very paternalistic about the assumption that some are better able than others to acclimate to change.

Still others, notably Okin (1998), point to the problems with defending minority group rights, however mistreated these national or indigenous minorities may have been in the past, or continue to be. Her concern is with a cultural group's most vulnerable members, women and children. She points out that sexual discrimination is rarely overt and states are rarely able or willing to patrol the private sphere. Finally, all liberal critics argue that cultural protection conflates the interests of the adult members with those of the children, and this portends difficulties with the younger generation being able to decide for themselves whether they wish to identify with the culture of their parents.

In philosophy of education, identity formation and maintenance has been a theme most frequently taken up in debates over religious (and recently, home-) schooling. An education that aims to strengthen identity and the commitments that derive from it can be described as a culturally coherent education (Merry, 2005). Cultural coherence describes a continuity of commitments, values and beliefs between the home and school which reinforces a child's cultural or religious identity and builds self-confidence and trust with others who share these commitments. While not without its critics, arguments for cultural coherence operate on the assumption that persons experience emotional stability by identifying primarily (though perhaps not exclusively) with a particular notion of the good life. Further, advocates of culturally coherent education recognize that limiting the range of identity choices/ options, particularly for young children, helps to solidify identity and enable agency to act upon the meanings one attaches to those identities, including the capacity to pursue and revise their self-understandings and attachments.

One advocate of this approach, Burt (1994), argues that excepting for cases involving abuse or neglect (a contested terrain if there ever was one), parents ought to have unchallenged prerogatives to raise children in ways specific to cultural or religious attachments. This is necessary, she argues, for equipping children with the necessary psychological resources to make sense of their inherited world and to live well. As a liberal, Burt stresses the importance of cultivating autonomy but argues that this can be done in a manner consonant with the parent's beliefs or cultural and religious practices. She also acknowledges that freedom to exit one's community is important, but believes that the resources to do this will come about either through exposure to outside influences or, more likely, by engaging with counter narratives within one's own tradition.

With culturally coherent school models, there are worries that parents and teachers may not only discourage critical thinking and dissent, but also use coercion and fear to achieve conformity. The obligatory authority of certain religious texts, or the charismatic authority of community leaders often distinguishes acceptable (e.g., heterosexual) identities from unacceptable ones. Further, critics of this approach to parenting and education insist that too little attention is given to the cultural construction and historical development of any assumed identity. Thus, children must not only be exposed to views outside of one's family and immediate community, but they must meaningfully engage with others whose views are decidedly different before it can be said that they have an informed understanding of what it means to live an identity from the inside. Finally, critics of culturally coherent parenting and education worry over the conflation of the interests, attachments and identities of children with those of their parents. Debates among philosophers of education continue over whether an upbringing to anchor identity during the primary grades is desirable, even necessary, in order to provide children with a foundation upon which to make comparative judgments about alternative identities, or whether children ought to be instructed and acculturated in ways that depart more manifestly from the opinions and habits of the parents (Feinberg, 2006; MacMullen, 2007; Merry, 2007).

A Brief Conceptual History of Inclusive Education

Segregation Versus Integration

The first polarity in the series is between segregated and integrated education, embodied in the UK Education Acts of 1944 and 1981 respectively. The former distinguished between normal and handicapped children, categorizing the latter according to their medical and psychological defects, and providing for them (insofar as it was considered possible to do so) in separate institutions. Many children, considered ineducable, received no provision at all. Categories of handicap included maladjusted and educationally subnormal, which many understandably found offensive.

The 1981 Education Act followed the Report of the Committee of Enquiry into the Education of Handicapped Children and Young People (DES, 1978), under the chairmanship of Mary (later Baroness) Warnock. Subsequently known simply as the Warnock Report, this was commissioned by the UK government to review an area of education that was increasingly seen as unjust. Inspired by a wish to normalize children who had formerly been marginalized educationally, the Warnock committee argued that no child is ineducable, and characterized education in terms of a set of goals toward which every child without exception may aspire. These goals were independence, enjoyment, and understanding, and the idea was that every child without exception must travel down a path toward these common goals. The difference between handicapped and normal children was that the former encountered all sorts of obstacles on the path, whereas the latter traveled with relative ease.

This led to the idea that, instead of classifying some children in terms of their medical or psychological handicaps, we should think of them in terms of their need for help in reaching the common goals. The 1978 Warnock Report, and the Education Act that followed, recognized a universal right to such help, and the concept of a special educational need replaced the concept of a handicap. The right to help imposed on schools and local authorities a duty to provide whatever assistance is required.

The conceptual shift from handicap to special educational need was a defining moment in our ethical and political history. Instead of seeing some children as defective and others as normal, the idea was that every human being has needs, but some are more pressing than others. The aim was to emphasize our common humanity, in

terms of universal educational goals as well as our shared neediness and vulnerability.

This shift was formulated in terms of a series of linguistic proposals. Not only was handicap off the agenda; no longer were we to categorize children according to their deficiencies, for example, their inability to see, hear, or learn quickly. Instead, we were to talk about the difficulties (visual, auditory, learning, etc.) they experienced, and the Warnock committee's concern to avoid negative labeling is the background to a complex debate which continues to this day.

Inclusion Versus Integration

Despite the desire to normalize children hitherto seen as inescapably different, Warnock's conceptualization gradually attracted criticism. The labels might have changed, but labeling continued, and was the basis for special school provision. Warnock had been optimistic that the change in nomenclature would reduce stigma. Doubts were raised about this, and searching questions started being raised about our tendency to differentiate between children by labeling them (in whatever form), and providing for them in special schools.

An effect of the 1981 Education Act was a gradual decline in the number of children in special schools. Many were integrated in the manner recommended by Warnock, with statements of special educational need in many cases, bringing an entitlement to additional help. However, all was not well. Though need and difficulty are arguably less stigmatizing than handicap, a fatal flaw in these concepts – a flaw to which handicap is less susceptible – is their fluidity. There exists a broad spectrum of needs, from those which are impossible to ignore to those which are debatable or even indulgent. Indeed the advantage of the concept of need, from Warnock's point of view, had been precisely this breadth, which spans the normal/abnormal distinction. However, it is impossible to meet all needs, and questions arose about which needs impose duties and which do not. Children hitherto described as blind, now described as having visual difficulties, have obvious needs. Children who struggle to read, on the other hand, have needs that are far less clear: do they, in every case, need additional help, extra time in exams, and so on? Answers to such questions are not always forthcoming; not, at least, in a way that commands general agreement. This was a weakness in the conceptualization of special education, and the practical effect was an explosion in the numbers of children identified as having

special educational needs. Parents fought for this label, and the statements that often accompany it, in order to receive extra support. Of course, the more successful parents tended to be those with social and economic advantages, and special education gradually became a social justice issue.

In this context, special educational needs (SEN) was seen by many as a label with the power to secure disproportionate amounts of resources. When this label secured admission to a special school – far more expensive than additional help in the mainstream – the resource injustice was seen as even greater. As the policy of integration reduced numbers in special schools, questions started to be raised about how the existence of such schools was justified. Why not (people asked) use this money to enhance the capacity of mainstream schools to respond to diversity? Questions were also raised about why some children are seen as having special difficulties, and the answer that presented itself to many was that schools create and sustain these by designing their educational delivery around so-called normal children. An alternative approach would be to re-conceptualize schools around the concept of diversity, in which difference is seen as universal – every individual is different from every other – and no one is seen as normal.

This was the philosophy of inclusion, as distinct from the philosophy of integration, and it was first articulated by UNESCO in a document that became known as the Salamanca Statement (UNESCO, 1994). This was a proclamation by delegates from 92 governments and 25 international organizations for the World Conference on Special Needs Education at Salamanca in Spain. It says:

Regular schools with this inclusive orientation are the most effective measures of combating discriminatory attitudes, creating welcoming communities, building an inclusive society and achieving education for all; moreover, they provide an effective education to the majority of children and improve the efficiency and ultimately the cost-effectiveness of the entire education system. (Section 2, p. ix)

This was a new conceptualization of schools, and it marked a significant shift from the principles of the 1978 Warnock Report. It was reinforced by a conceptual shift that was being promoted by disabled people, from a medical to a social model of disability. In 1975 the Union of the Physically Impaired against Segregation (UPIAS) had written “It is society that disables people,” and this gradually led to the imperative to change society by changing schools. The medical and social models of disability underpin the inclusion debate as we know it today, and these will be discussed now.

Medical Versus Social Model of Disability

The distinction between the medical and social models of disability emerged as a question: where is disability

located? Is it located within individuals or within society? Disability Equality in Education (2005) says:

We believe that the problem is not in the child and their impairment, but in the social and attitudinal barriers in the education system. This ‘social model’ draws on the thinking of disabled people and underpins all inclusive education (T. E. S. 08.07.05)

Inclusive education is a social response to the medicalization of disability. Instead of seeing some but not others as deficient in various ways, the idea is that society makes some people unable to function as they are capable of functioning. Install ramps and lifts in buildings, and people in wheelchairs will no longer be functionally disabled. Change attitudes toward wheelchair users, so that they are perceived as having different rather than impaired mobility and are welcome in society, and we are talking about inclusion.

The shift from a medical to a social model is synonymous, for many, with justice and equality for disabled people. Yet it has not been immune to criticism, even from people with disabilities. Lord Low (2007), who is visually impaired, says:

If education is about anything, it is about influencing and indeed changing the individual child. One may do this by modifying the social environments in which the child is placed, but one cannot eliminate the individual dimension altogether. (p. 9)

Norwich (1996) makes a similar point:

...it is one thing to attribute the disadvantage of a disabled person only to individual characteristics, it is quite another to exclude the role of individual characteristics. (p. 27)

Many sociologists and educationists see the medical and social models as mutually exclusive, and the former as responsible for discrimination against disabled people. Low and Norwich suggest, on the contrary, that these models need to be combined in some way if we are to do justice to all children. However, the idea persists that the medical and social models are exclusive, and this polarization now extends to the question of educational placement.

It makes more sense to see placement as a matter of either–or than it does to see models this way. After all, children attend either a mainstream or a special school (although special units in mainstream schools break down this polarity to an extent). What makes less sense, perhaps, is the idea that schools either exclude or include children, rather as disability models are either medical or social. This idea implies that special schools are necessarily exclusive, in the sense of being discriminatory, divisive, and unjust. This suggests that inclusion/exclusion should be seen as a polarity between types of institution.

Inclusion (Mainstream Provision) Versus Exclusion (Special Provision)

The Salamanca Statement introduced an argument about rights, saying that every child has a right to an education, which will be most effectively provided for the majority in mainstream schools which adapt to children's diverse characteristics and needs. This proclamation was seized upon by defenders of the social model, who interpreted the right to an education as a right to an inclusive education, which is only possible in a mainstream school. This is not what the Statement says; indeed, it clearly states that in exceptional cases, children should be educated in "special schools or special classes within ordinary schools."

The right to an inclusive mainstream education is not universally accepted, and it is legitimate under such circumstances to ask: where does this right come from? By whom or what is it authorized? It is not a legal right, so if anything it must be a moral right. But it is one thing to claim such a right, another to establish it as trumping all other rights, and imposing duties on others. If it exists, the right to an inclusive mainstream education (understood as a trumping right) imposes a duty on all parents to seek this kind of education on behalf of their children. Those who fail to do this will then be seen as violating their children's rights. This idea is naturally found provocative by parents who feel that their children need a nonmainstream environment, and that they are doing the best for their children by sending them to special schools.

The right to an inclusive mainstream education imposes a duty on mainstream schools to provide for all pupils without exception, that is, to welcome them and adapt to their diverse needs. However, this is problematic, for it is far from universally agreed (indeed many seriously doubt) that it is possible for all schools to do this (see, for example, Pirrie and Head, 2007; Rogers, 2007a, b; Moore, 2007). Some children (e.g., those with social, emotional, and behavioral difficulties) are disruptive to the extent that they compromise other children's rights to an education. Others (e.g., those on the autistic spectrum) find mainstream schools a social nightmare; their difficulties are social and communicative, and they seem to require a quiet, ordered environment very different from that of a mainstream school.

The implied duty of mainstream schools to adapt to all children is not (logically could not be) a duty to do this successfully. At most, it is a duty to attempt to do this. Doubts about the possibility of achieving this are often met by the idea that inclusion is a process of learning to adapt to diversity which will not succeed so long as parents withdraw their children from the mainstream when difficulties are experienced (see Ainscow, 1993). This is, in effect, a loophole for failure. Failures include children who, because of their particular difficulties, feel more excluded than included in inclusive mainstream

schools, and are consequently miserable and unable to learn. Concerns about exclusion within inclusion were recently articulated by Baroness Warnock, and we turn to these now.

Inclusion (Feeling Included) Versus Exclusion (Feeling Excluded)

Concerns about children who feel excluded within inclusively orientated schools gave rise to what could be termed a counter-movement that defended special schools for some children and offered a definition of inclusion that was independent of mainstream provision. It was argued that the range of abilities and needs is so great that some children will inevitably lose out on an education in mainstream schools, however inclusively oriented. This does not mean that inclusion is impossible. Rather inclusion should be taken to mean, as the UK National Association of Head Teachers (NAHT, 2003) puts it:

a process that maximises the entitlement of all pupils to a broad, relevant and stimulating curriculum, which is delivered in the environment that will have the greatest impact on their learning. All schools, whether special or mainstream, should reflect a culture in which the institution adapts to meet the needs of its pupils and is provided with the resources for this to happen. (Quoted in Warnock, 2005: section 3, p 41)

Inclusive education means being educated, the NAHT paper goes on:

... in the most appropriate setting. This will be the one in which [children] can be most fully included in the life of their school community and which gives them a sense both of belonging and achieving. (Warnock, 2005: section 3, p 41)

In 2005, Mary Warnock published a booklet called *Special Educational Needs: A New Look*, in which she quoted the above passages from the NAHT paper, and argued that the concept of inclusion is a disastrous legacy of the 1978 Report. There was an outcry in the media and the special educational world. Educationists and disability activists accused Warnock of trying to segregate society, and she was attacked with particular vehemence by organizations like Parents for Inclusion who wanted to bring about the closure of all special schools by 2020. This organization exemplifies the idea that special is synonymous with exclusive in passages like this:

The 2020 Campaign is based on the experience of disabled adults who went to special education schools and colleges. They experienced abuse, isolation and failure that emotionally scarred thousands for life. End this shameful exclusion that ruins lives. (Parents for Inclusion, 2004)

In effect, Warnock was leading the way for a moderate philosophy of inclusion, as distinct from the universalist philosophy which seeks to place all children in the same schools. In her 2005 booklet, Warnock drew attention to certain groups, such as autistic children, many of whom, she said, are bullied relentlessly and suffer all the pains of the permanent outsider when placed in mainstream schools. She wrote:

The reality seems to be, in many cases, that [inclusion] is experienced as a painful kind of exclusion. (p. 43)

This is a new concept of exclusion – exclusion as a painful experience of nonbelonging – and it is one that is likely to be of particular concern to parents. Baroness Warnock was arguing for a new polarity, between feeling included and feeling excluded. She was saying that the former, rather than mainstream attendance, is an essential component of a good education.

This sensitivity to the feelings of children, and tendency to cast some as particularly vulnerable, was seen by universalists as playing into the hands of indulgent middle-class parents who favor selective education and expect more than their fair share of resources. Warnock spearheaded a deep distress among many parents (and, it must be said, many teachers too) about the neglect of some children, albeit a small minority, in the promotion of inclusive education. The distress had been mounting during the 1990s and early 2000s, and it came to a head with Warnock's 2005 publication. At the launch of this publication, disability activists tried to bar the entrance, and a parent who had been struggling against the closure of special schools openly broke down in tears. At the heart of the debate was a violent clash of views about the meaning of special schools. Are they lifelines for some, which any decent society must provide? Or do they represent shameful exclusion, as Parents for Inclusion were arguing?

It is against the background of such questions that we finally turn to the philosophy of inclusion. According to one argument, there is no inclusion in special schools. According to another, inclusion means being educated in the most appropriate setting, which has the greatest impact on learning, and this may be special or mainstream. Which is more defensible? In order to answer this question, we need to examine the values and assumptions at the heart of these positions, and ask what they imply about education.

The Inclusion Debate: A Philosophical Perspective

The debate about inclusion is a fierce debate about values. What values are in dispute? Are there any values about

which universalists and relativists/particularists? or thin and thick, weak and strong universalists? moderates agree? When they call themselves inclusionists, do they use that word with the same or different meanings?

In a recent publication (Cigman, 2007a) about the post-2005 inclusion debate, Brahm Norwich wrote:

It is rare to find arguments against inclusion, as it is rare to find arguments against democracy. Where disagreement lies is in the nature and extent of inclusion. (p. 71)

It is true that it is rare to find arguments against inclusion, but unless we understand the meaning of this term, it is possible that disagreements are misleadingly couched in terms of a single concept. We want to suggest that there is a common concept, a basic value shared by all those who support educational inclusion in some sense. Unfortunately, this common meaning is often buried in the heat and rhetoric of the debate.

Recalling segregation in the post-war period, it seems clear that one reason why there has been no call for a return to this system is that it is seen as demeaning to people who are cast as handicapped. Like sending children to secondary modern schools because they are deemed unintelligent, or to racially segregated schools because they are not white, the mandatory placement of a child at an institution that caters for abnormality is indeed education by deficit. Our objection to this is that it is deeply disrespectful, because it disregards the interest we all have in being accepted and welcomed in society. The shift to integration wherever possible acknowledged this disrespect, and tried to de-stigmatize groups that had suffered under such a system.

It gradually became obvious, first, that segregated education was often a matter of convenience rather than necessity, and second, that many people suffered terribly from the feeling of being excluded. Indeed, they were in a real sense excluded, particularly if they were unable to benefit from the kind of education that was offered to the majority of children. The barriers to inclusion (an expression now in frequent use by inclusionists) were an unwillingness to make appropriate physical or technological adjustments, and more fundamentally, negative or unwelcoming attitudes.

Philosopher Margalit (1996) has argued that a decent society is one "whose institutions do not humiliate people" (p. 1). Humiliation, he says, is defined as "any behaviour or condition that constitutes a sound reason for a person to consider his or her self-respect injured (p. 2)." We have argued (Cigman, 2007a) that our objection to segregated education – that is, the objection of most members of our society – is rooted in the sense that we do not want to belong to a society that institutionally humiliates its members. Post-war segregated schools did this, and their continued presence would have prolonged an indecency that we want no part of. What it means to

say that such schools institutionally humiliate their members is that children who attended such schools had a sound reason to consider their self-respect injured. This is not the same as simply feeling that one's respect is injured, which can be based on an exaggerated or misplaced sense of one's own dignity.

The shift from segregated to integrated education was widely welcomed because it accorded with the fundamental moral principle that every human being should be treated with unconditional respect. To send a child to a segregated school because her needs are difficult to deal with is to disregard her basic interest in being accepted as a member of society. This, many would argue, gives a person a sound reason to consider her self-respect injured, and the imperative not to do this lies, we submit, at the heart of the philosophy of inclusion. The recent history of inclusion is a history of divergent interpretations of this basic principle.

Interpretations are divergent because people disagree about what constitutes a sound reason to consider one's self-respect injured. Specifically, they disagree about whether special school placement constitutes such a reason. Universalists justify their argument that special school placement is inherently humiliating by saying that it is never really voluntary. It is and can only be chosen as the lesser evil in a society that fails to provide a properly inclusive education for every child.

However, there is a weakness in this argument. If someone chooses a special school, believing they do so freely, the argument that this was not really a free choice depends on the view that such a choice is in every case contrary to human interests. It can only be chosen, according to this view, insofar as the universally desired mainstream option is either unavailable or not inclusive enough. However, the mainstream option is not universally desired. This could be because a parent has selective impulses – she wants a better school for her own child than she is prepared to accept for other children – or it could be because she sees mainstream education as contrary to the basic interests of her child. Some parents argue that mainstream education is by its nature inadequate for some children, and good intentions will never overcome this. Furthermore, they experience the denial that parents can and should make judgments about the basic interests of their children as disrespectful.

We have written that the universalist position:

... is universalist in aspiration but not in meaning. It aspires towards a society in which *all* children attend mainstream schools, but it is based on an understanding of what special schools *mean* which is conspicuously unshared. (Cigman, 2007b: xviii)

The discrepancy between aspiration and meaning is a serious problem for the universalist position. To a universalist, special means exclusion, segregation, and humiliation.

To many others it means the only setting in which a child with particular difficulties may feel included and learn effectively. This difference of perspective should prompt a meta-question: how is the difference to be explored or negotiated? Instead of addressing this question, the universalist reiterates undefended claims, like the claim that every child has a right to an inclusive mainstream education.

This disagreement about the meaning of special is underpinned by a disagreement about the meaning of disability. The social model which underpins the universalist concept of inclusive education says that all disability is located in society, rather than in individuals. Philosophically, this disjunction is dubious. Wittgenstein's later philosophy (see, for example, Wittgenstein, 1953: *passim*) should make us wary of the idea that a concept like meaning is intelligibly discussed in terms of location. Practically, too, the social model is problematic, because it wrongly assumes that everyone is at ease with this interpretation of disability. In fact, the interpretation is disputed, not simply by professionals who seek gains from the medicalisation of disability, but also by disabled people themselves. The following is by a disabled woman:

... there is a tendency within the social model of disability to deny the experience of our own bodies, insisting that physical differences and restrictions are entirely socially created. While environmental barriers and social attitudes are a crucial part of our experience to disability—and do indeed disable us—to suggest that this is all there is to it is to deny the personal experience of physical or intellectual restrictions ... (quoted Oliver, 1998: 38)

Interestingly, this passage is quoted by Mike Oliver, a disabled activist, one of the first and most vociferous promoters of the social model. By quoting it, he effectively acknowledges the limitations of the social model and the possibility, as Norwich (1996) puts it (quoted above), that:

... it is one thing to attribute the disadvantage of a disabled person only to individual characteristics, it is quite another to exclude the role of individual characteristics. (p. 27)

To exclude the role of individual characteristics is to perpetuate the offence that the inclusion debate seeks to address: treating people with disrespect. It is disrespectful to deny people's personal experiences of bodily and mental restrictions. The anguish of children forced into mainstream schools is ignored in the service of a theory which says that all differences are to be subsumed under the heading of diversity. This exclusion of individual experiences has elicited outraged responses precisely because (according to my argument here) it is experienced as deeply disrespectful.

At the heart of the universalist position is denial of the dilemma of difference, according to which:

[w]e either treat all children as essentially the same, which means treating them as fairly as possible but with the risk of neglecting individual differences. Or we treat them differently, with the consequence that some are better off than they would otherwise have been, but there is a risk of being unfair by devoting more resources or expertise to some than others. (Cigman, 2007b: xxii)

Inclusive education is complex, conceptually, politically, and ethically, because it presents us with the conflicting values of fairness as equality and fairness as attention to individual or special need. This dilemma does not go away when a decision is made to emphasize the first at the expense of the second. Both values need due attention, and the way forward is to engage in good, respectful dialog between all interested parties, and pay proper attention to empirical evidence.

Glossary

Autonomy – Capacity for self-determination; ability to guide one's conduct on the basis of one's own judgment and reasons.

Care ethics – Moral theory for which caring relations between particular individuals are central to all morality.

Contractualism – The view that morality is best understood as based on a contract or agreement (actual or hypothetical).

Dignity – Moral status appropriate to autonomous beings.

Distributive justice – Fair allocation of social and economic benefits and burdens.

Empathy – Capacity to adopt the point of view of another, "put oneself in another's shoes."

Impartial – Give equal consideration to all without favoring some over others.

Original position – John Rawls's hypothetical choice situation in which parties, from an impartial point of view, choose principles of justice that will govern the fundamental institutions of society.

Particularism – View that denies a central role to moral principles and general rules in morality; moral attitudes display unmediated responses to particular circumstances, including unmediated concern for particular individuals.

Reasonability – Capacity and willingness to consider reasons others can share when evaluating and justifying actions, positions etc.

Respect – The attitude of recognizing the rights and dignity of autonomous agents; for many moral theories, the fundamental attitude toward persons.

Rights – Morally justified claim or entitlement that protects liberty or autonomy against interference from others, or provides justified expectation to assistance from others.

Sentimentalism – The theory that moral attitudes are grounded in emotions or feelings rather than in reason.

Universalizability – The principle that moral claims applying to any individual must apply to all whose circumstances are relevantly similar to those of the individual concerned.

Vulnerability – Personal features or circumstances making a person susceptible to unfair treatment or exploitation.

Introduction

It is not self-evident that justice and care are mutually exclusive. The contrary view is due to early proponents of the ethics of care (Gilligan, 1982; Noddings, 1984), who attempted to provide a radical alternative to what they took to be the traditional, male-dominated moral philosophy which they referred to as the ethics of justice. This is characterized by a commitment to universal rights, impartiality, disinterested evaluation, rationality, and to universal principles of conduct. The ethics of care in direct contrast embraces particularism, takes moral judgment to be motivated and informed by caring attitudes or sentiments, and is concerned about protecting and sustaining attachments and relations with particular individuals.

The justice–care debate emanates from this assumed bifurcation of moral perspectives. Engagement in the debate has been uneven. From the beginning, it has lacked a well-defined set of alternatives on which disputants could join issue, and many developments within the ethics of care have blurred what were initially presented as stark differences. Although debate talk cannot be entirely avoided in discussing the relations between justice and care given its centrality to the original formulations of care theory, it is important to keep in mind that questions of their conceptual relations are far from settled.

Justice has not lacked able defenders. It is widely recognized that John Rawls's *A Theory of Justice* is the defining work of contemporary political philosophy, setting its basic parameters and guiding its articulation and development. Social justice theory, its centerpiece, focuses on the most basic and formative institutions of society (social, political, and economic), which exert pervasive influence on the choices, life prospects and opportunities of individuals. Its central aim is to specify principles concerning the conditions under which the basic structure of society is just, ensuring that activities that they regulate result in just outcomes, or, as Rawls puts it, that the burdens and benefits of social cooperation are fairly distributed. Principles of justice define the fundamental terms of association, agreement, and forms of social cooperation which regulate and determine the distribution of wealth, income, goods, and opportunities. In addition, they mediate both intimate and nonintimate relations between people, providing the means by which they discharge at least some of their moral duties to one another. For Rawls, this requires that the principles be endorsable by free, equal, reasonable, and rational people. For our purposes, the

salient features of Rawls's theory of justice are its commitment to moral equality, respect for the dignity of persons through recognition of rights, the moral constraints (within which individuals may pursue their interests and principles) that determine the fair distribution of benefits and burdens of social and economic activity, and reasonable agreement as the central method of justification.

Against this background, the ethics of care stands out as a radical approach to morality that challenges traditional positions not only on substantive matters but also on what is involved in moral thinking and experience. It rejects the priority of justice and favors particularist values on the ground that personal relationships and attachment are much more significant than relations with strangers, and accordingly that establishing and sustaining such relationships should be taken as far more important, morally speaking, than co-coordinating interests or resolving conflicts impartially on the basis of principles. For the ethics of care, morality is based, not on principles, but on unmediated relations with others, and its main concern is the welfare, rather than the moral powers, or dignity, of others. Moreover, some care ethicists suggest that this contrast marks a gender divide: men and women tend to conceive morality in different ways. The former are drawn to autonomy, rights, justice and the latter to connection and caring.

These seemingly abstract concerns raise many questions central to moral education. Given its traditional emphasis on autonomy and critical thinking, moral education derives much of its impetus from the ethics of justice. For example, civic education emphasizes the inculcating of capacities required in order for individuals to fulfill responsibilities and enjoy the rights of democratic citizenship. Autonomy, civic toleration, and a critical attitude toward contending political claims are deemed essential for participation in liberal society (Gutmann, 1995). These competences and virtues are also seen as inherently valuable or at least instrumental to the well-being of individuals (Nussbaum, 2000) and therefore central to moral education. Epistemic capacities like knowing how to think and reflect critically and being aware of nonrational influences on processes of belief formation have the dual effect of enhancing both personal well-being and the performance of civic responsibilities. Requirements of justice (arising especially from equality of opportunity) have also structured deliberations about educational resources and their distribution (Brighouse, 1998). The outcome of the debate, or at least developments in response to challenges to traditional moral philosophy from the ethics of care, thus has repercussions for moral and political education. If, on the one hand, the ethics of care replaces traditional concerns of justice, then corresponding upheavals in philosophy of education can be expected to follow. If, on the other hand, an integrated theory of justice and care ethics is attained, this would encourage a richer account of such entrenched concerns in philosophy of education as

the aims of moral education, the grounds of authority or legitimacy in education, and the distribution of educational resources.

The Ethics of Justice

Conceptions of Justice

The formal notion of justice (people should be treated equally unless there are relevant differences between them) and its correlates, namely impartiality (like cases should be treated alike) and reciprocity (others should be treated as one would expect to be treated by them), have a long pedigree, going back at least to Aristotle. Rawls's work preserves the core of this conception, while specifying it in terms of principles of fair distribution of the benefits and burdens of social life.

For Rawls, justice, the first virtue of institutions, is about securing fair terms of participation in a society made up of inescapably interdependent members. His conception of justice, formulated as two ordered principles, is tailored to (1) guarantee fundamental individual liberties, assigning them inalienability and absolute priority, and (2) embody an egalitarian ideal of social cooperation based on reciprocity, ensuring fair equality of opportunity and demanding that any inequalities benefit the worst off.

Thus construed, justice provides each person with the conditions and resources required to meet one's fundamental interests, to develop and exercise one's fundamental capacities (moral powers of free, responsible, and rational agency), and to realize one's conception of the good. The first principle secures that status of equal citizenship, and the second, fair opportunity and adequate resources for all.

The Argument for Justice as Fairness

In order to establish the legitimacy of these principles, Rawls employs a contractualist argument to show that they would be agreed to by reasonable people under fair conditions of choice. He describes a hypothetical original position in which parties to the agreement (representatives of actual individuals) operate under constraints on choice (corresponding to exclusion of information about morally irrelevant individual interests) with the result that they have no option but to consider matters from the point of view of all, thereby making decisions and choices that are fair.

Since the original position is merely hypothetical, Rawls addresses separately the question of whether the principles adopted in the original position are realizable. To this end, he provides an account of how citizens in a well-ordered society come to acquire a sense of justice. Contrary to what many of his critics allege, the account is not solely or even largely rationalistic. Central to learning to appreciate the point of view of others and developing

virtues of impartiality and considerateness, and ultimately a sense of justice are the love, trust, affection, and guidance experienced in the family. Reciprocity, according to Rawls's account of moral psychology, is contingent on experiencing and recognizing that others intend our good. On such experiences the desire to reciprocate, the desire to form attachments to persons and institutions, and social cooperation are based. For the purposes of this article, it is important to note the emphasis Rawls places on forming of attachments for the development of commitment to the moral point of view and the availability of a common vantage point from which fundamental political issues can be addressed by citizens in a reasoned and principled way.

The Ethics of Care

A Different Voice

The ethics of care at its inception was a predominantly feminine or feminist approach aspiring to foreground women's moral experience in developing a distinctive moral philosophy. Gilligan's founding work did not target Rawls or other theorists of justice directly but was a response to Kohlberg's canonical six-stage theory of moral development (which presented the morality of justice as the highest stage). Gilligan questioned Kohlberg's assumptions and conclusions, in particular, his finding that the ultimate stage of moral maturity involves a contractarian respect for persons, embracing and applying general principles, and taking fairness and rights to be fundamental values, and his relegating moral evaluations based on caring and relationships to a lower stage of development. She took these judgments to reflect a bias in favor of male values, interests, and psychological proclivities. Kohlberg's procedures and findings, Gilligan argued, captured the male approach to moral judgment but not the female voice of care, responsibility, and connection with others.

For the ethics of care, responsibility and relationships rather than rights and rules are central and these are inextricably bound to concrete circumstances and contexts. The ethics of care thus focuses on caring relations and on responsiveness and attentiveness to need, while the ethics of justice, concerned as it is with mediating and resolving conflicts, takes as central fairness, equality, individual rights, and abstract principles. Although Gilligan holds both to be normatively adequate, they are not compatible because moving from one to the other is like effecting a gestalt switch. A problem is construable either as one of justice or one of care, but not both.

The Particularity of Caring

Noddings' starting point is that traditional moral philosophy neglects people who, due to personal or social

circumstances, have not been able to attain the status of autonomous agents and so offers at best a partial treatment of central issues of the moral life. She seeks to remedy this by providing a permanent place within moral theory and practice for the cared for.

This leads her to deny that principles and rules are central to morality. Traditional ethics, centered on moral reasoning and the establishment of principles, employs the language of the father evidenced by the centrality of justice and fairness. It fails to recognize that sympathy or empathy feeling with the other, is the wellspring of moral conduct. Sentiments of natural sympathy are the fundamental source of moral conduct and the caring relation is both morally and ontologically basic (the desire to maintain and recapture the most caring moments undergirding the ethical ideal). Caring is rooted in receptivity, relatedness, and responsiveness, the feminine alternative to Kohlberg's last stage.

The radical nature of Noddings' position stems from her rejection of all general elements and procedures, both rationalist and sentimentalist. The ethical relationship is not an expression of universalizability or general benevolence, but is a relationship between two parties and two parties only: the one caring and the one cared for, a concrete process of caring for distinguishable from generally caring about. It involves actual people, who, in order to achieve caring for, need to fulfill specific requirements: on the part of the one caring, of engrossment in the other (e.g., empathizing with her, stepping into her frame of reference, and being concerned for her welfare) and on the part of the cared for, requirements of recognizing and responding to caring. In this scenario, principles are not only redundant, but also obstructive, since the essential elements of caring are located in the relation between the one caring and the one cared for. The desired moral response should be immediately elicited in attending to the cared for. Any moral decision making requires concretization rather than abstraction.

Noddings shuns talk of moral justification. She says that caring itself and the ethical ideal that strives to maintain and enhance it guide us in moral decisions and conduct. The marks of ethical behavior are feeling, thinking, and conducting oneself as the one caring. In part, ethical conduct is determined by one's actual receptivity. One is irredeemably evil when one intentionally rejects the impulse to care. Justice plays an ancillary, second-best role: it is needed only when it is impossible to exercise caring for. Noddings furthermore insists that the ethics of care can provide alternative notions of reciprocity and obligation based on the relatedness of caring, and so does not have to make concessions to the ethics of justice in order to account for these admittedly important elements of morality.

A Conflict?

Proponents of justice are inclined to assume or assert that care and justice are compatible, while adherents of the ethics of care tend to deny it, presenting care as a comprehensive ideal that provides answers to all moral and political questions. This section examines the issue by considering four points of conflict alleged by care theorists:

1. Care ethicists point to the different moral psychologies adopted by the two positions. The ethics of justice foregrounds rationally grounded, universal moral principles applied impartially across cases, while the ethics of care centers on empathically informed responsiveness to particular situations. Reservations about abstract reasoning in the moral domain range from meta-ethical concerns about adopting universalizability (understood as mandating uniformity and so excluding partial judgments based on empathy, caring, and connection) as a fundamental principle in moral reasoning, to worries that abstraction, while posing as a universal value, promotes the interests of dominant, male social agents. These suspicions are extended to justice and rights.

In response to this alleged conflict, Okin (1989, 2004), Herman (1993) and others have argued that the contrast between the reasoning employed in the two approaches is overdrawn, and is often based on a misconstrual of theories of practical reasoning. Proponents of universalizability do not deny the role of particular judgments in moral reasoning, recognizing that it involves identifying more restricted principles for application of abstract ones, and requires particular, contextual details. There is ample room for contextually sensitive elements to play a determining role in moral judgment. On the other hand, principles are indispensable to isolating morally salient features of a situation. For example, many instances of caring in the descriptive sense are clearly intrusive, abusive, or exploitative (Friedman, 1987). To determine whether an activity constitutes caring in the moral sense, it is not sufficient to rely only on the intentions or avowals of the caregiver. Engrossment is not self-authenticating; it cannot identify the normative features of a situation.

2. Impartiality, widely taken to define the moral point of view, is believed by care theorists to endanger attachment, and so requiring it is not only psychologically burdensome but also morally deleterious (Slote, 2007). Read as proscribing special obligations to intimates and associates, it leads to a morality that ignores the central importance of interpersonal relations in our lives, undervaluing love and other intimate feelings. The biases inextricable from empathy, for example, in favor of dealing with those in spatial and temporal proximity, favoring one's own children, are precisely

what make considerations morally salient. On this matter, it might appear that there is a real dispute between justice and care ethicists. However, on closer consideration, evidence of a deep divide evaporates. Moral philosophers who support impartiality are concerned to defend it as a second-order criterion, that is, one to be applied to the basic rules and principles of morality and justice, while care theorists attack it as a first-order criterion which most justice theorists would not want to defend (Barry, 1995).

3. The justice perspective conceives of individuals as autonomous, that is, responsible for and in control of their own lives, and as equal members in a moral community. This, some care theorists allege, reflects an erroneous view of human nature and circumstances based on male stereotypes of self-reliance. It reflects a failure to recognize human dependency, the prevalence of involuntary relations between people and, indeed, of the fact that individuals do not create themselves. In devaluing connectedness in favor of separateness, it fails to recognize that ethical activity is unmediated by general principles and inextricably bound to particular relationships. However, objections along these lines are at least partly due to misunderstanding of the thesis of separateness of persons, which is advanced by theorists of justice against the utilitarian move of aggregating individual interests, allowing individual benefits to be sacrificed for collective ones often without restriction. Its advocates (see especially Rawls) make it clear that separateness is meant neither as a metaphysical thesis nor as a rallying cry for self-reliance, and hence that autonomy does not necessarily imply sociological atomism (Okin, 2004).

It is difficult to see how the claim that autonomy is detrimental to caring can be upheld or how an adequate conception of care could jettison autonomy. Effective caretaking requires both that caretakers be autonomous and that the autonomy of the ones cared for be recognized and respected as well (Grimshaw, 1986). In short, respect for others is a non-negotiable requirement of adequate care (Friedman, 1987).

4. A central claim of early care theorists was that the ethics of justice ignores or does not take up the perspective on morality peculiar to or favored by women, resulting in their marginalization and exclusion from decision making in the public domain. But the ethics of care has itself occasioned feminist concerns. Its uncritical acceptance of all self-described relations of caring as ethically valuable puts it in danger of perpetuating existing gender inequalities, making a virtue of the contingent fact that women have borne the burden of caring in society. Moreover, the commitment to particularism has meant that even if care theorists were concerned about structural inequalities involved in discriminatory systems, they would not have the

resources to address them. Sensitivity and responsiveness to need alone seem too slight to handle social problems such as domestic violence and coercion or broader issues of structural inequality. The restriction to relations between pairs of interacting people, and the insistence on contextuality seem to limit care to a personal ethic concerned with meeting individual needs and maintaining particular relations in concrete situations.

A Possible Synthesis: Extending the Boundaries and Justifications of Care

The most recent general discussions of the ethics of care, presaged by important work by Tronto (1993), reflect a willingness to explore common ground with more traditional approaches.

Recognizing that care requires resources that are available only within the framework of appropriate institutional structures, Tronto argues that it cannot be confined to relations between pairs of individuals but must be located in a wider social and political context. This also counters the perception of the work of care as exclusively, except in the private sphere, concerned with the marginalized and needy, which has had the effect of foreclosing questions about the just distribution of care work.

Tronto responds also to what she deems the normative deficit of early-care theory by focusing, in analyzing care, on questions of justification. Disavowing one of the characteristic claims of the first wave of care theory, namely that the ethics of care is incompatible with universalistic moral reasoning or considerations of justice, she asserts that caring well involves making complex moral judgments for which wide-ranging considerations are relevant. Care and justice are not conceptually opposed or incompatible, nor do they hold sway in exclusive domains (private and public, respectively). Rather, they are complementary, neither being complete without the other. The role of care theory is to frame issues that justice has identified more concretely and immediately by drawing attention to dependency as a universal feature of human existence. It should inform practices of democratic citizenship through attentiveness to needs and augment the set of liberal values (rights and due process) making citizens more thoughtful, aware, and in short, better democratic citizens.

The trend evident in Tronto's work to bring the ethics of care into closer interaction with standard moral theories is advanced in the most recent literature in care ethics (e.g., Held, 2006; Slote, 2007; Engster, 2007) all of which develop aspects of her programmatic reconstrual. The notable shift in recent discussions of the ethics of care allows universality to be recognized as central to moral justification, endorses the augmentation of its scope to the public domain, is skeptical of the dichotomy of reason

and emotion, and treats justice, rights, and autonomy as indispensable moral concepts, without relegating care to a subordinate role. Several theorists (Held, 2006; Slote, 2007) argue that the capacity to care and be cared for provides a preferable criterion of moral status to autonomy, the candidate of choice of traditional universalist theories. Some also hold that care is the more inclusive, or causally fundamental notion (Held, 2006; Engster, 2007), presupposed by justice, rights, and autonomy (but not vice versa). Respectful relationships, required by justice, depend on a social fabric of trust and connectedness; families and intimate relations more generally are bases of wider social cohesiveness.

Reclaiming these foundational liberal concepts also involves reconceptualization in terms of care theory. This may involve a curtailing of their form or scope: for example, Slote (2007) argues that the liberal account of autonomy should be significantly weakened to exclude the requirements of critical vigilance of one's ends, because this puts at risk relationships and feelings. More positively, a distinctive care theory of obligation that focused on vulnerabilities stemming from dependency rather than promoting freedoms could lead to an augmented theory of obligation better able to protect directly activities aimed at meeting basic needs and functioning such as education and health-care (Engster, 2007; Held, 2006).

Educational Applications

Contemporary moral education has been strongly influenced by justice-oriented positions. Hence, the focus has been on the twin concerns of fair distribution of educational resources guided by the goal of ensuring equal opportunity, and on what justice requires of educational practice, in order to support and sustain a culture of justice, namely the developing of autonomous and well-informed citizens of a constitutional democracy. Care theorists maintain that the latter emphasis especially has been detrimental to the cultivation of responsiveness and receptivity. Noddings' proposals for pedagogical reforms of the educational system aim to rectify this. The goal of education is to produce caring people. Teachers should model caring behavior by interpreting and reflecting students' conduct in the best possible light. In addition, they should ensure that assignments cater to their interests so that they are willingly received and executed. At the policy level, curriculum requirements, especially in middle and high school, should not force students to take classes they do not find interesting, for example, algebra and geometry, but should reflect the dominance of care, both with respect to content and organization.

These reflections usefully emphasize a (recently) neglected but important pedagogical concern, namely the manner of education. Attentiveness and sensitivity no doubt enhance the experience of learning. But the suggestion that students'

responses be the sole criterion of adequate teaching, and that their current interests be allowed to determine the content of the curriculum raises legitimate concerns, not the least of which is that it is unlikely to result either in the development of crucial capabilities or of caring tendencies.

Later-care theory, in extending its scope, and accommodating autonomy, allows for more promising applications. Its recognition of dependency and vulnerability highlights the development of basic capabilities and functions as crucial preconditions both of well-being and the development of autonomy. Its insistence that those in authority meet standards of empathic care should have a salutary impact both on pedagogical practices and on educational results. Empirical research (Eisenberg, 1992) suggests that children who are treated respectfully display both responsibility for their behaviors and caring tendencies as opposed to those treated in an authoritarian manner who tend to behave heteronomously and have little empathy with others.

A synthesis may be expected to yield theoretical results as well. Improved accounts of both autonomy and dependency in moral development, avoiding, on the one hand, excessively strong construals of autonomy, and on the other, counterintuitive claims that assumptions of inevitable dependency should drive educational thinking, would focus on the common ground of capability development as a central educational aim. One way of putting the point is that autonomy-facilitating education would be a (circumscribed) part of capability-facilitating education (Engster, 2007; Nussbaum, 2000; Brighouse, 1998).

With respect to broader issues like the distribution of resources, the case for synthesis is even more obvious. From the perspective of theories of justice, education is privileged because it is crucial for equality of opportunity. This is attainable only if children are provided with access to institutions that foster the development of the capacities that enable them to live rich and rewarding lives, including autonomy-related ones. A broader-based ethics of care, concerned with providing an education that develops central capacities with the aim of ensuring that people do not suffer avoidably from their vulnerabilities, would, in practice, support justice-based endeavors.

Lifelong Learning

Policies for Lifelong Learning

The concept of lifelong learning seems to be unproblematic. It has been theorized extensively by Dewey (1966) and others concerned that too much emphasis is placed on learning at school and too little on learning in other places and at other times. The concept became problematic when it formed part of the focus for educational and social policy in the 1960s. It became unclear whether lifelong learning was the same as lifelong education or whether a new term was required which referred to a desirable type of society which came to be known as a learning society. It also became unclear whether the concept referred to learning beyond school or as a new type of master concept which transcended the preschool, school, postschool sectors of education altogether. Wain (2004), who is an important current theorist of lifelong learning, terms these references the minimalist and maximalist conceptions, respectively. As contributors to Aspin *et al.* (2001) note, inevitable conceptual conflict was present from the introduction of the concept of lifelong learning into social and educational policy worldwide.

In the first section of the article, some origins of policies for lifelong learning are explored. It is argued that policies with a humanistic concern for social justice shifted toward economic rationalism and the idea developed that lifelong learning primarily equips people with the skills needed to compete in a globalized and supposedly ever-changing series of workplaces. The section explores some of the issues arising from this shift, including the issue of whether lifelong learning should be more than an enhanced form of adult education (the minimalist conception). The section also explores whether such learning might be seen as the basis for a different kind of society within which a range of established dichotomies are no longer appropriate. For example, a humanistic concern with social justice need not necessarily be opposed to a concern with economic efficiency. Formal and informal learning, school and postschool institutional structures may be reformed (the maximalist conception).

The concept of lifelong education was proposed by both the United Nations Educational, Scientific and Cultural Organisation (UNESCO) and the Council of Europe “as involving a fundamental transformation of society so that the whole of society becomes a learning resource for each individual” (Cropley, 1979: 105). The vision outlined in the Faure Report *Learning to Be* (UNESCO, 1972) was that well-organized lifelong education would enable

all citizens to participate fully in a more just and egalitarian society. The Council of Europe saw lifelong education as a means of promoting European integration through preservation and renewal of the European cultural heritage. Both preservation and renewal were seen as public and private goods realized through new forms of educational provision. For UNESCO and the Council of Europe during the 1970s and early 1980s, the main focus for policies concerned with lifelong education was greater social justice.

Through such policies the concepts of lifelong learning, lifelong education, and a socially just learning society became conflated. The operational details of policy which depended on these concepts were not clear and a minimalist conception of lifelong learning prevailed. The term lifelong learning came to be used as an umbrella term for all those sectors of education not primarily concerned with compulsory schooling – further, higher, recurrent, adult, continuing education. Primary and secondary schooling was not generally conceptualized under the lifelong umbrella.

Education and learning are not the same however and a socially just society is not necessarily the product only of education or learning policy. Forms of learning are not equally worthwhile and as a minimum educational requirement it is important to have some idea of the kind of things that are worth learning. Politically too it is important to have some idea of the kind of things that are worth supporting with public money and other things that are best left to private preference. Moreover while lifelong learning might be seen as a means of countering the exclusion suffered by those who do not succeed at the school curriculum, such a vision depends upon there being a system of qualifications that values learning beyond school as much as learning in school. The so-called academic vocational divide may be seen to be based on the difference in value placed on what are often supposed to be two types of learning. This supposition persists, further complicating the conceptual complexities that surround a humanistic conception of lifelong learning. For many people success in an academic curriculum at school forms the gateway to successful and rewarding work whereas for others success in vocational subjects after school does not.

At the same time as these humanistic conceptions of lifelong learning were becoming embedded within the policy discourse at an international level, neoliberalism was gaining increasing political support in Britain

and elsewhere as a guide to education policy in general (Halliday, 1990). The idea that globalization produces such rapid changes in the world of work that learning must be ongoing to cope with it offers an attractive alternative and superficially coherent conception of lifelong learning which appears to bypass the distinction between education and learning. From around the early 1990s, this alternative conception has come to the fore.

According to this conception, it is the individual's responsibility to learn throughout life so that they and the State may prosper economically. Yet the learning opportunities on offer are largely controlled for them within a minimalist conception of lifelong learning. The market in which they are supposedly competing is also beyond their control according to the logic of globalization. The question of what to learn seems to be answered in terms of what the market requires. However of course, the requirements of the market must be unknown according to this conception which depends upon belief in an uncertain globalized future. Hence, this conception has been subjected to some serious sustained criticism.

Conceptions of lifelong learning are highly contested and normative. They necessarily involve ideas not only of what should be learned but also the type of society learning is supposed to encourage. The replacement by economic rationalism of the normative force of the earlier humanistic conception of learning for social justice is seen by many (Aspin *et al.*, 2007) to be in need of urgent reversal. A strong theoretical attempt has been made to reclaim the concept of lifelong learning from its neoliberal dominance within current policy in some parts of the world. There is by no means one common voice however. For example, British neoliberalism may be contrasted with French humanistic approaches. Social justice and economic efficiency are not necessarily incompatible goals for policies concerned with lifelong learning and in the following section a summary of the work of some leading social theorists is given in an attempt to show how they might be reconciled.

While none of the major theorists whose work is discussed in the following section is primarily concerned with the concept of lifelong learning or a learning society, they do shed light on how these concepts could become embedded within the kind of society each theorist thinks is desirable or possible. Wain (2004) is one among many (Usher and Edwards, 1994) who argue that today's world is in a postmodern condition and that in order to make sense of the concept of lifelong learning, it is necessary to see how the modernist assumptions of many current education systems are irrelevant to postmodernism. Hence for Wain (2004: x), it is necessary to move beyond modernist assumptions in which social justice and economic efficiency are seen as competing goals and to look instead at "the postmodern turn towards a non ideological world (with the collapse of any viable alternative to capitalism

and liberal democracy)." For this task Wain examines the work of some leading social theorists and a summary of part of his examination is given below.

MacIntyre's Educated Public

MacIntyre diagnoses a crisis in modernity as an inability to reconcile two tasks set for modern education systems: that of socializing the young and that of rendering them autonomous individuals able to go beyond and contribute to the reordering of that society, independent of it. He contends that the two purposes are only possible where there already exists what he calls an educated public or what others would call a learning society. For MacIntyre (1987: 18) such a society requires the existence of "a tolerably large body of individuals educated both into the habit and the opportunity of active rational debate, to whose verdict appeal is being made by the intellectual protagonists" and who "in their communication with one another . . . must recognise themselves as constituting a public". It also requires "shared assent, both to the standards by appeal to which the success or failure of any particular thesis or argument is to be judged, and to the form of rational justification from which those standards derive their authority" (MacIntyre, 1987: 19).

His notion of a practice is central. This notion provides an answer to the question of what ought to be learned. Learning a practice is similar to an apprenticeship and MacIntyre (1981) recognizes that there are many examples where people learn to do things under decreasing supervision of a master who provides the standards and whose authority must be recognized for learning to take place. The aim of such apprenticeship is to enable learners to come to love the practice so that they engage in it for the sake only of achieving the excellences internal to it and not primarily for some external reward. Practices do however enable economic productivity as many practices form the basis of paid work. Rather than completing a job in the minimum time compatible with being paid, a good practitioner completes a job with due regards to the standards of excellence internal to that practice. In many cases, it would mean that in the long term remuneration from the work is increased.

The rules and standards of the practice are not fixed however. Practices have traditions. Moreover, no one is just one type of practitioner. Rather at any time people should seek to raise the standards of excellence within practices in which they are involved still higher. A sense of purpose provides the learner with a life that has the unity of an unfolding narrative for MacIntyre. On MacIntyre's view, there cannot be one set of practices into which all learners can be initiated for practices themselves are varied and localized. For him a learning society could consist of a number of small-scale learning societies each with its own

forms of practical reasoning about the ends to which it should serve.

In this way, MacIntyre wants to preserve contesting voices in a pluralistic world yet enable them to communicate with each other and theorize each others purposes and methods. The spirit of such communication is conflict and combat, and the framework of communication to be sought is one of constraint and agreement to disagree on fundamentals. MacIntyre's work is highly relevant to theorists of lifelong learning because only a small number of practices can be learned at school. Communities themselves including working communities provide opportunities for learning far more. It is through practices that the dual aims of enculturation and independent practical reasoning can be achieved and a conception of social justice realized that depends upon the recognition that others are bound to differ in their view of the human good.

Habermas

Unlike MacIntyre, Habermas is sympathetic to both social democratic liberalism and modernism through the recovery of a critical public sphere. For Habermas (1988) late modernity is characterized by an increasing colonization of what he calls the life world of ordinary people by the system world of economic and political institutions. Like Dewey, he thinks that the dominance of learning at school is unhelpful and that such learning is part of the system world. He would like to see a reversal of such colonization. He argues for what he calls communicative action guided by a hypothetical notion termed an ideal speech situation. An ideal speech situation is one in which all participants have equal access to the decision-making arena and truth is determined through rational argumentation alone. Even though such a situation is hypothetical, the fact that it can be envisaged is sufficient to provide normative criteria for what a desirable society would be like for Habermas.

Habermas sees the increasing systematization of the life world as being in the interests of economic efficiency but going against a view of a socially just democratic society. For him, theory and the culture industry have come to act together to obliterate the need for a critical public sphere. Habermas (1989: 47) sees the media not so much or at all concerned with informing a critical public sphere as catering for increased sales driven by the need for relaxation and entertainment. The culture industry "produces suitable material for every taste and ability rather than upgrading the abilities of those previously excluded from it" (Habermas, 1989: 166). In this way, publicity loses its critical function and the possibility even for schooling to combat the pernicious effects of the media is unlikely. What is needed is some means of establishing or re-establishing a

critical public sphere within which rational debate and argumentation can take place.

Habermas has come to accept the idea of multiple publics and that the system and life worlds are dynamically interdependent. He holds on however to the necessity of a deliberating critical society that

no doubt abounds just as much in conflicts and meaning generated forms of life. . . . a secularised society that has learned to deal with its complexity consciously and deliberately. . . . the communicative mastery of these conflicts constitutes the sole source of solidarity among strangers – strangers who renounce violence and, in the cooperative regulation of their common life, also concede one another the right to remain strangers. (Habermas, 1998: 308)

For this to happen, Habermas relies upon an undisturbed life world capable of wild initiatives which disturb the system world. For Habermas and others (Field, 2006), it is through unpredictable informal initiatives that a learning society in the form of a critical public is enabled. While it might seem fanciful to expect that governments could actually promote the taking of wild initiatives out with the sphere of formal educational institutions, it could be hoped that governments might do nothing to discourage their formation and development, that is, what Habermas means by undisturbed subjects. Wain (2004) points to Japan as an example of a society with a government that supports forms of informal learning through exemptions, financial assistance, tax breaks, and other policies.

In Britain and elsewhere, the Japanese example has not been followed. Rather the possibility for informal learning depends crucially on how much money individuals have to support their learning. Those who already have acquired sufficient money through the primary opportunity to secure positional advantage through school-based examinations are in an excellent position to take advantage of opportunities for learning beyond school. Others are not in a financial position to do this. What has been left out is the Deweyan idea that learning together educates and what emerges according to Field (2006) are successive attempts to govern lifelong learning rather than letting it grow. A concern with social justice only features in policies for lifelong learning to the extent that an economically prosperous society is more likely to be a socially just one through government intervention. Such intervention is not likely to encourage the disruption of the system world by the life world however. Rather it may lead to what Wain calls a panopticon society.

A Panopticon Society

A panopticon is a structure which enables people to be incarcerated without knowing when they are being watched. In effect they may not be being watched at all but the

possibility that they might be is sufficient to deter them from doing something that is not considered normal. The possibility that the absolute power of government can be released upon individuals at any time is sufficient to convince most of them to accept the normalization required of them. If they should do the unexpected, then an educational institution serves to correct the deviation from the norm. Foucault's (1977) description of the emergence of modern institutions such as educational institutions may be seen precisely as a way governments seek to prevent the disruption of the system world. Whereas informal learning always risks such disruption, mechanisms of curriculum development and management within institutions control formal learning.

There are three primary techniques of control: hierarchical observation, normalizing judgment, and the examination. Within educational institutions, control can be maintained through forms of panoptic incarceration which disables people from knowing when they are under observation. Thus, they must act as if they were being observed. Moreover, they can be judged against what is regarded as normal through a series of techniques of which the examination or formal assessment is most powerful. For those who fail at such examinations, records of achievement can be used as means of getting them to confess what they thought they should be knowing and measuring themselves up against the criteria that they have set for themselves (Usher and Edwards, 1994). The record of achievement may be seen as a powerful means of surveillance of formal learning. It formalizes the informal through detailed records of the extent to which people are normalized into what is expected of them by the system world, that is, in contrast to encouraging the disruption of the life world by resisting the tendencies to formalization. While theoretically both maximalist and minimalist conceptions of lifelong learning can provide specific challenges to the normalizing agenda began at school, a maximalist conception is more likely to do so.

Theories of Learning

Sfard (1998) argues that two basic ideas have underpinned many theories of learning. The first is the idea of learning as acquisition and the second is learning as participation. Learning as acquisition dominates schooling. The idea that children should go to school to acquire knowledge, skills, and attitudes that will help them cope with later life and earn a living in a productive way is deeply held. A maximalist conception of lifelong learning challenges this idea however. The idea that people learn through participating at work, at home, in pastimes of various kinds, through relationships throughout life seems much more appropriate. The former idea is based on an even more fundamental idea that it is first necessary to acquire something in order to live. The latter is based on the idea

that living itself under the right conditions is educative (Dewey, 1966). On the latter view education is not so much a matter of a state of socially approved knowledge, skills, and attitudes. Rather it is a characteristic of a type of journey.

On the former view products are acquired in relatively standard contexts of school or other types of educational institution. These contexts follow fairly standard patterns of tables, chairs, paper, computers, pens, books, and so on. On the latter view learning takes place in a myriad of settings involving a multiplicity of tools artifacts and special relationships. Learning as participation emphasizes contextuality. It also emphasizes the important role of judgments in effecting successful action. Very often, learning is not written down or expressed verbally. Rarely does it make sense to say that something has been acquired.

For Hager and Halliday (2006) a recovery of informal learning for everyone is essential both for economic efficiency and social justice. These researchers develop a theory of informal learning as "a developing capacity to make sound contextually sensitive judgements." For them learning is best enabled when the learner has opportunity to participate in a wide range of practices which involve the multiplicity of artifacts and tools previously mentioned. If formal learning is defined as that which takes place intentionally within educational institutions of one sort or another, then creating opportunities for informal learning is central to any robust account of lifelong learning in the maximalist sense. Arguments in favor of such recovery including the ones advanced in this article are widely supported (Coffield, 1999; Field, 2006). Yet such arguments are often resisted at the policy level. It is worth speculating why this might be the case.

First, the idea that things can be learned once and for all in a relatively stable context for future application in a multiplicity of contexts appears economically efficient, enables control of what is learned, is amenable to standardized forms of assessment, and enables a dominant economic rationalist view of learning. Second, it is much easier to provide mechanisms for accounting for public money when a supposed product of public investment can be measured and tested. Third, the metaphor of learning as acquisition is firmly embedded within ordinary discourse and there is some agreement on the kind of things that ought to be learned in formal educational institutions. Even if resources were redirected away from formal learning toward providing opportunities for informal learning of a variety of sorts, the question would arise as to what kind of opportunities should be provided. It is possible to learn to be a bricklayer or a thief – which is most worthwhile? To put the question less provocatively, should the state provide public money to provide opportunities for a few people to learn to be bricklayers or more people to learn to play tennis or some people to learn philosophy or everyone to participate in the political process or what?

MacIntyre provides some such guides to answers to such questions through his distinction between practices and institutions. Practices are concerned with internal goods as explained earlier, whereas institutions are characteristically and necessarily concerned with external goods. Even though practices and institutions are intimately related (MacIntyre, 1981: 194), it is clear that practices are to be preferred. That is because doing something well for the sake of that action and the benefits it brings to everyone is preferred to doing something only for the sake of something else and the benefit that brings individually. So for MacIntyre, learning as acquisition should not be encouraged.

On this view governments might support those forms of voluntary associations open to everyone through which authority of experts is recognized without recourse to standards and goods external to those associations. Hobbies, clubs, societies, crafts, sports, informal political associations, and games would be examples of arrangements that enable practices to flourish. Moreover while work practices are always tied up with institutions and external goods to some extent, it is possible to recognize and encourage the practical aspects of organizations in the interests of learners. An increasing privatization of what could be communal spaces also works against MacIntyre's account of a desirable or learning society that promotes lifelong learning.

The outcomes of lifelong learning remain indeterminate and individualized. In many instances, it must remain unclear why some people participate in some ways and others in other ways. Means ends rationality is not a central guide to the learning that might be encouraged. Learning is opportunistic; throughout life opportunities arise to participate in different ways without there being any obvious guides other than the ones provided by MacIntyre as to which opportunities should be grasped. Hager and Halliday (2006) use the notion of wisdom as an indicator of what it might mean to be able to go on learning in a measured way. For MacIntyre the notion of the narrative unity of a life performs a similar function. The view that learning is acquisition through a series of forced encounters in formal educational institutions leads toward a panopticon society according to Hager and Halliday (2006). Such a bleak prospect might be avoided by recovering informal learning and making such recovery a central part of policies for lifelong learning.

Structuralism, Post-Structuralism, and Postmodernism

Structuralist analyses of education and other social phenomena have typically been characterized by: a concern with wholes, understood as complex structures; the notion of embeddedness, by which is implied the nesting of particular phenomena within broader networks or structures; ideas of presence and absence, which stress that what may be present or visible is usually dependent on deeper structures or on a host of complexly networked factors (as in the view that Charlene's failure in math is because, as a black girl from a low socioeconomic status background, she is a member of the underclass in a society whose education system reflects the interests of the elite); and a focus on relationships, among phenomena and the structures which underlie them. Typical of this theoretical approach in sociological analysis is, for example, the situation, conceptualization, understanding, and explanation of schooling within its wider societal context. Criticisms of structuralism, for its sometimes rigid, static, ahistorical, and reductionist perspectives on social phenomena and, in some cases, for its assumptions of the objectivity of social phenomena, its positing of abstract macro-level generalizations about human behavior, and its employment of the empirical methods of the natural sciences to generate these laws, have contributed to the development of post-structuralist analyses of education and other social institutions. Such post-structuralist analyses nevertheless display significant levels of continuity with structuralism, not least in their shared critique of humanism's rational and autonomous subject and their concern to de-center that subject. Both analyses would, for example, pay less attention to individual factors that might contribute to Charlene's failure in math – that she might be unmotivated, lazy, or not particularly capable intellectually – and more to underlying structural causes such as those to do with her socioeconomic background, ethnicity, and gender, and how these structures are related to broader structures associated with the distribution of opportunity, wealth, and privilege in her society. Post-structuralism would, however, treat these structural factors in a less systemic and a less deterministic manner than would structuralism, and would be more focused on the complex and probably recursive interplay among the networks of economic, political, social, and cultural factors involved.

Our concern here is with post-structuralism, a term frequently conflated with postmodernism, not least because of the theoretical perspectives they share. Post-structuralism shares postmodernism's skepticism of meta-narratives (Lyotard, 1984), of transcendental or totalizing theories of truth in the social sciences, principally of the paradigm of enlightenment rationality and its faith in scientific reason as the bearer of the promise of emancipation through knowledge. The linguistic turn associated with post-structuralism and postmodernism does not, as Peters and Wain (2003: 65) put it, "warrant the assumption of a metalinguistic neutrality or foundational epistemological privilege." Post-structuralism shares the postmodern perspective that is, in Bauman's conceptualization, concerned with the unmasking of the illusions of modernity: the essence of the postmodern approach to epistemology and ethics lies in "the rejection of ... the philosophical search for absolutes, universals and foundations in theory" (Bauman, 1993: 4). Our search for these absolutes, universals, and foundations has probably been tempered by our realization, as a consequence of the multicultural spaces we now inhabit in an increasingly globalized world, that ours is a plural world, with a diversity of perspectives and claims to truth, beauty, and goodness. Post-structuralism shares with postmodernism the latter's challenges to the claims associated with the enlightenment that our knowledge of society is holistic and cumulative; that we can attain rational knowledge of society; that such knowledge is universal and objective; and that acting upon social scientific knowledge can lead to emancipation and social upliftment (McLennan, 1994). Post-structuralism shares with postmodernism a genealogical ancestor in Nietzsche's (1886/1990) view that truth is little more than the solidification of old metaphors, that it is neither foundational nor universal, but merely the sedimented beliefs of a particular cultural worldview. Nietzsche's (1886/1990) claim of the death of God was, after all, a claim about the absence of any universal, foundational, or transcendental source of existential meaning. Derrida's deconstruction, a major philosophical thrust of post-structuralism, is primarily concerned with the unpacking of these old metaphors which have been solidified into truth, deconstructing them into multiple realities articulated as the discourses of particular knowledge communities, each with its own truth claims that are likely to be incommensurable with the discourse of any other community – hence the linguistic turn referred to above. Foucault's post-structuralist

approach to historical analysis, his genealogical or archaeological approach to the social sciences, accordingly dispenses with notions of linearity and causality and focuses instead on knowledges that is local, discontinuous, disqualified, and illegitimate (Foucault, 1984). Rorty's pragmatism suggests, therefore, that rather than seeking ahistorical and transcontextual rules, philosophy should search for new forms of description, rather than prescription, in a world marked by such radical contingency.

At the most general level, post-structuralism differs from postmodernism in the different theoretical object of the study of each. As Peters and Wain (2003) suggest, the object of study of the former is structuralism; while that of the latter is modernism, associated with which are postmodernism's critiques of modernity.

Post-Structuralism, Critical Theory, and Reason

In approximately the last quarter of the twentieth century, the so-called post discourses – including those of post-structuralism, postmodernism, postcolonialism, and critical feminist discourses – have offered various critiques of the approaches to critical theory typical of the Frankfurt School, which have extended these into new territory. Scholars associated with the Frankfurt School had, at the risk of oversimplification, been committed to reclaiming a notion of reason more consistent with Enlightenment notions of universal reason from the typically instrumentalist forms of reason into which the formations and practices of modernity had in their view degenerated. The post discourses have challenged this continuing commitment to reason and share a skepticism of the attempts to reclaim any notion of universal reason. In considering these more recent approaches to the critical theorization of education, we focus more substantially on post-structuralism and on the work of Michel Foucault, who, although he never referred to himself as a post-structuralist, has, through his work on discourse, power, and disciplinary bodily training, probably had more impact on the critical theorization of social institutions – not least education – than any theorist since Marx and the leading members of the Frankfurt School.

In his *What is Enlightenment?* (1984/1997), Foucault reflected on the history and ethos of the present through a consideration of questions such as the meaning of critique and of enlightenment. He framed his reflections in the form of a dialog with Kant, who had 200 years earlier written a text with the same title, in which he too engaged with notions of enlightenment, critique, and the meaning of the present moment in history. Foucault characterized the difference between his own and Kant's responses to these questions in terms of a contrast between a focus on critique that circumscribed the activities of reason and his

own view of critique as a practice of exposing the limits of what Judith Butler (2002: 217) refers to as the epistemological horizon, or, critique as exposing the limits of reason. Perhaps as importantly, he modeled a way of thinking as an ongoing dialog, involving responses to the challenges and questions pondered by Kant and his successors – a dialogical approach that is central to the concerns and practices of post-structuralist critical educators.

Post-Structuralism and Language, Knowledge, and Truth

Post-structuralism and many other post discourses share a substantial research focus with Habermas and the Frankfurt School on language. But, whereas for Habermas, language is, at least potentially, a vehicle for transcending ideologies and engaging in a free and equal exchange of communicative reason in an ideal speech situation, for post-structuralist-influenced critical pedagogy, language is a socially shaped resource, steeped in culturally and historically sedimented attitudes, values, and assumptions, which precedes and exceeds any single individual. It is these coagulations of social meaning that comprise discourse, in the sense of "ways of being in the world, or forms of life which integrate words, acts, values, beliefs, attitudes and social identities" (Gee, 1996); and it is these discourses that, in post-structuralist theory, produce, or become constitutive of, social reality. Moreover, rather than regarding language as providing a transparent mirror of nature (Rorty, 1979), where words simply and clearly represent objects or concepts, post-structuralism, in common with its forebear, structuralism, sees meaning as deriving from differences within the linguistic system, so that dog means not cat or not horse, sacred means not profane, with the consequence that words or concepts are always defined in relation to other words, *ad infinitum*. Following Saussure (1959), linguistic signs act relationally rather than referentially. Hence, for post-structuralism, meaning is always partial and provisional, emerging as it does from an endless process of difference and deferral within the linguistic system, rather than from direct reference to the real world. This linguistic turn has significant implications for key educational notions of truth, progress, and emancipation: post-structuralism's claim "that all truths are textual, that the way we see the world is 'always already' infected by language" (MacLure, 2003: 4), means that language becomes both constitutive and – critically for education – a site of contestation, since there is no unproblematic one-to-one match between language and reality. Hence, the meaning and implications of terms like democracy and freedom invite and merit ongoing debate and negotiation, rather than being settled and simply requiring transmission to future generations.

Far from being committed to reason, then, post-structuralist thought is committed “to discourse, literally narratives about the world that are admittedly *partial*” (Aronowitz, 1987: 103).

Post-Structuralism and Power

The constitutive role of language-as-discourse in relation to knowledge raises issues of power and social (in)justice, insofar as education involves ultimately contestable knowledge, as well as asymmetric relations between holders and seekers of the symbolic capital provided by education (Bourdieu and Passeron, 1990). Questions arise as to who has the right to determine the meanings of key concepts and terms and whether the voices of educators should carry greater weight than the voices of those being educated. Post-structuralist pedagogy thus embraces an ongoing interrogation of the relations between knowledge and power. However, post-structuralism conceives power rather differently to more conventional formulations, seeing it as something that circulates in all human relations; as a potentially productive, rather than just a repressive, force – and as something that can be used “as a point of resistance and a starting point for an opposing strategy” (Foucault, 1978: 101). Foucault mentions the relationship between a teacher and student as an example of such potentially productive power relations (1988). This suggests that if power is an inevitable and potentially productive feature of social relations, then the challenge for educational practice is more one of strategically managing, rather than overcoming or simply ignoring, such power relations. In Foucault’s words,

The thought that there could be a state of communication which would be such that games of truth could circulate freely, without obstacles, without constraint and without coercive effects, seems to me to be Utopia. It is being blind to the fact that relations of power are not something bad in themselves, from which one must free one’s self. I don’t believe there can be a society without relations of power, if you understand them as means by which individuals try to conduct, to determine the behaviour of others. The problem is not trying to dissolve them in the utopia of a perfectly transparent communication, but to give one’s self the rules of law, the techniques of management, and also the ethics, the ethos, the practice of self, which would allow these games to be played with a minimum of domination. (Foucault, 1988: 18)

Post-Structuralism and Subjectivity

Foucault proceeds to draw connections between these games of truth – involving knowledge and power relations – and ethics. Ethics, or, as he constructs it, practices of the

self, draws attention to the issue of subjectivity, or identity, the third component of his three-dimensional grid of intelligibility (Dean, 1994: 194), which post-structuralist theory sees as co-constituted along with knowledge and power relations in social and educational practice. Accordingly, “language is the place where actual and possible forms of social organization and their likely social consequences are defined and contested. Yet it is also the place where our sense of selves, our subjectivity, is constructed” (Weedon, 1997: 21). In this reading, post-structuralist critical education is not just about questioning particular constructions of knowledge, or the social power relations operating in educational or pedagogical practice, but also about questioning or problematizing the creation of particular educational subjects or individuals. For example, albeit at the risk of oversimplification, didactic and inquiry-based pedagogical methods are each likely to produce different types of learners. It is important to recognize that this co-construction of knowledge, power relations, and subjectivity does not occur through the operation of disembodied ideas alone. In particular, post-structuralist theories consider the ways in which emotion and desire play a critical role in educational practice (McWilliam, 1999; Zembylas, 2007a, b), as well as the ways in which discourse as power/knowledge operates on and through the body via disciplinary practices and means of training, as ideas operate and circulate in conjunction with physical, spatial and temporal arrangements, techniques, and practices. We can see this, for example, if we consider how early literacy education operates through bodily, as much as cognitive, training and produces particular disciplined individual subjects (e.g., in the form of pupils who know how to comport themselves in educational settings, particularly in relation to books and other texts) and particular social power relations (e.g., in the form of the teacher’s right to be heard and students’ obligations to listen), as well as constructing and conveying particular bodies of knowledge (e.g., the ability to manage and extract meaning from written texts) (A. Luke, 1992).

Post-Structuralism and Critique

In critical post-structuralist educational research, the focus is generally on a historical, or genealogical, tracing or uncovering of the ways in which knowledge, social power relations, and subjectivity are constructed and inscribed within institutional practices – not so much to determine whether these ways are right or wrong, good or evil, but rather in the spirit of a “recurrent disturbance and negotiation of the numerous paradoxes of [political] life over attempts to conceal, resolve or suppress them” (Connolly, 1998: 124). From this perspective, reason and the practices of rationality, often seen as the essence of criticality, are themselves open to historical, genealogical critique,

rather than being understood as transcendent, universal, and timeless forces for good (communicative reason) or bad (instrumental reason). For some authors, however, the possibility of a critique of reason is unhelpful: Best and Kellner, for example, are skeptical about “the rational critique of rationality, totalizing rejections of totality, and the subjective hubris of dismissing the category of subjectivity” (Best and Kellner, 1991: 281). It might be argued in response to this that Foucault does not call for a rejection of reason but for an acknowledgment that, like many phenomena that humans tend to naturalize, it has taken different forms in the past, and could consequently operate differently in the future. Indeed, one way of characterizing the differences between Habermas and Foucault is that Habermas is interested in the theory of reason, whereas Foucault is interested in the historicity of reason (Hoy, 1998). In this sense, Foucault’s post-structuralist critical theory can be read as complementing that of Habermas.

[Post-structuralist] critical theory conceived genealogically may unmask substantive injustices, but it need not justify this unmasking through the methodological picture of inquiry presented by traditional theory. It need not construe itself only as seeing through illusions and constructing a timeless, context-transcendent theory of rationality from which we can then measure present society. Instead, when practiced genealogically, critical theory can present itself as offering new interpretations. Along the way it may be unmasking previous interpretations. Since what is unmasked is self-interpretation, this unmasking through genealogical critical history can now be seen not simply in traditional epistemological terms as ‘revealing reality’, but also modally as ‘deconstructing necessity’. That is, genealogical research will show that self-understandings that are taken as universal, eternal, and necessary have a history, with a beginning, and therefore, possibly, an end, (Hoy, 1998: 31)

The consequences of this emphasis on the contingent and constructed nature of some cherished ideas, values, and structures of social organization have implications for critique, which in this view should assume an attitude of humility coupled with a ceaseless interrogation, while resisting the temptation to be judgmental: for “judgements operate ... as ways to subsume a particular under an already constituted category, whereas critique asks after the occlusive constitution of the field of categories themselves” (Butler, 2002: 213).

Critical Challenges

Genealogical critique – what Hoy (2004) refers to as postcritique or genealogical deconstruction – in education entails in this view broader, deeper, and more

sustained forms of vigilance than those directed by earlier forms of critical education toward falsehoods or ideologies; for if education as a social practice entails “the triple fabrication of the subject ... [as] not simply an effect of domination but a complex result of practices and techniques of power, knowledge, and ethics” (Dean, 1994: 113), then pedagogical practice accordingly needs to problematize issues and probe horizons in multiple directions. Among the complex critical pedagogical issues facing educators, the following can be considered a small sample:

1. How to acknowledge “minority discourses, diasporic voices, texts and statements that are ‘written out’ and over by dominant institutions” (Luke, 2002).
2. How to address the complex, subtle, ways that power operates through/on bodies and space beyond indoctrination into belief systems (Olssen, 2006).
3. How to acknowledge, challenge, and extend students’ investments in particular discourses and positions (Misson, 1996).
4. How to harness the creative energy of desire and resistance without domestication (Lankshear and Knobel 2006; Misson and Morgan, 2006).
5. How to expand our sense of possibilities in the present rather than just imagining alternative social orders (Clarke, 2008; Connolly, 2002; Sawicki, 1998).
6. How post-structuralist educators might ensure that critical pedagogy does not become just another regime of truth (Ellsworth, 1989; Gore, 1993), as oppressive in its own way as the pedagogies it critiques.

Each of these challenges reflects an overarching problem of how post-structuralist educators are to negotiate the complex intertwining of knowledge, power, and subjectivity at individual, institutional, and societal levels. Each can be seen by these educators as encapsulating Foucault’s challenge: “the endeavour to know how and to what extent it might be possible to think differently, instead of legitimating what is already known ... , to learn to what extent the effort to think one’s own history can free thought from what it silently thinks, and so enable it to think differently” (Foucault, 1985: 9).

Post-Structuralism and Critical Pedagogy

A distinction should be drawn at this stage between critical thinking and critical pedagogy (Burbules and Berk 1999). They of course share an aim to arm people against delusion, but while critical thinking understands such delusions in terms of false or unreasonable assumptions, invalid reasoning and irrational thought processes, post-structuralist and other forms of critical pedagogy understand such delusions in terms of a metaphorical colonization by entrenched and unjust social assumptions, discourses, and practices. Critical thinking, frequently grounded in an epistemological

distinction between facts and values and an ontological focus on the individual, aims to enable individuals to develop as autonomous rational agents; post-structuralist and other forms of critical pedagogy, on the other hand, are skeptical about the possibility of distinguishing facts from values and, because they construe the social world as prior to, and the origin of, the individual, their target is taken-for-granted assumptions and socially received ideas, practices, and arrangements (Popkewitz, 1999). More particularly, critical pedagogy frequently draws on post-structuralist views of language in relation to knowledge, power, and subjectivity to challenge prevailing assumptions and practices in relation to, for example, class, gender, ethnicity, and sexual orientation.

In her important article, "Why doesn't this feel empowering? Working through the repressive myths of critical pedagogy", Ellsworth (1989) makes the telling claim that "while the literature states implicitly or explicitly that critical pedagogy is political, there have been no sustained research attempts to explore whether or how the practices it prescribes actually alter specific power relations outside or inside schools" (1989: 301). In response to this critique, she premises the shift to a post-structuralist critical pedagogy on "[the] recognition . . . that all knowings are partial, that there are fundamental things each of us cannot know – a situation alleviated only in part by the pooling of partial, socially constructed knowledges in classrooms – [which] demands a fundamental retheorizing of 'education' and 'pedagogy'" (1989: 310). This post-structuralist critical pedagogy has been substantially influenced by antiracist and feminist theories, each of which has emphasized that any individual's voice, any individual's knowing, will always be, in the words of Alcoff (1988), partial, multiple, and contradictory. These influences, including, not least, feminism's "reject[ion of] the 'universal subject'" (Luke and Gore, 1992: 5), have rendered problematic earlier forms of critical pedagogy that focused on helping each student to identify his or her authentic voice, even multiple authentic voices, inside him- or herself, as a means to empowerment. Ellsworth has remarked that such a notion of an inner voice ignores the

often contradictory intersection of voices constituted by gender, race, class, ability, ethnicity, sexual orientation, or ideology, . . . [as well as] the fact that the particularities of historical context, personal biography, and subjectivities split between the conscious and the unconscious will necessarily render each expression of student voice partial and predicated on the absence and marginalization of alternative voices (1989: 312).

Worse than this, in Ellsworth's view, conventional notions of dialog assume what is impossible: "rationalized, individualized subjects capable of agreeing on universalizable 'fundamental moral principles' and 'quality of life' that [apparently] become self-evident when subjects cease

to be self-interested and particularistic about group rights" (1989: 316). In a feminist post-structuralist perspective on critical pedagogy, "social agents are not capable of being fully rational and disinterested" (Ellsworth, 1989: 316), constituted as they are by the conscious and the unconscious, by multiple and frequently conflicting social positioning, by their own particularities. Post-structuralist perspectives deny, moreover, the possibility of the existence of any absolute or universal fundamental moral principles. Spivak (1988) refers to the search for such a coherent narrative as counterproductive, asserting instead the importance of persistent critique (1988: 272), as echoed by Butler, above. These perspectives need to be understood, in the words of Luke and Gore, in terms of

post-structuralism and postmodernism, [both of which] take issue with the centuries-long rule of Enlightenment epistemology and the fictions of the individual that it spawned. Both reject the self-certain subject, . . . the fixity of language, and the functionalist order imputed to the social and to theories of the social (1992: 5).

While post-structuralist feminist theories of critical pedagogy share many epistemological and axiological commitments with post-structuralist and postmodern theories of critical pedagogy, there are distinct differences, not least in post-structuralist feminism's assertion of distinct theoretical foundations, such as their grounding of their epistemology "on the foundation of difference, . . . on a politics of location and identity [crucial in] . . . the feminist project of standpoint" (Luke and Gore, 1992: 7), a commitment that in some respects places this discourse at odds with postmodern and post-structuralist rejections of such foundations.

Similarly, while antiracist theories of critical pedagogy share many epistemological and axiological commitments with (post-structuralist and postmodern) theories of critical pedagogy, there are distinct differences, not least in emphasis. Why, asks Allen (2005: 54), has critical pedagogy been based for so long upon class rather than race? "For critical pedagogy to become anti-racist", he asserts, "it will need to be much more serious about the race-radical philosophies of people of colour around the world and move away from the comforts and constrictions of a Marxist Eurocentricity" (Allen, 2005: 54). The arguments of W. E. B. DuBois (1902) in *The Souls of Black Folk* and of Carter G. Woodson (1933) in *The Mis-Education of the Negro* are, after all, frequently cited for their early contributions to the field. Frantz Fanon's (1963/1968) *The Wretched of the Earth* has not been without influence either. Contemporarily, writers such as Gloria Ladson-Billings, bell hooks and Zeus Leonardo have had a substantial influence on the field.

Feminist post-structuralist critical pedagogy is thus "profoundly contextual (historical) and interdependent (social)" (Ellsworth, 1989: 323), as it tries to find "a commonality in

the experience of difference without compromising [the] distinctive realities and effects [of difference]" (Gentile, 1985: 7). Greene (1992) describes it as "relational, practice-centred, contextualized, open-ended, ... demand [ing] confrontations with discontinuities, particularities, and the narratives that embody actual life stories, ... [and] renewed attentiveness to the construction of knowledge and the life of meaning" (1992: x). Luke and Gore premise it in an epistemology that views knowledge as "always provisional, open-ended and relational" (1992: 7). Ellsworth thus suggests a more humble starting point for feminist post-structuralist critical educators in their classroom practice aimed at a kind of communication across differences:

If you can talk to me in ways that show you understand that your knowledge of me, the world, and the 'Right thing to do' will always be partial, interested, and potentially oppressive to others, and if I can do the same, then we can work together on shaping and reshaping alliances for constructing circumstances in which students of difference can thrive (1989: 324).

Conclusion

Post-structuralist critical pedagogy is not without its own internal inconsistencies. (This fact might not, of course, be construed by post-structuralist critical pedagogs as especially problematic.) Ellsworth, for example, claims that "the antagonist [is] power itself, as it is, [for example], deployed within classrooms" (1989: 322). This is inconsistent with Foucault's conceptualization of power, as we considered earlier. He did not believe there could be a society without relations of power, understanding them not as something bad in themselves, from which one must free one's self (Foucault, 1988: 18). As indicated above, he saw power as something that circulates in all human relations, as a potentially productive, rather than just a repressive or antagonistic, force, as a point of resistance and a starting point for an opposing strategy (Foucault, 1978: 101).

Against the post-structuralist/postmodern skepticism of enlightenment notions of truth and rationality in contemporary theories of critical pedagogy, Siegel (1997) has argued that if we were to

give up our 'conservative' understandings of truth, warrant, rationality and rational justification, then we [would be] unable to establish, for example, that apparent victims of marginalization or oppression at the hands of a hegemonic dominant culture are actual victims. Similarly, we [would be] unable to establish that such victimization, even if actual, is a bad thing. In order to establish these judgements as true and/or justified, we must have recourse to conceptions of truth, justification, etc., which provide us with the conceptual resources to establish these claims. Without those resources, there is no possibility of acting, in a

morally motivated and justified way, so as to alleviate the suffering wrought by injustice (1997: 152).

We can, according to Siegel, reject these epistemological presuppositions of evidence, reason, rational justification, and truth "only at the price either of incoherence or arbitrariness. For to reject them *justifiably* is to reject them for reasons which satisfy the very conditions concerning rational justification which one wants to reject" (1997: 147).

Mason (2005) has argued that

we need to talk about the limits of reason, rather than its limitations. *Sophie's Choice*, in the novel by that name, about which of her children to give up to death at the hands of the Nazis is not susceptible to a rational process of decision-making. But that says less about the limitations of reason and more about its limits, the extent of the domain in which it is applicable. ... [It says more] about domains beyond the scope of reason where problems are tractable only and ultimately by moral choices (2005: 313).

Although educational critique has recently sought to incorporate, as we have described, post-structuralist, post-modern, antiracist, and feminist insights, it probably still remains vulnerable to criticism for what C. Luke (1992) has referred to as its attempts to subsume these different perspectives within just such a master narrative of critique, and for what Buckingham (1998) has claimed as an overly strong emphasis on rationalistic analysis and a sometimes simplified worldview of oppressors and dupes. Buckingham notes that the research shows that "it is more productive to relate critical analysis to students' own concerns, tastes and identities rather than engaging in the more abstract analyses of ideology that have traditionally been prevalent" (Buckingham, 2007: 163). He suggests that in an age when digital media texts are a central part of students' experiences beyond the school, the critical understanding sought by teachers "can [also] be developed – in some instances, more effectively and enjoyably – through the experience of creative production" (Buckingham, 2007: 163). This entails an emphasis on constructing, as well as deconstructing, texts in various media so as to develop critical and creative literacy in how textual elements work singly and in concert to produce particular social realities, relations, and identities.

This assertion of the importance of cultural production by students that might describe an alternative to the consumerism-dominated and consumer-oriented cultural production of late-modern societies reflects Maxine Greene's concern with the role of esthetic literacy, of creativity and the imagination, in a post-structuralist feminist pedagogy, and it is with her words that we conclude:

We cannot negate the fact of power. But we can undertake a resistance, a reaching out towards becoming *persons* among other persons ... To engage with our students

as persons is to affirm our own incompleteness, our consciousness of spaces still to be explored, desires still to be tapped, possibilities still to be opened and pursued. At once, it is to rediscover the value of care, to reach back to experiences of caring and being cared for (as Nel Noddings writes) as sources of an ethical ideal. It is, Noddings (1984) says, an ideal to be nurtured through “dialogue, practice and confirmation”, processes much akin to those involved in opening a public sphere. We have to find out how to open such spheres, such spaces, where a better state of things can be imagined; because it is only through the projection of a better social order that we can perceive the gaps in what exists to try to transform and repair It demands the exercise of imagination, enlivened by works of art, by situations of speaking and making I would like to think that this can happen in classrooms, in corridors, in schoolyards, in the streets around (2009: 95).

Reason and Rationality

P Hogan, National University of Ireland, Maynooth, Ireland

© 2010 Elsevier Ltd. All rights reserved.

Introduction

To deal with this extensive theme in an encyclopedia article calls for a degree of conciseness that requires important points to be treated in a summarized way. In the first part of the article, central philosophical issues are identified and briefly reviewed. The second part then sketches some educational implications and consequences of these earlier reviews.

Some Central Issues

In everyday conversation, reason and rationality are often used interchangeably. For instance, people frequently say: “where’s the rationality in that?” for “where’s the reason in that?”, or “his outlook lacks rationality” for “his outlook lacks reason.” Staying more strictly with dictionary definitions however, an important distinction can be drawn between reason and rationality. The Oxford Dictionary states that the noun reason refers to an intellectual faculty, or capacity, characteristic of human beings, that enables them to draw logical conclusions from premises. As for the noun rationality, this is not listed as a separate entry in the dictionary, but appears as a cognate noun of the adjective rational, where rational itself has a range of meanings, including, endowed with reason, reasoning, sane, not foolish or absurd, or rejecting what is unreasonable or cannot be tested by reason in religion or custom. On this stricter account, reason refers to the human capacity and rationality to its use; namely to good or less-than-good embodiments of that capacity in human thought and action. Not surprisingly then, while reason remains for the most part a term of approval, rationality attracts more critique and criticism, chiefly because it reveals itself in contrasting kinds of embodiments. These embodiments take place not just in the thoughts and actions of individuals but also in cultural traditions, in social and economic arrangements, in work practices, in systems of justice, and so on. This point is brought home to us by the tensions among the unprecedented diversity of rationalities of which we are conscious today, not only internationally but also within particular countries or societies.

Many find the plural form of the word (rationalities rather than rationality) a bit disconcerting, holding that rationality is simply that which is in accordance with reason and irrationality that which is not. To speak of

rationalities however, as for instance Alasdair MacIntyre does in detail in his book *Whose Justice? Which Rationality?* (MacIntyre, 1988) is not only to claim that the use of reason can produce contrasting or conflicting stances, but to suggest that it regularly does so, even necessarily does so. Such claims would be rejected by rationalists, who are invariably keen to claim that reason is singular, not plural, in nature, and that conflicts of rationality can be traced either to faulty premises or to faulty logic in arguing from premises, or to a combination of both faults. For rationalists, a proper understanding of reason would acknowledge that it is an *a priori* capacity, uncolored and unclouded by bias, and accordingly that anything worthy of the term rationality would be a model of consistency and even-handedness.

Debates about the merits of one form of rationality over another normally come down to two key issues, to the justifiability of the premises and to the adequacy of the associated reasoning – in other words, how rational (as distinct from biased or prejudiced) one’s starting premises are, and how consistent and thorough is the body of arguments issuing from these premises. The European Enlightenment of the seventeenth and eighteenth centuries is a good focus for attention here as it marks a high point for critiques of a range of historically inherited rationalities, or if you prefer, of contrasting kinds of rationality. Most notably these were rationalities that granted privileged standing to monarchy, to ecclesiastical authority, to various kinds of nobility, and more generally to a cosmic order, a great chain of being, where people and things had their allocated places, with accompanying expectations and practices.

Not only the rationalities inherit from the past, but also reason itself, became the subject of critique for the Enlightenment, particularly for Kant (1724–1804). His three major critiques (*Critique of Pure Reason* 1781, *Critique of Practical Reason* 1788, and *Critique of Judgement* 1790) sought to provide thorough investigations of reason itself and comprehensive foundations for its valid exercise in a range of domains. Arising from these investigations, Kant announced the Enlightenment’s major educational theme with the declaration “Enlightenment is man’s emergence from his self-incurred immaturity.” Such immaturity he described as “the inability to use one’s own understanding without the guidance of another” (Kant, 1784). Among the new directions for a rationality appropriate to education proposed by Enlightenment thinkers were ones like the following sample:

1. In education, as in other forms of action, the claims of long-established authority and tradition can no longer remain unchallenged, as many of these claims have stronger roots in prejudice than in rationally justifiable premises. All such claims must therefore be submitted to the judgment seat of autonomous human reason.
2. Education must enable learners to make full use of their own understanding. Learning must therefore be a form of emancipation. It must cultivate the rational autonomy of the individual rather than be an instrument for securing conformity in thought and belief.
3. As humans have a capacity for reason, they have a unique standing among other beings. While everything in nature conforms blindly to laws, rational beings can formulate laws, to which they themselves can then conform or not conform. Humans therefore have a status which is incomparably higher than anything in nature, and this higher status commands moral respect.

Challenges such as these, Enlightenment thinkers maintained, could be successfully tackled only to the degree that unwarranted assumptions or overlooked preconceptions could be brought to light and capably dealt with by pure reason. Deficient forms of reason, it was claimed, could be identified in much of previous philosophy, including the major metaphysical systems of Plato, Aristotle, and Aquinas. In particular, certain articles of faith, whether springing from pagan religion, from Greek beliefs about politics, or from Christian doctrines, were seen to be active in an influential way in metaphysical philosophy, but remained outside of the critical focus of metaphysical enquiry itself.

How far the Enlightenment and its intellectual legacies have succeeded in establishing a conception of reason that is freed from all assumption and presupposition however, remains controversial. Indications of this can be seen not just in contemporary discourse on ethics, politics, and religion, but in rationalities embodied in different domains of human work; for instance, in the rationalization of industry (e.g., from human assembly lines to robotic manufacture), of agriculture (from the land enclosures of history to today's technological agribusiness), and of education (from the monitorial system of Bell and Lancaster to current forms of e-learning). All of these have involved forms of rationality that draw sharp distinctions between means and ends – in effect between prized ends on the one hand and the use of humans (or substitutes for humans) as instruments on the other. Max Weber's famous distinction between instrumental rationality (*Zweckrationalität*) and practical rationality (*Wertrationalität*) comes to mind here. It should be stressed that the term practical rationality, as used by Weber and by philosophy more generally since Aristotle, refers to moral-practical reasoning, not to a kind of practical mentality that sidelines moral issues in its keenness to achieve certain practical goals. This latter would be an example of

instrumental rationality. The premises informing instrumental rationality (e.g., the maximizing of profit, the defeating of enemies, or the securing of power for one's party) can quickly be seen as laden with different kinds of taken-for-granted assumptions. Although issues of justification are not always irrelevant here, they are removed to the background. Reason is already spoken for, as it were, as it is already embodied in procedures and practices designed to accomplish, without questioning or interruption, certain previously decided purposes or goals. Practical rationality, by contrast, is concerned with questions of how one should act, and of what kind of reasonable belief could inform such action. In this case, the issue of presuppositions and their justification remains critically at the center.

Apart from illicit activities which do not have even a hint of honor among thieves, virtually all human occupations involve some combination of instrumental and practical rationality. In occupations like medicine, nursing, social work, and not least education, because of their nature as caring professions, demands for explicit justification are likely to arise more frequently than they would, for instance, in the exercise of management functions in public administration or in industry and commerce. Even where procedures are already decided on, and may thus look like instrumental rationality, these procedures regularly come up for review, or fresh ones have to be considered for new situations and circumstances. Where practitioners in such fields lean too heavily toward instrumental forms of rationality (e.g., where a profession has become heavily bureaucratized) it is likely that the values underlying practice itself will become semiautomatic in their operation. Assumptions which at one point had to be debated, justified, and decided upon by practitioners, can become ingrained in practice over the course of time. To the extent that they do, an instrumental rationality prevails in a taken-for-granted way and practitioners themselves can all too often become creatures of habit.

Resistance to the kinds of debates that involve practical reasoning can be quite common among members of different professions, sometimes because practitioners see them as endless, or believe some colleagues talk too much at meetings, or want to go into each issue twice over, and so on. Much of the apparent interminability of practical reasoning however arises from the failure – so far at least – to deliver on the Enlightenment's expectations of pure, or unbiased, reason. That is to say, humankind still seems to lack an effectual conception of reason from which hindrances like preconceptions, prior assumptions, not to say prejudices, have been removed. The most that seems to have been achieved along these lines are temporary or stipulative conceptions, where different parties agree for present purposes to certain definitions, or meanings.

In different ways, the attempts of major philosophers such as Descartes, Kant, and Husserl sought to provide

a methodical procedure whereby rational thinking could become free of deceptive predisposing influences. Success in such attempts would secure a foundational or irrefutable conception of reason, and furnish universally valid thought procedures for the most important of human enquiries. In the case of each of the three thinkers, however, the goals being pursued by their attempts became so intractable that reason itself had to be disconnected in one or more ways from human experience, or more precisely, from the fullness or integral-ness of human experience. Descartes had to create a methodically doubting human subject with a contrived style of thinking that radically disengaged the thinker from others. Kant created an even more elaborate system that included categories of understanding that were distinct from categories of reason, analytic *a priori* judgments that were distinct from synthetic *a priori* judgments, as well as a range of other highly abstract distinctions. Despite Kant's best intentions, these distinctions led inquiry elsewhere than toward an illumination of what befalls human experience itself, and what befalls reason itself, as reasoning is attempted. Husserl, keen to retain sight of this fuller experiential context, developed a discipline of phenomenological reduction that sought to bracket out the distorting influences of uncritical, or pre-reflective consciousness. Again, however, Husserl's efforts became involved in intractable difficulties that led to successive new starts on his own part, until thinkers such as Heidegger, Wittgenstein, and Dewey brought inquiries into reason and thinking on quite different paths.

Before reviewing the fruits of these latter enquiries, it is important to point out that efforts to secure a unitary conception of rationality that would keep preconceptions at bay, and that would have universal application, still continue, not least where practical rationality is concerned. Among the most influential of such efforts in recent times has been that of John Rawls in his book *A Theory of Justice*. This book is not an investigation of reason as such but an attempt to establish a universal rationality for justice. Rawls seeks to provide a standpoint that can overcome all partisan positions and furnish neutral or impartial grounds that manifest such a universal rationality. He presents a thought experiment involving the adoption of an original position in matters of justice. The thought experiment seeks to establish what principles of justice might come to the fore if one placed oneself behind a veil of ignorance, thus depriving oneself of any knowledge of the beliefs, gender, social standing, ethnic background, religion, or abilities of others. Adopting the veil of ignorance thus means ridding oneself of all assumptions and preconceived ideas that might otherwise cloud one's thinking and prevent one from taking an original position. The original position would therefore be a purely disinterested stance. Critics of Rawls point out that, whatever its merits as a thought experiment, his argument fails in its claim to universality. The charge is that Rawls's theory implicitly privileges

a stance of individual liberalism over others and that it ignores the social and historical factors that give substance to principles of justice – factors that remain inescapable features of human rationality itself.

But what if an original position, or disinterested stance, is actually unattainable by the rational efforts of humans? What if the attempts to seek such a position are mistaken? Such were the thoughts that began to exercise the young Heidegger in the 1920s as he struggled with the difficulties bequeathed by efforts such as those of Descartes, Kant, and his own teacher Husserl. Heidegger concluded that human understanding is not something separate from human reason, human judgment, or human interpretation, but includes all three, albeit deficiently, from the start. More startlingly, he argued that interpretation and prior judgments remain inescapably active in all understanding. He concluded, uncontroversially, that critical reflection can helpfully identify and discipline many of the predisposing influences that orient human understanding. More challengingly however, and against all rationalist epistemologies, he argued that such influences cannot be finally overcome and laid aside through the conquest of some supposed neutral starting point. On this account, human rationality must accept a more modest view of its own accomplishments and of the possibilities of human reason. What the pursuit of these possibilities achieves now becomes acknowledged as something that is at best partial, and in both senses of that word: incomplete and burdened by bias.

Arguments like these advanced by Heidegger have subsequently been developed into major themes in the philosophical hermeneutics of Gadamer and Ricoeur. They also find parallels and resonances in the works of philosophers as different as Dewey, Wittgenstein, and Popper, and more recently in writings such as those of Charles Taylor, Seyla Benhabib, and Richard Bernstein. These philosophers argue that the search for secure and certain foundations for reason and its exercise must be given up and replaced by something more self-critical – something with a better understanding of the implicated-ness of history in human reason and a more discerning assessment of human possibility and limitation. The accounts produced by thinkers like those mentioned in this paragraph still make universal claims however, albeit in a provisional, or fallibilist sense, as distinct from any *a priori* sense.

Such thinkers are broadly called nonfoundational philosophers. But there are also more radical forms of nonfoundational philosophy, associated chiefly with postmodern currents of thinking that arose in the last quarter of the twentieth century. These are associated particularly with the writings of Jean François Lyotard and Michel Foucault, and also in some respects with those of Jacques Derrida and Richard Rorty. The characteristic tendency of postmodern thinking is not only to dismiss metaphysical and epistemological accounts of reason and rationality, but also

to reject any philosophical claims to universality. With this goes an insistence that all reasoning must be merely local, as must all accounts of reason itself (small narratives rather than grand narratives). Such a stance is recommended by postmodernists in order to: (1) expose the often oppressive features in hegemonic forms of rationality that claim universality; and (2) destabilize any emergent successors to forms of such rationality that have historically enjoyed a place in the sun.

Critics of both kinds (hermeneutic and postmodernist) of nonfoundational thinking often argue that allowing interpretation such a central role in the exercise of human reason does away with the notion of objective truth and invites the charge of relativism. A related version of this criticism is that independent norms of practical reasoning (i.e., about how to act and what to believe) are now abandoned and that reason itself falls prisoner to the conditioning influences of historical and social circumstances. Responses to this criticism would differ from both forms of nonfoundational philosophy that we have just considered. Postmodernist responses would likely say good riddance, both to objective truth and to independent norms of practical reasoning. Both would be seen as involving pretensions that are no longer credible and that have in the past all too often led to invidious social and political consequences. In the case of the other forms of nonfoundational philosophy, the broadly hermeneutic ones, there would likely be a variety of responses, but with a concentration on arguments like the following: objective truth, rather than being dismissed, now features as something that can be suggestively imagined, but hardly attained, by human efforts – much as omniscience can be humanly imagined, but not humanly attained. Truth is seen on this account as something to which reasoning remains on the way, rather than something possessed with certainty, and for good. For the purposes of practical reasoning, truth is thus associated with what Dewey called warranted assertibility (Dewey, 1938/1986: 15), or with what Popper described as theories that have so far withstood refutation, but remain open to it. This is not to devalue the importance of truth however. If anything, it is to do the opposite, and in a threefold way: first, to suggest that pure reason is something more godly than human, but that still beckons the best efforts of human enquiry; second, to disclose the predisposed nature, including the possibilities and the limitations, of the human capacity for reason; and third, to remind us of the provisional character of the forms of rationality accomplished by the exercise of that capacity.

Educational Consequences and Effects

We have noted the radical challenge of the Enlightenment for education in Kant's declaration about humankind's emergence from its self-incurred immaturity, and in his aspiration that understanding might be used without the

guidance of another. In this, Kant was influenced by Rousseau's memorable and forceful arguments in his *Émile* (Rousseau, 1762/1993) for promoting independence of mind among learners (albeit male learners). Kant announced the motto of Enlightenment as "*sapere aude!*" (dare to know). Have courage to use your own understanding!" (Kant, 1784). Cultivating such understanding and the courage to use it thus become predominant educational aims in those forms of rationality championed by the Enlightenment. Enlightenment thinkers were keenly aware that this marked a sharp break with paternalistic and custodial forms of rationality that were hitherto influential in the history of Western education. These earlier forms would include not only those that had origins of one kind or another in Plato's metaphysics. Crucially, they would also include the long traditions of teaching in cathedral and monastic schools prior to the Reformation. These were based on a theological–philosophical rationality that owed its effective allegiance to the papacy. During the Reformation and its aftermath, this kind of rationality endured much turbulence, before becoming reconstituted along mutually opposed denominational–cum–political lines: Catholic–political, most notably in Spain; Lutheran–political, as in northern Europe; Calvinist–political in Geneva, Scotland, and elsewhere. From a critical Enlightenment perspective however, such breakup and reconstitution meant that the traditional paternalistic rationality that had long underlain European education became strengthened rather than weakened in becoming plural. Each denominational tradition developed a form of rationality that became doctrinally more exact, and more exacting, with new sectarian dimensions reinforcing the already authoritarian constraints on teaching and learning.

In the wake of the Enlightenment itself, however, the rational autonomy championed by Enlightenment thinkers as a goal of learning fared ill, at least for a few generations, in European schools and colleges. Efforts by Pestalozzi in Switzerland to encourage learners to be more active agents in their own learning met with some moderate success, as did those by Froebel in Germany to transform pedagogical thinking from a paternalistic rationality to a more pedagogically perceptive one. Neither Pestalozzi nor Froebel were advocates however of the Enlightenment's bolder kind of rational autonomy. Wilhelm von Humboldt's measures in the early nineteenth century to reorganize university education in Berlin and higher-secondary education in Prussia along Enlightenment lines successfully broke new ground, but these measures were exceptions in a Europe that grew increasingly reactionary after the fall of Napoleon in 1815. In fact, it was not until the twentieth century that notions like encouraging students to dare to know made substantial progress in Western countries. The first wave of this progress was associated with the work of John Dewey in the USA, though in an urbane rather than a revolutionary way. Dewey argued that educational practice should be

constituted as far as possible on democratic lines – that practice itself should exemplify a democratic rationality. He tried to embody such a rationality in his Laboratory School, attached to the University of Chicago. In the context of deeply conservative attitudes in educational policy circles in the United States however, much of Dewey's work was misunderstood or misconstrued. The educational philosophy he developed over his long lifetime found an influential following, including some uncritical devotees; but it was also frequently caricatured or dismissed, including by President Eisenhower in 1959.

Elsewhere, rational autonomy began to make some strides as an explicit research theme in education. For instance, in the 1970s in the United Kingdom, much research in the philosophy of education was concerned with exploring rational autonomy as an educational aim. Associated in particular with the writings of analytic philosophers Richard Peters, Paul Hirst, and Robert Dearden, this research focused characteristically on an analysis of the logical properties of the concept of rational autonomy, and on the conditions that needed to be satisfied for a person to be called rationally autonomous. It also gave much attention to elucidating forms of rational thinking into which learners were to be initiated through education. A key mark of an educated person would thus be his or her ability to make rational choices based on public criteria of judgment. Some critics of this analytic approach, which featured strongly in many teacher-education courses during the 1970s and early 1980s, argued that it paid insufficient attention to the importance of personal authenticity (in addition to public criteria) in any account of rational autonomy (Bonnett and Cuypers, 2003). Others charged that this approach, while retaining a declared allegiance to the disinterested stance and second-order procedures of analytic philosophy, often ignored its own rules: that its philosophical accounts – of curriculum, of development, of teaching, of rationality itself – were frequently value laden, and were more of a first-order than a second-order character (O'Connor, 1973; Carr, 2004).

Toward the end of the twentieth century, a new interest in Dewey's work became evident, in the United States and internationally. This was helped by the emergence of a more receptive climate for many of his ideas. This was not because there was now a widespread appreciation among policymakers of the kind of rationality that Dewey envisaged for healthy environments of learning. Rather, it was for more pragmatic reasons, such as the importance given to learner-centered education as a desirable strategy to promote newly ascendant international goals like the knowledge society and lifelong learning. It is difficult to say how this revival of interest in Dewey's educational thought will fare in the future, or in what directions it will lead. It seems clear however from the many recent reports on education by bodies like the

Organization for Economic Cooperation and Development (OECD), the United Nations Educational, Scientific and Cultural Organization (UNESCO), and the European Commission, that themes like learner-centered education, lifelong learning, and the knowledge society will remain central in the context of intensifying policy debates on globalization.

Developments like these provide timely opportunities for exploring the theme of educational rationality as a distinctive type of rationality. MacIntyre's book mentioned earlier examines at length four contrasting kinds of rationality – Aristotelian, Augustinian, Scottish Enlightenment, European Enlightenment – and reviews some others in less detail. Among the hallmarks of MacIntyre's approach are his illustrations that particular rationalities are historical human accomplishments; accomplishments that are embodied in, and developed through traditions of enquiry. Rationalities that are thus embodied can be strengthened, or alternatively have their weaknesses exposed, MacIntyre claims, by engaging in active debate with rival traditions. He gives educational institutions, particularly universities, a special importance here, but only if they speak as protagonists of one contending party (MacIntyre, 1988: 401). Liberal universities cannot do this successfully, MacIntyre claims, because they conduct their research and teaching "as if there were indeed shared standards of rationality, accepted by all teachers and accessible to all students" (p. 399). MacIntyre insists, in common with both forms of nonfoundational philosophy mentioned earlier, that it is an illusion to hold that there are such universally shared standards, but he adds that this is an illusion on which the liberal university itself is based. In denominational universities by contrast, MacIntyre continues, traditions of research and teaching are associated with the shared standards of a particular rationality – Catholic, Protestant, or other as the case may be. Their members are thus better placed than their counterparts in liberal universities to engage in the combative dialogue through which particular rationalities are further articulated and sustained against the claims of their rivals. Here, MacIntyre locates himself, and his philosophical efforts of recent decades, within an Aristotelian-Thomistic, or Catholic tradition.

MacIntyre holds that subscribing to a form of rationality embodied in a particular religious tradition is what makes it possible for teachers in a denominational college or university to share the kinds of standards he talks about. On this kind of account however, it would be possible for people who understand themselves first and foremost as teachers to do something that MacIntyre does not envisage – to share, for educational purposes, certain provisionally acknowledged standards for the conduct of teaching and learning. These would be standards that do not claim to be universal in any *a priori* sense, but that claim to be worthy of assent, to the best of our fallible knowledge to date. In fact, this is the more convincing

rationale, not only for the liberal university, but for any educational institution that seeks to withstand charges of indoctrination. Where educational practice, in liberal universities or elsewhere, fails to meet the standards of such a rationale, it is often because there is insufficient attention paid by teachers and students to their own preconceptions; preconceptions that are often all the more powerful in their influence because they are undeclared or even undetected by those who hold them. Far from faulting the universalistic pretensions of liberal universities, a more promising way to remedy this is to try to work out more fully what an educational rationality, properly so called, would look like. This is a large undertaking, the tenor of which has been initially touched on in some earlier remarks, but a few key features can be indicated here by way of conclusion.

An educational rationality that hopes to be adequate to its task seeks, in the first place, to be alert to its own predisposing influences, especially those preconceptions that habit and custom in institutions of learning might occasion it to overlook. Such a bringing to light and disciplining of presuppositions cultivates a self-critical disposition in would-be teachers and learners. This needs to be accompanied however by positive action to promote distinctive environments of teaching and learning – environments that give priority to the exercise of constructive criticisms and to enquiry itself as a community endeavor by learners. Such environments would also be marked, in a special way, by a hospitality to imaginative venturing.

Religious and Spiritual Education

Religious Education – Contested Concept and Competing Expectations

It is arguable that religious education is both more contested and more regularly denigrated than any other area of the school curriculum across a range of polities. This contestation arises as a consequence of much diversity in the conceptualization and the pedagogical realization of religion, and because the relationship between religious communities and public policy in late industrial political communities has become fraught as the church and state have become increasingly separated.

There are those who, supporting the existence of religious education as a necessary feature for a rounded education in the public school, argue that, religion is an important dimension of human life in both historical and contemporary contexts; religious ideas have been hugely influential in the creation of cultures and civilizations, in literatures, and in modes of thought; religion is an important component of personal and collective identity for many people; religion provides exemplars of ethical codes that enable a virtuous life. Moreover, a number of scholars (Conroy and Davis, 2008; Wright, 2007) have argued that the growth of religious illiteracy is a central educational problem for late industrial liberal democratic polities. On the other hand, those opposed to any concord between religious communities and the state believe that religious education merely extends and enfranchises epistemological and moral infantilism whereby individual moral responsibility is usurped by authoritarian regimes. Another related refraction of such arguments is rooted in the post-Enlightenment rejection of transcendentalism.

Nevertheless, it is hard to escape the claim that cultures, including secular cultures, are themselves bred out of a sense of the religious (Scuton, 2007). Hence, the influence of Christianity in the development of Western civilization is particularly marked in historical structures of governance and codes of law and ethics. It has supported technologies, such as mass print (to disseminate the word of God), which themselves produce certain kinds of intellectual shifts; the Renaissance gives rise to the Reformation which in turn is midwife to the Enlightenment and eventually produces late-nineteenth-century atheisms. Religion, then, even in its negative manifestation, is an inescapable and important dimension of human life, worthy of study at various levels of education, including school.

There are equally robust national and international philosophical debates about the aims, purpose, and scope

of religious education in schools located within denominational, nondenominational, and multid denominational school systems informed by historical religious traditions, modernist and postmodernist theoretical frameworks, and multireligious perspectives. The diversity of conception and practical realization of religious education is marked not only in debates among academics or teaching practitioners but, perhaps more significantly, also between legislators. What constitutes religious education in different polities differs quite markedly. In the United States, for example, there being little or no religious education in public schools, it is normally seen as a synonym for religious nurture or catechesis in religiously denominational schools. In other Anglophone cultures, such as Britain and Ireland, South Africa, and Australia, it may take quite different shapes and have quite different purposes. Across Britain, despite national differences, there has been some broad general agreement about the nature of religious education as primarily a place to encourage the study of a range of world faiths. In Australia, there are certificated programs in religious education, although these have not been widely supported in state schools; some would argue that this is because there exists continued right of access by representatives of religious communities who can teach, on a voluntary basis, those whose parents actively choose to have their children introduced to their own faith. Yet again, across Europe, there are a range of provisions which elide any clear distinction between the public and the private, between the educational and the evangelical or catechetical (e.g., UK). The complexity of the debate is reflected in the nomenclature within different school systems which often provide a key to understanding these localized conceptions of the subject and the compromises reached. While the term religious education is popular throughout the Western world, there are many variations (e.g., religious instruction in Estonia; knowledge about Christianity in Denmark; and religion in Romania) and, in some cases, a broadening out of the intended scope (religions and ethics in Slovenia; Christian knowledge and religion and ethical education in Norway; and religious moral and philosophical studies in Scotland). In some countries there are options that provide a nonreligious alternative (confessional religious education or civic education in Serbia and Montenegro; and religious education or ethics in Slovakia). Often religious education, in whatever form, is compulsory for school children up to a certain stage, although there may be a conscience clause and the possibility to opt out (Kuyk *et al.*, 2007).

As the subject is often compulsory, contemporary debates, especially within the nondenominational and multi-denominational school systems, can be the sites of inter- and intra-religious and cultural maneuvering as different religious groups or denominations position themselves to claim a stake for their interest group in the construction of rationales and syllabi for national and local religious education in the classroom (e.g., Germany and Romania). This claim can also be for a stake in state education, and hence some form of state recognition and public legitimization of the religious group (McKinney, 2006). Indeed, it is difficult to see how any other subject on the curriculum would be susceptible to such pressures.

Religious education is often perceived as a subject that can make a contribution to whole-school initiatives, although Broadbent and Brown (2002) warns that, as a consequence, religious education could lose its focus as a discrete subject. In recent years, strong links have been established between religious education and forms of personal, social, and health development, moral and values education, citizenship education, and spiritual education. In such instances, religious education functions as a surrogate for other forms of education. This is of course a move that parallels similar philo-theological shifts in approaches to religious language, evident from the middle of the nineteenth century on and finding a strong voice in R. B. Braithwaite's celebrated essay (Braithwaite, 1971), which suggested that religious language serves as a form of reified moral language. Arguably, such links help to explain competing expectations of religious education from different stakeholders in society and in school education – expectations that are not simply related to examination results and uptake of the subject by school pupils but related more to a variety of constructions of the value of religion, religiously influenced attitudes, values, and lifestyles (Schreiner in Kuyk *et al.*, 2007). Civic society can harbor expectations that the subject should engender mutual tolerance and respect between different religious and cultural groups. Parents can expect the subject to provide a background and a literacy in religion that many of them are no longer able or willing to provide. Religious communities can often expect religious education in schools to aid them in the formation and development of religious identity and can attempt to impose exclusively orthodox representations of their religion to ensure adherence and continuity in their tradition (McKinney, 2006). Politicians often expect religious education to promote ethical conduct and support the creation of good citizens. This range of expectations can place enormous pressure on religious education as the different stakeholders judge the merits of the subject and its position in the school curriculum according to the results that are linked to their expectations. The unreasonably diverse and unattainable nature of these expectations can lead to a discourse, or discourses, of failure that can destabilize public confidence in the validity and efficacy of

religious education in schools. Perhaps, more importantly, so busy are those who try to co-opt religious education to their particular mission that they ignore what it is that constitutes the religious.

Models of Religious Education

A useful starting point for the mapping of religious education is Hull's proposal that religious education can promote education into religion, about religion, or education from religion, while acknowledging the simplistic nature of these distinctions and the creation of artificial boundaries between potentially complementary and overlapping activities (Schreiner in Kuyk *et al.*, 2007). Religious education into religion is into one specific religion (often a Christian denomination). Religious education about religion involves learning about beliefs, values, and practices of a religion. Religious education from religion helps children develop their own views by considering different answers to major religious and moral issues. The next sections explore three models of religious education that exemplify religious education into, about, and from religion: the confessional approach; the phenomenological approach; and the interpretive approach. These sections should be read with the caveat that these three models are not necessarily mutually exclusive nor do they exhaust the range and complexity of the models in religious education.

Confessional Approach

Reinforcing and simultaneously emanating from the controversies alluded to at the beginning of this article are the models of religious education currently adopted in faith schools (private or state funded), often referred to as catechetical, confessional, or faith formational models of religious education (e.g., Belgium and Scotland). Of course, it may be true that such approaches are generally limited to faith-based institutions in the twenty-first century, but this has not always been the case. Until the 1970s, in Britain, for example, most religious education was rooted in bible knowledge with the express aim of nurturing children in the Christian tradition – a formal position that has its roots in the 1870 Education Act. While it is the case that faith schools have traditionally belonged to a Christian denomination (a classic example of the catechetical or faith formational approach would be the worldwide network of Roman Catholic schools), Western liberal democracies have witnessed a growing diversity in religious schools, including the emergence of an increasing number of Islamic schools (e.g., Netherlands, Denmark, and England) (Kuyk *et al.*, 2007). Religious education in faith schools, often perceived within faith schools as a vehicle for religious nurture, is frequently suspected by outsiders of being overly transmissive and coercive, despite much diversity in the models of

faith schooling (ranging from liberal to conservative). This discussion of religious education in faith schools is further complicated by the difficulty of extricating religious education within the faith school from the related issues of collective or corporate acts of worship and the religious character of the school (Parker-Jenkins *et al.*, 2005).

A number of key questions emerge in the academic debate concerning the position and role of religious education in faith schools where religious education slips into religious practice and nurture. Some academics, such as Feinberg (2006), a proponent of liberal education, have challenged the models of religious education within faith schools. Feinberg questions how some of the aims of liberal education can be achieved by religious education in a faith school. While he acknowledges the diversity of religious education within, for example, American Roman Catholic schools, he wonders how religious education in a faith school can address moral novelty (new problems raised in science and technology) and allow children to be authentic and make authentic choices for their own good? He doubts if there is sufficient scope for critical reflection and is concerned that faith schools are not open enough to other religious perspectives.

A number of points can be raised here. First, this kind of position is located within the chain of argument that has moved from the claims for rational autonomy of the child being brought up in a religious family to be protected to the more recent claims that the rights of the child are compromised in faith schools (Manson in Gardner *et al.*, 2005). Second, such a line of argument often fails to fully recognize the wide variety of faith schools and the variegation within specific faiths that range from theologically conservative to the liberal (McKinney, 2006). The model of religious education as conceived and implemented within some faith schools may readily be perceived as compatible with the aims of liberal education. In other cases, a more restrictive, theologically dependent approach is adopted. Yet, even here, there is some evidence that some of these more conservative institutions have been influenced by religious, cultural, and ethnic plurality and their approach to religious education is becoming ever more open to other faiths and worldviews, embracing some degree of critical reflection (Schreiner, 2007).

The Phenomenological Approach to Religious Education

The move in public schools from an implicitly Christian-based, biblically rooted religious education to a more descriptive reified pedagogy has its roots in philosophical theology, which, in its own turn, goes back to nineteenth-century hermeneutics. The central questions of the hermeneutical endeavor: How am I to stand in relation to this text? How does this text appear to me? gave rise to the phenomenological excursions of such early-twentieth-century

thinkers such as Edmund Husserl. Such phenomenology represents one attempt in a line going back to Kant, to disclose *das ding an sich* (the thing-in-itself); in other words, to get to the essence of things. Accompanying this journey to unearth the inscape of things, we have seen the emergence of late-nineteenth-century anthropology with its drive to map the topography of others beliefs and practices. Against the backdrop of these developments, the study of religion or religious studies emerges as a discipline. *The Religious Experience of Mankind* (Smart, 1969), with its focus on a morphological approach (mapping perceived common features of religion), becomes a standard text as departments of theology or divinity (traditionally Christian) begin an evolution into departments of religious studies. At the same time, in the postwar period in Britain, immigration came to play an increasingly important role in shaping the curriculum. How were we to offer religious education to children whose own religious beliefs and practices are quite different from those of the majority indigenous population? The shift from theology to the study of religion(s) was pioneered in Britain by Ninian Smart, who also chaired an influential Schools Council Working Party, which, in its turn, recommended the adoption of a phenomenological approach to religious education. However, the practical application of phenomenology as a ground for a radically different justification and pedagogy for the conduct of religious education was rooted in morphological description rather than the search for essences. The practical consequence of this shift was that religious education came to be seen as a means for comparing and contrasting a variety of religious belief systems. Frequently, in the classroom, this meant a comparison between ritual practices with little-enough attention paid to the more-difficult epistemological and ontological questions which suffuse doctrine and belief.

The Interpretive Approach to Religious Education

Over the subsequent three decades, increasing disquiet emerged about the efficacy of a strictly phenomenological approach (although it is not entirely clear that the diluted practices in schools count as phenomenology). This gave rise to a number of modifications or alternatives. One important shift has seen the emergence of the interpretive approach, propounded by Robert Jackson and his colleagues at the University of Warwick, which is grounded in the conceptualizations and methodology of ethnographic research (Jackson, 1997, 2004). Rooted in, but distinct from, the phenomenological tradition Jackson attempts to chart a *via media* between a pedagogy hypothecated on the presentation of prescribed and normative beliefs and practices on the one hand, and the deconstruction of religion on the other, arguing for the preeminence of the personal narrative. Jackson argues that the interpretive

approach enables a more nuanced understanding of religion that recognizes a variety of, sometimes contested, expressions of religious belief and practice that are often interrelated or inextricably bound with culture and identity. An important aspect of the approach is the explicit recognition of the religious and ideological backgrounds of the pupils, and the children are encouraged to draw on their own experiences and those of their peers. This should enable them to derive their own personal positions within key debates and questions concerning religion and religious plurality. There are clear advantages to this approach that are focused on a model of religious education that draws from the complexity of religious situatedness. This, he claims, enables religious education to break out of the stranglehold of stereotypical orthodox discourses and the dominance of the Christian discourse. It allows the children some insight into the diffuse and variegated nature of religious expression within particular religions (especially the Eastern religions, such as Hinduism). It also promotes a greater understanding of religion as evolving and engaging with new sociocultural contexts. There may be a perception that this approach relies too heavily on experience, and the balance of the *via media* would have to be carefully monitored as this approach could easily become restricted to personal narrative. Some religious groups may be uncomfortable with this approach as it places less value on orthodoxy and orthodox representation but is more open to a variety of expression and representation. Some critics (Wright, 2007) argue that this approach fails to sufficiently recognize the importance of religious literacy, although Jackson would argue that his approach complements others.

Key Issues for Religious Education in the Twenty-First Century

Perhaps a key issue for the delivery of religious education is the manner in which professionals have attempted to construct conceptual maps of religion for children in school curricula. Whether these are grounded in organizing principles, emanating from pedagogy or religion, they tend to be rooted in a Christian worldview. In this, history is hard to escape – many religious education programs in Western Europe have their roots in a Christian imperative as a consequence of the historic strength of denominational schooling. Despite conscientious and well-intentioned attempts to incorporate a world-religions perspective in curricular developments, these maps can often be refracted, to varying degrees, through an implicit or explicit Christian lens. Sometimes this is demonstrated in the paradoxical, and ultimately meaningless, use of language and concepts borrowed from Christianity to construct frameworks that can be applied to all mainstream religions. As knowledge and understanding of Eastern religion in Western society

has deepened, and the influx of immigrants from diverse religious traditions (and denominations within those traditions) has increased, the use of these frameworks has become increasingly problematic and contested. Perhaps a series of more complex or sophisticated heuristic frameworks is required? Does this pose an unwelcome dilemma for those who wish to retain the dominance of Christianity in religious education?

This problem of perspective has been exacerbated by a recent challenge yet to be properly recognized by many religious educators, which has emerged out of the growth of a range of groups and spiritual movements that can lay claim to the description religious. The paradigm of six mainstream world religions, identified by academics such as Cole (1998), has been modified by the inclusion of other faiths in interfaith dialogs and networks (e.g., Baha'i; and Zoroastrianism in the Inter Faith Network for the UK); however, even this wider frame is facing serious challenge from the emergence of new religious movements and new-age spiritualities (Cowan and Bromley, 2008). Such terms are crude generalizations but nevertheless point to a wide variety of expressions of religion from liberal or Western developments of mainstream faiths (e.g., engaged Buddhism and neo-Hinduism) to the groups previously (and pejoratively) identified as cults (e.g., Church of Scientology and Unification Church), and those viewed with historical suspicion (e.g., Wicca and witchcraft) (Clarke, 2006). The understanding of what constitutes a religion is being challenged as some of these groups and movements lobby for charitable status and official participation in interfaith networks and dialogs (Clarke, 2006). A key question for the twenty-first century will be how models of Western religious education, primarily focused on the six mainstream religions (often through a Christian lens), can negotiate this shift in the religious landscape and recognize or even accommodate these increasingly popular groups and movements without some form of possible re-entrenchment or recalibration of the nature of religious education.

Another major issue for the continuation of religious education in state school education is not the much-publicized and premature prediction of the terminal decline of religion in Western society, but the tension caused by the political and ideological pressure to create a permanent disjuncture between the state and organized religion at all levels of society. While liberal democracies defend the rights of individuals to hold and practice religious beliefs, these beliefs and practices should not impinge on or influence the social polity. Religious education in state schools can become a visible focus of the invidious intrusion of religion into public life and the unwelcome challenges of religious worldviews for the principles of liberalism. This is compounded by the emergence and growth of religiously motivated terrorism in the early twenty-first century, which has created an unfounded and unjust perception in some quarters, that religious

adherence is somehow synonymous with, or will inevitably lead to, fundamentalism. This, in turn, can lead to claims for a greater prominence for intercultural education, citizenship education, and values education in school education – forms of education that are explicitly grounded in educational ideologies that promote social tolerance and political participation but can be perceived to compete with, rather than complement, religious education (Jackson, 2004; Keast in Gardner *et al.*, 2005).

Conversely, some academics in the liberal tradition, such as Feinberg (2006), argue that it may be advantageous to a secular liberal democracy to include religious education in the curriculum in state schools. These academics suggest that a state influenced religious education that is balanced and adopts a critical stance toward religion may be able to counter possible excesses and fundamentalist tendencies that can emerge in informal/formal faith formation in religious communities. Similarly, Brighouse (in Gardner *et al.*, 2005) warns of the dangers of unregulated religious education in some of the private faith schools in America that can be closed to plurality in religion and critical engagement with both politics and religion.

Concluding Comments

Self-evidently, religion has had a formative influence on Western liberal democratic thought. Moreover, it remains equally true that, despite being considered misguided by numbers of their fellow citizens, many continue to be attached to religion as not just a life enhancement but an epistemological and ontological reality. It is for them a fundamental option that directs and influences their life options. As such, religion remains an important aspect of human life and, from one perspective, if children are to learn what it is to be human, it remains worthy of study. From another perspective, religion is an irrational endeavor that enslaves people with false soteriological and eschatological hopes that inhibit authentic rational autonomy and engagement in the furtherance of a human rather than theistic utopia. Religious education simply serves to authenticate and perpetuate this irrationality and enslavement. It is within these kinds of contesting discourses, located at the center of the search for meaning in human existence, that

religious educators continue to argue for the importance of their subject and its place in the school curriculum.

Glossary

Agency – One's reflections and actions in shaping one's own life goals.

Capability/capabilities – The real, effective freedoms to pursue one's goal; genuine opportunities for functionings.

Development – The expansion of freedoms.

Equality – The fundamental principle of social justice; equal distribution of whatever goods are deemed valuable.

Functionings – The valued states and actions that are meaningful to people.

Normative framework – A framework specifying ethical principles, that is, how things ought to be.

Practical reason – The capacity to form and revise one's conception of the good.

Originally formulated by philosopher and welfare economist Amartya Sen, and further developed by philosopher Martha Nussbaum, the capabilities approach has increasingly influenced academic research as well as policymaking in the last two decades, (Robeyns, 2006a: 351). The capabilities approach is a normative framework for the evaluation of human well-being, the justice of institutional arrangements, and the level of individual advantage or disadvantage in contemporary societies. The fundamental innovative insight of the approach is that the evaluation of people's quality of life should be based on their capabilities to function, that is, on their real freedoms (their capabilities) to be and to do what they value being and doing (their functionings). According to Sen and Nussbaum, what a person is able to be (e.g., being well or poorly educated) and to do (for instance, doing a rewarding job), determines a person's quality of life and his/her well-being. In their view, the freedom to choose among possible functionings is fundamental to the possibility of leading good lives, and this insight should inform processes of social evaluation, as well as the analysis of equality. In focusing attention on capabilities and functionings, the approach provides a compelling alternative to both welfare economic models based on utilitarian considerations and philosophical approaches, to equality, which concentrate primarily on an individual's preference, satisfaction or happiness, or on income and wealth (Sen, 1982, 1992; Nussbaum, 2000, 2006b).

The philosophical roots of the approach can be traced back to Aristotelian and Marxist insights, as well as, to the works of Adam Smith and John Stuart Mill among other (Sen, 1980, 1992, 1999; Nussbaum, 2000, 2006a; Robeyns, 2005). Certainly, the theoretical reach of the capabilities approach and its inherent interdisciplinary nature (Robeyns, 2005, 2006a) are attested by the considerable interest it has attracted from different academic disciplines and from policymaking. Political philosophers, development economists, scholars in gender studies, as well as in sociomedicine and disability studies, have all engaged the ideas of the approach. Furthermore, the approach has been operationalized in the United Nations' Human Development Reports (1990–2004) and has more recently informed the final report of The Equalities Review (2007), commissioned by the UK Prime Minister to assess the state of equality in the country.

It is only relatively recently that educationalists have started to analyze the potentially fruitful insights of the capabilities approach for educational theory, policy, and practice. Perspectives applying the capabilities approach to education emphasize primarily its contribution to the conceptualization of social justice and educational equality, and to the theoretical and empirical analysis of educational provision, both in developed and developing countries. Attention is also devoted to pedagogical and curricular elements, and to their importance for the expansion of people's capabilities and their overall freedom to lead flourishing lives.

The article offers an overview of the capabilities approach and its relevance for education. A critical discussion of the main normative insights of the approach, as differently developed by Sen and Nussbaum, is followed by an analysis of the role of education and of the conceptions of educational justice and equality informed by these insights. The analysis is based on the main theoretical and empirical research developed in education, and outlines some of the themes and the future possibilities of the capabilities approach in education.

Normative Insights

Sen's Capability Approach

In critically engaging perspectives in welfare economics, mainly based on commodities and the philosophical debate on what kind of equality institutions should seek to achieve, Sen's work aims to provide a more adequate framework for conceptualizing human development,

as well as a compelling form of egalitarianism (Sen, 1992, 1999). Key concepts in Sen's approach are the space of capability, the specific metric informing interpersonal comparisons of advantage, the concept of human diversity, and finally, the democratic decision process entailed by the approach. Each of these concepts requires some elaboration, and we begin with the space of capability.

According to Sen, evaluations of poverty, inequality, and the just design of social institutions should take place in the space of capability. This is the space of the effective freedoms that people have in which to achieve objectives that are meaningful to their lives. Within this space, capabilities are defined as the real and genuine opportunities available to individuals to pursue their valued ends, and thus choose one type of life or another (Sen, 1992: 40). Functionings are valued states and actions (Sen, 1992: 39); being healthy and being educated, reading, going to work, and participating in the life of the community, are all examples of functionings. Capabilities and functionings are essential to well-being, Sen maintains, and as such, any evaluation of individual well-being should take the form of an assessment of these elements (Sen, 1992: 39).

Sen endorses equality of capabilities – or, conversely, the elimination of unambiguous inequalities in capabilities (Sen, 1992: 7) – as the appropriate objective of social policy, and asserts the importance of addressing interpersonal comparisons in the space of capability. The emphasis is therefore placed on the equalization of people's genuine opportunities, rather than on their achieved functionings. In line with broad liberal views, Sen supports a perspective that equalizes the opportunities available to people, thus allowing for the pursuit of their objectives in accordance with their different conceptions of the good life. This is further confirmed by the importance of the role of reasoned agency in forming valued life plans, since agency relates to choosing one's own broad life goals and commitments, and to actively engaging in their achievement.

The assessment of poverty and disadvantage, according to Sen, should be based on a specific metric for interpersonal comparisons, which sees the concept of human diversity as central, thus reinstating considerations of individual differences as fundamental to this process. Human diversity is conceptualized in relation to internal features, such as gender, age, and physical and mental abilities, as well as external factors, including the design of the physical, social and cultural environment that people inhabit. Furthermore, and importantly, Sen highlights people's differences in converting resources and commodities into valued objectives (Sen, 1992: 85). He illustrates this element of diversity with the well-known example of children and lactating women who, for their functionings in their daily lives, require a higher intake of proteins than other people. Hence, in his view, this different conversion of resources into functionings should inform any comparison of individual advantage.

On the basis of these insights, Sen identifies the capability approach as a framework of thought and not as a theory of justice, while declining, in light of the variability of human ends, to specify a definitive list of capabilities or functionings. Sen leaves these processes to public choice, reasoning, and democratic procedures, that are themselves the most freedom-preserving means by which social policy can be determined (Terzi, 2005). Hence, his approach has a deliberately underspecified character.

This underspecified nature of the approach, however, has been the subject of critiques. These primarily highlight the difficulties in choosing what capabilities are deemed important, and how they can be evaluated. Consider, for instance, the capabilities of a visually impaired person and those of a person suffering from asthma: How can these two sets of capabilities be compared in order to determine disadvantage? Furthermore, difficulties arise in evaluating these sets of capabilities in relation to those of many other individuals, who may have, and value, certain capabilities and not others. The unspecified character of the approach, some critics maintain, leads to the difficulty of assessing and indexing the value of capabilities. Sen replies to such critiques by highlighting, on the one hand, his reference to some basic, fundamental capabilities – such as being well nourished, sheltered, healthy, and educated – which are truly essential to human well-being, and which he repeatedly identifies as such in his work (Sen, 1992, 1999). At the same time, he emphasizes the role of democratic processes in selecting and listing relevant capabilities in relation to specific and determined contexts. This latter defense, however, leaves open the problem of securing prior democratic principles and constitutional procedures that would allow the advocated process of participatory selection to take place.

Martha Nussbaum's version of the capabilities approach, as discussed in the next section, addresses some of these concerns.

Martha Nussbaum's Capabilities Approach

Nussbaum endorses Sen's idea of capabilities as the correct variable for comparisons of quality of life, but articulates and specifies the philosophical dimension of the approach in some important ways. In particular, she identifies a list of central human capabilities that have a universal dimension – in that they can be shared by people holding otherwise very different conceptions of the good – and sets a threshold of adequacy in the possession of these capabilities, which should be guaranteed to all. These elements form the basis for constitutional principles to be adopted by all governments (Nussbaum, 2000: 12).

The central human capabilities proposed by Nussbaum include life, bodily health, bodily integrity, senses, imagination, and thought, emotions, play, control over the environment and other species, and practical reason and

affiliation (Nussbaum, 2000: 78–80). While emphasizing that her list is open to changes, Nussbaum considers these capabilities as fundamental to human well-being. Furthermore, she assigns a central role to practical reason, in its Aristotelian meaning of being able to form one's conception of the good, and to affiliation, or the ability to establish meaningful relationships, with each seen as both foundational to other capabilities and essential for leading lives that are truly human (Nussbaum, 2000: 82).

A further, important specification in Nussbaum's version of the approach relates to her articulation of the concept of capabilities in basic, internal, and combined capabilities. This addresses the critique of underspecification of the approach. Thus, basic capabilities, in her account, relate to basic innate capacities of individuals, whereas internal capabilities are developed states sufficient for the exercise of functionings. These internal states of the person, unlike innate capabilities, are developed in relation to external conditions and circumstances. For instance, according to Nussbaum, most people have the internal capability for freedom of speech, but whether they can exercise it and achieve the related functionings depends on external conditions (Nussbaum, 2000: 84). Combined capabilities amount to the internal states and the external conditions for the exercise of the relevant freedoms.

Nussbaum's focus on central human capabilities is grounded on the intuitive ideal of the equal moral worth and dignity of each and every individual, seen as an end in themselves (Nussbaum, 2000: 5), and on the possibility of a political overlapping consensus on the importance of each capability on the list. She maintains that when we ask the question central to the capabilities approach, "What is this person able to be and to do?", we are evaluating what this person's liberties and opportunities are, and how the resources at her disposal allow her to function in a truly human way (Nussbaum, 2000: 71, 74). Thus, the central capabilities act as guidance for political action as well as for policy design, since governments should provide both the conditions for the development of internal capabilities and the external conditions for their exercise, in ways and to levels that reflect the dignity of the human life.

In specifying a list of universal capabilities and in setting a threshold level that should be guaranteed to all, Nussbaum provides an answer to the charge of vagueness and underspecification leveled at the approach. However, her version of the capabilities approach is open to other critiques. In particular, these have been expressed in relation to the universality of her list of capabilities, and to the method used in formulating the list, which is seen as departing from the democratic consultation processes that could give it a more general endorsement. In reply, Nussbaum maintains that the list is indeed open to adaptations, and that people who otherwise belong to very different cultural and social environments share the capabilities on the list, thus reinstating the validity of her perspective (Nussbaum, 2000: 115).

While these and related matters remain far from settled, Nussbaum's approach contributes fundamentally to the theory of justice, in particular with her formulation of precise understandings of the constitutive elements of well-being and the good life. Further, in her more recent work, she extends these considerations to previously unexplored issues of justice, such as justice beyond national borders and justice for cognitively disabled citizens (Nussbaum, 2006a).

Both Sen's and Nussbaum's versions of the capabilities approach have influenced educationalists who have recently started to apply these ideas to the theory, policy, and practice of education. The next sections present the main insights which the capabilities approach offers to the field of education.

The Capabilities Approach and Education

Both Sen (1999, 2002) and Nussbaum (2000, 2004, 2006a, b) highlight the importance of education in the capabilities approach. They emphasize the contribution that being educated makes to the formation and expansion of capabilities and hence the contribution it makes to people's lives. Sen includes the capability to be educated among the small group of basic capabilities that are fundamental to well-being and to development and points out, for instance, the broadening of women's freedoms resulting from education and its related benefits, such as a reduction in infant mortality (Sen, 1999: 198). In her work, Nussbaum reflects extensively on the value of education, which, she maintains, should be seen "not merely as a provider of useful technical skills, but also, and more centrally, as a general empowerment of the person through information, critical thinking, imagination" (Nussbaum, 2006a: 323). She stresses the importance of education for democracy, for equality, and political action, as well as for the flourishing of human life (Nussbaum, 2006a: 322). This view of education as fundamental to the development of capabilities is further explored in her defense of the cultivation of humanity, regarded as central to a project of liberal higher education. The promotion of forms of critical self-examination, the idea of world citizenship, and the fostering of processes of narrative imagination, all contribute to individual development as well as to a political aim of global citizenship (Nussbaum, 1997).

Inscribed in these positions are some of the fundamental insights of the capabilities approach to education, which, for the purpose of this analysis, can be subsumed in three main areas. First, the approach emphasizes, together with its instrumentality, the intrinsic value of education and its functions, both for the individual and for society. Second, it contributes a valuable framework for the assessment of inequalities in education, while suggesting a conception of equality in terms of equal, effective, opportunities for the achievement of important functionings which are promoted

by education. Finally, it informs pedagogy and models of curriculum that enhance freedom and agency. Each of these insights has been recently explored in the growing literature on the capabilities approach in education, and each is analyzed in more detail in what follows.

The Value and Functions of Education

In contrast to current approaches mainly concerned with the instrumental role of education, such as human capital theory – with its accent on the acquisition of skills and competencies for the promotion of economic goals – the capabilities approach provides a broader view of education as having both an important intrinsic value and a range of different instrumental values for the individual, and for society more generally (Dréze and Sen, 2002; Robeyns, 2006b; Saito, 2003). The emphasis of the approach on well-being and the expansion of individual freedoms relates to an understanding of education as intrinsically valuable. Being educated provides and enhances the possibility of engaging in activities that contribute to one's fulfillment in life and are not simply instrumental in securing better jobs or positions in society. The capabilities approach highlights how, for instance, being introduced through education to the appreciation of literature, or science, or different kinds of music, leads to forms of personal fulfillment and personal reflection that have their own inherent value. On the other hand, the approach importantly points to the several instrumental aims served by education, which are fundamental in attaining better life prospects and career opportunities, as well as in promoting forms of social and economic development. Education, and specifically formal schooling (however imprecise and questionable this distinction may be), is crucial in securing standards of living, since it allows the acquisition of knowledge and skills that play an important role both for well-being and for the exercise of agency. In addition to this, as Robeyns notes (Robeyns, 2006b: 73), the roles of education are valuable also at the collective level. Economic growth and higher standards of living are promoted by educated people, as are more tolerant and diversified views of what constitutes a good life, thus indirectly enhancing the well-being and freedom of all.

The fundamental functions of education in the capabilities approach lead to a further set of considerations which see the approach as an innovative framework for the assessment of inequalities and for conceptualizing educational equality.

The Capabilities Approach and Justice in Education

One of the most distinctive insights of the capabilities approach to education concerns both its normative contribution to the theorization and analysis of inequalities in education, and its possible operationalization in evaluating

the justice of current educational systems. As we have seen, the approach provides a normative framework for the assessment of the just design of social and institutional arrangements, and suggests an idea of capabilities equality as equal opportunities for valued functionings. Applied to education, this framework shifts attention from the amount of resources spent on education, or from a consideration of education as a resource in itself, aimed at unilaterally promoting economic goals. It also provides a richer, and more articulated framework than those based on assessing educational outcomes, in terms of exam results and levels of qualifications. Instead, the approach suggests a comprehensive framework that has at its center the equalization of the actual effective opportunities for the achievement of important functionings in education, such as being able to read and to write, or to concentrate and accomplish tasks, or to reflect critically on one's own actions. While the exact specification of these fundamental functionings may, to some extent, be considered as the result of democratic processes similar, for instance, to those exercised in devising national curricula, the actual educational provision in terms of equal opportunities for functionings has a distinctively normative force. Here, effective and real opportunities are to be understood as including educational resources, settings such as school buildings and facilities, and external conditions such as policies and legislation that are necessary to promote educational achievement (Terzi, 2008). An example may illustrate this point. Consider, for instance, Emily and Emma, who have achieved different outcomes in mathematics. Suppose they are otherwise similar, and have both attended an excellent school. However, Emily has spent most of her time in leisure activities, whereas Emma has devoted more attention to her studies. The different achieved functionings in this case are not a matter of justice for the capabilities approach, since a degree of personal choice relates to the different outcomes. Suppose instead that these different achieved functionings are the result of Emma attending a much better equipped school than Emily's: in this case, the difference in functionings is a matter of justice, since it relates to a clear inequality of capabilities. The attention to capabilities, and their relation to achieved functionings, constitutes an innovative contribution to educational thinking about issues of justice. However, the actual operationalization of this framework to more practically oriented aims is still rather unexplored.

Furthermore, it must be noted that while referring to capabilities is paramount in relation to what governments can provide through public policy, the question becomes more complex with regard to the education of children, given their restricted agency, freedom, and choice. On this issue, Sen (Saito, 2003) highlights the future dimension entailed by education, while Nussbaum (2006b) specifies the importance of considering functionings, rather than capabilities, when enacting forms of compulsory education for children.

Pedagogy and Curriculum

Rather less explored than the previous two dimensions, the potential contribution of the capabilities approach to forms of pedagogy and the design of curricula relates to the expansion of individuals' freedoms and their reasoned agency. A focus on critical understanding and reflection on valuable knowledge, as well as on the capabilities for the formation of valued aims and life plans, is central to both capabilities-based pedagogy and curriculum. Questions arise in relation to the distinctive institutional designs and the forms of teaching and learning that would promote valued capabilities, while taking into due account the different sociocultural elements that might influence learning.

Nussbaum (1997, 2006b) explores the pedagogical dimension of an education aimed at freedom, in relation to her defense of a liberal project (as mentioned above), specifically, but not limited to, higher education. The three elements that are foundational to that project also provide valuable suggestions for pedagogical and curricular design. The critical examination of oneself, and of one's own and other traditions, informs not only pedagogy that privileges dialog and critical dispositions, but also logical reasoning and rigorous judgment. The understanding of oneself as a citizen of the world indicates the importance of forms of multicultural education, of historical and political knowledge, and of other languages. Finally, Nussbaum highlights ways in which the ability of narrative imagination is specifically cultivated by the arts and literature (Nussbaum, 2006b: 391). The importance of creativity relates also to the human-central capabilities of senses, imagination, and, finally, play. Nussbaum reinforces the idea that the exercise of these functionings is crucial for the formation of the adult's future capabilities, thus further guiding the design of curricula and of forms of pedagogy that enhance, rather than hinder, their development (Nussbaum, 2000).

While these are only some indications of ways in which pedagogy and curricula may be informed by a capabilities perspective, they nevertheless strongly suggest that forms of teaching and contents that undermine, exclude, devalue, or hinder human freedom are incompatible with the insights of the approach. However, more research is necessary for an application of these ideas to the policy and practice of education.

Summary

The centrality of well-being and the expansion of freedom advocated by the capabilities approach, its engagement with issues of justice and questions of equality, as well as with the value of democratic processes are all fundamental insights for educational theory, policy, and practice. While it is important to bear in mind that the capabilities approach is not an educational framework, and has not emerged in relation to educational concerns,

it is nevertheless equally important to highlight ways in which its theoretical and normative insights provide extremely important understandings of the value of education, of issues of educational justice, and of forms of pedagogy and the design of curricula that place individuals' well-being and their flourishing as central.

The insights suggested by the approach have the potential to contrast and provide valid counterarguments to current approaches to education, which narrowly focus on the acquisition of skills and competences unilaterally aimed at the furthering of economic goals, and to forms of pedagogy and curriculum that center on performativity rather than on the expansion of human freedom.

However, further theoretical and empirical research is needed to advance thinking along these lines.

Introduction

In many countries over the world, there has been a hotly contested and widely reported debate over the educational consequences of class-size differences. Opinions vary from those academics and policymakers who argue that class-size reduction is not cost effective to those who argue that it should be a cornerstone of educational policy. In some countries, policy has changed in favor of small classes. In the USA alone, 33 states have enacted legislation for class-size reduction (CSR) programs. Current government policy in England and Wales is for a maximum class size of 30 at reception and KS1 (4–7 years), and larger cuts are planned in Scotland. There have been initiatives involving class size or pupil to adult ratio reductions in the Netherlands and New Zealand. In East Asia, starting from the mid-1990s, many countries and cities (including Mainland China, Hong Kong, Korea, and Japan) have implemented policies to reduce class sizes. The controversy about class size has been very noticeable in Hong Kong where, in the context of a sharp decline in birth rates and school closure, mounting political pressure on the government to reduce class sizes led to the commissioning of a 3-year research project, only for political developments to lead to implementation of CSR in primary schools starting from 2009/10.

Despite the important policy and practice implications of the topic, there has been a wide gap between professional belief – that small classes are likely to lead to better teaching and learning – and research findings which have

not always been clear. There have been a number of comprehensive reviews of the class-size literature: Anderson (2000); Biddle and Berliner (2002); Blatchford and Mortimore (1994); Blatchford *et al.* (1998); Blatchford *et al.* (2009); Ehrenberg *et al.* (2001); Finn *et al.* (2003); Galton (1998); Grissmer (1999); Hattie (2005). Given a limited word length, in this article, we provide a selective review, describing important studies and identifying issues that seem to be important to us at this time. We address the issues of: (1) whether class-size differences affect children's educational attainment and learning, (2) whether class size affects classroom processes like teaching and pupil behavior, and (3) educational implications, in particular ways in which teachers can make the most of small (and large) classes. We provide a more international perspective than many reviews which have tended to be dominated by research in the USA. We cover recent developments in East Asia, where class-size effects have figured prominently in research and development. We also provide suggestions for future research.

Class Size and Educational Performance

Overall, it has often been pointed out that much previous research has not had designs strong enough to draw reliable conclusions about the effects of class-size differences (Blatchford *et al.*, 1998; Ehrenberg *et al.*, 2001; Finn *et al.*, 2003).

Correlational Designs

There has been considerable interest in the consistently superior performance of East Asian students in large-scale international studies, even though they have larger class sizes than most Western students (e.g., Pong and Pallas, 2001; Woessmann, 2006). This has led many to query the benefits of small classes. We take up below the issue of cultural factors in interpreting research findings, but here we make the general point that simple correlational designs, which examine associations between a measure of class size or pupil–teacher ratios (PTRs) on the one hand, and measures of pupil attainment on the other, are misleading. These studies – which often find that pupils in larger classes do better than pupils in smaller classes – are difficult to interpret, because we often do not know whether the results can be explained by another factor, for example, that poorer-performing pupils are placed in smaller classes.

Many econometric studies tend to use a measure of PTR rather than class size. It is not always realized that these two measures are not the same thing. PTRs are usually calculated by dividing the number of pupils on a school's roll by the full-time equivalent number of qualified teachers, and do not take into account noncontact time. It should not be assumed, therefore, that teachers who entered into the calculation are teaching for the whole time. PTRs are important from an administrative or economic point of view because they are closely related to the amount of money spent per child. However, in terms of pupil learning, the number of students physically present is more important. Researchers need to derive measures of class size as close as possible to that experienced by teachers and pupils. Here, we review several main studies of class-size effects on academic outcomes.

Student Achievement Guarantee in Education

The Student Achievement Guarantee in Education (SAGE) program began in Wisconsin in 1996 for K–3 pupils and involved several parallel interventions that targeted more disadvantaged schools and included reducing PTRs to 15 students. Results suggest that SAGE students significantly improved as a result of being in smaller classes, the gains for African-American students being greater than for white students (Ehrenberg *et al.*, 2001). One of the limitations of this study was that it involved changes to PTRs not class size as such and also that the effect of PTR reductions was not separable from other interventions in the program.

California

This began in 1996 and involved a massive state-wide implementation of CSR in grades K–3 at a cost of well

over 1.5 billion dollars and involving 1.8 million students. The overall aim was to reduce class sizes from 30 to 20 or less. Results showed a disappointingly small advantage in achievement for students in smaller classes but it is commonly recognized that it is very difficult to interpret results because the research design was limited. The intervention depended on the hiring of many unaccredited and inexperienced teachers and the use of portable classrooms and nonclassroom space (Bohrnstedt and Stecher, 1999).

To arrive at sounder evidence, two kinds of research design are needed. We concentrate on two studies which represent each approach.

Student/Teacher Achievement Ratio

It is often assumed that the problems of correlational research are best overcome by the use of experimental research or randomized controlled trials. Such studies are unique in potentially being able to provide clear evidence of causal direction. This is one reason for the great attention paid to the Tennessee Student/Teacher Achievement Ratio (STAR) project. A cohort of pupils and teachers at kindergarten through to grade 3 were assigned at random to three types of classes within the same school: a small class (around 17 pupils), a regular class (around 23 students), and a regular class with a teacher-aide. In brief, the researchers found that in both reading and mathematics, pupils in small classes performed significantly better than pupils in regular classes, and children from minority ethnic group backgrounds benefited most from small classes (Finn and Achilles, 1999). In fourth grade, the pupils returned to regular classes and the experiment ended, but gains were still evident after a further 3 years, that is, grades 4–6. Although some aspects of the project are still contentious, reanalysis of the data, using more sophisticated techniques, supported the central finding of a difference between small and regular classes (Goldstein and Blatchford, 1998).

Class Size and Pupil–Adult Ratio

Although experimental studies can provide sound evidence of causality, it should be recognized that they are extremely difficult and expensive to set up, and have validity problems of their own, not always appreciated (Goldstein and Blatchford, 1998). An alternative approach was adopted in a large-scale UK study the Class Size and Pupil–Adult Ratio (CSPAR) project (see e.g., Blatchford (2003); Blatchford *et al.* (2005); Blatchford *et al.* (2003); Blatchford *et al.* (2002). This studied the effect of class size on pupils' academic attainment and on classroom processes such as teaching, pupil attention, and pupil relations. It tracked over 10 000 pupils in over 300 schools from school entry (at 4/5 years)

to the end of the primary school stage (11 years). It employed a nonexperimental multimethod longitudinal design, measuring the effects of natural variations in class size with multilevel regression statistical analyses in order to determine effects of class size controlling for other factors, such as pupil prior attainment.

There was a clear effect of class size on children's academic attainment over the reception year (4/5 years), in both literacy and mathematics, even after adjusting for other possible confounding factors. The effect is comparable to that reported by the STAR project. Small classes (below 25) worked best in literacy for children who were most in need academically. Effects were still evident on literacy progress at the end of the second year of school (Year 1), though by the end of the third year, the effects were not clear. There were no clear longer-term effects of class-size differences on mathematics achievement. Although this indicates that the early benefits wash out after 2 years in school, there were no restrictions in terms of which size of class they moved to from year to year. Moving to a class of a different size, especially a larger class, had a negative disruption effect on progress.

Some issues connected to class-size effects on attainment

Results from both experimental and longitudinal observational studies are therefore consistent in showing positive effects of smaller classes on academic outcomes, in the first years of schooling. But there are several complicating factors when considering effects of class size on pupil attainment.

Overall class sizes

Research evidence is usually based on class sizes normally experienced in countries within North America, Europe, and Australasia. However, average class sizes can vary greatly between countries and in some countries can be very much larger. Hattie (2005) has pointed out that different class sizes will affect what is considered effective in teaching. Very different styles of teaching will be necessary, and different class size effects can be expected, when faced with class-size bands as different as 80+, 30–80, and 15–30 students in a class.

Age of student

The STAR and CSPAR projects are consistent in showing that effects on academic outcomes are clearest with the youngest students and there would seem to be clear support for policies involving CSR in the first years of school. There is no evidence that smaller classes benefit students later in their school careers. There is, though, still debate about whether CSR effects are best seen as age dependent or a start-up effect. If the latter, then it may be that CSR is advantageous soon after strategic points

of transition in student's school lives, for example, primary to secondary education. Research evidence to settle this debate is needed.

Other characteristics of students

Studies such as STAR, SAGE, and CSPAR suggest that CSR tends to benefit some students more than others, particularly lower attaining and disadvantaged pupils. This is probably because extra individual attention is especially beneficial.

Threshold effects?

It is often assumed that class sizes need to fall below a certain number (the figure of 20 is often mentioned) before they can have an impact on educational outcomes. However, this is likely to have much to do with the class sizes chosen in research. The STAR project, for example, compared classes of about 17 with class sizes of about 23 – and this is a main reason why the mid-point between the two is seen as important. However, this range of class sizes is not common in many countries, even in the USA, and an alternative approach is to examine effects of class size across the full range of class sizes, rather than presuppose class sizes likely to be important. In the CSPAR, this approach suggested that 25 or less was important for lower-attaining pupils in literacy.

In general, it is probably oversimplistic to talk about optimal class size in an exact way. Teachers' views about preferred class sizes are likely to be affected by what they have experienced and what they perceive as realistically achievable. Judgments are also likely to be affected by culturally bound views about teaching and about learning, and for these reasons it would not be surprising if views and effects differed between countries.

Alternatives to CSR

Conclusions about the efficacy of CSR are often made on the basis of comparisons with other interventions. Hattie (2005) argues that we should consider effects of class size not in relation to zero – that is, having no effect – but in comparison with other interventions, for example, one-to-one tutoring, phonics training, and Success for All. In general, CSR does not do well in these comparisons. But this is not a fair test in the sense that CSR is not an intervention like phonics training but simply involves changing the number of people in a room, with no control over what happens in the room. A fairer test is to compare it with effects of other, alternative classroom contextual changes (see below and Blatchford *et al.*, 2009).

School and cultural effects

For the most part, studies have examined effects of class size on processes and performance isolated from school and other local contexts within which they take place. But

teachers and pupils in any given class will operate in the context of the school ethos, social background, and local policies. Lai (2007) has shown the important role of school principals in providing a supportive environment for teachers to prepare for small-class teaching and engage in professional development.

One needs to be cautious about generalizing class-size effects in isolation from other factors in education systems (Biggs, 1998). In East Asia, research findings from the US and UK have been extensively cited by both proponents and critics of CSR, despite the fact that the class sizes studied were much smaller. Biggs (1998) has argued that Westerners often wrongly perceive large classes in Confucian heritage cultures (CHCs), such as China, Japan, Korea, and Singapore, as conducive to teacher dominance and passive and rote learning. Meaningful learning can take place in whole-class teaching as children in CHCs are socialized in ways that make them amenable to work in large classes.

Effects of Class Size in Relation to Classroom Processes

It is now widely appreciated that attention needs to move from studies of the effects on academic outcomes to better understanding of the classroom processes that might be involved (Anderson, 2000; Finn *et al.*, 2003; Grissmer, 1999). Unfortunately there are methodological weaknesses in much research in this area. Studies have been relatively anecdotal with a reliance on teacher opinion and comment (Blatchford *et al.*, 1998). Finn *et al.* (2003) have pointed out that there is relatively little strong systematic observational research which would permit objective study of relationships between class size, teaching practices, and student behavior. Much of the evidence from China and Hong Kong is anecdotal in nature (e.g., Lai and Ip, 2007).

Teacher's Individual Attention to Pupils

Perhaps the most consistent finding is that the most important classroom process, affected by reduced class size, is individualization of teaching (Ehrenberg *et al.*, 2001). Results from the CSPAR systematic observation studies (e.g., Blatchford *et al.*, 2005) showed that though there was a heavy reliance on whole-class teaching and individual work in primary schools; pupils in small classes were more likely to experience one-to-one teaching and were more often the focus of a teacher's attention. Separate research has shown this trend continues into secondary schools (Blatchford *et al.*, 2008). In this vein, Anderson (2000) sees small classes encouraging a more personalized and appropriate curriculum for individual pupils.

Easier Classroom Control and Management

A number of studies have reported that pupil discipline tends to be more difficult in large classes and more of an intrusion into the teaching and learning process. In contrast, smaller classes tend to be quieter and more easily managed. Bourke (1986) found that more nonacademic procedural arrangements were necessary in large classes. Once again, cultural factors may be important: Lai (2007) found some teachers in Hong Kong and Shanghai felt overwhelmed by the increased level of student activity and movement in small classes, compared with traditionally large classes under tight teacher control.

Less Teacher Stress and Better Morale

Many studies report that teachers are put under more strain when faced with large classes. Teachers' morale is better in smaller classes (Biddle and Berliner, 2002). This probably comes about because of the increased demands on them and also because they are faced with compromises to their preferred pedagogy (Blatchford *et al.*, 2007). The underlying point, which informs much research stemming from teacher report, is that teachers feel better about teaching in small classes.

Better Relationships with and Knowledge of Pupils

Teachers in small classes tend to experience better relationships with, and have more knowledge of, individual pupils (Finn *et al.*, 2003). In smaller classes, it can be easier for teachers to spot problems and give feedback, identify specific needs, and gear teaching to meet them, and set individual targets for pupils.

Active Involvement with Teacher

Larger classes can lead to pupils having a passive role in class. Research in the UK found that children in large classes were more likely to simply listen to the teacher but in smaller classes, pupils were more likely to interact in an active, sustained way with teachers (Blatchford *et al.*, 2005). Bourke (1986) found more student questions to teachers in large classes but these were mostly requests for clarification or for other help from the teacher.

Pupil Attentiveness/On-Task Behavior

Finn *et al.* (2003) developed a theoretical and empirical case for why student classroom engagement is the key process that explains why smaller classes lead to better attainment. They conclude that class size seems to affect student engagement more than teaching. Research in England has found student engagement increases with smaller classes, but this particularly applied to low-attaining

students (Blatchford *et al.*, 2008). However, the CSPAR study found no effects on pupil attentiveness in 10/11-year-old pupils, and Bourke (1986) found no class-size effect on primary school student engagement.

Peer Relations

It might be expected that in larger classes there would be more negative and aggressive behaviors between children. This is supported by some reviews (e.g., Finn *et al.*, 2003) but other research with older pupils seems less clear. In the CSPAR, it was not found that pupils in smaller classes had better peer relations; indeed, peer relations were if anything worse (Blatchford, 2003).

Size and Number of within-Class Groups

Class size and grouping of pupils in the classroom are closely linked. As the size of the class increases, the size and/or number of groups necessarily increases. Group size can have effects on teaching, for example, larger groups can result in more off-task behavior, and miss out on a teacher's attention (Blatchford, 2003). Bourke (1986) found that teachers in larger classes tended to form more groups during mathematics lessons and that this led to fragmentation of the lesson and inefficient use of the teacher's time. Worryingly, research finds a tendency for less groupwork to take place in smaller classes, no doubt because teachers are availing themselves of the opportunities for more contact with individual pupils (Blatchford *et al.*, 2009).

Curriculum Effects

Class-size effects on classroom processes can vary by school subject. Rice (1999) found that in mathematics, but not science, as class size increased, less time was spent on small groups and individuals, innovative instructional practices, and whole-group discussions. In the CSPAR study, the overall effects of class size on individualized attention were found in all subjects but English, probably because English is the most discussion-based subject and relies less on questioning of individual pupils. (Blatchford *et al.*, 2005). Interim findings from classroom observations in the Hong Kong government's longitudinal study (Hong Kong Education and Manpower Bureau, 2007) revealed signs, particularly among teachers of Chinese and mathematics, that participant teachers were changing their practice in ways that resulted in higher levels of problem-solving questioning and a greater range of feedback responses, although, overall, there was little evidence of a dramatic change in teaching modes.

One direction for future research would be to identify more precisely ways in which class-size effects vary in relation to particular school subjects and student age, and to explore factors that explain any differences found.

Research has tended to identify associations between class size and individual teacher and pupil variables, rather than position these in an overall conceptual framework. With some exceptions, for example, Finn *et al.* (2003), research has tended to be atheoretical and there is a lack of an overriding conceptual understanding of class-size effects. Following the lead of Anderson (2000), it is important for future advances in this field that possible frameworks are advanced and tested. Further, much more effort needs to be put into testing causal connections linking class size, type of pupil, teaching practices, pupil behavior, and academic outcomes.

Implications for Practice

Research therefore suggests that small classes can benefit pupils academically. There can also be benefits in terms of classroom teaching but it has often been pointed out that teachers do not necessarily change the way they teach when faced with smaller classes. This might well account for the relatively modest effects of class size on achievement. One reason for this lack of change is that existing pedagogical and curricular approaches put constraints on teachers. There is a need for more research to understand how teachers can take advantage of reduced class sizes. Lai (2007) investigated teachers' experiences in changing from teaching in large to small classes, and found that teachers had different approaches to change. In Chinese cities implementing small-class teaching, there are many action-research reports and reflective accounts published by principals and teachers in books and journals and presented in seminars (e.g., Nanjing Education Bureau, 2007; Zhao, 2002). Though valuable, it is difficult to determine the scale of impact in the absence of large-scale empirical studies. Future work could do well to coordinate larger-scale and/or linked studies.

How should teachers change the way they teach? As Galton (1998) has said, one problem is that we do not have a lot of knowledge about effects of class size on teaching on which to base practical advice. In addition, and more fundamentally, we do not have a well-worked-through theory underpinning teaching and pedagogy, and teachers do not have a theory to draw on. It may be helpful to distinguish those processes most likely to follow from differences in class size and those that are potentially likely to follow but which will depend on what a teacher makes of a smaller class. Drawing from the review above, it seems likely that the following things are likely to follow from smaller classes:

1. more individualization of teaching;
2. easier classroom control;
3. more time for marking, assessments, and planning; and
4. less teacher stress.

One needs to be careful, however, about the tendency toward more individualization in smaller classes because classroom management can become very teacher centered and there can be little development of student independence and control of learning. This is why Blatchford *et al.* (2009) have suggested several ways in which CSR can be accompanied by pedagogical changes to enhance beneficial effects for students. These include taking advantage of the possibilities of more-effective collaborative learning between pupils, and more adventurous and flexible teaching. The experiences in Chinese cities implementing CSR show that small-class teaching has played a key role in teachers' professional development and set the conditions for student-centered learning, creativity, inquiry learning, assessment change, and delivery of the new curriculum (Zhang, 2007). This can be further strengthened by professional-development networks (Lai and Ip, 2007).

Overall, it may be too simplistic, especially in an international context, with its huge variety of resourcing, structures, cultures, and pedagogies, to seek to identify particular educational practices that will be affected by class size and which should be adopted in small classes. Rather, we may do better to be clear as educators about the educational aims that we consider important and then think through carefully where CSRs can help. Teachers will vary in their educational goals for very good reasons – because of the age of pupils, the subject area, the emphasis at a given point in the year, in response to a particular cohort of pupils, and because of fundamental differences of opinion about appropriate pedagogical approaches. Teachers may be better equipped, when given the opportunities afforded by small classes, if they consider educational principles, for example, increasing mastery orientation and teaching for understanding, rather than specific practices, and then to consider how small classes can help. This is line with Achilles (1999) who argues that small classes can allow teachers to do what they feel is the right thing to do.

Some have argued that teacher professional development is a better investment than CSR, but as illustrated by the examples in East Asia it is better not to see them in opposition. Rather, professional development should be used to help teachers harness the opportunities of small classes, and help teachers develop strategies for realizing educational objectives in large classes. We feel that there could be a much bigger role in professional development for a close consideration of classroom-contextual features, of which the number of children in the class is one. CSR should also be addressed at the whole-school level, to ensure that structural and instructional approaches make the most of CSR, and that planning with classroom teachers ensures that their efforts complement each other. Smaller classes can facilitate opportunities for teachers to teach and students to learn.

We therefore suggest that CSR should be accompanied by pedagogical changes to enhance beneficial effects for students. We also suggest that CSR should be evaluated in conjunction with these particular interventions, that is, it is the combined effect of CSR along with appropriate pedagogical and curricular changes that is of most relevance, and which needs to be evaluated.

Continuing Professional Development of Teachers

P Earley, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

The ongoing or continuing professional development (CPD) of teachers is crucial for organizational growth and school improvement. One of the hallmarks of being identified as a professional is to continue to learn throughout a career and teachers' CPD is a key component for developing children's learning and also for the implementation of policy, be it government or school policy. As Day and Sachs (2004) state in the introduction to their *International Handbook of the Continuing Professional Development of Teachers*, it is often used to describe all the activities in which teachers engage during the course of a career which are designed to enhance their work; yet, they state "this is a deceptively simple description of a hugely complex intellectual and emotional endeavour which is at the heart of raising and maintaining standards of teaching, learning and achievement in a range of schools, each of which poses its own set of special challenges" (2004: 3). Bolam and McMahon (2004) go further and argue for a conceptual map which they say despite a huge CPD literature has not been forthcoming. In part, they suggest this is because CPD studies:

are written from diverse perspectives, for instance focusing on individual teacher self-development, classroom or subject teaching, school organisation and leadership, national policy-making or theoretical development. It is also because they draw upon a range of theoretical sub-fields, some of which have a strong discipline base (for example, sociology, cognitive psychology, social psychology and occupational psychology) and some of which are more eclectic (such as teacher education and training, andragogy, evaluative research, change theory, management studies and policy studies). (Bolam and McMahon, 2004: 52)

One consequence of this is that there are too many rather than too few approaches and theories, a situation of conceptual pluralism. Bolam and McMahon distinguish between four categories of CPD literature:

- 'knowledge for understanding,' which includes theoretical and critical policy analysis
- 'knowledge for action,' which includes evaluations
- 'policy makers,' which includes national and state level policy statements, and
- 'practitioner' literature, which includes two subsets – instrumentalist and reflexive – and consists mainly of accounts of practice and methods (Bolam and McMahon, 2004: 53).

Given this conceptual pluralism and diversity of perspectives it is necessary to state clearly that in considering CPD this article draws from all categories of literature and is written predominantly from a management and policy studies perspective. More specifically, this article begins by asking what is CPD, before considering entitlements and responsibilities, what we know about what works, and how we evaluate the impact of teachers' CPD.

What is CPD?

CPD has become the phrase or term widely used for the ongoing education and training of teachers, while in England the term workforce development is becoming more common in recognition of the fact that schools increasingly employ as many, if not more, support staff than teachers. If teaching is seen as a profession – and a case for this has long been argued – an important characteristic or hallmark of a member of a profession is the commitment its members show toward self-improvement or development. This is not, however, for its own sake but to ensure that the beneficiaries or clients – pupils and parents – are provided with the best possible service. The responsibility for securing individual professional development of teachers is not, however, the exclusive concern of the employer – teachers themselves must expect to play a key role – and professional development opportunities must be available to help them become better practitioners.

However, what do we mean by the term CPD and is it different from personal development or staff development or in-service education and training (inset)? Broadly speaking, CPD encompasses all formal and informal learning that enables individuals to improve their own practice. It involves "reflective activity designed to improve an individual's attributes, knowledge, understanding and skills" (TDA, 2007) and it means maintaining, improving, and broadening relevant knowledge and skills in subject specialisms and teaching so that it has a positive impact on practice and learner experience.

Professional development is an aspect of personal development and, wherever possible, the two should interact and complement each other. The former is mainly about occupational role development, whereas personal development is about the development of the person, often the whole person, and it almost always involves changes in self-awareness. As Waters explains: "It is the development

that can occur when teachers are construed first and foremost as people, and is predicated on the premise that people are always much more than the roles they play” (Waters, 1998: 30).

A definition of CPD might refer to: “any professional development activities engaged in by teachers which enhance their knowledge and skills and enable them to consider their attitudes and approaches to the education of children, with a view to improve the quality of the teaching and learning process” (Bolam, 1993). In this sense, it is perhaps a little different from how some have defined in-service training or staff development. The seminal James Report (DES, 1972) defined INSET as: “the whole range of activities by which teachers can extend their personal education, develop their professional competence and improve their understanding of education principles and techniques.”

An analysis of the literature does, however, reveal a number of nuances and slight differences between the different concepts used. A simple but most useful conceptual breakdown is offered by Bolam (1993) where he makes use of a threefold distinction among:

- professional training, for example, short courses, workshops and conferences emphasizing practical information and skills;
- professional education, for example, long courses and secondments emphasizing theory and research-based knowledge;
- professional support, for example, activities that aim to develop on the job experience and performance.

CPD embraces those education, training, and support activities that teachers engage in, following their initial certification, which aim to add to their professional knowledge; improve their professional skills; help clarify their professional values; and enable pupils to be educated more effectively (Bolam, 1993).

CPD is an ongoing process, building upon initial teacher training (ITT) and induction, including development and training opportunities throughout the career and concluding with preparation for retirement. At different times and at different stages, one or other may be given priority; however, the totality can be referred to as CPD. Development is about improvement, both individual and school improvement.

In a survey of continuing education for the professions, Madden and Mitchell (1993) state that CPD can fulfill three functions:

- updating and extending the professional’s knowledge and skills on new developments and new areas of practice – to ensure continuing competence in the current job;
- training for new responsibilities and for a changing role (for example, management, budgeting, teaching) – developing new areas of competence in preparation for a more senior post;

- developing personal and professional effectiveness and increasing job satisfaction – increasing competence in a wider context with benefits to both professional and personal roles.

Other definitions (e.g., Day, 1999: 4) are more wide ranging and go well beyond the mere acquisition of knowledge or skills. Bubb and Earley (2007) see staff development as:

an on-going process encompassing all formal and informal learning experiences that enable all staff in schools, individually and with others, to think about what they are doing, enhance their knowledge and skills and improve ways of working so that pupil learning and wellbeing is enhanced as a result. It should achieve a balance between individual, group, school and national needs; encourage a commitment to professional and personal growth; and increase resilience, self-confidence, job satisfaction and enthusiasm for working with children and colleagues. (Bubb and Earley, 2007: 4)

Alternatively and put more simply, it is about creating opportunities for adult learning, ultimately for the purpose of enhancing the quality of education in the classroom. To summarize, CPD is an ongoing process of education, training, learning, and support activities which is:

- taking place in either external or work-based settings;
- engaged in by qualified, educational professionals;
- aimed mainly at promoting learning and development of teachers’ professional knowledge, skills, and values; and
- helps decide and implement valued changes in their teaching and learning behavior so that they can educate their students more effectively, thus achieving an agreed balance between individual, school, and national needs.

It is clear that long gone are the days when initial training and induction were seen as a total or final preparation for a career in teaching; nowadays they have to be seen as merely providing a platform on which further professional development will be built. Nevertheless, the initial period in teaching is crucial as the experience of the first year is most formative. There is therefore a need to set high expectations and standards when there is the greatest receptiveness and willingness to learn and develop.

Perhaps the single most important feature of CPD is to encourage and promote a commitment on the part of the individual to professional growth. Leading and managing human resource development – making CPD work – therefore means providing structures and procedures to coordinate developmental opportunities so as to promote such growth and to help staff develop and improve their workplace performance.

The CPD of teachers has to be seen as a collective responsibility – the responsibility of both individual staff and the schools and colleges in which they work. Individuals and their places of employment should take joint responsibility for professional development and training, which should be for the benefit of both. Growing attention has been given to organizational cultures and the emphasis that may or may not be given to the training and development or the learning of its members. The experience and expertise of staff – both teaching and support – are generally recognized to be the school's most important and most expensive resource. The term learning organization or professional learning community is becoming more commonly known and attempts are being made in many national education systems to ensure that more schools are aware of what this means for themselves. Leading and managing people and their development have to be seen as a central part of the responsibility of managing the school's total resources. Governments throughout the world are now turning their attention to this particularly as schools become more autonomous and have a major responsibility in managing their people.

An Entitlement to CPD

The notion of an entitlement to CPD is something that has been promoted in many countries in the developed world. The General Teaching Council in England and Wales sees an entitlement to professional development as “career long and sustained so that on entry to the profession a teacher has a clear expectation of continuing, relevant and planned professional development.” England's General Teaching Council (GTC, 2003) has drawn up an entitlement to professional learning and states that teachers need the opportunity to:

- Have structured time to engage in sustained reflection and structured learning;
- Create learning opportunities from everyday practice such as planning and assessing for learning;
- Develop their ability to identify their own learning and development needs and those of others;
- Develop an individual learning plan;
- Have school-based learning as well as course participation, recognized for accreditation;
- Develop self-evaluation, observation and peer review skills;
- Develop mentoring and coaching skills and their ability to offer professional dialogue and feedback;
- Plan their longer-term career aspirations (GTC, 2003: 6).

In some education systems, teachers and employers are seen as having different but complementary responsibilities in relation to CPD (Jones, 2003):

- *Employers.* To provide professional development opportunities for teachers to support a broad range of priorities which occur during the normal work cycle and an entitlement to professional development which focuses on the individual professional and personal needs and objectives of the teacher is emphasized.
- *Teachers.* To develop themselves as reflective professionals by reflecting on their work and by identifying new ways of working. These activities should be undertaken as part of a teachers' work.

In others, the emphasis continues to be on seeing CPD as a way of meeting national policies or organizational objectives. In more mature systems, there is a focus on the individual, the organization and national/local priorities (see **Figure 1**; Jones, 2003: 37).

Meeting teachers' needs while also addressing whole-school and collective needs is a challenge. A more personalized approach is crucial if limited CPD funds are deployed most effectively. Teachers' previous knowledge and experience needs to be taken into account and the school will need to respond, if possible, to individuals' preferences and learning styles. Bolam and Weindling (2006) in a detailed review of 20 recent UK research studies into CPD provide strong evidence “that the more influence teachers have over their own CPD the more likely they are to consider it effective. More generally, the (findings) lend support to the importance of teachers' professionalism and agency as key components of effective CPD” (Bolam and Weindling, 2006: 3).

With entitlements come responsibilities and professional development is seen as a responsibility throughout a teacher's career. However, in many education systems with the change of emphasis on the importance of training and development and greater control from the center, there has been a corresponding move toward a higher degree of prescription and statutory requirements regarding CPD. In some other professions there is specified mandatory CPD for all its members. Since 2007, for example, teachers and lecturers in the English further education (post 16) sector were expected to clock up 30 h of CPD, something which teachers in Scotland have been required to do for some time. What is key however is not the specified amount of CPD undertaken but rather its effectiveness.

What is Effective CPD?

Any discussion of what constitutes effective professional development needs to begin by asking effective for whom – the individual, the school and its pupils, or the education system as a whole? Also, for what? The beneficiaries of CPD may not always overlap, although in many cases they will; what is helpful for an individual is also likely to be of benefit both for pupils and for the school. On the other

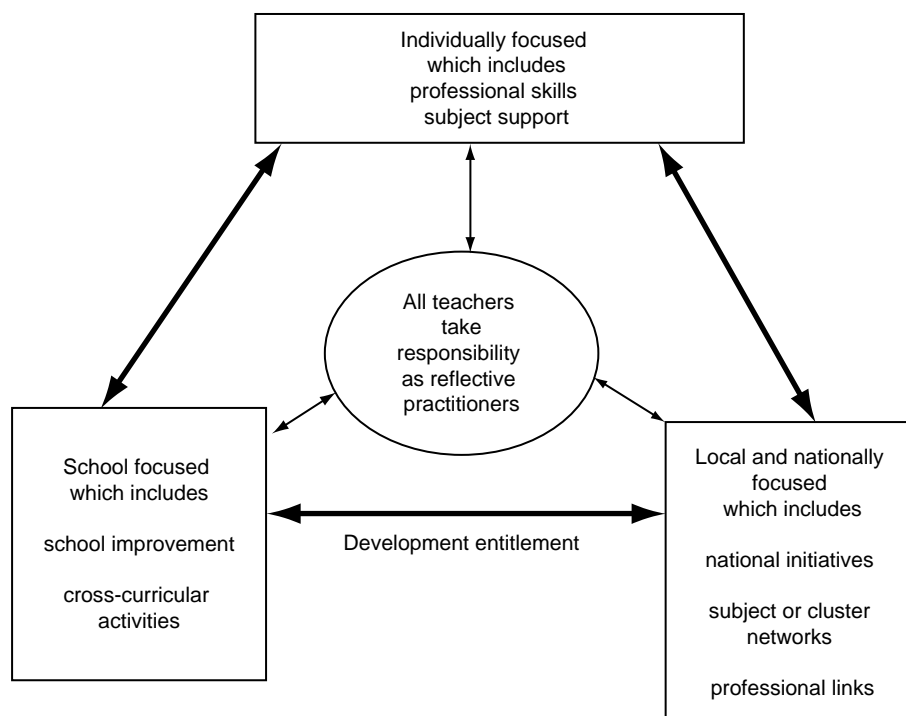

Figure 1 Continuing professional development framework. From Jones, T. (2003). Continuing professional development in Wales: An entitlement for all. *Professional Development Today* 6(1), 37.

hand, training to meet the latest government initiative may be effective for implementing a particular strategy but not necessarily for the overall long-term development of staff or the school. Effective CPD is likely to consist of that which first and foremost enhances pupil outcomes, but which also helps to bring about changes in practice and improves teaching, as well as management and leadership skills and qualities. It should be fit for purpose and add something to the school's overall capacity to develop; the school should be able to build upon the collective learning of its people. Exposure to and participation in a wide range of professional development opportunities are likely to bring about change to individuals' beliefs, values, attitudes, and behaviors, and these may well lead to changes in classroom and school practices.

Much has been written about what constitutes effective CPD but it should be remembered that the characteristics influencing effectiveness are multiple and highly complex. It is worth noting an important caveat: the technical and methodological problems of measuring the direct effects or impact of CPD, especially on classroom performance – of both staff and pupils – are considerable. This is, among other reasons, because the term embraces a wide variety of modes and methods, and includes professional training, education, and support. The number of variables to be taken into account is considerable.

Teachers' CPD can only have an indirect impact on pupil learning and outcomes. Very few research studies have considered the relationship between the

characteristics of professional development and any change in classroom teaching practice or the gains in pupil achievement or learning outcomes more broadly. Despite this, there is a growing body of research evidence and informed professional judgment that gives a broad indication of the essential characteristics of effective CPD. These include the clear identification of aims and objectives, and an analysis of training needs to ensure training and development activities matched existing levels of expertise. Opportunities for reflection are also important, as are action research, ongoing evaluation, and follow-up work. Effective training was seen to form part of a coherent program and was not a one-off activity. The optimum use of existing resources and facilities was most likely when CPD activities were well planned, helping to promote targeted and tailor-made training, avoiding overload and minimizing disruption (Bubb and Earley, 2007). The practice in schools however is often quite different.

The range of professional development activities which teachers can access is huge and can be categorized as on-the-job, off-the-job, and close-to-the-job opportunities. A recent report from inspectors in England has described the management of professional development as a logical chain of procedures, which entails "identifying school and staff needs, planning to meet those needs, providing varied and relevant activities, involving support staff alongside teachers, monitoring progress and evaluating the impact of the professional development." They note that schools which had designed their CPD effectively and integrated it

with their improvement plans found that teaching and learning improved and standards rose (Ofsted, 2006: 2).

Fragmented one-shot workshops and conferences at which staff listen passively to experts rarely make a difference. These traditional approaches to professional development appear insufficient to foster learning which fundamentally alters what teachers teach or how they teach. The following types of professional development activities are more likely to offer sustained learning opportunities:

- study groups in which staff are engaged on regular, structured and collaborative interactions around topics identified by the group;
- observation – observing others and being observed;
- coaching or mentoring arrangements, where staff work one-on-one with an equally or more experienced teacher;
- networks, which link people either in person or electronically, to explore and discuss topics of interest, pursue common goals, share information and address common concerns;
- immersion in inquiry, in which people engage in the kinds of learning that they are expected to practice with their students (Boyle *et al.*, 2003: 3).

Involvement in development activities by staff is, to a large extent, voluntary but there are a number of factors that will encourage participation. Boring, repetitive, and dependent work discourages professional development and growth, whereas challenging, variable, and independent work encourages it – certainly there are parallels with the classroom here. Equally, personal factors and life changes can cause individuals to reconsider career priorities and goals. Professional development can help enhance performance through improved self-esteem – this, along with personal well-being and a sense of professional control, are all essential components of job satisfaction.

The kinds of teacher professional development which make the most difference to practice are based on professional dialog about teaching and learning and the improvement of practice through a variety of activities, including coaching, mentoring, shadowing, and peer support. Awareness-raising events are useful for absorbing information and updating knowledge but are not likely to lead to skills development. Joyce and Showers (2002) concluded that, for training to be truly effective, it needs to include the following five components or stages:

- theory – where the new approach is explained and justified;
- demonstration – to give a model of how this can be put into practice;
- practice – so that the teacher can try out the new approach;
- feedback on how well the new approach is working; and

- coaching – to help the teacher discuss the teaching in a supportive environment and consider how it might be improved.

Their research showed that, without the opportunity to receive feedback and coaching, there is no measurable impact on classroom practice. However, once these two components are added, particularly the final coaching stage, there is a large and measurable impact on practice. Attention to evaluating impact is given in the next section.

The Impact of Teachers' CPD

Evaluating the impact of teachers' professional development and training is a neglected area partly because it is perceived to be difficult. Few evaluation studies concerning CPD make any reference to its impact on teacher behavior or pupil learning outcomes. However, evaluation is necessary to provide a sound basis for improving and upgrading teacher development programs but it needs to be relatively easy and inexpensive, otherwise it may be seen as diverting scarce resources away from other more important activities. Evaluation was found to be effective when the professional development activity had a clear, predefined outcome and a suitable method for collecting evidence of its impact.

Over the years, a number of models to evaluate the impact of training and development have been devised. One of the first and perhaps the best known is the framework for evaluating training developed by Kirkpatrick (1959). This has been adapted and developed over the years but Kirkpatrick's four-step framework remains the model or framework for evaluating most training programs in business and commerce. The model explores the relationship between training and the workplace at four levels: reactions, learning, behavior, and results. These are measured at suitable points during the training process. The first three are essentially trainee based, while the fourth changes emphasis and centers on the effectiveness of the training for the organization.

Another American, Thomas Guskey, has developed and refined Kirkpatrick's model more specifically for education. He is clear that: "We need to make evaluation an integral part of the professional development process ... Systematically gathering and analysing evidence to inform our actions must become a central component in professional development technology" (Guskey, 2000: 92).

Guskey talks in terms of five levels of evaluation of CPD with improved pupil outcomes being the desired result. These five levels are:

1. participants' reactions;
2. participants' learning;
3. organization support and change;

4. participants' use of new knowledge and skills; and
5. pupil learning outcomes.

Level 3 – organization support and change – is not found in the Kirkpatrick model and refers to the key role that the school can play in supporting or sabotaging any CPD efforts. The focus needs to be on the attributes and organizational features of the school that are necessary for success. Were changes at the individual level encouraged and supported at all levels? Were sufficient resources made available, including time for sharing and reflection? Were successes recognized and shared? (Guskey, 2002: 47).

Each level builds on those that come before but reversing these five levels can be useful in planning for teachers' professional development. Therefore, planning might begin by asking, "What improvements in pupils do we want and how will we know when they're achieved?" Then ask, "If that's the impact we want, what needs to change?" Next, consider what types of organizational support or change are needed, and so forth (Guskey, 2005).

Guskey notes that, in some cases, information on pupil learning outcomes is used to estimate the cost effectiveness of CPD, sometimes known as return on investment (Guskey, 2002: 49).

Conclusion

If the ultimate purpose of CPD for teachers is to bring about improvement in the quality of teaching and learning in schools and classrooms – and thus impact positively on pupil outcomes – then it is important to have evaluation processes in place which give an idea whether this is happening or not. Evaluation should be considered at the outset and not at the end of a professional development activity.

Bolam and McMahon (2004) discuss the developments in CPD over the last 20 years and remark how it is striking just how much has changed and yet other things remain the same. For example, technological developments such as e-learning, Teachers TV, networks (both virtual and real), and the Internet have made possible new CPD methods and approaches. They comment:

The increased emphasis on school-focused CPD which was evident in the late 1980s has developed into a much more sophisticated approach which takes account of school culture, work-based learning and professional learning communities (p. 51).

Yet, other things remain largely unaltered, such as the potential tension between the needs of teachers and those of the organization or national policy, and "the evidence from research and experience in several countries demonstrates that national needs have been dominant since the mid 1980s" (Bolam and McMahon, 2004: 51). It is clear

that "governments and systems are using CPD as a means of achieving broader education reform agendas" (Bolam and McMahon, 2004: 27).

CPD is about ongoing or lifelong learning which will help teachers and other staff respond to ever-changing situations and exercise judgment in informed and creative ways but, as Pachler and Field state, it should also be seen as a means "to rejuvenate practice, to expand our professional repertoire, increase our self-esteem, self-confidence and enthusiasm for teaching or, for example, our level of criticality and, thereby, achieve enhanced job satisfaction" (Pachler and Field, 2004: 2). As Bolam and McMahon note, "the image of the teacher as an autonomous professional is being replaced by the concept of the school as a learning community in which the teacher works collectively as a member of a wider group of staff in a joint effort to improve the quality of learning" (Bolam and McMahon 2004: 55). Finally, Bolam and McMahon remark that the longer-term health of schools and students depends on well-educated teachers, not just well-trained and well-informed ones, asking crucially: What part should democratic values play in the CPD of teachers? and what kind of teachers are needed for the twenty-first century?

Homeschooling

P Farenga, Medford, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

An Introduction to Homeschooling

Books about learning at home were categorized under domestic education by the United States Library of Congress until recently. This category holds books and resources that colonists, pioneers, and city dwellers used to help their children learn to read, write, and calculate at home, on the farm, and in their local communities, as well as books about private tutors, governesses, and related topics. In the late 1980s, due to the rapid growth of books and materials that help parents teach their own children at home, a new category was created in the Library of Congress, Home Schooling.

Why Do People Choose to Homeschool?

Though homeschooling represents a small percentage of the total school-age population, it serves as a growing counter-trend to educators and others who insist that children need to spend more time in school, more time studying for tests, and less time pursuing subjects such as music, art, religion, philosophy, foreign languages, and literature, let alone extracurricular activities. However, it is not correct to conclude that the growth of homeschooling indicates a rejection of the public school system because private schools are losing enrollments to homeschooling as well. The growth of homeschooling suggests that more factors are at play. Personalized learning, closer family ties, inviting children to learn among adults doing real work, and an emphasis on the delight of learning are common factors among homeschoolers regardless of the educational philosophies they hold, and these are factors homeschoolers do not find in their local schools.

In 1981, the author and teacher John Holt cited these reasons as to why parents choose homeschooling: they feel that raising their children is their business and not the government's; they do not want their children to be hurt morally, spiritually, or physically; and they enjoy being with their children and do not want to give that pleasure up to others. While these continue to hold true today, reasons cited more recently by homeschoolers include a desire for alternatives to conventional learning for their children (see **Table 1** for more information).

Policy Context and Issues

Many philosophical and social themes are entwined whenever educational matters are discussed and homeschooling

provides a unique lens for exploring institutional versus family concerns about school. Indeed, these issues have long been embedded in discussions about compulsory school laws, but they were largely not of much public concern until the resurgence of homeschooling in the late twentieth century. Since homeschooling itself was never illegal in any state in America, if schools took homeschoolers to court it was typically on educational neglect or truancy charges, not because they were homeschooling. Children are compelled to attend school by law, but school can take different forms, though few families opted to call their home a school until recently. The right of parents to select a child's education is cited in both British and American law, and US Constitutional Amendments one, nine, and fourteen support individual rights and the right to privacy for a family to choose alternative forms of education (Arons, 1983; Whitehead and Bird, 1986).

Homeschooling was the primary way people were educated until the mid-nineteenth century when public schools were established and universal compulsory attendance laws were passed. The tensions caused by claims from professional educators and the state for dominion over students' lives and learning against similar claims by parents and child advocates have increased substantially with the emergence of homeschooling as a way to satisfy compulsory attendance laws (Arons, 1983). Homeschooling can be seen not only as an educational movement toward individualized learning, but also as a political statement against the delivery of mandatory public services into one's private family life.

The growth of homeschooling was slow but steady throughout the late 1970s and 1980s, but in the 1990s it grew very quickly. By 1999, the US Department of Education claimed that 850 000 children were being taught at home. In 2007, the number of homeschooled children was 1.5 million, representing 2.9% of the total United States school-age population (National Center for Education Statistics, 2008) (**Table 2**).

Approaches to Homeschooling

Homeschooling can be broadly divided into two streams of educational philosophy, the nontraditional and the traditional. The nontraditional approach emphasizes a learner's autonomy and encourages questioning authority. For instance, a mother writing to New York City school officials in 1923 claims that she will teach her son at home

Table 1 Reasons for homeschooling^a

<i>Reasons for homeschooling</i>	<i>Percentage of homeschooled students whose parents reported particular reasons for homeschooling: 2003 and 2007</i>	
	<i>2003 Percent</i>	<i>2007 Percent</i>
Concern about the school environment ^b	85	88
Dissatisfaction with academic instruction at other schools	68	73
A desire to provide religious or moral instruction	72	83
Nontraditional approach to child's education	n/a	65
Child has a physical or mental health problem	16	11
Child has other special needs	29	21
Other reasons ^c	20	32

^aExcludes students who were enrolled in school for more than 25 h a week and students who were homeschooled only because of a temporary illness.

^bThese include safety, drugs, or negative peer pressure.

^cParents homeschool their children for many reasons that are often unique to their family situation. Other reasons parents gave for home schooling include: it was the child's choice; to allow parents more control over what child was learning; and flexibility.

Percentages do not sum to 100 percent because respondents could choose more than one reason.

so he can truly learn how democracy and self-determination work. Some of the chapter titles in the book she wrote about her homeschooling experiences summarize the non-traditional approach well; for instance: "In which it is plainly to be seen that democracy cannot be learned in a place where it is not lived" and "Wherein is shown how by guiding a child's natural interests, he enters into that heritage whereby he 'begins to learn everything the moment he begins to learn anything'" (Anonymous, 1923). These sentences illustrate an educational approach that eschews standardized curricula and seeks to fit schooling to the child rather than the other way around.

In contrast, the traditional approach emphasizes structured curricula and obedience to authority. For instance, the British educator Charlotte Mason advocated teaching one's own children in the late nineteenth century. Though her approach is rooted in the medieval university and its Trivium curriculum she is no taskmaster; her attitude toward children emphasizes understanding and gentleness. However, both approaches to homeschooling declined by the mid-twentieth century as the vast majority of children were taught in traditional schools while their parents worked or ran the household. In the late 1970s, this situation began to reverse itself as families sought other ways of helping their children learn besides sending them to school all day.

John Holt, whose books were influential in the school-reform movement of the 1960s, became dissatisfied with the progressive school-reform movement's lack of success and, throughout the 1970s, he sought new ways to help children learn and grow. Already influenced by the ideas of social and education critic Paul Goodman, who advocated student-initiated learning, Holt became particularly

Table 2 Number of homeschoolers

impressed with the ideas of the philosopher and activist Ivan Illich, who wrote that we did not necessarily need schools to educate people, and we should instead invest in other social institutions and projects that improve people's lives and help them learn to do things better (Illich, 1971). Holt's support for children's innate abilities to learn and grow through informal education meshed well with Illich's ideas about our need to reform social institutions into smaller, local, more responsive entities. When Holt learned that some parents were simply refusing to send their children to school and were teaching them at home, he founded the first journal about homeschooling, *Growing without Schooling*, in 1977 as a way to connect and support people who were already homeschooling or who wanted to do so. Holt identified homeschooling with the burgeoning ecology movement, back to the land communarians, do-it-yourself enthusiasts, advocates for religious and individual rights, and those who held a strong skepticism

of institutional authority. Holt did not like the terms deschooling or homeschooling to describe the learning children did without going to school, so he invented the word unschooling to better describe learning that does not have to occur at home and that does not resemble school. However, unschooling, as a word, did not catch on with the public and Holt himself used the word homeschooling often to describe learning at home. In 1980, homeschoolers who were uncomfortable with Holt's secular outlook and advocacy for children formed their own publication, *The Teaching Home*, and organized tight-knit groups to foster homeschooling that identified itself closely with religious instruction.

Dr. Raymond Moore, a professional educator and researcher, became a major figure in Christian homeschooling when he created his own program for homeschooling based on delaying academics until children were 8–10 years old. Moore and Holt corresponded and worked together on homeschooling issues, exemplifying how liberals and conservatives can join to fight attacks on homeschooling. Holt died in 1985 and Moore gradually became less influential as other Christian homeschooling advocates became popular and the homeschooling movement became more polarized along secular and religious lines. By the early 1990s, many Christian homeschooling groups required signed statements of faith for membership and these groups became an overtly conservative political force that promoted only certain methods of homeschooling and supported political issues that went well beyond homeschooling. Influential conservative Christian evangelists, such as James Dobson and Pat Robertson, became vocal supporters of homeschooling to their audiences. Michael Farris, a founder of The Home School Legal Defense Association, engaged the political situation head on by creating Patrick Henry College in 2000. Patrick Henry College is both a college specifically for homeschoolers and in general for any Christian who believes in the inerrant Bible and who wants to transform America through political service.

Secular and religious homeschoolers who were uncomfortable with the hard right political positions put forth by major Christian homeschooling groups tried to organize counterbalancing groups to promote a more inclusive vision of homeschooling to the public, but they never achieved the political momentum that right-wing homeschoolers did (Stevens, 2001).

During the 1990s, the number of homeschooling families increased to the point that many schools, institutions, and businesses recognized it as a niche market and they began to market a multitude of learning opportunities for home learners. Homeschoolers who desire to follow a specific learning philosophy for their children, such as Montessori or Waldorf/Steiner, find they can adapt these concepts or purchase materials to make them work in homeschooling settings. Homeschooling

families can join groups or schools that provide support for many different approaches to learning at home, including support for homeschooling gifted or special-needs children.

Homeschooling refers to all forms of teaching and learning that are used to help children learn, but researchers and homeschoolers themselves often create categories to identify different models of learning. So, in between the approaches noted earlier, there are eclectic homeschoolers who use anything they think will work; classical homeschoolers who incorporate the study of Latin and emphasize the use of classic books; pagan, Catholic, Mormon, and many other groups who see homeschooling as a way to not just teach children reading, writing, and arithmetic, but also as a way to pass on values that they feel are, at best, not addressed or, at worst, belittled in conventional schooling.

Nontraditional approaches to homeschooling, such as unschooling, emphasize the child as one who learns all the time and these families work with each child's interests and abilities on a much longer and broader schedule than conventional schooling permits. Unschoolers do not use a predetermined curriculum; instead they use learning opportunities that are embedded in the activities the children engage in. Unschoolers often use real-life experiences, such as traveling and volunteering, acting in shows or building projects, and unrestricted reading and questioning as the primary means of learning in lieu of seat-time in class. If school transcripts are required of them, unschoolers can supply portfolio evaluations, personal references, work samples, and dynamic assessments to establish completion of work and competency, or they can engage outside evaluators to assess their children's work.

Traditional approaches emphasize completing the same work as their age mates in school do, often using the same curricula, textbooks, and grading systems as schools. Many of the major Christian Independent School curriculum suppliers began selling their conventional school materials to homeschoolers in the early 1980s and eventually created products and curricula just for home use, well before the larger, more mainstream curriculum providers did. The lines between these two approaches, and the many positions in between, are blurred though. For instance, it is not unusual for an unschooler to decide that he/she wants to take a class in order to learn something in more depth or for a traditional homeschooler to decide to take a break from a subject or drop a course to take advantage of a new opportunity. The most common element among all homeschooling approaches to teaching and learning is flexibility of scope and sequence. This shows that the use of packaged all-in-one curricula among homeschooling families is declining and a strong majority of parents are choosing to tailor curricula for their children by handpicking major components (Ray, 1997).

Government schools are gradually working with homeschoolers, but private enterprises and new forms of private schools, such as online distance-learning schools, are actively creating alternatives that are attractive to families. For example, families who want their children to be fluent with current-day media and technology are finding many opportunities to do so at home, while many schools are not providing their students with such access.

Today, the Internet contains numerous cyber schools and other distance-learning programs that are marketed to homeschoolers; some public schools allow homeschoolers to participate in their classes and activities; numerous independent and alternative schools have programs designed to award homeschoolers their diplomas for work done at home; and a few public schools have created cooperative education programs that provide school textbooks and resources to homeschoolers who agree to follow the school's curriculum at home (Lines, 2003). Learning centers that cater to all sorts of niches, from how to write science fiction to learning world history using film, have found many members among homeschoolers, as have libraries and museums.

These options are not necessarily an abundance of riches for homeschoolers since they blur the distinction between one's private home and public school when companies seek public-education funds for enrolling homeschooled students in their programs. For instance, in exchange for tax-funded school programs at home, families typically agree to adhere to the school's curricula and grading system. This is a trade-off some families are willing to make, but most homeschooling families seek something different than school at home and wish to avoid the strings that come attached to government funding. These new programs are creating another type of schooling experience, one that is not totally independent from public schooling as homeschooling can be.

Teaching and Learning in Homeschooling

Most parents who homeschool do not possess teaching credentials and the vast majority of them do not have college degrees, but that does not prevent them from helping their children learn. Rather than view themselves as teachers of all subjects, homeschool parents often cast themselves in the role of facilitator, connecting their children to classes and teachers as needed. These parents learn to be better teachers of their children by doing it every day; they are free to discard texts and classes that are not working and to try something different quickly. One study was able to compare the test scores between an extreme of teacher contact – certified teachers who homeschooled their children – to nonteacher parents and found “an insignificant relationship between the test scores of

homeschooled students and whether the parent-teachers were state-certified teachers” (Ray and Wartes, 1991).

Many homeschoolers begin by purchasing a curriculum, following its instructions and, if it works for them, they continue using it. Most homeschooling parents are confident teaching the basic school subjects to young children, especially for the early elementary years, but if they get in over their heads, they are able to find help. There are curriculum fairs, private consultants, support networks and local groups, private tutors, and other resources for homeschooling parents to fall back on.

Teaching Children of Different Ages at the Same Time

Most homeschooling families are larger than the average family, so very often they have one or more school-age children being taught at home and a preschooler to care for at the same time. How does a homeschooling parent handle such different needs at once? By maximizing his or her use of available resources and differentiating the instruction for each learner.

Addressing Each Child's Unique Way of Learning

Without reference to education theory, many homeschooling parents nonetheless find ways to help their children learn due to their intimate knowledge of their children's personalities, whereas educators must use a more formal approach to discover how a particular child learns best. For instance, the theory of multiple intelligences identifies eight intelligences that we use in order to learn:

- linguistic intelligence;
- logical–mathematical intelligence;
- spatial intelligence;
- bodily–kinesthetic intelligence;
- musical intelligence;
- interpersonal intelligence;
- intrapersonal intelligence; and
- naturalist intelligence.

Here is how a homeschooling parent might put these ideas into practice whether or not she is aware of multiple-intelligence theory. Mom knows that her 9-year-old son loves to touch and build things, so she uses building blocks to explore and explain arithmetic with her son. Math manipulatives can be useful tools for bodily–kinesthetic learners like her son. After she explains the concept of fractions using the blocks, she asks her son to make a building then break the building into halves, fourths, and so on. While he builds and divides, she can work with her other children, responding to her son as needed. Establishing different centers of activity and then moving among them was a common technique used in one-room

schoolhouses that is also used today by homeschoolers with large families.

Since her teenager likes to learn by reading, analyzing, and discussing what she read, her mom emphasizes linguistic and logical–mathematical learning for her. She will read the same materials as her daughter and discuss them with her. But what if her teenager wants to learn chemistry and mom knows very little about it? Here is where mom shifts roles from being the sage on the stage to the guide on the side. Mom can help her daughter find chemistry courses online or at the local community college. She can post requests for a chemistry tutor online, at local stores, and at local schools. She can also evaluate various chemistry books and kits with her daughter, choose one and learn chemistry together, or have her daughter go through the text or kit on her own, asking for help as necessary.

Encourage Independent Learning

Making children figure things out for themselves does not have to be treated as the last resort of an exasperated parent. Indeed, parents usually take great pride in watching infants and toddlers independently learn to speak, walk, think, and socialize with little formal instruction from adults and homeschoolers can continue to nurture that ability. Homeschoolers can allow plenty of quiet time for their children to reflect or daydream since they are not changing classes every hour. Reading a book or a website, watching a video, listening to books on tape, drawing, writing in journals or creating a story, making a video or play, practicing an instrument or sport, working on a model or other project, are common ways homeschoolers encourage independent learning throughout their day. By talking with their children about what they are doing these parents help their children make connections to other topics or people that can expand their learning.

Engage the Children to Help Each Other

The homeschooling mom mentioned above might try to get her 4-year-old to play with the building blocks alongside her son, or perhaps have her son read to the young child while mom works with the teen. She can also ask the teen to work on arithmetic with her son while mom plays with the 4-year-old. Inviting other kids to their house to play or study is another way homeschoolers foster independent learning and make time for parents to have time with their other children.

Research about Homeschooling

There is not enough unbiased quantitative data about homeschooling to justify making direct comparisons about the academic performance of homeschooled

children to school children, but what research does exist so far indicates there are no significant differences in achievement among them (Thomas and Pattison, 2007; Ray and Wartes, 1997). However, the lack of research or concern among parents for seat-time in school for their children has not stunted the growth of homeschooling. Further, data consistently show that homeschooling is not a harmful or irrevocable decision. Homeschoolers matriculate back to school with no significant difficulties when they wish to attend. Indeed, homeschooling can be a phase of schooling in most children's lives rather than a constant: just 15% of secular homeschoolers and 48% of religious homeschoolers continue to homeschool after 6 years (Isenberg, 2007).

Many parents considering homeschooling find the conviction to do it not from academic research but from their own experiences and those of others they know or read about. History shows that children are able to learn social skills from their parents and culture without being forced by law to attend school; alternative schools successfully help children learn in different ways than conventional schools allow, and the wealthy have always used private tutors, special classes, and travel to provide elite educations for their children; so homeschooling has significant antecedents.

However, since school has become the primary place for children to spend their time in recent decades, many people think that socialization skills are best developed in schools, so a primary objection to modern homeschooling has been that homeschooled children will lack socialization skills. Many homeschoolers note the antisocial structure of school and the bad behavior of many schoolchildren as a primary reason for removing their children from school or for not sending them. Studies in the United States consistently show the major reason for homeschooling is a concern about the school environment (Table 1).

Homeschool advocates note how homeschooled children are socialized not in classes where everyone is the same age but by being around adults and children of mixed ages within a variety of groups and activities. There are studies that demonstrate homeschooled children are socially well adjusted, as well as studies conducted on adults who were homeschooled. The latter indicate homeschooled adults are engaged in their communities, enjoy life, and are gainfully employed. However, all such studies are to date limited by the self-selection and self-reporting of homeschoolers who participate and the difficulty of comparing standardized school system results to individualized family results.

Colleges and universities now encourage homeschoolers to apply, with some even sending recruiters to homeschooling conferences. A majority of American colleges and universities have admission policies for homeschooled applicants (Jones and Gloeckner, 2004).

Summary

We have seen how homeschooling has been successfully used in lieu of conventional schooling well before compulsory laws were enacted in the mid-nineteenth century. Toward the end of the twentieth century, homeschooling had a resurgence from the efforts of liberal and conservative parents and educators that continues to gain adherents in the twenty-first century. Businesses and private schools have supported the growth of homeschooling by identifying and selling to this market, while families who are less focused on consuming education products support the growth of homeschooling by encouraging self-reliance and creating opportunities within one's local community. Though there is considerable research about homeschooling, there is no true random sample of homeschoolers that one can definitively compare to a random sample of public schoolers; so claims about the academic achievement of homeschoolers are hard to generalize. However, there is no evidence to support claims that homeschoolers fare worse than those who go to school, particularly with regard to employment and college admissions. The myriad methods and philosophies that support homeschooling also drive considerable debate about the role of compulsory education in our lives, sometimes resulting in political action about the rights of families, parents, and children.

As more children move in and out of school and homeschool, new conceptions of where, how, and from whom learning takes places can be studied and explored. In fact, many homeschooling families also have children who attend public or private school full or part-time, so it would be wise for schools to not alienate homeschoolers and instead form fruitful partnerships with them. New methods of evaluation, new scopes and sequences for learning, and new ideas about standard school assumptions and practices can emerge from such partnerships (Thomas and Pattison, 2007). The growth of homeschooling proves that parents, regardless of their educational background, can be trusted to help children learn and that whether or not schools decide to support their endeavors, homeschooling will continue. Homeschooling parents are deeply involved in their children's educations and though schools openly claim they want parental involvement, they have yet to figure out how they can work positively with this vivid example.

Homeschooling is not a solution to school problems since it is so different from school: the skills one needs to manage a class of children from diverse backgrounds who all need to be taught the same thing at the same time are totally different from the skills a parent needs to help their own children learn in the comfort of their home. Nonetheless, homeschooling can inform the future direction of schooling not because it is better than school, but, as John Holt wrote,

because it is not a school at all. It is not an artificial place, set up to make "learning" happen and in which nothing except "learning" ever happens. It is a natural, organic, central, fundamental institution; one might easily and rightly say the foundation of all other institutions. . . What I am trying to say, in short, is that our chief educational problem is not to find a way to make homes more like schools. If anything, it is to make schools less like schools. (Holt and Farenga, 2003)

Innovations and Early Intervention in the Teaching of Literacy

R E Slavin, Johns Hopkins University, Baltimore, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

From the time they enter kindergarten through their first years of elementary school, children substantially define themselves as learners. Those who end third grade reading well are not guaranteed success in school and in life, but they have cleared a major hurdle. Those who do not succeed during this critical period, however, are likely to have serious problems throughout their subsequent school careers. For example, Juel (1988) found that almost all 7-year-olds who had reading difficulties also had reading difficulties as 10-year-olds. Lloyd (1978) reported that high school drop-out could be predicted to a substantial degree based on the learning levels of 9-year-olds, but could not be accurately predicted based on characteristics of 6-year-olds, supporting the idea that early school learning success (or failure) is a key factor in long-term outcomes of schooling.

In recent years, research has found that the outcomes of early schooling can be substantially affected by the programs and practices adopted by elementary schools. Recognizing the importance of personal and home factors and of preschool experiences, there is no doubt that elementary schools can make a profound difference in children's learning trajectories during the crucial early years.

Beginning-Reading Programs

The most important criterion for success in the early elementary years is success in reading. Reading is the basis for success in all other skills. Poor progress in reading is the main indicator of need for special education, for example, and for retention in grade.

In recent years, a consensus has emerged among most researchers about the importance of systematic, synthetic phonics in the teaching of beginning reading. That is, children have been found to learn to read best if they are taught to apply consistent strategies for blending letter sounds into words, rather than trying to learn whole words. Definitive reviews in the US by Snow *et al.* (1998) and the National Reading Panel (2000) emphasized the strong evidence base for synthetic phonics, and the Rose Report in the UK (Rose, 2006) came to the same conclusion. However, it is not enough for teachers to be given textbooks that emphasize phonics, or to have policies promoting phonics. Research finds that particular approaches to synthetic phonics and particular professional-development approaches are more effective than others.

Slavin *et al.* (in press) recently carried out a review of research on the learning outcomes of core

beginning-reading programs. In order to be included in the review, studies had to meet the following standards:

1. They evaluated core reading programs that began in kindergarten or first grade (remedial programs are discussed in a separate section).
2. They compared children who used the program to those in matched or randomly assigned control groups.
3. The study took place over at least 12 weeks, but usually a year or more.
4. On pretests, the experimental and control groups were no more than a half standard deviation apart, and were well matched on demographic variables.

Studies of programs that posttested at the end of kindergarten were reviewed separately, as such studies often find positive effects just because programs teach phonics or reading skills that the control group has not yet been taught. However, by first grade, all children are being taught to read; so experimental-control comparisons are meaningful. Programs that began in kindergarten and reported end of first grade (or later) outcomes were included in the main review.

An exhaustive search of published and unpublished articles written since 1970 produced a total of 63 studies that met the inclusion standards and posttested in first grade or later. The qualifying studies were done in the US, Canada, Norway, Denmark, and Germany. They involved more than 22 000 children. The reading programs were divided into four categories: reading curricula, technology, instructional-process approaches, and combined curricula and instructional-process approaches.

Beginning Reading: Curricula

Beginning-reading curricula have been evaluated in seven studies, five of which used randomized quasi-experiments. These studies evaluated four core basal-reading programs, Open Court Reading, Reading Street, and Scholastic Phonics Readers with Literacy Place, plus three supplemental programs, the Open Court Phonics Kit, Phonics in Context, and Elements of Reading: Phonics and Phonemic Awareness.

With the exception of a small study of the Open Court Phonics Kit, none of the programs had effect sizes in excess of +0.20. The sample size-weighted mean effect size across all seven was +0.12, with the four studies of core basal programs reporting a weighted mean effect size of +0.11 and the three studies of supplementary programs

with a weighted mean of +0.12. Effect sizes averaged +0.23 for decoding measures, but only +0.09 for comprehension/total reading measures.

Beginning Reading: Technology

Thirteen studies of instructional technology for beginning reading met the inclusion standards. These were divided into three categories: (1) supplemental technology programs, such as Waterford, Wireless Internet Center for Advanced Technology (WICAT), and Phonics-Based Reading, which are programs that provide additional instruction at students' assessed levels of need to supplement traditional classroom instruction; (2) mixed-method models, represented by Writing to Read, are methods that use computer-assisted instruction (CAI) along with non-computer activities as students' core reading approach; and (3) embedded multimedia, represented by Reading Reels, provides video content embedded in teachers' whole-class lessons.

The weighted mean effect size for all technology approaches in beginning reading was only +0.09. A large, randomized study by Dynarski *et al.* (2007) and Campuzano *et al.* (2009) found no impact of five current supplemental CAI models. This study's findings greatly affected the weighted mean of nine studies of supplementary CAI, estimated at +0.08. The weighted mean effect size for decoding measures, also substantially affected by the Dynarski/Campuzano findings, was only +0.05, although comprehension/total reading effects (not measured in the Dynarski/Campuzano study) averaged +0.20. Large effect sizes were reported in small, matched studies of Waterford and WICAT. Reading Reels, which uses multimedia embedded in teachers' class lessons, had modest positive effects in two large randomized experiments (weighted mean ES = +0.20). With these potentially promising exceptions, research on the use of technology in beginning reading instruction does not show positive achievement effects of the types of software that have been most commonly used.

Beginning Reading: Instructional-Process Approaches

Instructional-process programs are methods that focus on providing teachers with extensive professional development to implement specific instructional methods. These fall into three categories. Cooperative learning programs (Slavin, 1995, 2009) use methods in which students work in small groups to help one another master academic content. Phonological-awareness training is an approach that gives teachers specific classroom strategies for building phonics and phonemic-awareness skills. Phonics-focused professional development models, including Reading and Integrated Literacy Strategies (RAILS),

Sing, Spell, Read, and Write, Ladders to Literacy, Early Reading Research, and Orton Gillingham, provide training to teachers to help them effectively incorporate phonics, phonemic awareness, and other elements in beginning-reading lessons.

Effects for instructional process programs were very positive. Across 17 studies, five of which were randomized quasi-experiments, the weighted mean effect size for instructional process approaches in beginning reading was +0.37. The mean was +0.47 for decoding measures and +0.30 for comprehension/total reading measures. In particular, positive effects were seen on cooperative learning programs such as Peer-Assisted Learning Strategies (PALS) and Classwide Peer Tutoring (mean ES = +0.46), phonics-focused professional development programs such as Sing, Spell, Read, and Write, Early Reading Research, and RAILS (mean ES = +0.43), and teaching of phonological awareness to kindergartners (mean ES = +0.22 on tests at the end of first or second grade).

Beginning Reading: Combined Curriculum and Instructional Process Approaches

Two programs, Success for All and Direct Instruction (DI), both provide teachers with structured, phonetic reading materials and extensive training in the teaching of systematic phonics and other reading skills. These are by far the most extensively evaluated of all beginning-reading approaches, with 23 mostly large qualifying studies of Success for All and three large studies of DI.

Success for All is a whole-school reform model mainly used with high-poverty elementary schools. It provides schools with a K–5 reading curriculum that focuses on phonemic awareness, phonics, comprehension, and vocabulary, beginning with phonetically regular minibooks in kindergarten and first grade. Cooperative learning is extensively used at all grade levels. Children are frequently assessed on curriculum-based measures, and struggling first graders may receive one-to-one tutoring. Teachers receive extensive professional development and follow up, and a full-time facilitator in each school helps all teachers use the model effectively. A solutions team works with parents to help them support their children's achievement and to deal with issues such as attendance and behavior problems. Evaluations of Success for All, including a 3-year national randomized experiment, have found substantial positive effects of the approach, averaging an effect size of +0.29.

DI is a structured approach to beginning reading that emphasizes a step-by-step introduction of synthetic phonics, use of decodable text, and extensive professional development. A large, national evaluation of DI found only small positive effects on reading outcomes. A large Houston study found substantial positive effects, but a Baltimore study found few differences.

Kindergarten-Only Studies

As noted earlier, studies that began and ended in kindergarten were treated separately because of the problem of determining whether any program effects are due to early teaching of skills ordinarily taught later. However, several kindergarten-only programs are at least promising in their outcomes. The kindergarten-only program with the strongest positive effects is an instructional process approach called Ladders to Literacy, which provides extensive professional development on the teaching of phonics. Two large studies of this model found positive effects on reading outcomes, especially when Ladders to Literacy was combined with PALS. Two studies of a phonics program called Voyager Universal Learning System found conflicting results, with one showing positive effects and one no differences. Kindergarten studies of the phonetic Waterford CAI model also had conflicting outcomes, while another CAI model called Destination Reading had significant negative effects.

Conclusions: Beginning-Reading Studies

The most important overall conclusion of the Slavin *et al.* (in press) review is that systematic, synthetic phonics are necessary but not sufficient to build strong reading skills in the early elementary years. All of the programs that were successfully evaluated had a strong emphasis on systematic phonics, but so did many of the programs that were not found to be effective. Beyond phonics, what made the greatest difference is professional development. The most successful models provided extensive training and in-classroom follow-up in cooperative learning, phonetic teaching strategies, or (usually) both. The most extensively evaluated and successful model, Success for All, provides about 26 person-days of in service and follow-up in the first year, as well as an on-site facilitator. In contrast, none of the programs that provide only phonetic textbooks without extensive training or follow-up were found to have educationally significant positive effects. The same pattern was found in reviews of research on upper-elementary reading approaches (Slavin *et al.*, in press) and secondary-reading models (Slavin *et al.*, 2008a): instructional-process approaches with extensive professional development generally produced positive outcomes in rigorous evaluations, while textbook approaches made little difference. Instructional technology approaches showed more promise in beginning reading than in upper-elementary or secondary reading, but the amount of research on technology approaches was limited. Particularly promising were embedded multimedia approaches used with the whole class, in contrast to the individualized approaches that have been more typical applications of CAI.

Cost Effectiveness

The only cost-effectiveness analysis of any of the beginning-reading programs was done in a longitudinal study of Success for All by Borman and Hewes (2003) that followed Baltimore children who had been in Success for All or control schools in grades K–5. At eighth grade, the Success for All students still scored significantly better than controls, and they had been retained or assigned to special education substantially less than control students. The authors found the cost-effectiveness of the program to be greater than that of other interventions that had been studied longitudinally, the Perry Preschool, the Abecedarian Program, and reductions in class size to 15.

Beyond the Basics: Programs for the Upper-Elementary Grades

From second to fifth grade, children go through a critical transformation as readers. Most beginning second graders are able to decode, recognize key sight words, comprehend simple texts, and read with some degree of fluency. The tasks that lay ahead of them, however, are qualitatively different from those they have navigated so far. They must consolidate and extend their basic skills, to be sure, and they must become fluent, confident readers. But most importantly, children in the upper-elementary grades must become strategic comprehenders of increasingly sophisticated text. They must build a vocabulary of words and concepts as well as a vocabulary of cognitive and metacognitive approaches to texts. While decoding skills may develop in a fairly step-by-step progression, the skills mastered in the upper-elementary grades emerge as children read in many genres and learn how to make sense of what they read in a less-straightforward process. Stage theorists (e.g., Chall, 1983) point out that the upper-elementary years are when children transition from learning to read to reading to learn.

Due to the different objectives and requirements of the upper-elementary grades, programs that are effective in building beginning-reading skills are not necessarily optimal in the upper-elementary grades, and vice versa. For this reason, in reviewing research on effective reading programs, it is important to review programs at each of these levels separately. Slavin *et al.* (2008a) reviewed research on upper-elementary reading programs. The following sections summarize the findings of this review.

Upper-Elementary Reading: Curricula

The reading curricula category includes seven qualifying studies of core basal textbooks and nine studies of supplementary texts used as initial instruction with all students. Professional development is typically provided

with these curricula, but there is far less of it than would be typical of the programs categorized in this review as instructional-process programs or combined curriculum and instructional-process programs. In the reading-curriculum programs reviewed in this section, the theory of action is that improved content and curriculum-embedded assessments aligned with national or state standards will improve students' reading achievement. Reading outcomes of core and supplementary textbooks for the upper-elementary grades have not been previously reviewed. The Slavin *et al.* (2008b) review of middle and high school reading programs did not find any qualifying studies of reading curricula.

Both core and supplemental reading curricula for the upper-elementary grades have been studied in high-quality evaluations. Among 16 studies, there were six randomized experiments as well as three randomized quasi-experiments. These studies found few effects on student reading achievement. The weighted mean effect size for core reading curricula was only +0.06, and for supplementary curricula it was +0.07, with an overall weighted mean of +0.06. The only curriculum with promising effects was Open Court, but in both of the studies of this program, teachers received far more professional development than that usually provided, and in both studies Open Court was used for 2½ h per day while control students had 90 min of reading.

Upper-Elementary Reading: CAI

The effectiveness of CAI has been extensively debated over the past 20 years, and there is a great deal of research on the topic. Kulik (2003) concluded that research did not support use of CAI in elementary or secondary reading, although Chambers (2003) came to a more positive conclusion, giving a mean effect size of +0.25. A large randomized evaluation of various computer software programs by Dynarski *et al.* (2007) found no significant effects on the reading achievement of first and fourth graders.

Thirty-one studies of CAI met the standards for the review. These were divided into three categories. Supplemental CAI programs, such as Jostens/Compass Learning, Academy of Reading, LeapTrack, My Reading Coach, and CCC/Successmaker provided additional instruction at students' assessed levels of need to supplement traditional classroom instruction. Computer-Managed Learning Systems included only Accelerated Reader. This program uses computers to assess students' reading levels, assign reading materials at students' levels, score tests on those readings, and chart students' progress, but students do not work directly on the computer. Innovative Technology Applications included Fast ForWord and Lightspan.

A total of 31 qualifying studies evaluated various forms of CAI, eight of which used random assignment to treatments. The studies involved a total of more

than 10 000 students. Overall, the sample size-weighted mean effect size was very small ($ES = +0.06$). The randomized evaluations ($n = 8$) had a weighted mean effect size of +0.05. These findings support Kulik's (2003) conclusion that effects of CAI in reading are minimal.

Outcomes were similar across the three categories of CAI programs. Across 25 studies of supplemental programs (such as Jostens and CCC), the weighted mean effect size was +0.05. Two studies of Accelerated Schools had a mean effect size of +0.06, two studies of Fast ForWord had a mean effect size of +0.21, and a study of Lightspan had an effect size of +0.42.

Upper-Elementary Reading: Instructional-Process Programs

Instructional process programs are methods that focus on providing teachers with extensive professional development to implement specific instructional methods. In upper-elementary reading, instructional process programs are quite diverse. Thirty-two studies, six of which used random assignment, evaluated a broad range of approaches. Cooperative learning programs (Slavin, 1995, 2009) use methods in which students work in small groups to help one another master academic content.

Strategy-instruction programs teach students cognitive and metacognitive skills such as summarization, graphic organization, and prediction to help them comprehend text. Strategy instruction is often combined with other methods, especially cooperative learning and peer tutoring. Structured phonetic-intervention programs are approaches emphasizing phonics, systematic instruction, and frequent assessment of student progress. Phonics-focused professional-development programs are ones that teach teachers the National Reading Panel (NRP) elements, especially phonics and phonemic awareness, mostly in workshops. Integrated language arts programs are less structured and less phonetic, and focus on integrating reading and writing, literature study, and pleasure in reading. Cross-age tutoring programs involve older children working with younger ones, and same-age tutoring involves having children take turns tutoring one another. Classroom management and motivation programs focus on building a positive learning environment.

Both the methods and the findings of instructional process programs for upper-elementary reading were quite diverse. Across 33 experimental-control comparisons, involving more than 17 000 students, the weighted mean effect size was +0.21. These include four randomized and two randomized quasi-experimental studies.

Ten of the studies evaluated two forms of cooperative learning. These had a weighted mean effect size of +0.21. All but one of the cooperative learning studies evaluated Cooperative Integrated Reading and Composition (CIRC), which involves students in well-structured cooperative

groups within which they help each other master and apply metacognitive learning strategies. CIRC was the basis for middle school reading programs called Student Team Reading and The Reading Edge, which had a weighted mean effect size of +0.29 in four secondary studies. The consistent positive effects of this family of cooperative learning approaches support the idea that programs focusing on professional development in structured activities that engage children in discussions about reading, giving them opportunities to help each other learn and use metacognitive skills, may have particular promise for enhancing reading achievement from the second grade onward. Positive effects were also found for cross-age tutoring programs ($ES = +0.26$ in 4 studies) and for same-age tutoring ($ES = +0.26$ in 2 studies), reinforcing the conclusion that interaction among students on reading strategies is an effective approach. Another promising category was programs emphasizing metacognitive strategy instruction, such as Reciprocal Teaching and Thinking Maps, which had a weighted mean effect size of +0.32 in five studies. In these programs, students were taught skills such as prediction, summarization, and self-evaluation.

Upper-Elementary Reading: Combined Curriculum and Instructional-Process Programs

Five reading programs, Direct Instruction, Corrective Reading, Spell Read, Wilson Reading, and Project Read, were categorized as combining curriculum and instructional process approaches. In each case, the programs provide complete curriculum materials, replacing (rather than supplementing) basal texts. Yet, all five also provide extensive professional development, far more than that provided with basal texts, and their theories of action depend on creating significant changes in teachers' daily instructional behaviors. All five programs strongly emphasize phonics, and all five provide step-by-step teacher's manuals, training, follow-up, coaching, and frequent assessment of educational progress.

Three of the programs (Corrective Reading, Spell Read, and Wilson Reading), as well as Failure-Free Reading, were evaluated in the same randomized evaluation by Torgerson *et al.* (2006). Each program was compared to its own control group, so these are treated as four separate studies.

The six qualifying evaluations of combined curricula and instructional process programs involved a total of only 867 students. However, the evidence from these studies suggests that combining phonetic curricula and extensive professional development in instructional strategies is effective. The sample-size weighted mean effect size was +0.29. There were particularly positive effects for Direct Instruction/Corrective Reading in three studies ($ES = +0.34$).

Programs for Struggling Readers

Beyond the studies of core reading programs, there is extensive research on programs targeted to individual pupils who are struggling in reading. This research was reviewed by Slavin *et al.* (2009). The review concludes that one-to-one tutoring is very effective in improving reading performance. Tutoring models that focus on phonics obtain much better outcomes than others. Teachers are more effective than paraprofessionals and volunteers as tutors. Small-group phonetic tutorials can be effective, but are not as effective as one-to-one phonetically focused tutoring. Classroom instructional-process programs, especially cooperative learning, can have very positive effects for struggling readers. CAI generally had few effects on reading. Taken together, the findings support a strong focus on improving classroom instruction and then providing one-to-one phonetic tutoring to students who continue to experience difficulties.

Conclusions

Research on reading approaches for the elementary grades finds several programs with significant promise for increasing children's learning and school success. The evidence particularly supports the use of approaches such as cooperative learning, which provide extensive professional development to teachers to help them make their teaching more active, motivating, and interactive for all pupils. Particular uses of technology may also contribute to children's success, and tutoring approaches for struggling pupils can help them get off to a good start in school.

What is most important about the evidence cited here is that it clearly indicates that schools need not accept the current reading levels of young children. Proven, replicable approaches are available and others along similar lines could be developed. A judicious policy of using what works, while expanding the number and variety of available programs, could make a broad and meaningful difference in students' success during the crucial early elementary years.

Personalized Learning in School Age Education

D Hopkins, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Personalized learning is an idea that is capturing the imagination of teachers, parents, and young people around the world. It is an idea that has its roots in the best practices of the teaching profession and has the potential to make every young person's learning experience mind-enlarging, creative, fun, and successful.

Personalization is the guiding motif that allows a system to evolve from one based on delivery of services to one that emphasizes mass customization and co-production. It is about putting citizens at the heart of public services and enabling them to have a say in the design and improvement of the organizations that serve them. In education this can be understood as personalized learning – the drive to tailor schooling to individual need, interest, and aptitude. This emphasis provides a bridge from prescribed forms of teaching, learning skills, curriculum, and assessment to an approach to classroom practice that is predicated on enabling every student to fulfill their potential. In his pamphlet *Learning about Personalisation: How Can We Put the Learner at the Heart of the Education System?* Leadbeater (2004: 16) clearly and sensitively links the concept of personalization with personalized learning as the key driver for the transformation of schooling:

The script of a system characterised by personalised learning . . . would start from the premise that the learner should be actively engaged in setting their own targets, devising their own learning plans and goals, choosing from a range of different ways to learn. . . . By making learning the guiding principle of the system, personalisation challenges some of the current divide and boundaries that exist – for example between formal and informal learning; between academic and vocational learning and between different ages and types of learners. (Leadbeater, 2004:16)

In one sense, personalization represents a logical progression from the standards and accountability reform strategies of the 1990s. These strategies marked an important first phase in a long-term large-scale reform effort, but in order to sustain systemwide improvement, societies are increasingly demanding strategies characterized by diversity, flexibility, and choice.

It is moral purpose that drives personalization. We see it most vividly in the concern of the committed, conscientious teacher to match what is taught, and how it is taught to the individual learner as a person. That is not just a question of sufficient challenge of aligning pedagogy to the point of progression that each learner has

reached, even though that is vitally important. It is also part of the teacher's concern to touch hearts as well as minds, to nourish a hunger for learning, and help equip the learners with a proficiency and confidence to pursue understanding for themselves.

In exploring the concept of personalized learning in this article, we shall:

- define the concept a little further and review its main components;
- explore the curricula implications of taking personalized learning seriously;
- emphasize the meta-cognitive aspects of personalized learning; and
- in the coda briefly discuss how to move personalized learning to scale.

What Is Personalized Learning?

Personalized learning is not a new idea. Many schools and teachers have tailored curriculum and teaching methods to meet the needs of children and young people with great success for many years. What is new is the drive to make the best practices universal. It is reimagining the education system around the learning needs and talents of young people that is the basis for every school becoming great.

To build a successful system of personalized learning, we must begin by acknowledging that we should be giving every single child the chance to be the best they can be, whatever their talent or background. Personalized learning means high-quality teaching that is responsive to the different ways students achieve their best. There is a clear moral and educational case for pursuing this approach. A system that responds to individual pupils by creating an education path that takes account of their needs, interests, and aspirations will not only generate excellence but will also make a strong contribution to equity and social justice.

One can summarize this approach to personalized learning as follows (Hopkins 2007):

- As an educational aspiration, personalized learning reflects a systemwide commitment to moral purpose, high excellence, high equity, and to every school being or becoming great.
- As an educational strategy, personalized learning relates to and builds on the learner's experience, knowledge, and cognitive development; develops their confidence

and competence; and leads toward autonomy, emancipation, and self-actualization.

- As an approach to teaching and learning, personalized learning focuses on individual potential, develops the individual's learning skills (particularly ICT), and enhances creativity and social skills.
- As a curriculum orientation personalized learning offers an approach to subject teaching that balances societal aspirations and personal relevance and unifies the curriculum offer across sectors and age groupings.

This leads directly to the following implications that can help guide day-to-day practices:

- for children and young people, it means clear learning pathways through the education system and the motivation to become independent, e-literate, fulfilled, life-long learners;
- for schools, it means a professional ethos that accepts and assumes every child comes to the classroom with a different knowledge base and skill set, as well as varying aptitudes and aspirations; and because of that, there is a determination for every young person's needs to be assessed and their talents developed through diverse teaching strategies;
- for school governors, it means promoting high standards of educational achievement and well-being for every pupil, ensuring that all aspects of organizing and running the school work together to get the best for all pupils;
- for the national and local authorities, it means a responsibility to create the conditions in which teachers and schools have the flexibility and capability to personalize the learning experience of all their pupils, combined with a system of intelligent accountability so that central intervention is in inverse proportion to success; and
- for the system as a whole, it means the shared goals of high quality and high equity.

The rationale of these principles is clear: to raise standards by focusing teaching and learning on the aptitudes and interests of pupils and removing any barriers to learning. The key question is how to collectively build this offer for every pupil and every parent.

There are six key components that can help to deepen and extend this personalization of education. **Figure 1** illustrates the central components of personalized learning within and beyond the school. They are:

1. Assessment for learning implies:

- that the school, its teachers, and the system develop a high-level capacity for using data to promote student learning;
- the process of seeking and interpreting evidence for learners and teachers to decide where the learners are in their learning, where they need to go, and how best to get there; and

Figure 1 Central components of personalized learning within and beyond the school.

- shared objectives, feedback that identifies targets for improvement, higher order questioning, and self and peer assessment.
2. Powerful learning and teaching implies:
- the curriculum should focus on understandings and competencies that have enduring and intrinsic value;
 - high expectations and challenging targets should be set for all, but while standards should remain constant, time and support should be varied according to individual student need; and
 - teachers should show students how to incorporate new information into their existing knowledge through activities that induce critical thinking with conceptual problems.
3. Self-directed learning implies:
- that such learning contracts provide the basis for project work that is an essential and ongoing feature of the curriculum offer;
 - individual learning profiles; and
 - counterintuitively, strong emphasis laid on cooperative group learning and social interaction.
4. Customizing the curriculum offer implies:
- modifying the framework of the national curriculum to ensure a continuum for personalized learning across the three phases of education—foundation, middle, and 14–19;
 - using the enquiry into subjects within the context of standards as the building block of curriculum provision; and
 - involving students in the formulation of their own educational goals. This is the key to them establishing engagement in learning as well as a long-term commitment to schooling.
5. The contribution of the new technologies implies:
- opportunity for personal creativity, the ability to match curriculum to individual learning styles, and putting the pace of learning under the individual's control;
 - concurrent and extended learning opportunities outside of normal school day; and

- building diagnostic assessment for learning with different pathways to follow.
6. Organizing schools for personalized learning implies:
- differentiating the workforce for student learning, enhancing the role of the learning mentor, and providing each learner with the link to an adult;
 - block timetabling and grouping students on basis of learning need, within and between schools to ensure network and community learning; and
 - establishing a system of transferable learning profiles and credits to underpin assessment and ensure flexibility.

Obviously, all of these six components are important as they intend to shape a modern pedagogy centered on learning, but they are not necessarily exclusive. Here, however, two aspects of personalization that are crucial to ensuring that all students reach their potential are highlighted. The first is customizing the curriculum offer in order that breadth of study, personal relevance and flexible learning pathways can be delivered throughout the education system. The second is meta-cognition or learning how to learn.

Toward the Personalized Curriculum

It is the curriculum that provides the means for every school becoming a great school and all students realizing their potential. Yet in many educational systems the curriculum is often a barrier to achieving the forms of personalized learning so necessary for such a transformation. One way of both pinpointing the curriculum issue and drawing the argument together is to pose the question “What does it mean to be educated” at any particular phase of education.

Being educated at any particular age has four central elements:

- a breadth of knowledge gained from a curricula entitlement;
- a range of skills on a developmental continuum that reflects increasing depth at ages 7, 11, 14, 16, and in many cases, 18;
- a range of learning experiences; and
- a set of key products, projects, or artifacts.

It also means that students are sufficiently articulate to:

- sustain employability through basic skills;
- apply their knowledge and skills in different contexts;
- choose from and learn in a range of post-14 study (assuming an entitlement curriculum up until then); and
- draw on wider experiences to inform further learning and choice.

We suggest that most national curricula do not meet these desiderata. In general, central authorities set out

mandatory programs of study in all subjects, with schools generally free to determine their own timetables and design their own programs of teaching. In particular, the following issues seem to be shared across many jurisdictions and militate against the realization of personalized learning:

- curriculum congestion – the curriculum suffers from content and process overload;
- expected levels – do clear levels of attainment exist in the mother tongue, maths, and science?
- poor catch-up provision or progression for low-attaining pupils;
- inadequate embedding of core skills;
- lack of clarity for students on the common learning skills;
- insufficient stretch for the most able; and
- staffing problems.

Although the following proposals are based on the author’s understanding of the Key Stage 3 (11–14) curriculum in England, they represent a broader attempt to imagine a structure that enables schools and teachers to personalize the curriculum across all stages of education.

The first is to focus on core study. Functional literacy, numeracy, and communication could be clarified as expected attainment at the end of the KS3 curriculum. ICT would also need to be explicitly added to a suggested core of mother tongue, math, and science. Functional skills would similarly need to be embedded across the curriculum.

The second would be a condensed statutory curriculum in noncore subjects combined with an optional entitlement. In many countries, this is referred to as the essential curriculum. This means that the statutory curriculum content and processes in noncore subjects would be reduced. As a rule of thumb, in most national systems this would mean that the content removed would be approximately 20–25% of current specifications. The reduction could be redesignated as an optional entitlement.

Third, the flexibility of an optional entitlement would allow schools to guarantee time to:

- secure essential knowledge and teach common learning skills through the curriculum; and
- organize the curriculum to meet the needs of a range of abilities, tailoring support for underachieving and underperforming students, and to stretch gifted and talented students.

Fourth, there needs to be clarity on common learning skills. This requires that a common framework of skills is identified across the whole curriculum, as is seen in the following section.

Finally, there is the need to champion effective pedagogy. There needs to be external support to help schools organize the curriculum to meet the needs of a range of

abilities. It must also help teachers bring curriculum knowledge and common learning skills together in the classroom.

The clear prize from pursuing these actions would be a curriculum tailored to the needs, talents, and aptitudes of all students. This would ensure that every student had the core and common skills required to learn at each stage of education, and that the best students were properly stretched.

In this section, WE have taken a view on the necessary reform of any national or local curriculum to accommodate personalized learning. But underpinning the importance of structural curriculum change is the necessity that it accommodates not just curricular knowledge, but also learning how to learn. This essential aspect of personalized learning is dealt with ahead.

Meta-Cognition and Learning How to Learn

Meta-cognitive skills enable students to develop the capacity to monitor, evaluate, control, and change the way they think and learn. There is clear evidence that the acquisition of these skills can significantly increase achievement. To ensure more students gain these skills we need:

- first, teaching strategies that consistently and strategically develop students' learning skills. For example, instead of simply presenting information for knowledge acquisition, teachers can ensure that in tandem with learning new knowledge, students also extract ideas, memorize information, build hypotheses and theories, use metaphors to think creatively, and work effectively with others.
- second, a framework of common learning skills, as there is currently a lack of clarity for students on the skills they should acquire and how they can develop these as they progress. These skills would need to be identified and taught coherently across the curriculum.

We explore the framework for learning skills in this article. Inevitably, there is overlap between these two vital aspects of personalizing learning as they are crucially the opposite sides of the same coin. This point was made by Joyce *et al.* (2002: 7) by arguing that it is the teacher's task not simply to teach but to create powerful contexts for learning. It is a truism that no one can teach anyone anything: the best that can be done is to help another to learn. That idea and the essence of personalized learning was expressed thus:

Learning experiences are composed of content, process and social climate. As teachers we create for and with our children opportunities to explore and build important areas of knowledge, develop powerful tools for learning, and live in humanising social conditions.

It is the integration of “content, process and social climate” that puts the power into the personalized learning experience. But at the heart of personalized learning is its impact, not just on test scores and examination results, but also on the students' learning capability. If the teacher can teach the students how to learn at the same time as assisting them to acquire curriculum content, then the twin goals of learning and achievement can be met simultaneously.

A fundamental aspect of personalized learning is therefore the ability of learners to respond successfully to the tasks that they are set as well as the tasks they set themselves – in particular to:

- integrate prior and new knowledge,
- acquire and use a range of learning skills,
- solve problems individually and in groups,
- think carefully about their successes and failures,
- evaluate conflicting evidence and to think critically, and
- accept that learning involves uncertainty and difficulty.

The deployment of such a range of learning strategies is commonly termed meta-cognition, which can be regarded as the learners' ability to take control over their own learning processes. The key point is that within whatever context learning takes place, it involves an active construction of meaning. This carries implications for the management of learning opportunities, in particular that an active construction of meaning requires practical, cognitive, and other learning strategies. As learning is interactional it can occur only as the learner makes sense of particular experiences in particular contexts. This making sense involves connecting with an individual's prior knowledge and experience. Thus, new learning has to relate to, and ultimately fit with what individuals already understand (Vygotsky, 1962).

If we are serious about personalized learning, then we need to be clear as to the typology of the skills students should gain in order to develop their personal effectiveness and employability. These skills fall into three categories:

- functional skills,
- thinking and learning skills, and
- personal skills.

Functional skills are literacy, numeracy, and ICT. In most countries, these are regarded as key priorities and therefore tend to be taught and assessed in the core subjects of mother tongue, math, and ICT. We have already discussed how they can be integrated into a revised curriculum structure.

Thinking and learning skills are the skills young people need to acquire in order to become effective learners. Gaining mastery of these skills equips students to raise their achievement by developing their ability to:

- improve their achievement by applying a wide range of learning approaches in different subjects;
- learn how to learn, with the capability to monitor, evaluate, and change the ways in which they think and learn; and
- become independent learners, knowing how to generate their own ideas, acquire knowledge, and transfer their learning to different contexts.

Personal skills are the skills young people need to acquire in order to develop their personal effectiveness. Gaining mastery of these skills equips students to manage themselves and develop effective social and working relations, initiative, and self-motivation.

This framework provides clarity on the skills students should gain. But to ensure students gain mastery of these skills there needs to be agreement on how the skills should be:

- embedded in teaching and learning, especially since in most systems these skills are not well-taught in all schools and consequently students' skill development is patchy and
- developed coherently across the curriculum especially as again in most systems, these skills are not specified or developed in a systematic way and progression is assumed and not explicit.

This skills framework is consistent with trends in other countries. For example, the OECD's (2005) Definition and Selection of Competencies (DeSeCo) Project, which classified individuals' key competencies for a successful life into three broad categories:

1. Use tools interactively (both physical and sociocultural ones):
 - a. use language, symbols, and texts interactively,
 - b. use knowledge and information interactively, and
 - c. use technology interactively.
2. Interacting in heterogeneous groups and specifically to:
 - a. relate well to others,
 - b. cooperate and work in teams, and
 - c. manage and resolve conflicts.
3. Acting autonomously:
 - a. act within the big picture,
 - b. form and conduct life plans and personal projects, and
 - c. defend and assert rights, interests, limits, and needs.

So in summary, the clarity provided by a single skills framework allied with better guidance and training on pedagogy will itself create greater coherence across any national curriculum. This is the necessary foundation for ensuring that the essence of personalization is available for every student. This in turn is a critical building block in ensuring that every school is a great school. In the final section we examine further how these initiatives can be taken to scale.

Coda – Moving Personalized Learning to Scale

In this final section of this article, we discuss briefly how to move personalized learning to scale. At a minimum three complementary sets of activities are required to successfully move personalized learning to scale:

- First, the personalized learning offer needs to be developed and made the centrepiece of the range of national policy options. In parallel, curriculum content and subject specialism need to be reviewed in light of the key components of personalized learning and relentlessly connected to the standards agenda. For example, **Table 1** illustrates how this work was carried forward in England as part of the Key Stage 3 (lower secondary, 11–14 years old) national support program.
- Second, the personalized learning offer needs to be the central agenda of all national and local partnership arrangements, for example, national/local negotiations, the developing of a consensus amongst national support organizations, and mobilizing nongovernmental organizations.
- Third, personalized learning and moral purpose must be made synonymous, that is, personalized learning is important because it will enable all young people to reach their potential. It becomes the key message in national and local government's communication policy and conferences as well as the recipient of a series of symbolic (and substantive) policy initiatives, for instance, learning vouchers for every 14-year-old.

Table 1 Key Stage 3 and personalized learning

Assessment for learning	<ul style="list-style-type: none"> • Setting personal pupil targets • Introducing self and peer assessment • Developing more effective feedback to pupils
Powerful learning and teaching	<ul style="list-style-type: none"> • Developing thinking and learning skills across the curriculum • The learning challenge program • Mentoring skills
Self-directed learning	<ul style="list-style-type: none"> • Teaching study and research skills • Introducing learning contracts
Curriculum	<ul style="list-style-type: none"> • Guidance on different curriculum models for KS3 • The 2-year KS3 pilot – creating time for the tailored curriculum
New technologies	<ul style="list-style-type: none"> • Implementing ICT across the curriculum • Teaching the use of the Internet • Interactive teaching programs
Organizing schools for personalized learning	<ul style="list-style-type: none"> • Models and materials for catch-up provision • Involving parents project • Teaching strategies that include and challenge everyone

To meet the full range of individual needs and aspirations inherent in the goal of excellence for all requires extensive, but disciplined, innovation of many different kinds and at different levels in educational provision and professional practices. This entails changes (1) at the level of the classroom, for example, through ICT training for classroom teachers and leaders to build on the ICT infrastructure; (2) at the level of the school, for example, through workforce reform to ensure that teachers spend more time actually teaching; as well as at (3) system level such as the creation of federations between schools and other collaborative arrangements. It should by now be clear that the dissemination of the outcomes of innovation and new methods of achieving excellence cannot be achieved by a center–periphery model alone, but requires new mechanisms of lateral transfer through networks. The challenge for personalized learning is to create a

learning system that is capable of adapting to deep changes in our economy and society by pursuing universal participation and achievement.

Perspectives on Schooling in the Middle Years

V J Russell, The University of Melbourne, Melbourne, VIC, Australia

Introduction: Betwixt and Between

The beginning and final years of schooling, with their focus on foundational skills or school completion achievements and opportunities, commonly act as magnets drawing strong public, parental, political, media, and educational attention. Less public interest has been generated by the years of schooling in between. These in-between years have been termed the middle years (or middle grades/phase) of schooling; they, generally encompass students of ages 10–15 or, in a K–12 system, grades 5–9, with some flexibility in the upper and lower limits of these groupings. The term middle schooling implies a characteristic orientation to the education in the middle years, centered on early adolescents' needs, interests, and capacities and linked to certain psychological, sociological, philosophical, and educational concepts. Another relevant concept is the middle school. This refers not to an orientation to schooling but to an organizational unit—a separate school, or a separate campus or section of a larger school. The middle school is a structural concept. Middle schools do not necessarily implement a middle schooling approach.

In this article, consideration is given first to recent interest in the middle years of schooling, amid changing global contexts, increasing complexity of stated goals of learning, and expanding research-based knowledge of young adolescent students and their learning. From the diversity of individual school and system approaches to schooling in the middle years, two different characteristic types of approach are identified, the first focusing on the middle school as structure and the second focusing on middle schooling as practice. A description is given of what is thought to constitute high-quality middle schooling. The question of an evidence base for middle schooling approaches is an important one. Two aspects are discussed: the extent to which middle schooling approaches have actually been implemented and the effectiveness of such approaches in achieving stated goals of learning. Evidence is far from abundant, although what there is suggests that better designed macro-level research would support existing, sound, micro-level research to provide the evidence base that is sought.

Increasing Interest in the Middle Years

The last two decades have witnessed a groundswell of interest in the middle years of schooling and a deepening

of understanding of what constitutes good middle years schooling. From the late 1980s, there has been a spate of publications in this area, including journal articles with regard to fundamental psychological processes relevant to early adolescence; special journal issues regarding middle schooling; establishment of targeted journals; investigations and reports linking adolescence, engagement, and approaches to schooling; and advice concerning appropriate forms of middle schooling. Several factors have contributed to this renewed interest.

Reduced Progress During the Middle Years

Evidence has been accumulating that the growth trajectory of students' learning flattens during the middle years; a decline in student engagement underpins the reduced growth in achievement. A large, longitudinal Australian study based on repeated measures of 5 year-level cohorts revealed a lack of growth (even some decline) in literacy and reducing enjoyment of school in grades 5–8 (Hill *et al.*, 1996, cited in Hill and Russell, 1999). Similar dips in achievement and engagement of students have been reported in a range of countries, particularly in the lower secondary years, with socioeconomically and ethnically disadvantaged students being most affected (Whitby *et al.*, 2006). The role of transition from primary to secondary school in such dips has been highlighted (Galton *et al.*, 1999), although the decline begins prior to transfer. Improvement resumes at the end of the compulsory years, perhaps reflecting the fact that disengaged students have left school.

Declining Engagement During the Middle Years

Engagement, or directed energy in action, is evidenced in students' actual learning behavior. It is student engagement rather than underlying motivation to achieve that reduces markedly during the middle years (Russell *et al.*, 2003). Student engagement is responsive to the nature of the learning environment; maintenance of a stimulating, positive environment is a factor under school control.

Indicators of declining engagement in school vary from the less to the more serious, for example, from boredom or passivity to delinquency or self-harm. All can act as indicators of potential early school leaving. An English study of Key Stage 3 students suggested to Barber (1996) that nearly 20–30% of students were bored, 10–15% were behaving badly and truanting regularly,

while 2–5% had given up school altogether. The consequences for individual students of lost opportunities for realizing their potential are clear; so, too, are the economic consequences for the country. The disadvantaged are affected disproportionately.

Adolescence

An earlier theoretical and descriptive focus on the negative in adolescence, the storm and stress of troubled youth and their risky behavior, led many educators to the view that declining adolescent engagement in learning was inevitable and therefore immutable. In recent decades, a shift to interest in the capacities of adolescents, particularly their expanding cognitive potential, coping strategies, individual agency, and potential for positive development, has been accompanied by well-honed, methodologically sophisticated, often longitudinal research on specific aspects of adolescent behavior.

The needs and challenges of adolescence continue to be acknowledged: adjustment to physical, social, emotional, and intellectual changes; development of a positive self-concept, identity, and values; growth of independence, agency, and responsibility; establishment of positive relationships with peers and adults; and growth in the capacity to respond constructively to the physical, social, and political environment. However, the present research emphasis on the capacities of adolescents points to educational approaches that improve the course of adolescent experience and development (Steinberg and Lerner, 2004).

Deeper Understanding of Learning Processes

The strongest school contribution to student learning is commonly acknowledged to be the classroom teaching and learning process. Understanding of the learning process has deepened, moving beyond dependence on simple concepts of drives and rewards or discovery and activity, to focus on the perceptions, thoughts, and beliefs of the learner, the way the learner takes in information, interprets and processes it, draws meaning from it, and stores it. Learning is seen as an active process of building meaning; it takes place in all situations, even the least promising, but the best-quality learning takes place when students have the opportunity to think, use and manipulate ideas, create new connections, develop deeper understandings of existing knowledge, construct more complex mental models of the world, and gain greater confidence and capacity to regulate their own learning. As the basic understanding of constructivism has increased, so too has the quality of its translations into classroom practice. Contributions also came from the pursuit of thinking-skill development, careful brain-based research, deeper understandings of student motivation, engagement and self-regulation, and recognition of the value of the student voice, giving rise

to more productive pedagogical approaches within a context of positive classroom climate and student–teacher relationships.

Changing Contexts and the Goals of Learning

The developing globalized knowledge society necessitates rethinking of the goals of schooling and the means of meeting them. Change is rapid, continuing, and pervasive: change in knowledge, information, work, communication, mobility, diversity, and relationships. In such a context, educational goals that focus on literacy, numeracy, and current factual knowledge are inadequate. One of the main goals in this context of change should be the development of people with the capacity to adapt – lifelong learners who want to continue to learn and who know how to go about doing so. Many related skills, characteristics, and qualities are also required (Russell *et al.*, 2003). To achieve these goals, young people need to enjoy their learning and complete their education. This means taking reform in middle years' schooling seriously. Such reform would affect the whole of schooling, transforming the "whole ecology of formal education" (Hill and Russell, 1999: 180).

Approaches to Schooling in the Middle Years

Although national education systems, based on different values and structures, vary in their approaches to middle schooling, common issues do exist. Schooling in the middle years is commonly seen as the weak link in a review of eight European systems (Hirsch, 1994), showing a tendency to emphasize examinations assessing core knowledge transmission via didactic teaching to the detriment of attention to the developmental needs of early adolescents. Another multinational study of 16 systems (Greenaway, 1999) highlighted the unclear role of lower secondary education and negative effects of transfer between phases of schooling.

The English system illustrates many of the common challenges. The lower secondary years (grades 7–9), are a cause of considerable concern (Barber, 1999). English middle schools (encompassing both upper primary and lower secondary grades) have been accused of insufficient academic rigor and thus of being part of the problem, yet it is the transition from primary to secondary schools that is commonly viewed as producing a decline in student progress (Galton *et al.*, 1999). Although English middle schools are being closed, improvement is unlikely via a structural solution. In the lower secondary Key Stage 3 Strategy, emphasis has been placed on potentially more productive approaches aimed at increasing student engagement and positive transition experiences through improving the quality of pedagogy and teacher learning.

Among the school systems that have sought change from the traditional primary student-centered or secondary subject-centered approaches in the middle years, two characteristic orientations are evident. One has focused historically on school structure, the other on school practice. These two orientations are not mutually exclusive.

Middle School Structures

The USA has long been an active participant in the provision of middle schooling. Its dominant orientation for many years was a structural one. Several waves of middle years' reform are discernible. Serious national economic issues stimulated the creation of junior high schools (grades 7–9) at the beginning of the twentieth century, in order to reduce early leaving and improve prevocational preparation and employment. Progressive reforms in curriculum were heralded but did not emerge, as junior highs aped their more powerful senior colleagues and became imitation high schools (Cuban, 1992).

Educators' dissatisfaction with junior highs in the 1960s and 1970s led to rapid development of middle schools (grades 5/6 to 8) aimed at meeting the needs of early adolescents. Organizations such as the Association for Supervision and Curriculum Development, the National Association of Secondary School Principals, and the National Middle School Association (NMSA) provided vision, publications, and other support (e.g., *This We Believe*, first published by NMSA in 1982, with the latest revision in 2003) (NMSA, 2003). However, by the late 1980s, little seemed to have changed in terms of school curriculum, organization, and pedagogy (Cuban, 1992). Criticism was also leveled at middle schools by those who perceived them to lack academic rigor and discipline.

In a climate of economic uncertainty and concern about equity in a changing population, the 1989 publication of the Carnegie Council report, *Turning Points*, was influential (Carnegie Council on Adolescent Development, 1989). Its assertion of a mismatch between middle school organization and curriculum and the needs of young adolescents, both intellectual and emotional, provoked serious consideration of their recommendations for transforming middle schools: creation of small learning communities, teaching a core academic program, ensuring success for all, empowering school-based decision-making, employing specialist middle years teachers, fostering health and fitness, and involving families and community in schools.

In the following decade, some changes were detected, although these tended to concern within-school structural changes to enhance relationships and well-being rather than improvements of core student experience in curriculum, pedagogy, and assessment (Jackson and Davis, 2000). Concern was expressed about reform being confined to

pockets of excellence, lack of growth in student learning (reinforced by USA performance on international studies of achievement), and on-going lack of equity in achievement (Haycock and Ames, 2000). *Turning Points 2000* (Jackson and Davis, 2000) aimed to rectify the situation by providing a coherent framework for middle schooling that balanced caring relationships with more powerful and appropriate approaches to curriculum, instruction, and assessment. At present, the balance seems to be altering, with language use and goals highlighting rigorous public academic standards and high achievement. What happens will depend on how these concepts are spelled out in practice. A narrow interpretation could see the return of traditional forms of curriculum and classrooms. This was not the intention of Jackson and Davis (2000).

Middle Schooling as Practice

In Australia, discussion of early-adolescent education has been more recent and has focused on the orientation of practices used in the middle years rather than on school structure. From the early 1990s, a body of mainly national but also state reports stimulated debate, research, and adoption of changed practice in middle schooling. Motivating this activity were concerns with regard to schooling for early adolescents in grades 5–9 (grade levels that crossed the primary–secondary school divide) that did not match their needs or capacities, with consequent negative effects on engagement, retention, employment, and skill development for the globalized knowledge society. In contrast to the USA situation, there was little focus on minority urban group disadvantage or extreme, risky behaviors.

Victoria and Queensland are two Australian states that have developed coherent and comprehensive approaches to the middle years. Local research findings in the early 1990s stimulated Victorian concern regarding the middle years: the grade 5–8 plateau in student progress, decline in engagement, and greater between-class than between-school differences, pointing to the vital role of classroom pedagogy (Hill and Russell, 1999). The government established the *Middle Years Research and Development (MYRAD) Project* (1998–2001), aimed at evaluating a whole-school approach to improving student outcomes in grades 5–9. Evidence from the project shaped the subsequent middle schooling approach in Victoria.

Emphasis was placed on classroom climate and practices that established a balance between developmentally appropriate supportive relationships and challenging, authentic pedagogy, curriculum, and assessment. Other processes were seen to be necessary if changes inside the classroom were to be developed and sustained, for example, cooperation, planning, and consistency between clustered primary and secondary schools; use of a whole-school approach to vision and planning; adoption of an evidence-based approach; and system–policy coherence and alignment in

curriculum, assessment, pedagogical, and accountability dimensions of schooling (Russell *et al.*, 2003). An outline of the key strategic intentions of the approach can be found in Hill and Russell (1999). Subsequent research and development projects fleshed out the MYRAD recommendations, while funded programs, such as *Schools for Innovation and Excellence*, scaled up government–school adoption of middle schooling and a new government P–10 curriculum framework was developed, incorporating these principles. The coherence of the Victorian middle years reform agenda could be seen in the policy documents, reports, resource materials, and system level support that were developed.

In 2003, Queensland published its *Middle Phase of Learning State School Action Plan*. This policy document encapsulates the middle schooling approach, adopted in that state for grades 4–9. It is predicated on the concepts of the needs, challenges, and expanding horizons of early adolescents; on the lack of learning progress, decline in engagement, and increased gap between high and low achievers during that period; and on the importance of developing more sophisticated thinking and related skills that are needed in the knowledge economy. Central to the middle schooling outlined in the *Action Plan* is alignment of authentic curriculum, pedagogy and relationships, and assessment. It commits the Queensland system to ensure that every student in grades 4–9 engages in purposeful, intellectually challenging, and successful learning, with particular support in transition periods, and interaction with developmentally appropriate and individualized teaching.

The Queensland government's policy was able to draw on extensive and intensive Queensland research, including research undertaken by Luke and colleagues that targeted middle years literacy and numeracy, *Beyond the Middle* (2002), and the *Queensland School Reform Longitudinal Study* conducted by Lingard *et al.* (2001). The latter gave rise to the Productive Pedagogies framework, which together with the real-world,

Rich Tasks, forms the conceptual pivots of Queensland's New Basics curriculum framework. The consistency and comprehensiveness of Queensland's approach to the middle years can be seen in its provision of systemic support and range of helpful publications, reports, and resource materials, in addition to the policies it has established.

High-Quality Middle Schooling

Separate middle school institutions are neither necessary nor sufficient for high-quality middle schooling. In fact, such restructuring can divert attention from and exhaust energy for the task of creating and embedding a successful middle schooling approach. There is no neat or even agreed definition of what constitutes high-quality middle schooling. The middle schooling approach is often described in piecemeal fashion – a series of signifying practices, such as teacher teaming, integrative curriculum, cooperative learning, and flexible timetabling, that lack a coherent framework to bind them together conceptually.

A whole-of-school conceptualization of middle schooling provides such a framework. It rests on the assumption that middle schooling involves not just separate add-on programs or strategies, but a transformation of all of the critical, interactive elements of school experience, centered on critical beliefs and understandings and creating a change in the whole ecology of schooling (Hill and Russell, 1999). The whole-school design approach used in the MYRAD project illustrates this (Figure 1). A description of each design element is set out in Table 1.

Other well-known examples are the *Turning Points* 2000 design (Jackson and Davis, 2000) and the 14 middle school practices and cultural characteristics delineated by the NMSA. The elements in the former design are eight principles or recommendations, the central one being to ensure the success of every student. Others concern responsive

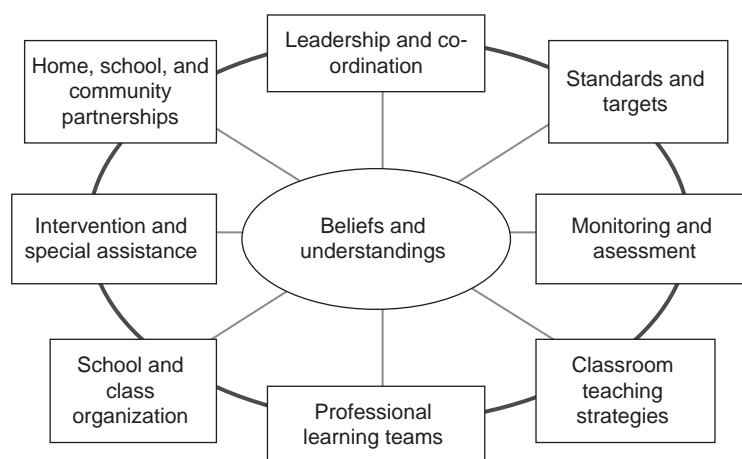

Figure 1 Whole-school design for improving learning outcomes. From Hill, P. W. and Crevola, C. A. M. (1997). *The Literacy Challenge in Australian Primary Schools*. IARTV Seminar Series No. 69. Jolimont: IARTV.

holistic provision of community services through schools

curriculum with rigorous standards; authentic and personalized classroom pedagogy and assessment; specialist middle grade teachers who continue to learn professionally; caring relationships with students in an intellectually challenging climate; democratic school governance and evidence-based decision-making about students; a safe and healthy school environment; and a collaborative relationship among the school, home, and community.

There is much in common among whole-school designs, particularly the balancing of the two broad interactive dimensions of schooling Newman and colleagues (Newmann *et al.*, 1992) define as essential to adolescent engagement and achievement: first, school and classroom culture and relationships that enable students to feel connected to school; second, student learning experiences that are challenging, interesting, meaningful, appropriate to their needs, and nontrivial. However, the issues highlighted reflect the particular middle years context of the systems concerned. For example, there is more concern to establish mixed ability grouping and cooperative learning in the US context, where tracking is standard practice and often considered publicly to be evidence of effort for high achievement, than in Australia where tracking is less common. Specialist middle grades teacher preservice qualifications are also a greater issue in the US context, where middle schools provide targeted employment.

Reflection on the description of high-quality middle schooling leads one to question whether this approach is unique to students in the middle years. In fact, the approach appears to be characteristic of good learning, teaching, and schooling for students of any age. The emphasis on tailoring practices to meet the developmental characteristics and needs of young adolescents is unique, but then good learning and teaching are responsive to the particular developmental needs of students, irrespective of their age group. Middle schooling could well stimulate improvement of teaching and learning at other levels.

The Evidence Base

Research evidence is required with regard to two aspects of middle schooling: first, the extent to which middle schooling has been implemented and second, the effectiveness of middle schooling in improving learning outcomes. There are complexities in attempting to investigate each of these. Writers commonly remark on the paucity of middle schooling research. There is much that is simply not known.

Extent of Implementation

It would be unreasonable to expect that a whole-school approach to middle schooling could spring to life in a school fully realized, given that design elements encompass

all aspects of school life. Implementation occurs developmentally (Russell *et al.*, 2003). Research evidence is required with regard to the following: variation in the development of middle schooling achieved within schools; aspects of middle schooling that are most and least likely to develop; the best starting point for successful development; the time scale required for full implementation; and variation in quality of development.

Some evidence comes from a study in which Felner and Jackson (1997) developed an index of middle school transformation to differentiate schools with high, medium, and low implementation levels of the *Turning Points* (1989) eight design recommendations. Scoring was based on indicators of implementation quality in each design area. Variation in implementation was evident. Of the 31 schools, nine were classed as high implementers, 12 as partial implementers, and ten as having achieved little if any implementation, each group being a representative demographic mix of schools. The authors commented on the value of having a whole-school design both for comprehensive school planning and for research purposes.

The most successful developmental sequencing began with key leadership practices and staff commitment to common attitudes, beliefs, and understandings regarding middle schooling. Other elements could then be established effectively on this basis. Much is yet to be discovered about how elements interact, for example, how the presence, absence, or intensity of element implementation affects development of other elements. It was noted that implementation takes substantial time – nearly 3 years for processes to be embedded. Thus, for a middle school program encompassing grades 6–8, it would take nearly 5 years before a cohort of students would have access to a full middle schooling experience.

An Australian study of primary, secondary, or P–12 schools engaged in middle schooling by Pendergast *et al.* (2005) concluded that there are three phases in the implementation of middle schooling reform: an initiation phase (1–2 years), a developmental phase (2–5 years), and a consolidation phase (5–10 years). The report emphasized that school reform takes much longer than usually allowed for. Pendergast and colleagues endorsed the view that leadership innovation and an agreed school vision for learning are critical variables. Enhanced pedagogies, especially the provision of greater intellectual challenge in classroom work, were deemed vital for progression from the developmental to the consolidation phase, thus reinforcing the present understanding that improving actual teaching and learning approaches is the most important strategy to implement, although the one most difficult to achieve.

What is the norm in the middle years of schooling these days? While case studies and extended experience with reform programs (Haycock and Ames, 2000), as well as systematic research, point to high-quality middle schooling being achievable, there is very little evidence

to indicate whether the fully realized middle schooling approach is widespread within interested education systems, even in systems that provide policy, targeted funding, and other systemic support.

Effectiveness

Evidence of the effectiveness of middle schooling is essential. Does it enable the range of current goals of schooling to be met better than a traditional approach? There is research evidence of the effectiveness of component processes of middle schooling. For example, leadership teams' school improvement practices, especially their vision for improved student learning in the school, are linked positively to teachers' perception of the quality of their own professional learning culture (Russell *et al.*, 2003). Evidence-based professional learning challenges and changes teachers' attributional beliefs about learning, increasing teachers' acceptance of responsibility for student learning and their preparedness to intervene (Timperley and Robinson, 2001). Students are more engaged and use better, in-depth learning strategies within classroom cultures characterized by task-focused mastery goals rather than ability-focused performance achievement goals (Meece *et al.*, 2006). Multiple affective and cognitive aspects of classroom learning environments are significantly predictive of student behavior, level of student task participation, and quality of thinking (Matsumura *et al.*, 2008).

Research evidence is also available with regard to individual signifying practices of middle schooling, such as teacher teaming, block or flexible timetabling, problem-based and transdisciplinary curriculum, and authentic pedagogy and assessment. Summaries of research on such middle schooling practices have been published (e.g., Anfara, 2001), while evaluations of large-scale middle schooling initiatives provide useful evidence (Mertens *et al.*, 1998), and design-based approaches to middle schooling such as *Turning Points 2000* (Jackson and Davis, 2000) use research evidence to underpin the practices they advocate.

There is less evidence, however, with regard to the effects of an integrated, whole-school design approach to middle schooling. More is needed. Felner and Jackson (1997), in the study already outlined, examined results cross-sectionally and longitudinally. Differences based on schools' level of implementation of middle schooling were found in sixth- and eighth-grade student achievement levels in reading, mathematics and language arts, as well as in teacher-rated student behavior, and student self-reported measures of self-esteem and affect. Longitudinal analysis (although over a 2-year period only) showed that gains increased as schools moved to higher levels of implementation and students had longer exposure to middle schooling approaches.

There is much to be done to improve research into middle schooling. The strongest evidence achieved with

methodological rigor is at the micro level. Research at the greater macro level is mainly qualitative, individualistic, nonreplicative in nature, and inconclusive in its results. Sound research designs, valid operational definitions of middle years practices encompassing the complexities involved (e.g., team teaching), joint use of quantitative and qualitative approaches together with more sophisticated forms of data analysis, 5–10-year longitudinal studies, and use of valid measures of complex student outcomes would enhance the evidence base considerably. Too often effectiveness is still evaluated in terms of standardized literacy and numeracy achievement test results, disregarding other skills, knowledge, and dispositions necessary for life in the twenty-first-century knowledge society. Use of inappropriate outcome measures can make nonsense of research in this area.

Concluding Comments

The perspectives on schooling in the middle years discussed in this article point to the complexity of the issues involved in designing, implementing, and evaluating purposeful, systematic, and appropriate education for young adolescents. Consideration has been given to the following issues: factors that have stimulated interest in the middle years in recent decades; the two major orientations to the middle years of schooling, one focusing on structure and the other on practice; the characteristics of high-quality middle schooling; and the quality of evidence concerning the extent to which middle schooling is being implemented and its effectiveness assessed.

Middle schooling implementation constitutes a subset of the more general areas of school effectiveness and school improvement research; much that is instructive for middle schooling can be gained from the study of this research. Characteristic approaches to middle schooling are, in turn, highly relevant to the achievement of effective school improvement. Luke *et al.* (2003: 139) advised that we should be "mainstreaming the middle." Three interpretations of this maxim are proposed. First, implementation of middle schooling, when undertaken by a school, should be fully realized, systematically transforming the whole school over time. Second, such a middle schooling approach should be implemented in all schools educating young adolescents. Third, the essential concepts and design of middle schooling should be implemented in age-appropriate ways at all levels of schooling, not just in the middle years.

If there is to be success in achieving the complex goals of learning demanded by a globalized knowledge society, if young people are to be enabled to develop the capacity to adapt effectively to rapid, continuing, and pervasive change, if students are to be helped to become motivated and able lifelong learners, then it is essential that adolescents'

experience of schooling in the middle years be a vital one, continuing and expanding their learning capacities, motivations, and satisfactions seamlessly from their early years through to their final years of schooling. The concepts underpinning high-quality middle schooling, in essence, concern excellent teaching and learning. Because of this, the implementation of such an approach to middle schooling has the capacity, in turn, to impact on, improve, and transform schooling at all age levels.

Reform of the School Workforce

H M Gunter, University of Manchester, Manchester, UK

G Forrester, Liverpool John Moores University, Liverpool, UK

Introduction

The status, workload, and expertise of teachers in publicly funded education within Western-style democracies remain a salient political issue. Reports identify common issues regarding heavy workload (e.g., Dibbon, 2004; Gardner and Williamson, 2005) affecting recruitment and retention (e.g., Smithers and Robinson, 2003). It seems that the advent of site-based decision making has led to increased demands for performance combined with public audits. The Organization for Economic Cooperation and Development (OECD) recognizes the importance of confronting supply and demand issues, not least because “teacher quality is a critical factor in determining student learning” (Santiago, 2002: 8).

The emerging policy strategy to secure and sustain quality, that is, in Ozga’s (2005) terms, traveling around the world, is the simultaneous incorporation of teachers as members of a diverse workforce combined with regulation through centralized performance leadership regimes. In schools in England those with qualified teacher status (QTS) are becoming the smallest group in many schools (Butt and Gunter, 2007) and are facing controls through inspections and the delivery of national reforms through local leadership roles. How such reforms are engaged with, locally, does depend on what Ozga calls embedded cultures and practices. For example, in Scotland Ozga (2005) emphasizes the professional role of teachers in comparison with the use of teacher assistants who teach in England; in South Africa managerialist strategies are in tension with the aim to build democracy (Berkhout, 2007); whereas in Australia (Vidovich, 2007) and New Zealand (Fitzgerald, 2007) policy borrowing from England, while highly problematic, seems to be normalized. While the demands of globalization seem to suggest that workforce reform is a traveling and totalizing discourse about teachers and their work, with demands for a flexible, accountable workforce which follows good practice, in reality there are local histories, cultures, and value systems that shape how the debate is being constructed and played out. Our intention is to focus on England in order to show the complexities of the origins and development of a particular approach to workforce reform. In this way we intend to make a contribution to problematizing the promotion of what Barber (2007), as the architect of New Labour education reform, called a world-class education system.

England: A Study in Rapid Reform

Over the two decades since the 1988 Education Reform Act a form of site-based performance leadership emerged, which combines the centralized direction of the purposes of schools and the curriculum with the local responsibility and accountability for delivery (see Gunter, 2008). Policy texts show that a central concern for successive governments has been to improve national standards by: (1) sufficiency of workers through recruitment and retention (Morris, 2001); (2) the credentials and the requirement to have qualified teacher status (QTS) (DfES/PricewaterhouseCoopers, 2007); (3) a workforce trained to implement national priorities and reforms (DfES, 2004a); and (4) a workforce which can be performance managed through local leadership of national reforms (DfEE, 1998).

Educational standards dominated government strategies from the 1970s onward, with Sir Keith Joseph in 1984 telling the North of England Conference that “this Government’s aim is to raise standards” (Joseph, 1984: 138). Whereas Joseph talked about the need for “open discussion” (p. 140) New Labour in 1997 presented a non-negotiable standards agenda where “each school will have its own challenging targets to raise standards, and will be held responsible for achieving them” (DfEE, 1997: 6). The approach was based on what Barber (2007) describes as deliverology where “... in one way or another, the minister can influence what happens inside the head of an eleven-year-old in, for example, Widnes” (p. 85). This regulated and audited standards regime needed a workforce that would operate as one link within a delivery chain (p. 85), and so New Labour reworked the concept of teaching professionalism in two main ways: (1) through remodeling the school workforce; and (2) through remodeling head-teacher work, and subsequently all teachers’ work, as a form of performance leadership.

Remodelling the School Workforce

Remodelling the School Workforce was launched from January 2003 with the National Agreement (DfES, 2003) between the government, employers, and unions (except the National Union of Teachers). A social partnership was formed so that workforce planning in relation to government policy priorities could take place. What had to be resolved was that site-based performance leadership

had made teaching an unattractive job, with reports of a working week over 50 h (PwC, 2001; DfES, 2000; Thomas *et al.*, 2004). The General Teaching Council (GTC) reported that “one in three teachers expect to leave the profession within five years, protesting about workload, government interference and poor pupil behaviour” (Woodward, 2003: 1). Remodeling was meant to handle work overload and the poor image of the job in two main ways: (1) by defining 25 tasks that teachers should not normally do such as routine clerical work, cover, and examination invigilation; and (2) increasing the status of teachers by constructing their role as leading non-QTS members of the workforce.

Remodeling was phased in from September 2003 (ahead of the evidence from the government’s own pilot project evaluation, see Gunter and Butt, 2007a, b), with requirements, for example, to limit teachers covering for absent teachers, to use the wider workforce to invigilate examinations, and to guarantee time for planning, preparation, and assessment. There is some evidence that it has worked well in places with gains made in school by moving certain types of work from teachers to the bursar, site manager, teaching and administrative assistants (see Gunter *et al.*, 2005; Butt and Gunter, 2007; Higham *et al.*, 2007). Indeed many schools were ahead of the process because site-based management from 1988 was premised on the school being able to identify curriculum need and plan the type and deployment of the workforce. The growth of information and communications technology (ICT) has created opportunities for efficiency, and the workforce has been encouraged to access teaching resources and lesson plans from the Internet in order to cut workload. However, there is also evidence that the claims for increasing the status of teachers as managers of learning through the use of ICT, personalized learning, and teaching assistants has not been based on understandings about professional knowledge, identity, and the reality of the job (Gunter, 2007). In particular, there are issues about the growing role of non-QTS members of the workforce taking over professional work such as teaching, assessment, and pastoral care, with challenges to the assumption that the design of teaching (by teachers and/or through resources obtained via the Internet or government curriculum strategy packages) can be separated from its delivery (Edwards, 2007; Gunter and Butt, 2007a, 2007b; Gunter, 2007; Yarker, 2005).

Since September 2003 there has been no requirement for a headteacher to have QTS. Indeed, the DfES/Price-waterhouseCoopers (2007) report regards the credentializing of leadership in this way as a form of monopoly, and so the top job (e.g., chief executive) should be open to anyone with proven leadership credentials. Plans have been announced to cut the time needed to train as a teacher to 6 months in order to facilitate mature entrants

(BBC, 2009). The role of the school as an isolated provider of education is undergoing change through the Every Child Matters (DfES, 2004b) agenda where the emphasis is on integrated services including education, health, welfare, police, and community services. The label of workforce to encompass teachers together with clerical, teaching assistant, and bursar roles can be easily extended to embrace a wider group of public workers (e.g., police, librarians, welfare officers, doctors, and nurses) who provide local services (see Gunter and Rayner, 2007).

Performance Leadership

Another connected intervention into workforce practice has been through the promotion and delivery of performance leadership. The comprehensivization of schools from the 1960s created an imperative for school leadership, where larger schools (over 1000 students) and a mixed ability student intake, meant that more attention had to be given to organizational arrangements. The 1988 Education Reform Act intensified the need for organizational leadership in order to deal with the budget and staffing due to competition based on open enrolment within a quasi-market. From the early 1990s onward the emphasis on performance leadership through the publication of output data, inspections, and performance-related pay meant that systems for the gathering, analysis, and use of data to examine individual student, teacher, and school compliance with national standards had to be developed. New Labour from 1997 tightened this performance regime through a focus on the headteacher as leader who must deliver national reforms (Gunter and Forrester, 2008). In *Excellence in Schools* (DfEE, 1997) policy is explicit:

The vision for learning set out in this white paper will demand the highest qualities of leadership and management from headteachers. The quality of the head often makes the difference between the success or failure of a school. Good heads can transform a school; poor heads can block progress and achievement. It is essential that we have measures in place to strengthen the skills of all new and serving heads. (p. 46)

New Labour drew on school improvement and effectiveness research to increase the status of the head as effective leader, connected pay to whole school performance, and provided a model of leadership that emphasized the transformational agency of the single charismatic and inspirational leader who could build commitment to the localized implementation of national curriculum strategies for literacy and numeracy. Such investment was symbolic in the form of attention given to headteachers through speeches and conferences, and financial in the form of pay and investment in training.

The work of headteachers was redesigned around national standards based on the appropriate attributes, skills, and behaviors of effective leaders, and largely drawn from private-sector models and produced by private-sector consultants. Interconnected with this is the training agenda, were the programs set up by the previous Conservative Governments (e.g., National Professional Qualification for Headship) were incorporated into a national training framework housed within a National College for School Leadership (NCSL) from 2000. The NCSL is a nondepartmental public body and as such it enables centralized control to operate through a remit to deliver on national policy priorities, together with clear accountability mechanisms for supplying the next generation of school leaders (Gunter and Forrester, 2009).

The NCSL scoped the field of knowledge and research, and presented a model of effective school leadership (Hopkins, 2001), and through training, research, and conferences, has sought to structure the practice and performance of school leaders. There have been successes in regard to access to training and the production of resources to support the NCSL role in reform implementation, but there have also been concerns about its role in colonizing the field (see Gunter and Fitzgerald, 2008; Weindling, 2004). Furthermore, there has been increased recognition that the transformational leader model was causing additional workload, and was unattractive to many headteachers who did not see themselves as charismatic visionaries. Notions of distributed and shared leadership have emerged, in order to ensure that middle leaders, teacher leaders, and the wider workforce (e.g., bursar/financial manager) are directly involved, and consistent with remodeling, in the delivery of outputs. The lack of research evidence and conceptual clarity of distributed leadership has not prevented it from being advocated, and what is emerging is a form of distribution that is more about job redesign, or even a form of localized steering where the headteacher is required to manage the risk of implementation (Gunter, 2005). Indeed, as Hartley (2007) has shown, distribution to the school is in the form of tactics or how to implement within context, and is not about distributing decisions about strategy because policy control remains centrally regulated.

Challenges also remain in regard to headteacher recruitment, and currently the NCSL is working on the delivery of the DfES/PricewaterhouseCoopers (2007) shift from effective school and headteacher leadership toward effective executive leadership for the local delivery of children's services. What remains a constant in New Labour strategy has been the single person who delivers locally, but what is changing is the type of person who might inhabit that role. Remodeling leadership means that an expert in teaching and learning may not be the chief executive, and so the language and approach is about leadership as a generic task and set of behaviors which

others from the public, voluntary, and private sectors can do. The endurance of the single leader who is responsible and accountable for delivery is a feature across the public and private sectors, and so the culture and practice in education and children's services is congenial with such interagency and intersector movement. As Ball (2007) has shown, the delivery of public services through and with private-sector roles, practices, and cultures is now endemic within education and so non-QTS appointments making educational decisions has been normalized. A final point on this is that as Coffield *et al.* (2007) have shown the recent reform strategy (Prime Minister's Strategy Unit, 2006) is about the need to encourage bottom-up market responses and provision through parents and the community. Within the advocated approach the term used is leadership, and public-sector experts such as teachers are absent (Fitzgerald and Gunter, 2009).

Explanations for Workforce Reform

Following Raffo and Gunter (2008), we examine these rapid and far-reaching changes through a particular approach to understanding modernization. What is modern, new, innovative, twenty-first century, and pathfinding is empty until filled by those who have a commitment to do this (Gunter and Butt, 2007a). New Labour's approach to modernizing has shifted from job redesign (i.e., changing work from teaching and learning to organizational effectiveness) to a form of incremental upgrading (i.e., training headteachers to be effective school leaders), toward a reconceptualization of effective leadership (i.e., as generic transferable skills and behaviors). There are two ways of explaining this: (1) functional and (2) socially critical. Both recognize education, change, and improvement as essential, but both differ in terms of how the workforce is understood and engaged with.

Functional Position

The functioning of schools as effective and efficient organizations requires a workforce that is sufficient in terms of numbers and training to deliver on national and organizational goals in order to produce a world-class system (DFES, 2002). Functionalism in its current format has been captured by neoliberals who want to challenge the state and neoconservatives who want to attack socially just ideas about access to education as a public good. This alliance means the market and economic productivity is paramount in the discourse, and it is seen as means by which particular interest groups (class based, religious groups, etc.) can gain an advantage for a preferred form of schooling.

The literatures tend to challenge the state, bureaucracy, and welfare protection (e.g., Bobbitt, 2002; Chubb

and Moe, 1990; Osborne and Gaebler, 1992), where the argument is made that the workforce must be fit for purpose in a globalizing economy, is endlessly trainable, and deployable. There are no demarcation lines or claims to professional practices and knowledge, and instead there is a can-do culture where everyone is ready and capable to take on what is necessary to be successful. Barber and Mourshed (2007) argue that exclusivity and making teaching harder to get into, rather than higher pay, is what is needed to make it a high-status job. Indeed, in an education system where particular interest groups can control schools (e.g., philanthropists, religious groups) then commitment to values (e.g., sectarian beliefs, entrepreneurship) is what matters, and so teachers can be attracted to an exclusive brand, and so be trusted to implement as engaged collaborators.

Hence explanations regarding workforce reform tend to focus on teachers as the problem and the dysfunctions that are caused for children, parents, communities, and the economy, as a result. The narrative tends to go like this:

Teachers have used their professional knowledge and historical control of their work to protect themselves and to promote ideas that parents do not want. So they can make claims about teaching and learning that are not true, and they create work for themselves and each other by planning lessons, taking the register and covering lessons for absent teachers. Teachers have sought to prevent reforms, and have largely been unaccountable for what they do and the quality of the outcomes from their teaching. As a result parents and employers are concerned about levels of literacy and numeracy, the promotion of radical ideas which challenge parental control, and children are absenting themselves in large numbers. Teachers need to operate in the real world, and give better value for money, not least because they get so many holidays.

Consequently, interventions tend to be about tasks, structures, and cultures where strategic control over the work of teachers has been largely taken from them, and they now have to operate according to prescribed curriculum ring binders, assessments, and performance systems. The emphasis is on contractual compliance with targets, job descriptions, and reform priorities. Training is about enabling this delivery to be efficient and effective, and enables teachers to move from one reform initiative to another. Teachers are also expected to talk and engage in ways that show commitment and excitement about their work. In this way, teachers can also be employed by a range of educational providers, not least the new academies and trust schools where private-sector investors as sponsors can control the curriculum and the conditions of employment. Increasingly, the workforce may be recruited, trained, and developed within a particular school or academy brand based on the vision of the sponsors.

Socially Critical

This position also sees workforce reform as potentially beneficial to the workforce and to education, but claims are made that the drive for a world-class system masks inequity. Concerns are raised about the ability of functional interventions to work in the ways expected, but more importantly, dysfunctional outcomes are identified. In addition, the socially critical work position is based on values related to social justice and that schools are a public good. What is regarded as critical is twofold: (1) through confronting how existing power structures operate in ways that secure advantages for private interests (wealth and religion) (see Woods *et al.*, 2007); and, (2) through creating socially just ways of providing education and learning opportunities (Lingard *et al.*, 2003; Thomson, 2003).

Hence, explanations tend to focus on how teachers have been unfairly defined as the main problem. The consequences are that functionalism cannot operate in the ways intended because performance leadership creates the low morale and failure to recruit and retain that it claims to solve. Socially critical work therefore focuses on how teachers can be enabled to take more control of the purposes of education, to recognize how the alliance of neoliberal and neoconservative functional interventions and narratives position them and hence enable them to work for a more socially just approach to professionalism (Smyth, 2003). The narrative tends to go like this:

Teachers are unable to develop their professional contribution to teaching and learning, and to lead on school improvement because they are excluded from decisions about the purposes and practices of education. Consequently teachers are positioned in contradictory settings where they have to implement functional tasks such as targets and measure their valued added but the socio-economic context in which the school is located impacts on their ability to do this. Children and parents do not enter willingly into such processes, and so the relevance of such structures to their lives remains problematic. Teachers should be in a position to develop their professionalism through working with students and parents to develop the curriculum through community based action, resources, and seeking to improve the learning environment. Teacher development isn't separate from student involvement and the starting point for learning is to begin with students' interests so that capacity to learn is through building a project. This means that teacher professionalism needs to embrace student participation in the design, experience and assessment of learning.

Consequently, interventions in practice is through the professional development of teachers as researchers of their own and other's practice, with postgraduate study and reading as central to the ownership of the evidence

base. The generation of innovative pedagogic practices is therefore based on the interplay between agreed educational priorities, research, and local innovation (see Lingard *et al.*, 2003) and raising the status of children as active participants in the design of learning (see Smyth, 2006). This is located in both re-imagining schools and schooling with a commitment to education as a public good and the nation's children, where disadvantage is confronted and more socially just practices worked for.

Summary

The English experience of reform shows the reworking of the public provision of education through constructing small businesses where functional interventions are made in the composition, deployment, and accountability of workers. Tactical gains have been secured at the local level through more efficient and effective deployment of the workforce, with new ways of working being adopted. Leadership has been conceptualized, trained, and promoted as the means to secure change. The single leader as chief executive together with a remodeled workforce in a redesigned structure can deliver national reforms locally. While claims can be made for the outputs of delivery, and the fear of not delivering can be all consuming (see Barber, 2007), there remain concerns. First, there is a lack of reliable and accurate data regarding teacher supply and retention, which means that interventions may not be evidence based (Santiago, 2002); second, reforms are not evidence based (e.g., remodeling went ahead before the government's own pilot was completed) and so there is a combination of conviction politics with reforms based on functional beliefs combined with selective and *post hoc* evidence construction taking place; third, there are problems in the system that are not being directly engaged with, not least the issue of social justice representations in the workforce such as gender and ethnicity, which means that while the system functions it may be replicating disadvantage (e.g., Gunter *et al.*, 2005); fourth, reform is a product of elite adults outside of the school, making interventions into the practice of adults in school, and it does not begin with learners and learning, which means that those who are meant to be the beneficiaries of reform are excluded from the process in ways that are affecting the well-being and achievements of students (e.g., Smyth, 2006); fifth, the cultures of reform are based on caring about functional interventions in task completion and contractual compliance, and this is at odds with teacher-workforce identities where caring for children is more important than caring about paperwork (see Forrester, 2005); and, finally, functionalism is based on what tasks teachers should no longer do (e.g., photocopying) and it is not based on a defensible model of

practice that is rooted in pedagogic practices and expertise about learning (see Wilkinson, 2005).

Socially critical approaches can reveal the embedded nature of how localities respond to globalized good practice, and as Stevenson (2007) has shown there are big issues such as the graduate status of teaching that need to be confronted by teachers, otherwise they will disappear, like QTS for headteachers, without comment. Such issues can be confronted not only by defending graduate status but by providing an alternative approach to how workforce reform might be engaged with. Research has already produced interesting studies into rethinking school improvement (Hollins *et al.*, 2006; Thomson and Gunter, 2006) and the role of teachers in the development of their work and their identity (Gunter, 2005; Sachs, 2003). When combined with the growing international evidence about how children can participate in school reform (Gunter and Thomson, 2007; Smyth, 2006), meaningful opportunities for change can be opened up. If teachers have been an absent presence (Ball, 2003) in functional workforce reform then they are in danger of becoming just absent through the remodeling process in England. What is happening is what Thomson and Blackmore (2006) identify as work redesign “without a coherent and meaningful ethical and political (spiritual and moral perhaps) purpose” (p. 175). The irony is that the success of functionalism has been to create the conditions in which this has happened and through which teachers have complied. Evidence shows that school leaders can read policies differently, challenge and create site-based policies (Forrester and Gunter, 2009), and that there are local models in play where leadership is not assumed to be a function of a role but is communal (Grubb and Flessa, 2006). Hence socially critical work is taking place, and so the potential exists for such activism to not only challenge functionalism but also to recreate different narratives and practices.

Glossary

BEFA – Basic education for all.

Declaration of Human Rights – The UN declaration in 1945.

The Delors Report – The International Commission on Education for the Twenty-First Century Report.

Education for All (EFA) – The UNESCO program scheduled for achievement by 2015.

MGD, The Millennium Development Goals – The eight goals accepted by the UN for achievement by 2015.

TVET – Technical and Vocational Education and Training.

UN – The United Nations Organization.

UNESCO – The United Nations Educational, Scientific and Cultural Organization.

Education in the Developing Countries – A Changing Scene

Education in developing countries is varied and rapidly changing. Some countries have made massive advances, while the systems in others slide further into crisis. A common theme is the high priority given to education and particularly the commitment to achieve an effective primary education for all (EFA). Patterns in secondary education are not only affected by the major aim for primary education but also play a major role in that quest.

Most developing countries emerged into independence after World War II. At the end of the war, the allied nations acknowledged the importance of joint international efforts to avoid the threat of future wars, establishing in 1945 the United Nations Organization (UN). The UN as one of its early emphases sponsored the Declaration of Human Rights placing education as one of the essential rights of all people:

Everyone has the right to education. Education shall be free, at least in the elementary and fundamental stages. Elementary education shall be compulsory. Technical and professional education shall be made generally available and higher education shall be equally accessible to all on the basis of merit. (UN, 1945)

The commitment to achieve EFA has been difficult to deliver. One of the early actions of the UN was to establish the United Nations Educational, Scientific, and Cultural Organization (UNESCO) to assist countries to fulfill relevant aspects of the Human Rights Declaration. Since these early days, UNESCO has played a unique and important role, one which has grown exponentially with the emergence of the many new countries after 1946.

UNESCO was originally an organization of some 51 nations with a strong European–North American focus. It now has almost 200 member nations embracing all areas of the world with many more developing than developed countries. The UNESCO member nations originally had a total population of 2.1 billion: currently that population approaches 7 billion most of who are in developing countries. In 1950, there were 300 million students in schools, now there are more than 1.4 billion. However, almost 100 million children are still denied access to formal schooling, and many of those who are involved are taught in very large classes with few facilities (Dakar 1, 2000).

Given the central role played by UNESCO in education in developing countries, an understanding of its role is crucial. The founding meeting for UNESCO in London late in 1945 declared the central purpose in words that are still relevant:

The purpose of the Organization is to contribute to peace and security by promoting collaboration among nations through education, science and culture in order to further universal respect for justice, for the rule of law and for the human rights and fundamental freedoms which are affirmed for the peoples of the world, without distinction of race, sex, language and religion, by the Charter of the United Nations. (UNESCO, 1945)

As part of that thrust toward peace and security the countries saw education as an essential instrument in their economic and social development. Their activities are supported through the introduction to the world scene of major development agencies such as the World Bank, the International Monetary Fund (IMF), and the Asian Development Bank.

It is in the context of international efforts that the full story of education for developing countries can be told. The aim of EFA has been accepted by all countries, developed and developing, but remains unfinished in spite of major efforts over 60 years. It has become enshrined in the Millennium Development Goals (MDGs) of the UN,

signed by 147 nations, with a target date for achievement of 2015. The eight goals are:

- Eradicate poverty and extreme hunger; (reduce by half those living on a dollar per day and by half those living in hunger).
- Achieve universal primary education.
- Promote gender equality and empower women.
- Reduce child mortality; (by two-thirds of those under five).
- Improve maternal health.
- Combat malaria, HIV/Aids and other diseases.
- Ensure environmental sustainability.
- Develop a global partnership for development. (UN, 2008).

The goal of universal primary education (UPE) formed the central strategy for education development and EFA. The achievement of this goal remains incomplete after more than 60 years, and is increasingly discussed in tandem with sectors such as technical and vocational education and training (TVET), higher education, and secondary education. Over the past two decades, secondary education has come more and more into focus. The Delors Report, *Education for the Twenty-First Century* (Delors, 1996), described this sector as “the crossroads of education,” seeing it as a vital yet undervalued factor in the success of the EFA.

A Broader Concept of EFA

Three major international initiatives have emphasized the need for extensions of the concept of EFA: *The World Conference on Education for All*, (Jomtien, 1990); *The International Conference on Education for the 21st Century*, (Delors, 1996); and, the Dakar meeting in 2000, the *World Education Forum*. Initiatives emerging from these forums express a much more crucial role for secondary education.

At Jomtien in 1990, the commitment to EFA was reinforced by the agreement of the 200 nations attending. The report from Jomtien was bleak. In spite of major efforts, nationally and internationally, the situation was, in many ways, worse. The 1970 figure for illiterates in the age group 15+ was 760 million; by 1980, it was 824 million; and by 1990, there were 882 million, with an estimate of 912 million by 2000 (Jomtien, 1990). Access to primary education was progressing far too unevenly across developing countries.

The apparent failure of the world community’s extensive efforts toward EFA is partly attributable to massive population increases. The poor literacy and school attendance figures were paralleled by other social indicators: birth-rates, infant mortality, agricultural productivity, life expectancy, housing quality, availability of clean water, employment opportunities, and political participation. Where there was deterioration in one indicator there

tended to be deterioration in all others. The Conference called this grim conjunction “the convergence of disadvantage.” Education was the essential tool for breaking this cycle of misfortune, with a high priority being set for action. The concept of UPE was expanded to take a wider focus, basic education for all (BEFA). While not shifting the center of activity from primary education, this was clear recognition of the need to view educational and social development, holistically, thereby elevating interest in secondary as well as primary education. The report from Jomtien states:

These needs comprise both essential learning tools (such as literacy, oral expression, numeracy and problem-solving) and the basic learning content (such as knowledge, skills, values, and attitudes) required by human beings to be able to survive, to develop their full capacities, to live and work in dignity, to participate fully in development, to improve the quality of their lives, to make informed decisions, and to continue learning. (Jomtien, 1990)

In 1993, UNESCO set out to develop further its policy directions for the future of education. This was done through the International Commission on Education for the Twenty-First Century, *The Delors Report*. The report recognized a continuing commitment to good-quality basic education for everyone but stressed that this should include extension beyond primary to secondary education. It is important to note that this expanded commitment targeted not only the expansion of secondary education, but also the need to reform it. The Delors Report states:

Many of the hopes and criticisms aroused by the formal systems seem to focus on secondary education. On the one hand, it is often regarded as the gateway to social and economic advancement. It is accused on the other hand, of being inequalitarian and not sufficiently open to the outside world and generally failing to prepare adolescents not only for higher education but also for the world of work. In addition, it is also argued that the subjects taught are irrelevant and that not enough attention is paid to the acquisition of attitudes and values. It is now generally recognised that, for economic growth to take place, a high proportion of the population has to have received secondary education. It would thus be useful to clarify what secondary education needs to do to prepare young people for adulthood. (Delors, 1996)

At Dakar in 2000, mechanisms were established to oversee EFA until 2015. The nations reinforced the aim and set a target date of 2015 for the goal to be achieved; that is:

The commitment of EFA is to basic education. But this is not a fixed or clear-cut concept . . . Most but by no means all have chosen to restrict ‘basic’ to primary schooling. . . . which so many have still to attain. ‘Basic’ in an increasing

number of countries, however, now connotes not only early childhood care and education and primary schooling, in some it now encompasses junior secondary schooling and in others it extends to a full secondary education. (EFA Forum, 2000)

The term basic education was further redefined by the director-general of UNESCO:

Basic education denotes the minimum skills and knowledge needed in order to be able to make a full contribution to one's environment and to be in control of one's life. In an increasingly interdependent world, the contents, and therefore the very notion of the 'quality' of basic education are evolving. It can no longer be reduced to learning reading, writing and arithmetic. It must also teach individuals to be, to do, to learn and to live together. (Maatsuura, 2000)

Delors also stressed that basic education should also be made available to the 900 million illiterate adults, 100 million children not in school, and the more than 100 million children who drop out of school. The comments of Delors remain relevant for all countries. While the shortcomings of secondary education are obviously more apparent in developing countries, developed countries also fall short in equity terms as a substantial percentage of students leave school with no formal qualification or with poor standards of literacy and numeracy. Delors defined basic education essentially as a "passport to life"; or an enabling foundation on which diversity can be built; diversity in course and teaching-learning processes; and, diversity in context, including the alternating of study and work.

The existing secondary system was perceived as far too inflexible for current needs and a variety of formats was suggested, including alternation between school and work. The pressing need for societies is to make this stage of learning work for all, rather than using it as a filtering system, leaving a large proportion of students with a feeling of failure and frustration. A variety of pathways is necessary between these different educational opportunities – pathways which allow students to move in and out at different times depending on circumstances and needs.

In June 2007, the UN provided a progress report on the achievement of the MDGs. The assessment showed mixed results. None of the eight goals had made sufficient progress to ensure their achievement by 2015. The proportion of people living on less than a dollar per day had fallen from 23.4% in 1999 to 19.8%, broadly on target but with massive variations. The eradication of hunger was still remote with 46% of the under-fives in Africa registered as underweight: infant mortality is down by one-sixth, as against the target of two-thirds reduction. Whereas China and India and other parts of Asia had increased school attendance, 12% of children globally and 30% in sub-Saharan Africa were still out of school. Other targets,

particularly in Africa, displayed similar patterns. According to UN (2007):

The world is failing in the battle to combat hunger, reduce infant mortality and to put every child in school. The results show that there have been some gains and that success is still possible in most parts of the world but they also point to how much remains to be done.

The Dakar World Education Forum was particularly important in terms of shifting emphasis beyond primary education and redefining basic education to include secondary education. A focused session during the conference asked directly "After Primary Education: What?" (MacLean, 2003). The question captured the essence of the way ahead and acknowledged the fact that secondary schooling correlates positively with lower fertility and infant and maternal mortality rates. It also provides adolescents more powerful means to participate actively in social, cultural, and political life. When pulled together these, as governments around the world have openly acknowledged, have important implications for economic development.

The World Bank has also highlighted the importance of secondary education to economic and social development. Experience in newly industrialized countries has shown that growth in secondary education allows the formation of a pool of a better-educated workforce which can play an important role in attracting foreign investment. According to World Bank:

Secondary education... has been shown to contribute to individual earnings and economic growth. It is associated with improved health, equity, and social conditions. It buttresses democratic institutions and civic engagement. And the quality of secondary education affects the levels above and below it – primary and tertiary education. (World Bank, 2006: 17)

UNESCO has initiated a broad range of activities in an attempt to address the complexities of secondary education in developing countries. Maclean (2003) lists the major priorities as expanding access, assuring quality, reforming curriculum, and formulating alternate delivery systems. Curriculum reform emphasizes human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS) education, linkages between school and work, values education, and science and technology. Other priority concerns include equity issues, especially those related to gender, effective pedagogies, student dropouts, learning and teaching resources, recruitment, and professional development.

In short, building secondary education helps adolescents develop abstract reasoning, observation, analysis and synthesis competencies, and other higher-order thinking skills. The development of a broader and deeper base in the sciences, technology, languages, and other

subjects can not only provide the immediate skills needed by developing economies but also lay a foundation for future lifelong training.

Issues in Secondary Education

Whereas UNESCO and the World Bank develop priorities and delineate program areas, in line with a more holistic approach, they see them more and more as closely related – inevitably interacting with one another in an ongoing dynamic fusion. Here, we address three of these interactive areas – access and expansion, content and context, as well as delivery and relevance.

Access and Expansion

Perhaps the key drivers of change and development are those related to the expansion of secondary education and subsequent opportunities, or a lack thereof, of access to it to significant proportions of young people. The unprecedented expansion of secondary education has been driven by the achievement of UPE and forceful government agendas to provide open access. For example, India, Pakistan, and China have moved aggressively toward a secondary system providing for all students. The Indian Prime Minister Manmohan Singh clearly outlined this agenda:

The government will make secondary education in India universal, with at least one school for every cluster of villages over the next two–three years. The program will build on the success of Sarva Shiksha Abhiyan education for all programme) and will cover the entire country in two–three years. These publicly funded 6000 schools will establish benchmarks for excellence in public schooling, which would then be role models for the rest of the public educational system. (Gulf Times, 2007)

Policy implementation still has a long way to go. For example, in 2006, while China had achieved a participation rate in secondary education of just over 70%, India had just breeched the 50% mark and Pakistan approximately 27% (Kennedy and Lee, 2008).

A number of Arab countries have also instituted ambitious reforms to expand access to secondary education. In Qatar, the Rand Corporation has undertaken a long-term development program for K-12 education in the country. Currently in Qatar, 25% of primary students do not complete their schooling so that a major program at this level is planned as a basis for the reform at the secondary level (UNESCO, 2005). In Bahrain, a National Education Reform Project has been introduced.

We need to work closely with the private sector to ensure that students have access to courses that are required by the economy and that graduates are competitive once they

enter the job market because of the skills and experience provided by the education system. In order to achieve this certain steps need to be taken such as improving the quality of education institutions – focusing on teachers' training and education; providing alternative vocational education opportunities for students; and establishing an independent Quality Assurance Authority that will regularly review the performance of all education institutions. (Forrest, 2007)

In Oman, in 1970, there were only three schools, with enrolments of 909 pupils, all male. By 1990, there were 838 schools, with 365 000 students, both male and female. By 1997, the number of schools had grown to 1062 and the number of students to 529 000. Building on this base, there were major technical and higher education developments. Similarly, there have been striking advances in adult literacy rates. The country, which has a high proportion of migrant workers, aims to supply its own needs for skilled people and also contribute to other countries.

The dramatic expansion of secondary education requires substantial financial input. Given the relative current wealth differentials between societies, this has been a problem for many African countries where the advances in primary education have been disappointing and secondary development is still largely a matter of plans rather than results.

In Kenya, the debate on provision of free education to secondary schools has become a point of focus with several presidential aspirants using it as a key rallying point to woo voters. In what some critics label as a campaign tool, the government has provided a Sh4.3 billion subsidy for public secondary schools to cater to tuition fees from January 2008. Presidential candidate Raila Odinga has promised to go beyond subsidized education to a free and compulsory primary and secondary education.

A study by the state-owned Kenya Institute for Public Policy Research and Analysis (Kippra) on the feasibility of free secondary education (FSE), says such a bold undertaking is a good public initiative that, if implemented, would increase access to secondary education while relieving the cost burden on parents. This will allow households to increase spending on other needs, such as health and post-secondary education and training, hence impact positively on poverty reduction. The findings reveal that the number of teachers required will double in the first 4 years of implementation of FSE. If it is effected next year, the number will shoot up from the current 48 425 to 53 828 and peak at 99 115 in 2011. The country will also need 8600 additional classrooms as well as new day schools and an expansion of the existing schools. The Nation, 2007 states:

While this sounds encouraging, a comparison between estimated increased total Government revenue and the financing gap reveals that implementing a full FSE is quite a sacrifice with the FSE financing gap likely to consume 28 per cent of the increases in total revenue in

the initial year. This will rise to 50 per cent of any revenue increase by the fourth year of implementation.

The report warns that allocation of any revenue increase to FSE will reduce investment in other competing sectors of the economy. In Nigeria, the curriculum of the nation's senior secondary schools (SSSs) is to undergo a complete overhauling with students learning a trade as well as civic education. Professor Godswill Obioma, executive secretary, Nigerian Educational Research and Development Council (NERDC), noted that the overhaul of the curriculum of the SSSs was part of the reforms in the education sector and a follow-up on the restructuring of the 9-year basic education curriculum. The review of the curriculum is to ensure that children are properly educated and have entrepreneurial skills to be able to live a productive life (Nigerian Tribune, 2007).

Content and Context

A further challenge to developing secondary education is finding ways to shape, negotiate, deliver, and embed effective learning for all. This is difficult given that as much diversity exists within as between developing societies. Such diversity may relate to culture, politics, gender, race, or religion – all of which can influence the type of learning opportunities available and useful to students.

The shape of secondary education relates increasingly to globalization. Although there is little doubt that increased global interdependence means that schools can remain isolated within a single society, this does not mean that secondary education will or should adopt a one-size-fits-all model. Although key trends in secondary education, such as decentralization, quality education, outcomes-based education, and increased marketization, mirror trends common in developed countries, they can look very different at both policy and school levels.

At a policy level, marketization underpins broad moves to upgrade secondary education in many countries, but the meaning of market varies. The market in China is directly and explicitly regulated by the state. Educational policy continues to stress dedication to communist/socialist ideology across separate initiatives. At the school level, culture may determine to a greater or lesser extent the way secondary schools are governed and what happens in classrooms. Recognition of difference means that there is no global recipe for shaping secondary education at the operational level. Without such recognition, global initiatives by bodies such as UNESCO or the World Bank, regardless of their intentions, may struggle to take root in schools.

The growth in primary education has put extra pressures on secondary education. The changes will be fundamental if secondary education is to become an effective part of the whole. However, as developed countries continue to discover, the nature of a secondary education which covers

the entire age group is very different from that for a selective system, as is predominantly the norm in developing societies, essentially geared to prepare students for further education.

Delivery and Relevance

Spreading secondary education in terms of both quality and quantity is closely linked to the ways such education is delivered. The delivery of secondary education is an increasing issue as countries seek to expand their enrolments. Countries such as Brazil, Argentina, Mexico, India, Zambia, and Indonesia have significant portions of their student population receiving secondary education through distance-learning programs. Distance education is seen as an alternative way of organizing secondary education in order to reach a greater number of pupils than permitted by traditional means.

While recognizing the importance of differing values and other contexts, alternative models are needed to deliver secondary education. This may entail moving beyond understandings and structures currently engrained in more developed societies. Ironically, developing countries may benefit from more technologically savvy approaches being touted in the more developed world. Alternate delivery mechanisms may include nonformal means, the use of modern communications technologies and the vernacular, as well as the use of English as the medium of instruction. They may also integrate with more traditional community-based modes which were misplaced during periods of colonization. For example, programs in Argentina and Mexico provide lower secondary education in remote rural areas in a nonconventional way. Relying on tutors, teaching materials, and itinerant teachers, such programs allow disadvantaged children to attend school at relatively low cost.

When looking more to secondary education, we need also to look specifically at the following questions: Do we have the division between primary and secondary right? Should traditional divisions between primary, secondary, and further education be retained? How can secondary education be made more relevant to the labor market? What links between schools and employers should be established to facilitate the transition from school to work, and what role can TVET play in this respect? What strategies can be developed for young people at risk?

Where to Go?

An interesting byproduct of the knowledge age is that all countries, regardless of their stage of development, are reexamining their approach to and understanding of secondary schooling. Common drivers for this are broadening conceptions of EFA and recognition of the interrelated

and interactive nature of learning, education levels, and age. Reworked ways of thinking require that secondary schools take on multiple functions: preparation for higher education, preparation for work, preparation for citizenship, together with the two additional emphases identified so strongly in the Delors Report – learning to live together and learning to be. Being the endpoint of basic education, the last stage of EFA students presents problems few countries have solved.

This shift in direction has exacerbated the problems surrounding secondary education in developing countries. Perhaps the sharpest of the many dilemmas faced by developing countries and international support agencies is that while economic performance is necessary for social improvement and major systems upgrading, educational improvement is impossible without a major increase in expenditure. Where bodies, such as the World Bank, once followed a strictly economic agenda they now see the necessity to provide a substantial boost to education as an enabling measure for economic and social advance. The Delors Report stresses the urgency of a debate “at a time when educational policies are being sharply criticised or pushed-for economic and financial reasons-down to the bottom of the agenda.” This may well drive the continued search for better, more equitable, and meaningful secondary education in developing, and in developed, countries over the next 20 years.

PRIMARY AND SECONDARY EDUCATION – SOCIAL JUSTICE ISSUES IN SCHOOL AGE EDUCATION

Community Focused Schools

A Dyson, University of Manchester, Manchester, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Despite the transformations in education that have taken place in most countries over the past 100 years, the characteristics and functions of schools have remained remarkably unchanged. Schools are institutions whose function is to educate children and young people. They are staffed by teachers and support staff necessary to assist the teachers, carry out administrative tasks, or maintain the building. Typically, students attend for a limited number of hours each day, a limited number of days each week, and a limited number of weeks each year. When students are present, other family and community members have little access to the school, and when students are not present, the building may well be closed.

This pattern has been so common as to attract little comment. However, it overlooks two major considerations. First, the resource locked up in schools – the buildings and facilities, the intellectual resource of the teaching staff, the cultural resource of values and expectations, and the employment opportunities on offer – constitute a major investment in the areas where they are located. Second, those resources, powerful as they are, remain relatively weak in relation to other factors in the lives of children that impact on their well-being, their educational achievements, and their life chances. Family dynamics, local cultures, and material conditions remain beyond the reach of the school, while the health, social care, welfare, and other services that might impact on these factors operate, at best, in a way that is only loosely coordinated with the work of the school.

These considerations are important even where resources are abundant and students in general do well. However, they become crucial in contexts where social resources are scarce, or where there are deeply entrenched disadvantages and students who face multiple personal, family, and social difficulties. In these situations, it is arguable that the existing investment in schools is underutilized

in relation to its potential benefits for local communities, yet underpowered in relation to the needs of children and young people.

Not surprisingly, therefore, there have been attempts in many places to think about school resourcing differently. These attempts have been enormously diverse, but basically involve some mixture of enhancing the resources available in the school for working with students while making the school's resources available to families and local people. Often, these attempts result from the initiative of particular school principals attempting to meet what they see as the needs of their students and of local communities. Sometimes, however, they take the form of more or less well-organized programs sponsored by national or local governments, or by nongovernmental organizations (NGOs). In these cases, the preferred model of provision may be dignified with a title – full-service schools, community schools, extended schools, or schools plus, for instance. However, there is no internationally agreed term for schools that work in this way, and any label inevitably disguises the real diversity of approach.

With this caveat in mind, we shall refer to these schools here as community focused. This term is borrowed from the education system in Wales, where a community-focused school is defined as:

... one that provides a range of services and activities, often beyond the school day, to help meet the needs of its pupils, their families and the wider community. (National Assembly for Wales, 2003: 1.2)

Whatever the shortcomings of this label and definition, it at least draws attention to the recognition by these schools that there are communities beyond the school gates, that the school may have an obligation to those communities, and that the effective education of students may require the school to engage with communities and the resources available therein.

What Do Community-Focused Schools Do?

Rather than a single blueprint for community-focused schools, it is probably closer to the truth to say that there is a menu of activities and forms of provision. In broad terms, the menu has the following components:

- activities outside the standard school day and year to extend the curriculum offer to students;
- additional forms of support for students' learning, social, and health needs;
- opportunities for students to develop leadership skills and community engagement;
- support for families on personal, social, health, and welfare issues;
- opportunities for families to become involved with the school and, particularly, to support their children's learning; and
- opportunities for community members to use school facilities, and engage in arts, leisure, learning, and vocational development activities.

Delivering this menu in turn implies that schools have to make a series of changes to their practices. For instance, they may have to:

- change the use of the school site so that it is open beyond the school day and year and is accessible to parents and community members;
- change their staffing structures to employ more non-teachers able to work with students, families, and community members;
- develop new relationships with other education providers, child and family services, community organizations, and business in order to deliver a wider range of services on site or in collaboration; and
- develop new styles of leadership and governance, perhaps involving community members.

In practice, schools select from these menus and undertake changes selectively in line with how they understand their particular contexts, the requirements of any programs in which they are participating, their access to funding streams, and a whole range of other local factors. Two examples illustrate this point. Both are of community-focused schools, yet what this means in practice is very different in each case:

1. *The Arturo Toscanini Complex (ATC)*. It is a campus in New York City hosting three middle (grades 6–8) schools. It follows a model of community schooling promoted by the Children's Aid Society – a model which is as well developed and well evaluated as any in this field. ATC's provision recognizably derives from the menu outlined above, but does so in ways that meet the disadvantaged and multi-ethnic characteristics of its inner-city context. It includes:

- extended day provision, including homework support, literacy tuition, creative writing, and tutoring;
- programs focusing on personal and social development;
- fitness and health programs;
- performing-arts activities;
- access for students and families to health, dental health, and mental health services;
- social work support for students and families;
- opportunities for student involvement in leadership activities and community issues; and
- English as a second language, welfare assistance, family support, health-insurance advice, and cultural and leisure activities for parents and community members.

2. *The Evergreen School*. It is a small school in England catering exclusively for students with high levels of special educational need. Its concerns are not with the socio-economic disadvantages experienced by students, families, and local communities, but with the opportunities for its disabled students to integrate with their nondisabled peers, and the support available to students' families. Hence, its program includes:

- weekend clubs for students;
- arts projects in which the schools' students work alongside children from regular schools;
- access to the school's facilities for children from other schools and to adults from local communities;
- summer-school provision for the school's students alongside other members of their families; and
- support groups for parents of students and of younger children with special educational needs (see 4Children, 2007: 10).

Contrasting examples such as these could be multiplied many times. What differentiates these schools is the response to local contexts and, in particular, to the perceived needs of their students and their students' families and communities. What links them is the intention to bring additional resources to bear on the school's work with students, and to bring the school's resources to bear on family and community issues.

Rationales

If we are to understand the diversity of community-focused approaches, it is necessary to unpack a little further the idea that those approaches arise from schools' responses to their local contexts. As in the examples above, schools do indeed work in contexts where there are marked material differences and, particularly, where students, families, and communities have quite different characteristics. However, it is clear that the leaders of community-focused initiatives also interpret those differences in relation to a series of assumptions – among other things, about what counts as a

need, which needs are greatest, and what schools can and should do in response to those needs. The interaction between the material conditions of local contexts and the interpretations of those contexts give rise to different rationales on which community-focused approaches are based.

Again, two examples will serve to illustrate the point. The first is a rationale articulated by Joy Dryfoos, one of the foremost advocates of full-service schools in the United States:

... schools are failing because they cannot meet the complex needs of today's students. Teachers cannot teach hungry children or cope with young people who are too distraught to learn. Anyone working in an inner-city school, in a marginal rural area, or even on the fringes of suburbia will tell you how impossible her or his job has become. The cumulative effects of poverty have created social environments that challenge educators, community leaders, and practitioners of health, mental health, and social services to invent new kinds of institutional responses. (Dryfoos, 1994: xvii)

For Dryfoos, the problem is essentially one of the enormous social stresses produced by poverty. These stresses are reflected in the turbulent lives and unmet needs of children, who, as a consequence, come to school unable to learn. Traditional forms of service delivery cannot, she argue, meet these overwhelming needs. Instead, what are needed are full-service schools, where a range of child and family services will be co-located on the school site so that they can respond quickly and effectively to the difficulties that children face.

The second is taken from a memorandum of 1925 by Henry Morris, then chief education officer of the predominantly rural county of Cambridgeshire in England, proposing the establishment of village colleges. Morris' vision has been every bit as formative in the English context as Dryfoos' has in the United States, and village colleges and their like continue to flourish to this day. Morris' concerns, however, were very different from those of Dryfoos. He believed that the countryside was losing out, educationally and economically, to the towns, not least because its education and leisure provision was scattered, uncoordinated, and difficult for many people to access. His proposed village colleges would, therefore, house a range of community education and leisure facilities under one roof. In this way:

The isolated and insulated school, which has now no organic connection with higher education, would form part of an institution in which the ultimate goal of education would be realized. As the community centre of the neighbourhood the village college would provide for the whole man, and abolish the duality of education and ordinary life. It would not only be the training ground for the art of living, but the place in which life is lived, the

environment of a genuine corporate life. The dismal dispute of vocational and nonvocational education would not arise in it, because education and living would be equated. It would be a visible demonstration in stone of the continuity and never ceasingness of education. (Morris, 1925: XV)

These statements of purpose share the view that what goes on inside the four walls of schools cannot be separated from what goes on in the wider communities that schools serve and where their students live. However, each takes a different view of the nature of those communities, of their needs, and of the needs of learners within them. For Dryfoos, communities are ultimately aggregations of poverty, needs are to do with health and hunger, and the aim of full-service provision is to make students teach-able. For Morris, on the other hand, communities are the location for a viable social and cultural life, needs are for quality of life, and the purpose of village colleges is to make communities in this broad sense sustainable.

Again, these examples could be multiplied many times over. For instance, in Saskatchewan, Canada, community schools have the same focus as Dryfoos' full-service schools on children and communities at risk. Here, however, the target groups also include First Peoples, and the approach is based not simply on providing services, but on cultural affirmation and community empowerment. In South Africa, full-service schools are seen as a means of promoting inclusive education by locating services in the regular school that might otherwise be available only in special schools. In some of the new democracies of Central and Eastern Europe, community schools are seen as agents for fostering democratic engagement, involving students and adults in solving social problems rather than remaining dependent on state intervention. Even within the same initiative, there may be quite different rationales. For instance, a full-service schools initiative in Australia was accompanied by proposals that such schools might alternatively recreate a sense of community in the face of global change, break the cycle of disadvantage, or empower young people and families to become participants in the creation of dynamic communities (Kirner *et al.*, 1998: iii).

It is possible to see these different rationales as lying along two dimensions: a student-community dimension and a deficit-empowerment dimension. The first is to do with how the community-focused approach is targeted and who are seen as its intended beneficiaries. Some rationales – Dryfoos' being an obvious example – focus on the potential benefits for students. By concentrating resources on the school site, students can be offered higher levels of support or a richer array of opportunities. The community-focused approach is thus, in effect, a means of enhancing the school's capacity to play its traditional role in the education of the young. Other approaches – such as Morris' – focus by contrast

on benefits for families and the wider community. By opening up the school's resources to wider use, conditions beyond the school gates can be changed and local people can benefit by having their needs met, or by accessing enhanced opportunities.

The second, deficit–empowerment dimension is to do with whether the intended beneficiaries of community-focused approaches are seen, to borrow a phrase from Semmens and Stokes (cited in Kirner *et al.*, 1998: 26), as patients or as citizens. For some – Dryfoos again being a prime example – the students and families served by community-focused schools are, like patients, in medicine, defined by their needs. If they were not in such dire circumstances, if they did not present with such severe and multiple problems, there would be no need for schools to reorient their work. For others, the beneficiaries of community-focused approaches are not targeted because of their evident needs but because, as actual or potential citizens, they have rights and are entitled to a rich array of possibilities. For Morris, for instance, village colleges are not about addressing the problems and disadvantages of needy people, but about making available to rural citizens the facilities that their urban counterparts take for granted, and about ensuring the sustainability of the rural way of life.

The location of rationales along these dimensions, of course, itself implies yet more fundamental assumptions. One review of developments in France, Sweden, and the United States, for instance, found that the diversity of approach between these countries was grounded in the way they:

... **choose** to understand childhood and the relationship between children, family, local community and wider society. (Moss *et al.*, 1999: 39, emphases in original)

In particular, the two dimensions outlined above can be seen to emerge out of fundamentally different ways of understanding the role of schools in building the good society. Across the world and, particularly, across the countries of the affluent West, governments are concerned about using education to enhance countries' competitiveness in a globalized economy, and, particularly, about narrowing the gaps in achievements and capacity to compete between the most disadvantaged members of society and the majority. In this context, schools that combine powerful strategies for raising achievement with strategies for addressing students' personal difficulties, tackling family problems, and ameliorating some of the dysfunctional aspects of the communities where they live seem very attractive to policymakers. It is no coincidence that in England, for instance, a recent wave of interest in extended schools originated as part of an attempt to address the social exclusion of disadvantaged groups and, particularly, to promote the renewal of urban areas where those groups were concentrated.

This contrasts markedly with what some might call a communitarian view. Here, the focus is on building communities based on shared values and democratic participation, with social breakdown understood not in terms of socioeconomic disadvantage alone, but of alienation and disengagement. The role of education in general and schools in particular, is to promote social participation. As two American writers on school-community relations put it:

Participatory democracy provides an institutional mechanism in public schools whereby the condition of postmodern chaos and disorientation in the local community and indeed the wider society can be dealt with more effectively. What results, one hopes, are "communities of hope". (Mirón and St. John, 2003: 306, in-text citations omitted)

These fundamental differences are of much more than theoretical interest. For practitioners, policymakers and, indeed, researchers, the purposes of developing community-focused schools can often seem to be self-evident. As a result, underlying assumptions tend not to be made explicit, and activities tend to be embarked on without any systematic and rigorous analysis of the purposes they are expected to fulfill. At the very least, this may mean that actions are poorly focused and less effective than they might otherwise be. At worst, it may mean that well-intentioned professionals impose on local people their implicit and unproblematic views of where their difficulties originate and what it is they need.

Evidence of Impact

Impressive claims are made about the impact of community-focused schools. A review of evaluations from 20 US initiatives (Blank *et al.*, 2003) is typical in concluding that benefits can be anticipated for children, their families, local communities, and schools themselves. In brief, children learn more effectively, parents offer better support to their children's learning and engage more fully with schools, communities become more sustainable, and schools function more effectively. However, such claims need handling with care. Other reviews are much more cautious about what can be claimed. Keyes and Gregg (2001), for instance, are skeptical about whether there are any impacts on children's learning, while others point to the paucity and poor quality of evaluation studies. As Wilkin *et al.* conclude, there has been "little systematic, rigorous evaluation of the concept and its implementation" (Wilkin *et al.*, 2003: v). Instead, the literature tends to focus on advocacy and guidance – from an international perspective, it is not helpful that it is dominated by US publications.

It seems, however, that poor quality is not the sole problem. Given the differing rationales outlined above, and the differences in interpretation from school to school, it is far from clear what community-focused schools are

supposed to achieve and how success should be judged. For many potential outcomes there are no obvious indicators, and evaluations tend therefore to focus on more readily measurable outcomes, such as children's attainments. Even where outcomes measures are available, schools' community-focused approaches tend to be complex and to be implemented in turbulent environments. Attributing changes in outcomes to those approaches can, therefore, be highly problematic.

In this situation, some critics conclude that the claimed impacts of community focused approaches are, in fact, illusory (Rees *et al.*, 2007). However, this seems harsh. The weight of the evidence – if not always its quality – suggests that positive impacts are likely, particularly since community-focused schools frequently adopt programs and interventions that have been shown to be effective in other contexts. Moreover, where evaluations take proper account of the complexity of community-focused initiatives and the nature of intended outcomes, findings become more convincingly positive. For instance, the national evaluation of full-service extended schools in England (Cummings *et al.*, 2007) was atypical both in using a multistrand approach to evaluation and in incorporating a theory-of-change methodology that could be customized to the intended outcomes of different schools. As a result, it was able to demonstrate the significant positive effects these schools were having on highly disadvantaged students and families, and the (marginally) superior achievement outcomes compared to other, similar schools. It was also able to show the benefits of these schools in relation to their costs, and to indicate how they might come to have widespread effects on engagement with learning and other indicators of well-being in communities.

In this situation, it is possible not only to be optimistic about the likely impacts of community-focused schools, but also to be realistic about the outcomes that can be claimed. Such schools are likely to bring appreciable benefits to their students, to families, and to local communities. Those benefits may be significant for some groups and individuals, but are unlikely to bring about large-scale transformations. Moreover, the kinds of outcomes that can be anticipated depend very much on the focus of each school's work. Above all, further robust evaluations are urgently needed and, in their absence, the leaders of initiatives need to build their own theories of change and ensure they are in a position to evaluate them.

Beyond the Community-Focused School

Community-focused approaches are essentially about strengthening schools' access to community resources and communities' access to school resources. It is remarkable, then, how few of them form part of wider strategies

for community development, area regeneration or, indeed, social justice. Despite the emphasis on community at the level of rhetoric, in practice most remain as school-centered initiatives, driven by school leaders, or leaders in local education departments or the education arms of NGOs. This may be because of the dominance of US initiatives and thinking in this field. As Moss, Petrie, and Poland point out in their review of international developments, American initiatives tend to be seen as ways of reversing the economic inequalities and social dislocations that in some other countries (they refer specifically to Sweden) are addressed through other public policies (Moss *et al.*, 1999: 37).

One problem with this reliance on school-level action is that, however successful they are in reconfiguring community resources, schools remain underpowered in the face of structural inequalities and disadvantages. The implication is that any move toward community-focused approaches in schools has to be part of, rather than a substitute for, much more wide-ranging policies for social justice. Ultimately, these are matters for national governments. However, intermediate steps are possible. For instance, schools can adopt the more positive view of disadvantaged communities that we outlined earlier and become centers not merely of service provision for local people, but of community activism. There are also examples of schools working within the framework of local strategies for community development and area regeneration. Such strategies have the potential for taking individual schools' community-focused approaches, supporting them, and multiplying their effects by aligning them with a wide range of other interventions.

As the proposal for one such strategic development puts it:

A wider view has to be taken beyond that which applies in any one school. The impact of difficulties faced by an individual school and the outcomes for individual children are felt by other higher level schools, by alternative education & training providers and by the wider community at an economic, social and behavioural level. The stakeholders in education have to be prepared to come together to pro-actively plan for better outcomes taking the view that children and young people need to be helped throughout all their educational phases. Their success at the end is not 'owned' by any one stakeholder but is a shared achievement and one in which everyone involved can take pride in. (Ryan, 2004: 57)

It may well be, therefore, that rethinking the role of schools in relation to the communities they serve should not stop at the proliferation of community-focused schools in their current form. Instead of simply broadening the work of the school, we may now need to integrate that work within coherent cross-sectoral strategies for addressing disadvantage and promoting well-being at the local level.

Introduction

In considering the remarks the author makes, three distinct perspectives have been brought to bear. First, as an outsider with some knowledge of education systems around the world, the author comments on how the school system in the United States looks against international benchmarks. (Think of this as speaking from the head.)

Second, as a battle-hardened veteran of the Blair government's controversial school reforms, the author draws some lessons from that broadly successful but also messy, error-strewn experience, which took us from below average to above average but not yet world class. These are thoughts, as the great Theodore Roosevelt put it, "from the man in the arena whose face is marred by dust and sweat and blood" rather than from one of those critics who stand on the sidelines, "cold timid souls who know neither victory nor defeat." (Think of this as speaking from the gut.)

Third, as a committed friend of this country who majored in American History at Oxford and who has been fascinated by trying to unravel its mysteries ever since, the author comments on the struggle – across over two centuries – to close the gap between the American Dream and the American reality. One of the virtues of a good friend should surely be that he or she can say what, otherwise, might go unsaid. (Think of this as speaking from the heart.)

This author believes that school reform in this country is at a critical juncture. In the next year or so, it will be necessary to choose between two broad options: on the one hand, a retreat to the comfortable, introverted, input-focused, evidence-light approach that characterized education reform in the last three decades of the twentieth

century, during which time Americans tried and failed to live up to the towering ambitions of the civil rights movement; on the other, an advance to the demanding, outward-looking, results-focused, evidence-informed approach toward which some promising progress has recently been made.

That choice will have to be made in governors' mansions, state capitols, city halls, and school boards across the country but, symbolically and substantively, the reauthorization of the No Child Left Behind (NCLB) Act – the most important piece of education legislation for many years and the most equitable legislation of the new century so far – will be the moment of truth.

The decisive factors in the making of this choice will be the accumulating evidence of what works (and what does not) and the courage of those who lead public education and who shape opinion within the system and among businesses and communities. This room is brimful of those courageous leaders and this author salutes their achievements so far – but they are only a beginning. In the words of the great poet, two roads are diverging in a wood and the choice this country makes – you make – will make all the difference.

As one prepares to face that fateful choice, three things need to be done – a glance back at the past, an assessment of the present, and a sketch of the future.

Section 1: The Past

In 1955, the year General Motors achieved a US market share of 50% and 2 years before the launch of Sputnik undermined America's post-war confidence, the American

high school reached its zenith – at least for white kids. A year earlier, the Supreme Court had momentarily decided that the education those white kids received should ultimately be available to all – setting the terms of debate for the ensuing decades.

Up to that time – and indeed beyond – the US had a huge comparative advantage over all other countries in the provision of universal, general education, as Claudia Goldin and Larry Katz have recently demonstrated. “During the first three quarters of the [20th] century educational attainment rose rapidly”, they argue.

This was, largely, due to the existence of universally available high school education but also to the growing availability of college. Because good schooling brings very long-term benefits, America’s educational leadership over the rest of the world brought substantial relative gains in economic growth right through to the end of the twentieth century. Even at present, the United States leads the world in the college-graduate share of those in the age range 55–64 years.

However, in the last quarter of the twentieth century, educational attainment stagnated in this country. Countries, which – educationally speaking – had been trailing in America’s wake for most of the twentieth century began to catch up. As Goldin and Katz explain:

The slowdown in the educational attainment of young Americans at the end of the twentieth century is especially striking when compared with the acceleration of schooling among many nations in Europe and parts of Asia, where educational change has been exceedingly rapid.

This relative slide in the educational performance of the United States has had – and will continue to have – economic consequences. Since “A greater level of education results in higher labour productivity [and] . . . tends to foster a higher rate of aggregate growth” relative weakness in education puts at risk long-term growth rates. The recent work of Eric Hanushek and others reinforces the case by demonstrating the strong, positive correlation between the performance of countries in Programme for International Student Assessment (PISA) and Trends in International Mathematics and Science Study (TIMSS) and their rates of economic growth. Having looked at the international comparisons in science and math over the past 40 years, they conclude: “higher levels of cognitive skill appear to play a major role in explaining differences in economic growth.” They show that the United States has fallen, relatively, in these international comparisons and is now, at best, average.

Some suggest – given strong economic growth in the United States over the last two decades – that this does not matter or, as Gerald Bracey has argued, “Our schools are better than the critics claim.” This is a dangerously complacent line to take – the time lag in the relationship between

schooling and economic growth is long. Look at the data of Andreas Schleicher of the Organization of Economic Cooperation and Development (OECD)-PISA. In the 1960s, the United States led the world in high school qualifications and Korea was 27th. At present, Korea leads the world and the United States is 13th and falling. As recently as 1995, the United States was second in the world on college-level graduation rates; just a decade later, it has slipped to 14th – slightly below the OECD average.

This slippage is not the result of a lack of investment, which remains relatively high in the United States. Rather, it reflects – to use hard economic terms – a lack of productivity. The point is reinforced by the fact that, in international comparisons of younger children, the United States does relatively well which – given the country’s wealth – is what one would expect. The problem is that, as they get older, children make less progress each year than children in the best-performing countries. In this instance, the discussion is not just about poor kids in poor neighborhoods; it is about most kids in most neighborhoods.

Moreover, there is no comfort in the belief that future economic success depends not so much on the overall levels of cognitive skill in the population but rather on ensuring that at least a few brilliant rocket scientists come through. Hanushek *et al.* show convincingly that, in the twenty-first century, having “a substantial cadre of high performers” and “near universal basic skills” are both essential. In short, the choice is a false one and the debate a distraction.

Summarizing then, long term, the future success of the American economy will depend on significantly improving the US school (and college) system with all the urgency that can be mustered. Indeed, because of the inevitable time lag, even with the most rapid imaginable education reform, it will be some years before the impact is felt on economic growth. No wonder business leaders often play a leading role in driving school reform in this country; they see the hard edge of these issues. It is one thing in the global economy to offshore unskilled jobs because labor is cheaper elsewhere; quite another to offshore highly skilled jobs simply because the qualified workforce cannot be found; but, too often, this has become the reality.

Equally importantly, however, school reform in this country has never been just a question of economics – important though that is. From the beginning of the Republic, education was seen as fundamental to building democracy and extending freedom. Jefferson was giving expression to a universal belief when he said, “If a nation expects to be ignorant and free in a state of civilisation, it expects what never was and never will be.” This idealism was one of the reasons why the United States made much

earlier and more rapid progress toward universal public education than many countries in Europe. The State of New York, for example, established universal public education in 1812 – not matched even remotely in England until 1870. In fact, in 1812, the British were more preoccupied with shelling the White House! The roots of the comparative advantage Goldin and Katz identified in the twentieth century lie deep in the previous century.

From the 1950s onward, the realization of this ideal – an ideal which underpinned the American Dream – became central to the burgeoning civil rights movement, at first in the Deep South where grotesque educational inequality was placed firmly on the agenda by the Brown versus the Board of Education decision and later in the northern cities as the hopes of the diaspora, all too often, turned to despair.

There were, of course, many strands to the civil rights movement – all wonderfully woven together in Taylor Branch's monumental trilogy *America in the King Years*. Two things in his account are both striking and relevant to our agenda, at present. One is that the movement in the 1960s, while symbolized by great set-piece speeches or new legislation, was – in practice – the accumulation of numberless acts of often unrewarded, unnoticed heroism, which, like ripples on an ocean, combined to become an irresistible tide. One can see equivalent inspiring acts of educational heroism in schools and communities across this country now; they too need to become an ocean tide.

The second is that the leaders of the civil rights movement believed firmly that once equal access to school and college had been achieved, equal success would follow. This is evident when one listens to King speaking to African American school students in Cleveland in 1964; “doors of opportunity are opening now that were not opened to your mothers and fathers. The great challenge facing you is to be ready to enter those doors.” If they are ready, he implies, access will be enough.

Similarly, one can listen to President Johnson promising “every child a place to sit and a teacher to learn from” – he makes the same assumption that access would be enough. While some civil rights leaders expected it to take decades to make up the ground – Bob Moses estimated it would take “fifty years to work this through” – all expected that the ground would be made up in time. In relation to education, those expectations have not been realized.

Dig deeper than the headlines and the evidence is compelling. Not only does the United States perform somewhat below OECD averages in the recent PISA, it also suffers from a very high socioeconomic impact on student performance. In other words, rather than overcoming the social differences children bring with them when they start school, the US system – similar to the one in the United Kingdom – tends to reinforce

them. As Goldin and Katz have argued, “The slowdown in the growth of educational attainment . . . is the single most important factor increasing wage differentials since 1980 and is a major contributor to increased family inequality.”

Those who led the civil rights movement, whether in Congress, churches, or communities, must surely be devastated by the actual outcomes 40 or 50 years later. One knows, at present, that access to school is not enough. It is success in school that matters. It is also understood that, at the heart of education reform, at the heart of success, it is not just access, it is the quality of what happens in classrooms – the skills and knowledge, the expectations and ambitions, and the consistency and dedication which teachers bring to the task of enabling students, whatever their background, to achieve the standards necessary for life, work, and citizenship in the twenty-first century. Though no one believes it would be enough on its own, achieving the ambitions for 2014 set by NCLB would be a great start. This far-from-easy task has become, one would venture to suggest, the emerging frontier in the drive to realize civil rights in this country.

History suggests, therefore, that – at present – there is a great challenge facing America. Both future economic success and the wider aspirations at the heart of the very idea of America depend on vastly improving the outcomes of public education. The great threat to the country's future is that, for a range of reasons, it might fail to rise to this challenge. Then, for many, the American dream will never be more than a dream. The great opportunity is that a combination of business and civil rights leaders – along with the cross-party consensus that passed NCLB – could become unstoppable. At present, the issue hangs in the balance.

Section 2: The Present

This section commences by assessing the negative side of the ledger – the author's fears. One worry the author has is the sheer difficulty of getting things done in this country compared to many other countries, including his own. Of course, successful large-scale change is never easy but, in the Blair era, when the government had a large majority in Parliament and significant popular support, rapid progress was possible – as, of course, were rapid blunders! Partly in conscious reaction to that very British constitution, your founding fathers separated powers between three branches and two levels; a similar dispersion of power is usually found at state level. Add to that a culture which is historically suspicious of the very concept of government – as if George III is lurking behind every filing cabinet – and the challenge becomes much greater than in most European or Asian countries.

Then, recognize the power and organization of those who defend the *status quo*, face up to the legacy of failed attempts to bring about bold reform and the result is a widespread sense of defeat in people's heads before they even begin. Across the country, people sigh, along with the Russian Prime Minister – in the 1990s – who said, on leaving office, “We tried to do better but everything turned out as usual.”

Moreover, these organizational and cultural barriers within the system are compounded by the worrying lack of anxiety among the American people with regard to public education. It appears that the public is resigned to the state of their public schools rather than satisfied or delighted with them. *Education Next's* Fall issue (2008) finds that if parents could issue letter grades to the system – as schools do to students – just 20% would give an A or B. People are significantly more satisfied with their police forces and post offices. Even so, there is little recognition that, unless public education significantly improves in the near future, there is a disaster in the making. Education systems do not fail with the suddenness of a natural disaster but the consequences can be just as devastating. In a moment of despair, James Baldwin once observed that civilizations are destroyed not by wickedness but by spinelessness.

How many Americans see education as the top priority in facing up to the country's economic challenges? If public education really is the frontier of the civil rights movement, where are the modern equivalents of the Freedom Rides and the Freedom Summer? Where is the clamor? How is it that, recently, a leading elected official could say that if one youth was beaten by the police there were mass protests but if thousands of youths were failed by the schools no one lifted a finger?

John F Kennedy first made his name in 1940, by publishing an essay with regard to the appeasement of Hitler in the 1930s and called it *Why England Slept*. This author hopes, in 10 year's time, no one looking back on this country's attempt to grapple with education reform will feel the need to write *Why America Slept*.

Fortunately, these anxieties are balanced by very real grounds for hope. To start with, all over in America, one can sense a growing recognition among the country's leaders at local, state, and national level that public education needs fixing. Furthermore, many of these leaders are ready to look abroad as well as at home for solutions. The growing interest from states in the American Diploma Project is a case in point.

Moreover, not the least consequence of the NCLB Act is much greater clarity in the data with regard to the extent of the problem. The diagnosis is becoming clearer and, while this does not automatically lead to the cure, it is a major step forward.

In addition – again assisted by the data – we are increasingly well-informed about, to use Tony Blair's

favorite phrase, what works. We have chains of schools, such as KIPP, Aspire, and Green Dot, that demonstrably succeed where many – in the past – have failed. The United States has whole systems such as Boston, Chicago, and New York City which are driving bold reform and delivering results. There are organizations, such as Teach for America (TFA), the New Teacher Project, and New Leaders for New Schools, showing how apparently insurmountable human capital challenges can, in fact, be surmounted. There are also not-for-profit organizations, such as Education Trust and Achieve with deep expertise in crucial areas. There are also foundations – Gates, Broad, and Dell, for example – willing to take risks and invest substantially in bold alternatives to the inadequacies of the present. At the state and local level, there are community organizations and foundations acting with a similar sense of purpose. Never before has there been so much insight into how to bring about successful change, nor such substantial capacity to deliver it. The question is whether political and educational leaders can seize that insight and capacity and bring irreversible progress.

There is a further point; the very international comparisons that make such depressing reading for the United States (and challenge the United Kingdom too), also indicate a way forward. They demonstrate what can be done – with evident progress in less than a decade – with a combination of the right strategy and courageous, sustained leadership. Singapore's story over 40 years is truly inspirational. Thus, in an entirely different culture, is Finland's over 30 years. Poland made remarkable progress in the last decade. The reforms in Alberta and Ontario, just across the US northern border, are working too. It can be done.

Which leads to the author's final ground for hope – the NCLB Act itself. This was legislation which reached across political divides and set ambitious goals. It put no ceiling on educational performance but, for the first time, it fixed in legislation a high floor. It has put the achievement gap on the agenda from sea to shining sea. To set a date for delivery as early as 2014 was aspirational, certainly; some critics say it is unrealistic and the due date should be postponed, perhaps indefinitely.

Others say, “provide the preschool and the capacity first and we'll come to the accountability later.” Even if the American people would accept a pay-first-and-ask-questions-later approach, this argument fails to recognize the degree of urgency. Moreover, the fact that there are schools – at present – achieving those goals surely suggests significant delay would be a mistake. In any case, from the perspective of the Freedom Summer of 1964, far from looking too soon, 2014 appears a half-century too late. As the then vice-president said rejecting pleas for patience, on the 100th anniversary of the Gettysburg Address, “It is empty to plead that the solution to the

dilemmas of the present rests on the hands of a clock. The solution is in our hands.”

Across the country there are promising, albeit early, signs that – prompted by NCLB – progress is being made. Performance is improving – not enough, but at least heading in the right direction. Achievement gaps are narrowing – not yet transformatively, but increments are better than nothing.

Therefore, NCLB is a source of hope. The question it raises to my mind is not “Should it be reversed or abandoned?” but “How can it be refined and followed through?” In the last section of this article, the discussion turns to this.

Section 3: The Future

It is clear that, for all its qualities, NCLB does need refinement. It is rare for any law to pass and for legislature in the world to be without blemish and rarer still not to find ways of improving it once implementation begins. There are plenty of people – many of them in this room – who are much better informed than the present author with regard to the finer points of this particular piece of legislation and the Commission on NCLB (which the Aspen Institute supported) has published a distinguished and instructive report on the subject. A number of refinements, in particular, stand out from an international perspective.

First, the power of the Act depends crucially on the quality of the assessments being used. Where poor tests are used, the information they provide will be misleading with potentially dire consequences for the students themselves when they leave school and meet the real world coming the other way. One option for solving this problem was advocated recently by the *New York Times*, and would involve asking National Assessment of Educational Progress (NAEP) to create a rigorous test to be given free to states – with those that choose not to use it being publicly identified and, therefore, asked to explain themselves. Whether this is the best solution is not sure, but the direction is certainly right.

Second, the introduction of growth models has brought welcome refinement to the accountability requirements and it makes sense to build on this development. Growth models are helpful as a measure of progress and explanation of the scale of the challenge; they are dangerous when they become a justification for poor performance or lower expectations. Our experience in England suggests growth or value-added models should be combined with a continuing focus on the absolute outcomes which are all that matter to students when they leave school. They need to be part of a refined, modern, student-based data system which puts the evidence at the fingertips of every professional at every level.

Third, districts and states need to develop the capacity to act decisively in response to the data. They need to be able to recognize and reward those who succeed, especially those who succeed in challenging circumstances; they also need to intervene effectively where progress is not what it needs to be. In England, not without difficulty and controversy, this latter capacity was developed. Under pressure from us in central government, our equivalent of school districts did learn how to intervene effectively in failing schools. They did not apply pre-packaged interventions in mechanical sequence; instead, they diagnosed the problem in each school and tailored the solution accordingly, answering the only question that matters in these circumstances – “what do we need to do to get these kids a good education as fast as possible?”

Sometimes, it meant closure of the school and dispersal of the students to other schools; sometimes, it required the introduction of new providers and, sometimes, the replacement of a principal. The districts varied in their technical capacity to do this; they also varied in the degree of political will they brought to it. It is always tempting in these difficult circumstances to give the benefit of the doubt – but doing so, in this author’s experience, is almost always a mistake. After all, it raises the question, “How come you were so doubtful?” Meanwhile, at the central government level, we intervened in districts which lacked the capacity to drive school improvement. This was done successfully in almost 10% of the total, which, among other things, incentivized the rest.

This raises the fourth point of this discussion: successful education reform is as much about means as it is about ends. Getting the policy right is difficult, to be sure; but it is relatively easy compared to making it happen, consistently and effectively, so that the benefits are felt in every classroom. Policy failure is as often a failure of implementation as it is of concept. Systems need to develop both the technical capacity and the necessary mindset to deliver results. This is what, in the Blair administration we self-mockingly called “deliverology,” but, when we applied it systematically, it worked. An American equivalent is needed across the country to ensure the ambitions of NCLB are realized rather than eroded. As one of our more hapless kings – Charles I – once observed (shortly before they cut off his head), “There is more to the doing than bidding it be done.”

Fifth, there is much more to do to ensure there is a highly effective (more important than highly qualified) teacher in every classroom and a highly effective principal in every school. It is especially important to ensure that the schools facing the toughest challenges have access as soon as possible to the most talented teachers and leaders. Doing so requires root-and-branch reform of inherited, traditional, bureaucratic systems of recruiting and training teachers and leaders, of paying and rewarding them and of shaping their incentives, both short term and long

term, including pension arrangements. There needs to be a constant focus on developing talent and building capacity. At the moment, all around America one can see fine examples of what is required – TFA, the National Institute for School Leadership, KIPP's leadership development programs and New York City's Leadership Academy, for example – but, at the moment, these remain exceptions to the rule, not the rule itself.

In relation to human capital, there is a more profound, underlying question. As McKinsey's Report *How the World's Best Performing School Systems Come Out on Top* makes clear, the world's best systems are recruiting teachers who have both the right personal qualities and come from the top-third of the graduate distribution; in the United States, most teachers are from the bottom-third. Without improving their underlying capacity to attract talented people, education systems will struggle to compete in the future.

In England, to address the massive teacher shortage we faced a decade or more ago, we completely overhauled our teacher training – making it more classroom based, more accessible to people in mid-career who wanted to switch into teaching, better aligned with the school reform agenda and much better quality assured. We offered students incentives to go into teacher-education programs and varied those incentives according to the degree of shortage in particular subjects. Inspired by David Puttnam, the film producer, we introduced the National Teacher Awards – covered annually on prime-time television. Once the product had improved, it was promoted vigorously through advertising with the slogan, *Those Who Can, Teach*. The result has been several years of sustained improvement in the numbers and quality of recruits into teaching, assisted by our own version of TFA called Teach First. Teachers' pay, too, was increased but evidence from around the world shows that increasing pay on its own brings poor returns.

For the United States, the question of where, in the long run, it will find sufficient teachers of real quality – especially in science and math – remains unanswered. There is a medium-sized state with great universities that produced just one new physics teacher last year – just one. Increasing the supply of talent into teaching will require in addition to major changes in policy, a change in the way teachers are perceived. TFA and similar programs are beginning to bring that about – but only beginning to do so.

Changing a culture also requires leadership from those in government, business, and the not-for-profit sectors. The chances of success would be greatly enhanced if teacher leaders too became advocates of reform. In the early 1990s, when this author worked for a teacher union in England, he suggested turning the traditional case for investment in teachers on its head. Instead of continuing to argue that if the government increased our pay we

might consider improving the system, this author suggested that accountability should be embraced, the system improved, and then the public told, "Look, now you can see a system worth investing in."

Accepting this case, at the time, required too great a leap of faith. However, history is instructive. In spite of teacher opposition, accountability was imposed, schools did improve, and, as a result, the biggest ever increases in investment in education – including in teachers' pay and professional development – did follow. Blair called it "Investment for Reform." While teachers did not always enjoy the journey, they arrived at a much better, if more challenging, destination. Given the wide range of opportunities available, talented people will not flock into a profession with lockstep conditions and a beleaguered image. Nor will skeptical citizens continue to invest precious tax dollars in a system that does not seem to be working. Citizens the world over, similar to good businesses, prefer to invest in success.

This raises the sixth point for discussion; the extent and distribution of funding for public schools. International benchmarks suggest that America's overall expenditure on schools is above the average but, compared to other countries, two questions of distribution stand out. The first is that, even after funding equity suits, often more money per student is spent in wealthier areas than poorer ones. It is easy to see how this came about; but to an outside observer in the early twenty-first century, this disparity makes no sense at all. If all young people are to reach high standards, as NCLB envisages, then the system has to provide greater support to those with the furthest to go. A child of age 4 of professional parents will have heard 45 million words; a child aged 4 years of welfare parents just 13 million words. Overcoming such a massive language deficit is possible but not if the school system merely reinforces the advantages of the already advantaged. The inescapable practical implication is that, over time, states will have to play a larger role in raising and distributing funds for public education.

US funding distribution is also skewed in another way which receives less comment. A much lower proportion of it actually reaches the classroom than in the best-performing systems; much more of it is tied up in administration. Of course, good administration matters but every dollar spent on unnecessary administration is a dollar that could have assisted that welfare child reach for the stars.

In England, the districts were required, by law, to devolve the vast bulk of the funding for schools to the schools themselves. Each school now has a 3-year delegated budget, based on a published formula. This direction was set by the Thatcher government and continued by all its successors. In effect, the burden of proof was reversed – a pound (or dollar) should be spent at the level of the school unless there is a convincing case for spending it elsewhere.

Any government in England that sought to return to the old opaque system would have a riot on its hands.

Along with the money, schools need to be given responsibility for how it is spent. The PISA evidence shows that increased management autonomy at school level is associated with better results but this lesson remains to be learnt in many parts of the country. Recently, in a northern US city, this author came across a good school principal setting out to turn around a failing school. She had all the right ideas but had no control over which teachers were employed at her school. She even needed permission from a teacher to visit a classroom. What chance did she have? The contrast with the nearby charter school, in similar social circumstances, was dramatic. Accountability and autonomy need to go together. The question for the United States is not just how many charter schools it wants but how soon all schools can have charter-like autonomy.

This leads to the seventh and final point of this article. The PISA evidence indicates strongly that there are benefits in holding schools to account through standards-based external assessments. In the global economy, the question of national standards inescapably arises. The emerging bipartisan alliance in favor of common or national – as distinct from federal – standards suggests growing recognition that the United States needs them to be fewer, clearer, and higher. Moreover, *Education Next's* recent poll showed ~70% support in the population for national standards – and over half of all public school teachers agreed.

The truth is that, across the world, standards in math, science, and English will inevitably be set by global benchmarks in a globalized economy. Quite simply, to succeed, countries will need world-class standards; algebra and geometry do not change at the Rio Grande or the 49th Parallel.

From this perspective, the question of national standards is straightforward; they will arrive anyway eventually. The only questions are whether they do so by accident or design; haphazardly or systematically; sooner or later. As they used to say in the civil rights decade, “If not now, when?”

Conclusion

The choice facing the United States is, as this article began by saying, a stark one. It will shape America's capacity to succeed over the decades ahead in the profoundly challenging global economy; it will shape too whether the American Dream in a stunningly diverse America, is genuinely open to every citizen. This is why progressive business leaders and civil rights leaders stand together. They know that the aspirations unlocked in the dawn of the civil rights movement have only partially been fulfilled. The school system has improved in many

ways since that time but surely no American can be satisfied by the outcomes. There is no ceiling on what individual Americans can achieve but, though enshrined in legislation, the high floor – on which economic success and social justice depend – has yet to be built. For those committed to a vibrant, successful America where the American Dream and the American reality more closely coincide, there can surely be, in Martin Luther King's phrase of old, “neither rest, nor tranquility.” It will be a long, hard road. Many of us – in the arena now – know this only too well. More and more people are watching us, and hoping.

Counting on your success in this endeavor are not just children and families across this great country, not just the future of the American economy, not just the idea of the American Dream, but all of us around the world. In the twentieth century, a strong, generous, outward-looking America was a decisive factor in enabling humanity to rise and meet the challenges it faced. As Goldin and Katz have demonstrated, public education was central to making that possible. How much more important for everyone then is US education in the twenty-first century when the world is so much more complicated and the clock is ticking?

At the bottom of the staircase in No.10, just outside the Prime Minister's office, there is an exceptional photograph of Winston Churchill. Facing the camera, he glowers with such defiance that, even at that uncertain hour, war-time defeat must have seemed inconceivable to the onlooker. In fact, one is told the real cause of his mighty frown is that the photographer had forced him to put down his cigar! Be that as it may, the time has surely come to heed his famous words, “America always does the right thing but only after it has exhausted all the alternatives.” In education reform, those alternatives have, indeed, been exhausted. It is time for America to do the right thing.

School Effectiveness in Developed Societies

The History of School Effectiveness

School effectiveness (SE) is a relatively recent educational discipline that has grown in many developed societies at a very rapid pace. It wishes to understand the functioning of schools, and their effects on their students. Some members of the discipline wish to go further than this and directly try to improve school functioning. The discipline set up its own organization to promote research – The International Congress of School Effectiveness and Improvement (ICSEI) only in 1988 – and its own journal, *School Effectiveness and School Improvement*, only in 1990. Reviews of the field are available in Teddlie and Reynolds (2000), and Sammons (1999).

The general intellectual, and particular policy, setting that saw the rise of SE was not a particularly hospitable one. In the 1960s, there had been a widespread belief that education could not compensate for society, and that the failure of the liberal education reforms of enhanced expenditure and school organizational change to achieve the hopes of their proponents showed that schools made no difference.

However, beginning in the United States, where it was initially a practitioner movement but became more research orientated, and in the United Kingdom, where it came initially from the research community, the field is now represented in probably 40 or 50 developed societies across the world, and in some developing ones too. In the United States, the School Board Superintendent, Edmonds (1979) made the best-known initial contributions, and in the United Kingdom, the researchers Michael Rutter (Rutter *et al.*, 1979) and David Reynolds (1976) were responsible for its initial offerings.

The range in the particular contributions to SE knowledge and practice from different societies is marked. The United Kingdom brought a well-developed focus, from its well-established sociology of the school within its sociology of education, upon school-level organizational characteristics and also was responsible for the generation of much of the methodological revolution in statistical methods that occurred in the mid-1980s. Its school improvement (SI) perceptions and links were also well developed, and virtually all SE work has been notable for the very wide range of student outcomes that have been measured in addition to the core one used internationally for academic achievement.

The United States has been notable for the high quantity and quality of its work done on effective teaching, and

for the associated successful teacher improvement programs of the 1970s and 1980s. It has also pioneered the emphasis upon any contextual specificity of what may be effective practices, with its sampling strategies that attempted to look at schools from diverse socioeconomic environments (Teddlie and Stringfield, 1997), unlike the United Kingdom which has sampled almost exclusively from disadvantaged communities because of its predominant equity concerns. The United States has also been notable for the development of special improvement programs to implement SE and other bodies of knowledge, as with the initial Effective Schools Programs of the 1980s and the federally funded Special Strategies Programs of the 1990s.

Elsewhere in North America, Canada (Fullan, 1991) has been notable for the development of improvement practice more than for SE research, although it has evidenced numerous useful studies on SE situated within the quantitative, organizational paradigms. The Scandinavian societies too have been mostly improvement orientated with particularly the generation of culturally sophisticated programs from Norway.

In Europe, the biggest contribution other than from the United Kingdom has come from the Netherlands, where interestingly a large volume of quantitatively orientated research studies have been paralleled with attempts to generate middle-range theories of school functioning. Dutch SE material has also been quite sophisticated at the classroom level, reflecting probably the historical popularity of learning and instruction perspectives from European social psychology within that country.

Elsewhere in the world, Australia has been notable for its rare attempt in the early 1990s to survey what key stakeholders, including pupils and parents, thought was effective, and has evidenced useful teaching effectiveness material also.

While in some parts of the developed world SE has yet to make its mark in any major fashion (Italy, Germany, and France evidence little penetration of the SE paradigm), virtually all the developed societies of the world participate in the studies that emanate from the IEA, which involve the ranking of societies on their educational effectiveness through use of their students' test scores and related attempts to explain the resulting international differences. Studies such as the Third International Mathematics and Science Study (TIMSS) from the mid-1990s and the Programme for the Evaluation of Student Achievement (PESA) from the mid-2000s have taken the

SI paradigm to many parts of the world, further encouraging its development.

It has perhaps been the enhanced educational focus upon the need for educational quality, necessary for any developed society to compete in a world where productive forces are subject to the pressures of globalization, which has spurred increased interest in SE from researchers, practitioners, and, especially, governments. Related concerns about educational efficiency, value for money, accountability, choice, and educational evaluation have also created a fertile ground for the discipline to grow. The associated enhanced governmental interest across the world in better management of schools, the professional development of teachers, and educational innovation/change more generally have also been potent for the development of knowledge upon good schools and how to make all schools good that is the intellectual and practical core of SE, although there have been critics in many developed societies who have criticized SE's contribution to what is seen as a narrow managerialism, a discourse of performativity, and a climate of blaming of the educational system.

The Methodology of SE

SE took a number of its core methodological characteristics from the American educational finance, educational production function, and educational administration specialisms that were already in existence in the early 1970s, particularly its core focus upon student inputs and how these were acted upon by school organizational processes to become educational outputs. In this framework, inputs are seen as the students and their characteristics in terms of their levels of prior achievement, their family background, and the nature of their communities, as they enter different schools.

Outputs are seen as their characteristics and attributes as they leave, in terms of their academic achievement, their social/affective characteristics, and, in some formulations, their psychological attributes. Therefore, public examination results, achievement test scores, levels of self-esteem, propensity for criminal behavior, school attendance rates, levels of problematic behavior in schools, and even levels of post-school employment have all been used as output measures. The concern in many societies to widen the mission of the schools into the tackling of economic and social disadvantages directly is stretching the array of those measures used in SE studies even more.

The third area where SE concentrates upon is that of school processes. Most SE research has looked at the formal organizational characteristics of schools in the search for factors to explain their variation in impacts, rather than at the cultural or informal characteristics. The leadership strategy and methods of the headteacher/principal, the

academic organization of the school, its pastoral/welfare organization, its facilities/resources, its involvement with parents and the other outside school stakeholders, its strategies for motivating children, and the methods, efficiency, and effectiveness of its classroom teaching/instructional level have all been major foci of interest.

Early methods of analysis in the SE of the 1970s and early 1980s involved simple multiple regression analysis in which outputs were regressed on inputs, with the resulting residuals (or differences in how schools actually performed compared to their inputs predictions of how they should do) being related to their organizational processes noted above. However, from the mid-1980s the use of multilevel modeling (MLM) became widespread, and is now the axiomatic method, used internationally. These methods permit the analysis of multiple levels of the education system with specific estimates of the effects of variance in, for example, the school level, the classroom level, and the district/local authority levels, permitting the disaggregating of the educational system into its component parts that simple regression analyses could not achieve.

However, it has been pointed out that the estimates attained using multilevel analyses are not dissimilar from those obtained using conventional regression analyses, and that multilevel methods also do not permit the study of interactions between levels that may be important in certain areas (e.g., school/classroom interactions). In addition, multilevel methods presuppose direct paths of educational influences upon outcomes, while multiple, interactive, and indirect relationships also seem to be likely. For these reasons, enthusiasm is now turning toward structural equation modeling (SEM) as a tool of analysis that gives advantages in the areas dealt with problematically by the multilevel methods mentioned above.

Whatever their precise nature, all these statistical methods adopt a value-added approach, whereby schools' outputs are not used raw but in which schools are assessed by the value they have added to their inputs.

Key Findings of SE

From the large number of SE studies conducted – 2000 reviewed in Teddlie and Reynolds (2000) and probably 3000 in existence now – a number of clear trends can be seen.

First, the influence of schools upon their student outcomes is always considerably less than that of their students' prior achievement and/or their family/community backgrounds, with perhaps 10–15% of variation in student achievement explained by the school and classroom levels together. For certain subjects, where exposure is usually exclusively from within the educational system, such as mathematics, educational effects are greater. Educational

effects are also greater for younger-age children and for those from socially disadvantaged areas. While schools do make a difference, in SE analyses, they do not make the major difference.

Second, school performance can be varied over time. Schools vary in their effectiveness level year on year, and some schools improve rapidly consequent on their organizational changes, particularly when generated by a new principal/headteacher. Nevertheless, probably two-thirds of any countries' schools are average over time, defined in terms of performing where they should be, with only a limited proportion adding considerably more or less value than expected. However, in many developed societies, there is a substantial size group of negative value-added, low-performing schools that have perplexed policy-makers and practitioners by their consistent poor performance and by their inability to respond to conventional school-improvement attempts. These schools in challenging circumstances form a contemporary focus for SE in many countries.

Third, there is a degree of variation as to how different kinds of students perform even within the same school. This will apply to boys/girls, ethnic groups, children of different achievement levels, and children of different social backgrounds: schools will be differentially effective for their subgroups of students. More recently, particularly in the United Kingdom, there is increasing discussion of within-school-variation (WSV) in the effectiveness of the different subject areas that children study, with some analysis suggesting that WSV dwarfs school-against-school variation by 4 or 5 times.

Lastly, there is also a degree of variation in the effectiveness of different schools on their different kinds of outcomes. Social or affective outcomes seem to be partially independent of academic/cognitive outcomes, and to be associated with different educational processes within the school/classroom.

The Process of Effective Schooling

In spite of the clear difficulties about making easy, global judgments as to what works in schools that are consequent on the substantive findings above, this has not stopped the generation of multiple descriptions of effective schools and of multiple visions about how to make all schools effective schools (see reviews in Reynolds *et al.*, 1996; Reynolds *et al.*, 1994).

Factors such as the varying financial resource levels between, and within, societies do not seem to determine whether a school is effective or not. Rather, it seems to be the ways in which schools actually use their resourcing that matters, although there are some hints that resource effects may be greater for schools with more challenging students. Building age, school-site quality, and the

quantity of educational technologies likewise do not seem important – it is site upkeep and the patterns of use of their plant and educational equipment that seem to be the keys to effectiveness.

The crucial factor in determining effectiveness is the quality of the leadership provided by the principal/headteacher, with effective schools possessing leaders who can set institutional directions, who have a clarity in their mission, who motivate and involve both senior management and their line teachers, who acquire cultural and financial support from external stakeholders, and who use educational change from outside the school to broker changes in the instructional attitudes and behaviors of the teaching force within it. Such effective leadership crucially appears to be focused on the classroom – effective leaders manage by walking about (MBWA) so they are aware of their teachers' strengths and any needs for support. They communicate high expectations about the importance of teaching, use programs of continuing professional development to potentiate it, and are particularly concerned with maximizing the quality of their teacher supply.

It may seem a truism, but effective schools also possess effective teaching. Class time is well managed, with no loss of instructional time due to lessons running over their allotted times or to time-wasting disciplinary interventions. There is a climate of high expectations about what students can achieve, and an academic press that generates high achievement. Lessons have clear purpose, are related to prior learning, and have clear, well-managed structuring. Classroom discipline is both firm and fair, with rules that are understood and clear to all. The students are involved in the learning process, both through generating and discussing curriculum content and through developing as reflexive learners who help determine their teaching and learning methods. Assessment data are used both summatively – to promote feedback – and formatively, to improve learning.

The students are involved in the school, as well as in the classrooms of effective schools. The school will possess multiple clubs, societies, sports teams, and associations to multiply the chances of student involvement. Prefect/monitorial systems and/or consultation systems and committees will be used to generate further involvement. The effective school will be incorporative of its student clients.

Parents will also be involved in the effective school both formally in systems of parent/teacher associations and more informally through the possession of a school ethos that encourages parents to become involved in lessons as helpers, in fundraising and in generally visiting the school. Information will be fully provided to parents.

The effective school itself will be intelligent in its use of data and in its management information system (MIS). A wide range of data will be used to track students, with data systems that are sensitive enough to quickly pick up any variation in how students are doing over time and in

different subjects. Such systems also usually involve the prediction of performance and the calculation of actual performance, with appropriate interventions to optimize outcomes. They may also involve the collation – at individual, class/teacher, and year level – of additional student data or student voice data that both motivates individual students through encouraging reflexivity and also provides the authorities of the school with valuable consumer-response material that can be used to check on the quality and reliability of their systems as seen from the learning level.

From SE to SI

Although there now clearly exists considerable knowledge about the characteristics of effective schools, the application of that knowledge to improve schools has been somewhat patchy across the developed countries of the world, with little evidence of any consistent improvement through utilizing it. In the United States, SE boomed and busted in the 1980s, when the early five-factor theories were tried in many schools and districts, but the knowledge base was unsophisticated and attention moved on to more transformational approaches. In the United Kingdom, SE informed the policies of the Labour Government from 1997, being reflected in the national strategies that ran from 1999 and in the number of SE researchers that advised government. However, this phase of prescription of what works was not matched by any subsequent improvement additional to the initial surge in UK national educational test scores that occurred from 1999 to 2002. In most other societies, SE has had a less-pervasive impact within their educational systems, although in perhaps 40 or 50 developed countries across the world there has been some take-up of SE practices at society, district and/or individual school level, often associated with the influence of SE researchers in their higher education establishments.

Part of the reason for limited take-up has been the historic separation between the activities of SE researchers and SI practitioners/researchers, which particularly meant that SE lacked some of the SI understandings that might have helped it to achieve greater reach. SI had been concerned more with school culture than school organization, was particularly keen to involve teachers in determining what should happen in any school being improved, and, in its most advanced formulations, was full of insight about the complex socio-psychological currency within schools that needed to be addressed to actually institutionalize improvement.

SE's more managerialist and organizational paradigm made it, perhaps, the paradigm of choice for the principal and the headteacher more than of the classroom teacher, and perhaps made it the policymakers' friend rather than that of any broader constituency of educationalists.

Contemporary Developments in SE

Perhaps the most likely reason for the somewhat limited take-up of SE, and its correspondingly limited effects, was that, as a knowledge base it was not particularly sophisticated in its first flowerings in the early to mid-1990s. Interestingly, since then a great deal of progress – intellectual and practical – has been made in a number of areas, virtually all of which have direct implications for education policies and for the SI attempts of practitioners.

First, it is now clear from recent SE research that the range of organizational variation within schools is considerably greater than that between schools when value-added assessments are made, by a scale of 3–4 times. In secondary schools, this can be seen in the variation in the academic outcomes of subject departments – in primary schools this can be seen in variation between the outcomes of individual teachers. While the reasons for the existence of these variations may be unclear – the effect of initial training or later professional development opportunities have been suggested as possibilities – the use of this variation to improve schools promises a stronger educational lever than whole-school reform.

These within-school differences are within the same organization, so should be amenable to easy diagnosis and remediation. Students in the different subject areas, or different classes in primary/elementary schools, will be relatively the same in their attributes, making alibis or excuses from teachers for any failure less likely. Schools may also be more able to develop a positive tone about improvement based upon studying their own best practice, rather than relying on outside school sources of improvement.

Second, attention in SE research has shifted away from the school organizational level to that of the classroom, with most analyses showing that the classroom, instructional, or learning level explains much more variation in student outcomes than the school level. The teaching behaviors and characteristics that potentiate classroom learning seem to be quite large in number – 50 or 60 in most formulations – and consequently effective teaching appears to be the result of doing a large number of things well, rather than doing correctly a smaller number of major things. Effective teachers seem to have both the appropriate behaviors and related associated beliefs, which appear to have additive effects, as in the case of the importance of factors such as a positive locus of control, positive attitudes to students, and strong belief in the power of education.

Third, SE has begun to explore the variation in what works by context that might affect commitments to what are effective educational practices. Building on the American work noted earlier, variations in the socioeconomic status of schools' catchment areas, their rural/urban status, effectiveness level, improvement trajectory,

governance structure, and, indeed, their country have all been shown to have implications for what is needed to generate effectiveness.

Conclusions and Future Research/ Practice Needs

Even though there has been rapid progress in some areas of SE, there are numerous other disciplinary areas that await attention. There are very few attempts to create theories about why certain educational factors, or groups of factors, have effects. Many of the new school outcomes that are regarded as essential in a world where simple knowledge is rapidly redundant, such as learning-to-learn skills, and some of the psychosocial attributes necessary in a more-stressful world for young people, such as personal resilience, for example, have not received the place in the SE knowledge base that they need. We still know very little about which of the SE correlates travel across cultural contexts, and why.

However, the increased pressure on the educational systems of developed societies internationally, consequent upon pressure on public expenditure across virtually all of them, will ensure that issues concerning educational efficiency and effectiveness will continue to be high profile, creating further opportunities for SE research. The rise of the new cognitive neuroscience paradigm is likely to create further knowledge about how student learning can be potentiated. The increased number of experiments of nature in which national governments try to change the governance, processes, and outcomes of their educational systems is creating an international laboratory of education. The prospects for SE could not be brighter.

School to School Collaboration: Innovation and Improvement

R Higham, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

A hypothesis that has long held appeal is that there are solutions elsewhere in the education system for challenges faced in individual schools. We have not always known, however, where these solutions are or how best to apply them into other contexts. Recent advances may have made such aims a little more realistic. Over the last decade or so, teachers have become increasingly expected and/or willing to be observed, to observe others, and to discuss their pedagogic practice. Schools commonly use comparative data in their own self-evaluation. A wide range of local partnerships and networks bring teachers and leaders together to innovate and share ideas. We may also be finding out more about how schools actually work collaboratively. Approaches under the banner of knowledge transfer, for instance, have not always been found appropriate in collaborative settings. Schools working together collegially may also be co-constructing new practices to common challenges (Fielding *et al.*, 2005).

Within this emerging context, this article explores the work of school-to-school collaboration as a lever for innovation and mutual improvement. To do so, it focuses on the Leading Edge Partnership Program (LEPP) as a case study for analysis. The article progresses in several main ways. First, it considers the emergence of school-to-school collaboration in policy and practice in England. Second, it describes the nature and work of Leading Edge partnerships. Third, it outlines the main collaborative advantages achieved by a sample of Leading Edge partnerships. Fourth, it explores the collaborative methodologies these partnerships have employed to do so. Fifth, it analyses the additional factors that appear important in developing a collaborative impact on student outcomes. Finally, the article concludes by arguing that where an ethos for mutual improvement remains undeveloped, collaborative advantage will be difficult to achieve. In partnerships where progress is made, it appears to be correlated with strong leadership and organization, the full involvement of partner schools and increasingly rigorous methodologies for collaborative work.

A Recent History of School Collaboration in England

It is estimated that nearly all schools in England are now involved in some form of networking (Hill, 2006). This would have been hard to anticipate during the late 1990s. A New Labour government came to power in England in

1997 having coined the now famous slogan 'Education, Education, Education'. The promise was for educational renewal aimed at improving school standards and social equity simultaneously. In reality, at the systemic level, New Labour's main approach was to evolve the more radical reforms introduced in the 1980s under Margaret Thatcher, albeit in a context of significantly higher public spending. Thatcherism had introduced an educational market to unleash competition-driven improvements. New Labour sought to advance market effectiveness through greater parental choice and institutional differentiation by curriculum specialisms. Similarly, where the Conservatives had introduced the National Curriculum and national tests, New Labour developed accompanying National Strategies that summarized a range of pedagogic approaches and promoted a minimum set that schools were strongly encouraged to implement.

It was at the more specific level of schools facing challenging circumstances that New Labour initially developed a range of funded initiatives aimed at school collaboration. The Excellence in Cities program, for instance, sought to share capacity for teaching, learning, and community engagement across urban schools. The Leadership Incentive Grant aimed to strengthen leadership in schools through collaborative professional development and mentoring. A growing number of specialist schools were expected to work with other schools to spread good practice and raise standards. This might have appeared contradictory to the broader approach of market-led competition. But this was New Labour and its third-way philosophy that prioritized eclectic pragmatism over ideological chastity. The forces of market competition were to be combined with collaboration and the sharing of best practice.

By 2003, the government felt sufficiently confident to argue that there were now system-wide benefits to schools working in partnership (DfES, 2003: 12). A range of reasons exist for this. First, faced with the limits of command-and-control policies, as well as the system inequalities that can result from competition, networks held the appeal of greater professional engagement, lateral working, and system coherence (Glatter, 2003). Second, there was an existing need for joint working in practice to resolve interconnected challenges in, for example, student welfare (Connolly and James, 2006). Third, this was to some extent a rediscovery of the professional collaborations that had been facilitated by local education authorities in the 1970s and 1980s (Glatter, 1995; Stevenson, 2007).

A decade or so on from 1997, there is a growing sense of the potential benefits of collaboration between schools as well as with other agencies. Different outcomes relate to local aims, activities, and ways of working. However, a range of studies and evaluations have found a relatively high degree of similarity in the benefits that can be achieved where partnerships are effective. These are summarized in **Table 1**.

Another common message is that achieving these benefits is far from easy. As Vangen and Huxham (2003: 62) found, reports of unmitigated success are not common. Instead, partnerships can develop collaborative inertia in which only hard-fought or negligible progress is made. In part, this results from the continuing coexistence of collaboration and competition. At the extreme, for instance, there remains “a spirit of intense competition and mutual suspicion” (Arnold, 2006: 6). This inevitably has an impact on the ability and desire of schools to overcome other common obstacles to collaboration. These include, as set out in **Table 2**, time, resource constraints, and distance. It also becomes more difficult to develop practices commonly associated with effective partnerships, including building trust, a willingness to compromise, and bearing the costs of partnership work usually before benefits occur.

What is significant is that, in many places in England, obstacles to collaboration appear to be being surmounted and a new interconnectedness developed. In research with urban schools, Ainscow and West (2006: 137) found head-teachers were beginning to identify shared principles around which their staff could be drawn together. This was generating a new impetus for change across schools, wider ownership of the improvement agenda, and reduced

polarization. They concluded that, despite the longer-term deepening of socioeconomic inequalities by market reforms, there are reasons for optimism as “the system has considerable untapped potential to improve itself” (Ainscow and West, 2006: 131). This exists in the accumulated skills, knowledge, and creativity within and between schools and their local communities.

How these skills and resources might be mobilized to support innovation and improvement beyond the individual school remains, however, a challenge. Indeed it is unclear what ways of working and collaborative leadership might best enable such work (Glatter and Harvey, 2006). This article seeks to consider these issues with reference to the LEPP. After introducing LEPP, it goes on to consider what:

- collaborative advantage is actually achieved in a sample of partnerships;
- methodologies these schools developed and deploy to work together; and
- other key factors related to a partnership’s effectiveness.

Leading Edge

The LEPP was launched by the government in 2003. It was a successor to the Beacon Schools Programme that had existed since 1998. The initial program had funded high-achieving schools to disseminate aspects of their practice to other schools, but usually without any sustained support. LEPP sought to learn from the limitations of this approach by demanding a clearly defined

Table 1 Commonly quoted benefits of collaboration

Good practice:	share effective practice or expertise identify shared problems and work collaboratively on solutions
Professional development:	provide mutual and informed support enhance quality of staff development and critical reflection joint staffing, wider career structures, solving staffing shortages improve leadership quality and support and/or whole school systems
Direct student benefits:	wider curriculum choice and learning pathways improved transition of pupils into secondary school raised student expectations and (in some cases) attainment
Local strategic leadership:	increase equity and reduce polarisation of schools promote coherent provision for local communities increased community involvement ensure the survival of rural schools
Resources:	drawing in additional funding and resources developing efficiency and economies of scale reduce risk and uncertainties of innovation and new projects

Table 2 Commonly quoted factors supporting effective collaboration and obstacles to it.

Factors supporting effective collaboration

Ethos:	Trust, honesty, respect, openness; a sense of joint ownership, with different views taken into account; staff values supporting co-operation; ability to compromise while seeing collaboration in one’s interests
Leadership:	Senior leadership commitment; a clearly identified and realist focus that is predominantly shared; monitoring and evaluation of progress
Activities:	A degree of consensus on the methods that will lead to success; purpose directly connected with needs of specific learners; a focus on goals that individual partners could not achieve alone
<i>Obstacles to effective collaboration</i>	
Resources:	time / distance; lack of funding; costs often occurring before benefits
Leadership:	apprehension of staff not acknowledged; poor communication; silo mentality; unwillingness to negotiate sovereignty
History:	a culture of competition; difficulty of working across old structures

local partnership in which a lead school and several partner schools could work together.

LEPP now connects about 200 lead secondary schools with about 800 partners. Lead schools receive around £60 000 per annum from the government on behalf of their partnership. It is intended that these funds are used to support both innovation and the raising of standards in partner schools. When spread across an average partnership size of four or five schools, this does not constitute a large contribution to school budgets. However, it does enable schools to seed new projects, backfill staff working out of school, and/or to take on coordination costs. With over 200 partnerships, covering about a third of secondary schools in England, LEPP represents a relatively significant systemic commitment.

In 2006, the central leadership of the program was migrated out of the government (and specifically the Innovation Unit) to the Specialist Schools and Academies Trust (SSAT). The Innovation Unit had, perhaps unusually for the government, allowed schools to develop projects organically without much guidance. The SSAT sought to combine this initial mandate with slightly more accountability for partnership progress and a clearer central offer, including national conferences, workshops, online tools, and visits by consultant heads.

This article draws primarily on research with five LEPP partnerships. The research included 1 day at the lead school with semistructured interviews with the headteacher and at least five members of staff and half a day each at two partner schools with interviews with the headteacher, a head of department, and a teacher. Where possible, a collaborative activity was also observed. To test the wider generalizability of the findings, a survey of the 32 consultant heads who make annual visits to all 200 partnerships was conducted. An earlier draft of this article was also presented to a workshop of about 40 school leaders at the 2007 LEPP annual conference in both York and London.

Collaborative Advantage

The partnerships were engaged in a wide range of work, but there were also several important similarities. These included:

- a collaborative ethos, with the majority of lead and partner schools reporting positively on each other's commitment to partnership working and their own willingness to contribute to the partnership's development;
- evidence of trust, with many of the partnerships demonstrating among a majority of schools a relatively high level of trust in one another to deliver their strategic and/or operational responsibilities;
- a history to partnership membership, with previous collaborative work often having taken place between a

number of the schools and with the explicit inclusion of one or more historically lower-achieving schools; and

- a coexistence of the partnership, with a range of other local collaborations that were emerging or ongoing, but that did not necessarily include all of the partnership's members.

There were also a range of positive impacts for professionals from collaborative work in the majority of partnerships. In increasing degrees of collaborative depth, these included:

- improved professional support, with the majority of teachers reporting the benefits of an extended network of curricular-relevant assistance, and heads of department finding a means to overcome isolation;
- increased opportunities to gain inspiration and pool ideas for practice with colleagues in an informal setting and based on professional dialog and judgment;
- professional development in the workplace with the opportunity to generate a wider learning community among staff, and support and coaching for leaders at a variety of levels; and
- the collaborative development of new practice, with not only the transfer or refinement of what was already perceived to be good practice but also the joint identification of challenges and research and innovation to develop responsive practices.

These latter innovative practices coalesced around five main categories:

- The development of new teaching and learning strategies and the use of information and communication technology (ICT) as a support for learning with, for example, podcasts posted on virtual learning environments for gifted and talented students, catch-up, and/or revision.
- Assessment for learning and the use of student data, with work to enable students to access and review their own progress and teachers to analyze attainment data to identify learning needs and review teaching strategies.
- Wider learning pathways for greater student enjoyment and interest. For instance, the collaborative provision of a substantial 14–16-year-old work-related learning offer and vocational qualifications.
- Support, guidance, and re-engagement for students with, for instance, students undertaking learning walks to develop a document for teachers on what they perceived to be effective teaching and learning.
- School organization becoming more responsive to student needs with, for instance, new transition arrangements and a primary link of teacher accompanying student to their secondary school to provide support and parent liaison.

There was some evidence of an impact of these activities on student outcomes. Two forms were most common. First,

a contribution to whole school improvement in a partner school that had previously been underachieving. Where this had occurred, the key strategies stemming from collaborative work that appeared to be most significant were: student tracking and assessment for learning; wider curriculum pathways; leadership support and mentoring; and approaches to challenging low expectations. Second, improved attainment, behavior, attendance, and/or engagement by students in a target group. In these instances, the strategies that had been most effective included: targeting students due to under-performance; supported and mentored small groups; and re-engaged student in new curriculum pathways.

There were some important caveats, however, to these perceived impacts. Identifiable progress was rarely partnership-wide, with usually only some schools moving forward. Where progress had occurred, Leading Edge work was often a contributing factor but it would have been difficult to demonstrate its proportional impact. Where a specific group of students had been targeted, it was rare for all to have moved forward, with (more usually) progress for a majority but less impact for a minority. There was also a range of work for which no improvement in student attainment could be demonstrated. Perhaps the most important reason for this was that the partnerships had initially viewed LEPP as not being bound to the strictures of short-term increases in standards. They had included longer-term challenges or objectives more amenable to professional judgment rather than those judged solely by increases in student attainment (at least in the short term).

Transferring Knowledge and Innovating Collaboratively

Across this range of collaborative work, two main methodological approaches were apparent. The first concerned the direct transfer of practice from a lead to a partner school. This was usually as a direct lever for school improvement, especially in partnerships with lower-achieving schools. This had strong parallels to what Fielding *et al.* (2005) termed the “delivery of ‘validated’ packages of pre-formed practice seen by others to be good for the recipient.” Fielding and co-workers critique such transfer as having “little validity amongst teachers.” However, in the majority of cases where this was occurring, the partner school’s leadership team had actively sought out such support from their lead school. The latter was often trusted and seen as more capable of providing effective solutions than other external advisers. Moreover, rather than simply being a one-off transfer of knowledge, the structure provided by the partnership often meant that this was an ongoing process that included a period of refinement in which transferred practice was developed into the new context. Lead schools also reported benefiting

from such work by, in several cases, reincorporating new ideas back into their own practice.

These were examples of success. There were cases where knowledge transfer had not been effective or sustained in practice. There were also obstacles to transfer. These included:

- a partner school pulling away from collaboration when it experienced difficulties;
- a partner school’s staff not wanting to receive transferred practice and/or considering (rightly or wrongly) the lead school’s practice to (only) be effective when serving students from different (usually more advantaged) backgrounds; and
- the lead school not actively seeking to engage in knowledge transfer and/or the partnership’s culture being at odds with such work.

The second and more typical approach to partnership working was collaborative innovation. This fits well with Fielding *et al.*’s (2005) alternative concept of co-construction and the useful notion of a mutuality of the process of innovation. Here, a range of methods was being employed, including:

- A series of informal planning meetings, with staff from each school researching and discussing new ideas before returning to their classrooms to try new approaches, with feedback given in subsequent meetings.
- Learning walks, as inspired by the Pittsburgh Institute, which included the processes of identifying a focus, undertaking a walk with observation and dialog, giving feedback, and undertaking a project informed by the insights gained. These were used both to look inwards at departmental practices and to system gaze for new ideas and inspiration in other schools.
- Formal research, with teachers encouraged to undertake in-school research to diploma and master’s levels under supervision from university colleagues. Staff often chose subjects of personal interest with a link to the school development plan.
- Innovation trios, where three teachers involved with the same teaching group, but in different subjects, worked to build more effective teaching strategies for the group and support each other in doing so.
- Conferences for staff to conclude and disseminate findings to other staff at the end of a term or project strand.

Across these methods, evaluation of the effectiveness of new practices was predominantly based on professional judgment. This was variously described as: a gut feeling during teaching; the reaction of students as to whether they were engaged; and professional dialog at review meetings. Some went further to structure the use of student tracking into projects as well as more formal reporting. However, a common question many leaders asked was how to maintain authentic professional engagement, and

informal networking, while bringing greater rigor into their approach. In particular, their concern was for evaluating the impact on student outcomes and documenting innovation so that it could be shared at a school level. With some degree of inductive development, **Figure 1** summarizes an emerging consensus across several partnerships about what greater rigor might look like.

The process of collaborative innovation is likely to be far messier in practice. It is also governed by professional judgment and thus the proposed cycle is not conceived as a strict flow but, rather, as a guide with openness to steps being rearranged or leading backwards. Each step is seen, however, to have its own value, with:

- analysis of information – bringing together professional judgment, contextual data, student voice, and/or research evidence to jointly interrogate current practice across the partnership;
- identification of the focus or target group – with collaborative development of aims and methods, be that at a whole-school, departmental, or classroom level, but with a common theme across the partners;
- joint planning of strategies – with time for collaborating teachers and school leaders to come together to plan strategies or interventions;
- experimental implementation in one's own classroom/school – with project members trialing and adapting the innovations in their own contexts;
- peer observation and feedback – with opportunities for individuals to observe each other and discuss their experimental implementation;
- feedback from students – with students engaged either as respondents (through surveys or questioning) or as researchers themselves;
- (back to) analysis of information – with this completion of the cycle focusing on reflection and evaluation of implementation; and

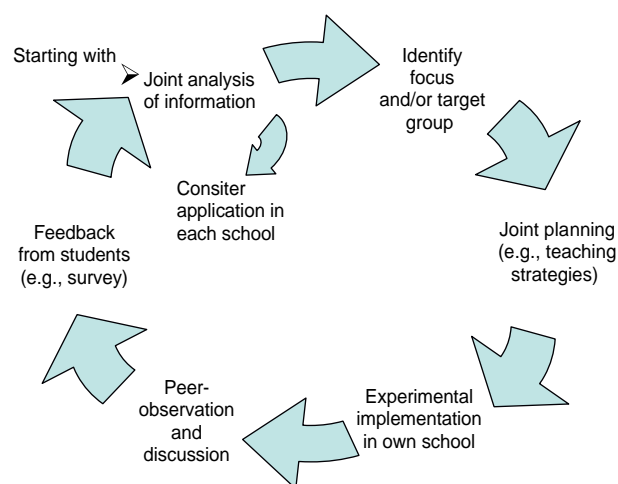

Figure 1 Innovating collaboratively.

- (and then, potentially) a wider applicability within each school – with the sharing of innovation with colleagues and/or the development of new whole-school practices.

This approach, or similar approaches in practice, corresponds well with the research evidence on action research. Kemmis and McTaggart (1988), for instance, proposed a circular planner for action research which comprises the steps: plan, act, observe, and reflect (and back to plan again). (McKernan (1996) proposes a similar but more detailed cycle of: define problem, needs assessment, hypothesize ideas, develop action plan, implement plan, evaluate action, and make decisions (reflect, explain, and understand action).)

Hopkins (2008) proposes a set of principles to guide classroom research by teachers that include:

- that research should not disrupt a commitment to teaching as a primary focus;
- data collection must not be too demanding on teachers' time;
- the methodology employed must be reliable enough to enable the formation of hypotheses and to develop strategies for classroom practice; and
- the research focus should be one to which the teacher is committed.

Leading Innovation Partnerships

These guidelines would have found acceptance among a majority of Leading Edge partnerships. However, there were at least four further factors that appeared important in developing a collaborative impact on student outcomes.

Building Capacity

The partnerships identified a number of collaborative capacity-building components that underpinned their joint work. These included:

- purposefully deploying staff motivated to lead the innovation process;
- supportive relationships, both informal and formal, nurtured by partners;
- well-established systems and procedures for collaboration; and
- the alignment of internal professional development to support collaborative innovation.

Collective practice also required senior leaders to commit existing resources, particularly in the initial years. Delegated funding from government covered some of this, but in the majority of cases, schools also needed to deploy their own resources. This took the form of staff time and goodwill, the use of whole-school in-service

training days, the provision of specific training courses, and, inevitably, staff knowledge, skills, and leadership resources. These investments came with a level of risk given the reliance on other partners. Indeed, each partnership had experienced events that depleted the emerging capacity among schools. These included:

- the unexpected shocks of key staff lost to long-term illness or to career progression elsewhere;
- the unraveling of projects following the arrival of a new headteacher with different priorities;
- the energy drained by a lack of full engagement by one or more partners; and
- the diminishing of trust from the souring of relationships.

New Models of Leadership

In response, the challenge a number of leaders faced, particularly in lead schools, was to become more flexible, more able to engage externally, and less vulnerable to staff turnover or changing priorities. In several more-advanced partnerships, the response could be described as bringing together three relatively common concepts in educational leadership:

- system leadership that, in these contexts, concerned leading beyond an individual school to contribute student outcomes at the wider local level;
- distributed leadership to effectively “orchestrate the skills of colleagues” (Arnold, 2006: 7), draw them into the decision-making process, and build their ability to take on wider leadership roles at the whole-school level;
- leadership of learning with the focus this implies on the classroom and “what constitutes effective learning . . . and how teaching and new technologies are best harnessed to support learning” (Stoll, 2001: 6).

The way these concepts were commonly being brought together is summarized in **Figure 2**.

Lateral Accountability

While leadership development was important in sustaining internal school capacity and partnership working, collaboration had also presented the challenge of holding partners to account. A common concern was that doing so could damage longer-term relationships. These issues were often complex and had emerged over time, including:

- the apathy of one or more partner schools, through absenteeism at meetings and events, or a gradual unwillingness to fulfill agreed actions; and
- to a lesser extent, concern about the ethos of the partnership, including the approach and focus of work, a perceived lack of support from the lead school, or

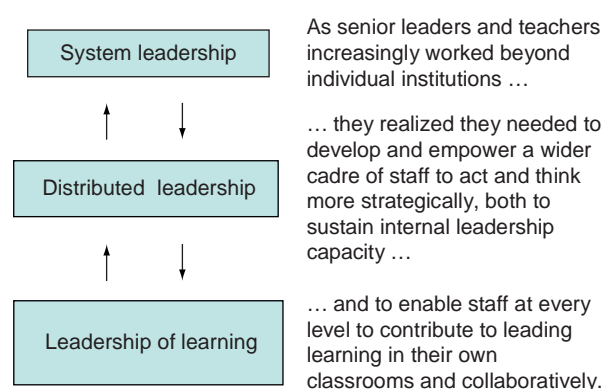

Figure 2 Leadership for collaborative capacity building.

uncertainty about how LEPP funding was being deployed by the lead.

For several partnerships, the solution lay in clearer lateral accountability. Invariably, this meant clearer expectations on issues of engagement and on developing benchmarks for progress. The strategies being developed by partnership leaders, either individually in lead schools or collectively with partner schools, included:

- more flexible involvement in specific activities, with not all schools needing to engage in every project;
- clarification of expectations with, at the most unambiguous, a minimum number of agreed yearly activities to be undertaken by each school;
- the holding back of LEPP funding by the lead school where specific actions had not been completed by individual partner schools; and
- inactive partners being left out when the partnership changed focus or moved to a new phase (e.g., following redesignation of the lead school).

Partnership Ethos

Perhaps the most powerful form of lateral accountability, however, was a widely shared collaborative ethos for mutual improvement. This was the conviction that partnerships should be collegial and have an impact on the identified needs of all partners. This did not imply an abdication of leadership by the lead schools. In most cases, they set the agenda for the partnership, usually collaboratively. It did concern moral purpose and a willingness to share expertise and resources, particularly with partners in need. This is not solely about the distribution of delegated funds. Rather it equates more directly to whether a partnership enables the full involvement and ownership by partner schools, how capacity for progress is built in practice, and, ultimately, whether student outcomes are improved.

Conclusion: Collaboration and Improvement

Enhancing learning and teaching remains a key priority for schools. Trends toward personalizing learning to individual student needs and interests, coupled with a greater responsibility for student well-being, represent real challenges for schools and their leaders as they attempt to continue to raise school standards and offer a broad, balanced, and engaging education. This article has explored how school-to-school collaboration might offer part of the solution. In particular, it appears collaboration can help to:

- build professional learning communities, within and across schools, that develop and widen learning and teaching strategies to respond to a range of student learning needs;
- use the full potential of school workforces to share and innovate practice, create new curricular and learning pathways, and extend services;
- develop new models of leadership to appropriately distribute an increasing range of responsibilities to a wider and differentiated pool of expertise; and
- impact on student outcomes, either for a targeted group of students or at a whole-school level, particularly in lower-achieving schools.

In partnerships where there is less willingness to work for the success of other partners, such collaborative advantages remain difficult to achieve. In cases where there is a lack of leadership capability or whole-school capacity, collaborative progress can be made, but it may often be a harder task and/or less widespread across the partnership. Where progress is made, it appears to be correlated with more advanced partnership organization, the fuller involvement of partner schools, and increasingly rigorous methodologies for collaboration. In the case of Leading Edge, the thrust for such effective collaboration is usually provided by the lead school's leadership team. However, partner schools are also involved, either in what one might call system working, as a spur to improve their own provision, or more directly in collaborative leadership.

Studies of School Improvement in Developing Countries

S E Anderson, University of Toronto, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

School effectiveness and improvement is an international preoccupation. Parents everywhere pin their hopes for the future economic well-being of their children on their participation in formal schooling. National governments see participation in primary and secondary education as vital to economic development, social welfare, and civic engagement. International agencies, such as the United Nations Educational Scientific and Cultural Organization (UNESCO), the World Bank, and many government sponsored and nongovernmental international development-aid organizations direct attention to the role of schools not only as key contributors to regional economic and social development, but also as critical players in the resolution of critical cross-national issues of poverty reduction, public health, and human rights. Concerns about school improvement arise not merely from common beliefs about the role and importance of schools in ensuring the quality of life, but also from the recognition of wide variation in the degree to which all schools and school systems are fulfilling these public expectations.

This article provides an overview of some key historical trends in approaches to and in the study of school improvement in developing countries over the past half century, including: basic resource-capacity building; the adoption and implementation of changes in curriculum content, materials and teaching strategies; changing the support system for improvement; decentralization and school-based management (SBM); school choice; and comprehensive school reforms. The article focuses on the knowledge base for improvement at the school level. It does not address country-level indicators of education quality and improvement, such as those generated by aggregate scores of student academic performance on international tests of literacy and numeracy, or through national statistics on access, attendance, retention, and completion rates. Nor does it take up initiatives focused primarily on improvement in initial-teacher-education programs.

Basic Resource-Capacity Building

Although there are disparities in material and human-resource inputs among schools in the developed world, basic inputs are essentially guaranteed in both public- and private-sector schools. Students are not sitting on the ground in the open air or forced to share desks with 50–100 peers in poorly ventilated classrooms originally built for 30 students. The students have access to textbooks and a supply of supplementary learning materials (e.g., school

libraries). They are not learning simply by copying and reciting what the teacher says or writes on a chalkboard that serves as the primary material instrument of teaching and learning. Sanitary toilets and running water are available for the children and teachers. The teachers have more than a primary or secondary school education, and the vast majority are professionally trained and certified to teach. Teachers are regularly paid. While conditions have improved since the middle of the twentieth century, in many developing-world contexts, school-improvement efforts are still heavily focused on building adequate facilities, getting appropriate and sufficient teaching and learning materials into the hands of teachers and students, and making sure that teachers have sufficient subject-matter content knowledge and teaching skills to guide the students' learning. Unfortunately, this situation has been exacerbated by international efforts to achieve universal access to free quality primary education by the year 2015. In Uganda, for example, primary school enrolment more than doubled from 3 million to 7.3 million after the government adopted its Universal Primary Education policy, while in Malawi, enrolment rose from 1.9 million to 2.9 million in response to the government's free primary education policy in the 1990s.

Comparative research in developing countries on student participation and achievement in schools that vary in the availability and quality of these kinds of inputs show, indeed, that the provision of basic material and human-resource inputs does make a difference to school effectiveness (Fuller, 1987; Lockheed, 1993; Reynolds, 2000). While satisfaction of basic resource needs is a key factor in the overall level of student learning in schools, it does not guarantee high-quality student performance, or equity in the quality of performance across schools within a school system. The problem and challenge then becomes one of finding ways to continue to elevate the standard and levels of student learning for greater numbers of students and more and more schools. The remaining approaches to school improvement reviewed here highlight strategies intended to enhance the quality of teaching and learning beyond that attained by ensuring basic resources.

Adoption and Implementation of Changes in Curriculum and Instruction

This approach to school improvement is premised on the idea that the quality of learning outcomes is a function of

the quality of the curriculum content, teaching and learning materials, and instructional practices that teachers put into practice. Thus, the way to make schools more effective is to replace or supplement existing curriculum content, materials, or teaching methods with others thought to be of higher quality, or perhaps a better fit to local needs and contexts. The new instructional programs, materials, and methods are typically developed and disseminated by external experts (government agencies, textbook publishers, university professors, aid agencies, etc.). In theory, the quality of education in schools will incrementally and cumulatively improve as a result of implementing new programs and practices often limited to particular subjects or grades at a given time. Scholars of educational change characterize this as the innovation adoption and implementation approach to change (e.g., Fullan, 2001).

Research on the process and outcomes of innovations in curriculum and teaching in schools demonstrates that neither the form an innovation takes in practice nor its effects on student learning can be predicted from the characteristics of the product or practice as originally adopted. Some innovations never actually get implemented, especially when support for their use in the form of teacher training and assistance, material resources, funding, time, and supervision is lacking or poorly planned and executed. Typically, when new programs are put into practice, the implementing educators modify the innovations in response to unique needs and conditions of their local context or to more closely resemble what they were doing before. Education change theorists refer to this as mutual adaptation. Researchers have also found that when innovations are implemented, there is no guarantee that their use will be sustained over time. The lessons of research on both positive and negative instances of innovation implementation in schools are well reviewed and reported (e.g., Fullan, 2001; Hall and Hord, 2006). The key to successful implementation of changes in curriculum content, materials, and teaching methods lies partly in the quality and practicality of the innovations and their fit with local needs and context, but most importantly, in the effectiveness of the support provided by school-system authorities and other external change agents to those expected to put the innovations into practice (e.g., resources, initial and continuing training, supervision, and incentives). In studies of innovation adoption and implementation, improvement is often equated with evidence that the changes are being used as per the developer or policymaker's intent, rather than with reliable measures of impact on student learning at either the individual student or school levels. That said, the adoption and implementation of discrete new programs and practices are fixtures in the educational change and school improvement landscape, although often embedded within other conceptions and approaches to school improvement as described in subsequent sections of this article.

A distinct history of educational innovation and research in the developing world began in the 1970s (Havelock and Huberman, 1978). Early educational improvement work in the developing world often exemplified the innovation adoption and implementation approach to change (e.g., Verspoor, 1989; Lewin and Stuart, 1991). Verspoor (1989), for example, analyzed 21 high-outcome education improvement projects selected from a sample of 282 World-Bank-funded projects between 1963 and 1984 in Africa, Latin America, South Asia, and Asia. His findings echoed findings on innovation implementation elsewhere. In-service teacher training, for example, was critical to implementation success, and effective teacher-training designs provided local training (at the school or school-cluster level) to support implementation of change programs, with regular classroom visits, support, and assistance from supervisors and program staff. Some of Verspoor's findings foreshadowed later trends in approaches to school improvement. More successful projects combined project assistance with interventions to develop the capacity of education systems to plan, coordinate, monitor, and support innovation on a continuous basis. He also found that change projects that focused on a single component of education provision (e.g., curriculum, teacher training, school management, and material resources) had lower outcomes than projects that addressed multiple components in a coordinated manner. Finally, Verspoor described four pathways to change: progressive innovation (multiple linked innovations introduced over a period of time); incremental expansion (innovation introduced in a small number of settings with gradual increase in the scope of use); discrete change (isolated projects in limited settings and uncoordinated with other projects); and permanent pilot (an experimental program that never gains political support and resources for broader use). While not discounting the benefits for the few schools involved, discrete change and pilot projects remain a common phenomenon in the developing world, often linked to efforts by nongovernmental organizations (NGOs) to stimulate and model innovations in curriculum, teaching, and learning (e.g., Anderson, 2002). This has contributed to a major preoccupation by governments and aid agencies with how to scale up and sustain successful small-scale changes across the larger system.

Changing the Support System for Innovation

The realization that change and improvement do not happen simply by presenting school personnel with new programs, materials, and introductory training workshops, has led government and other education-change agents in developing countries to experiment with alternative organizational systems for supporting the implementation of change in curriculum and instruction. These efforts to

change the ways innovations in teaching and learning are professionally supported represent another approach to school improvement, though they are often instituted in conjunction with particular pedagogical change initiatives. Many of these changes focus on alternative in-service teacher-development processes, such as school-based action research, peer coaching, mentoring of new teachers, or structured opportunities for joint work among teachers focused on sustaining and improving the quality of teaching and learning (see Shaeffer, 1990, for overview of participatory approaches to teacher development and the section titled 'Further reading' for examples of research on specific strategies in developing-country contexts). These kinds of changes often do not require change in organizational policies and structures so much as a shift from reliance on periodic external workshops and courses to more school-based and collegial means and norms of ongoing professional learning. In-service teacher-development projects involving nontraditional teacher-learning strategies are often reported as discrete initiatives affecting a few schools, rather than as school district or broader-system initiatives with reliable indicators of their impact system wide on school improvement.

Other support system changes involve the creation and implementation of new organizational structures designed to enable more sustained introductory and follow-up support to school personnel involved in change. In developing countries, intermediate levels of educational organization similar to school districts in the United States and Canada, or local education authorities in England, often operate as a bureau of the municipal government whose primary purpose is to manage the flow of funds, resources, and information from central government agencies to schools, to hire and appoint school personnel, to carry out formal school-supervision procedures on behalf of the government, and to oversee public-school examination processes. They often do not have the professional capacity or explicit function of support for school improvement. In rural areas, the working relationships and communication between district and school educators may be further complicated by poorly kept roads and lack of transportation.

Two organizational support system innovations that have been experimented with intermittently in developing countries over the past quarter of a century are teacher centers and school clusters. Teacher centers are distinct facilities typically staffed by one or more government-appointed master teachers. They are often set up in unused portions of a school. The centers serve as sites for workshops and other professional-development events run or organized by the center staff for schools within a designated catchment area accessible to neighboring schools by foot or public transportation. They are typically expected to maintain professional libraries for teachers, and may provide materials and facilities for teachers to

come individually or in groups to create learning materials. Teacher centers are administered by local management committees that represent the schools and any partner organizations (e.g., local teacher's college). Teacher centers were popularized in East Africa with support from the British Council in the 1980s and 1990s. In Kenya, for example, several hundred primary school teacher-advisory centers were created, though the central government has had persistent difficulty developing and sustaining the operational capacity of the centers to support schools (for an overview of the East African experience with teacher centers see Knamiller *et al.*, 2000). The school-cluster approach is similar. It involves a local network of neighboring schools which are expected to work together on an ongoing basis on curriculum and teacher-development initiatives. One of the schools, however, is typically designated as a lead or coordinating school for organizing and hosting cluster activities, and for facilitating contacts with external administrative and support services from government agencies, teacher-training institutions, and education-focused nongovernmental aid organizations (for an example of a school cluster-based support system see Tsang and Wheeler, 1993).

The cascade model for introducing large-scale changes in curriculum and teaching at the national level has been commonly practiced and reported in developing countries. In this approach, governments set up and implement temporary systems through which a core group of experts involved in the development of the programmatic change at the national level introduce and train regional teams in the content of the change and expectations for practice. The regional teams are responsible for replicating the introductory training processes with selected trainers at a more local level, who then deliver the introductory training to key school personnel, which finally cascades down to program delivery by these key teachers to the targeted implementers in the school (e.g., for an application of this model see Ibrahim, 1991). While the cascade approach works in a way as a mobilization strategy for delivering and creating some basic awareness and knowledge of new programs and practices at a large scale, the emphasis is on getting an innovation into the hands of those expected to put it into practice, not on providing ongoing support and expertise during implementation. The model needs to be combined with local organizational designs for continuing support and expert assistance at the school level.

In sum, as noted by Verspoor early in the history of school improvement efforts in developing-world countries, one of the major obstacles to improvement has not simply been the provision of basic resources, and high-quality programs and teaching methods, but also the creation of sustainable support systems capable of providing effective professional assistance to schools. Some of the difficulties of integrating new support system

positions and organizational structures into existing government-regulated administrative structures and norms at the local level are illustrated in a book of case studies of school district-level school-improvement initiatives sponsored by an international NGO in East Africa (Anderson, 2002).

Decentralization and SBM

Decentralization trends are premised on the belief that centralized control and regulation of economic activity and social services by government authorities inhibits organizational effectiveness. Decentralization policies have been strongly advocated by some international donor agencies that are key actors in providing aid to developing countries, such as the World Bank. Decentralization trends extend beyond education to all sectors of government-regulated economic and social services activity. In education, the push toward decentralization has manifested itself in two key ways. One is to adopt policies and organizational arrangements that devolve more decision-making authority for school management, improvement, and in some cases, funding, to the local level. The second is to create a more competitive marketplace of schools characterized by greater school choice and privatization (see the next section of this article).

The SBM approach to school improvement, often referred to as a form of restructuring, became popular in the 1980s and 1990s. Proponents of this approach argued that the needs and circumstances of schools were too varied to mandate a single solution and plan for improvement, and that schools were constrained from innovation by education bureaucracies and policies that required standardization in structure and practice (for overviews of the restructuring movement see Elmore, 1990). They further held that the solution was to allow school-level stakeholders (e.g., educators, parents, and taxpayers) greater freedom (and responsibility) to determine their needs for improvement, as well as greater control over the use of resources (e.g., money, staffing, and time) and organizational arrangements (e.g., professional roles and duties, decision processes, and grouping of students and teachers).

In North America and other developed countries, advocates of SBM have argued that this approach honors the professional expertise of those working closest to the problems of teaching and learning to determine what and how to improve. SBM policies and initiatives typically consist in requiring schools (often on a voluntary basis) to establish school teams of administrators, teachers, and parents to produce school-improvement plans. Sometimes, this is accompanied by waivers that permit the schools to opt out of certain school district and government-policy regulations. Government policies mandating the establishment of school councils dominated by parent and

community representatives, not by teachers and principals, are another common approach to SBM. The logic of improvement differs from the professionalization arguments, because this strategy shifts greater power and authority over school decision making to school clients not to education professionals. In practice, many of these policies, at least in North American schools, only assign an advisory role to school councils, reserving management decisions (e.g., hiring principals and teachers or allocating school budget) and educational decisions (e.g., school goals or program change) to professional educators. A decade of experimentation and research on SBM in North American schools yielded little evidence that SBM strategies in and of themselves made any significant difference in school effectiveness in the short or long term on a recurrent basis (Leithwood and Menzies, 1998).

SBM initiatives in the developing world have placed more emphasis on strengthening parent and community influence on school decision making than on expanding the scope of authority of school personnel (for syntheses of research see Task Force on Education and Gender Equity, 2006, United Nations Millennium Project). The arguments for increased local control center on increasing parent and community pressure on school personnel to carry out their duties in a professional manner, enhancing parental commitment to sending the children to school, and strengthening parental involvement in managing and perhaps supplementing school funding. This typically takes the form of school-management committees that are formally empowered with decision-making authority over staffing (hiring and firing of principals and teachers), teacher supervision, school finances, school maintenance, and to a lesser degree, curriculum and instruction. When the right to hire and fire teachers (and principals) shifts from education authorities to school parents, research on decentralization effects shows improvements in teacher attendance. When parents take responsibility for the management and upkeep of their children's school, they are more likely to ensure regular attendance. Use of funds for the purchase of school resources is more likely to happen when parents have ways to ensure that principals are accountable for funding. It stands to reason that student achievement will improve if teachers are consistently on the job teaching, if students regularly attend classes, and if school funds are transparently spent on essential teaching and learning resources. It is not the act of decentralization, however, that improves schools, but the quality of implementation at the local level, including supports such as management training for school committees. Schools operating under SBM systems can be run just as ineffectively as schools operating under more centralized policies and systems. Finally, there is little research on the impact that decentralization through SBM has on school quality and improvement over time. Local parent/community management may help raise the baseline level

of school performance, but does not guarantee ongoing improvement unless combined with measures that more directly affect the quality of teaching and learning.

School Choice and Privatization

School choice is a cover term that encompasses an array of strategies and policies based on the premise that competition for clients (students and families) among schools would compel school personnel to find ways to get better at what they do. The literature on school choice identifies two key policy strategies:

1. Public choice refers to the provision of greater choice among schools in the public sector through such mechanisms as open enrolment among schools within or between school districts; access to alternative schools or programs serving students with special needs or interests (e.g., arts or technology); and parallel publicly funded school systems based on religious preferences or language of instruction.
2. Market choice refers to the use of funding mechanisms such as educational vouchers and tax credits to create competition between public and private school providers for students and government funding. Of these, voucher programs are the most widely known, implemented, and debated. The idea is that a government allocates a voucher worth a set amount of dollars per child, that parents choose where to send their children from an open market of public and privately managed schools, and that government funding follows the child to the chosen school. In theory, a voucher system would lead schools to compete for students and dollars in order to survive and thrive in the education marketplace. School-choice policies are silent, however, on what mechanism and knowledge schools might use to respond to the pressures to improve.

School-choice programs have been widely debated, but only implemented on a large scale in a relatively small number of developing and developed countries (see Plank and Sykes, 2003, for overview of choice policies and case studies from Chile, South Africa, China, New Zealand, Australia, England, Sweden, the Czech Republic, and Hungary). In Chile, for example, since the 1980s, the government has funded a national voucher program whereby a set amount of money is allocated per pupil, and students can elect to attend either public schools or private schools (except those that charge tuition). Funds are allocated based on enrolments and actual attendance. Findings from research on the implementation and outcomes of strategies for school choice (e.g., vouchers or open boundaries) internationally are ambiguous and do not generally support the claim that increased market-oriented choice strategies lead to more effective schools

overall. It is not uncommon to find that schools of choice modestly outperform and cost less than mainstream public schools (the former may not offer same pay scale and benefits to teachers as public schools); however, the effects of greater choice are found to exacerbate the problems of low-performing schools often serving the most socioeconomically disadvantaged communities. More academically motivated students (whose parents tend to be more educated and to have higher aspirations for their children) and wealthier families are most likely to exercise choice options, leaving the source schools with an even greater proportion of hard-to-serve students, with fewer funds to do it, and with reputations guaranteed to deter recruitment of quality teachers. Competition for admissions may also lead higher-performing schools to restrict entry to the academically strongest applicants, creating an illusion of school improvement that is really more a function of student selection than of organizational strategies to improve existing practices.

The issues of choice are more salient and complicated in developing countries where extremely large numbers of private schools may account for a substantial proportion of available primary and secondary schools (e.g., see Srivastava and Walford (2007) for an overview of issues and studies of private schooling in developing countries). Tooley and Dixon (2007), for example, share findings from a comparative study of private-education provisions in low-income communities in Nigeria, Ghana, India, and Kenya. They report startling statistics on the number of children enrolled in private schools, including surprisingly large numbers of nonsubsidized and nonregistered schools. In the Lagos State, Nigeria, for example, 34.3% (185) of schools in low-income areas were publicly funded government schools, while 65.75% (355) were private unaided schools. In Hyderabad, India, 65% of children in low-income areas were reportedly attending private unaided schools. These numbers pale in comparison to the situation in Bangladesh where a parallel system of private schools in low-income communities run by a large NGO (Bangladesh Rural Advancement Committee (BRAC)) operates over 30 000 community schools without government aid. While some developing countries have created policies to encourage and even subsidize private-school alternatives to government-run public schools, this is happening more because the public demand for universal primary and secondary education outstrips the government financial and resource capacity to provide, not as a school-improvement strategy. Comparative studies of outcomes and costs of government and private schools tend to support the case for higher-quality outcomes in the private-sector schools. Some would argue that the main role of government should be limited to establishing common expectations for student learning outcomes, and to creating school accreditation and accountability systems, leaving responsibility for the actual delivery (and perhaps even

funding) to private providers and their clients. The moral issues and controversy surrounding the growth of private education providers (regulated and unregulated, for profit and philanthropic) are too complicated to attempt to cover here. It will suffice to note that some observers maintain that government-run school systems in many developing countries have proven themselves persistently ineffective, inefficient, and incapable of achieving quality education on a large scale, and that the only viable alternative to improving the quality of education is to support the increasing privatization of primary and secondary education. Complete privatization, thus, represents a more drastic form of decentralization than SBM of public schools, and a more drastic version of choice than that envisioned and embodied in voucher and government-subsidized private-school policies and options.

Comprehensive School Reform

The comprehensive school-reform (CSR) movement emerged in the United States in the 1990s (Murphy and Datnow, 2003). The basic idea is that change has to be whole school, involving all participants, and the improvement process needs to encompass a comprehensive array of interrelated factors – for example, program (curriculum, materials, and program structure), teaching methods, school management and leadership, teacher development, funding, parent involvement, monitoring, and evaluation (echoing Verspoor's arguments from back in the 1980s). A CSR model provides a blueprint, process, and support system for school development across multiple components of school governance, teaching, and learning. The models identify themselves with a brand name, such as Success for All, Accelerated Schools, the Coalition of Essential Schools (Murphy and Datnow, 2003). In the CSR approach to school improvement, individual schools voluntarily choose to adopt and implement a CSR model (which may come with requirements for additional funding). School personnel receive implementation training, on-site assistance, and program materials from the model developers, which may be NGOs or based in universities. CSR schools become members of networks of schools using the same model, and the model developers facilitate information sharing and assistance across the network. The CSR developers and networks function like a kind of alternative but dispersed school system. The technical capacity and expertise of formal school district or government education agencies to programmatically support these schools, however, is unclear. While the evaluation research evidence shows variable impact of different CSR models, the CSR approach to school improvement fares better than the other approaches to school improvement reviewed here when outcomes are considered on a school-by-school basis. As

an approach to improvement at the school-system level, however, it is problematic due to its reliance on voluntary participation by individual schools, and due to its uncertain fit with government-mandated program expectations and government-managed support and accountability systems for improvement.

Independent of these developments in the US, similar programs of CSR with similar tales of success have evolved in various regions of the developing world, though descriptive and evaluative research on these models of schooling and school improvement is not readily accessible (see Further Reading for specific reports on the examples listed below). The two best known are *Escuela Nueva*, which began in Colombia in 1979 and has since been replicated in Central America, and the BRAC network of community-based schools in Bangladesh. Other CSR models have emerged elsewhere in the developing world. The Aga Khan Foundation, for example, sponsored the evolution of a whole school-improvement program (SIP) through a series of school-improvement initiatives in East Africa beginning in the mid-1980s and extending into the current century (Anderson, 2002). In Northern Pakistan, faculty from the Aga Khan University Institute for Educational Development created a Whole School Improvement Program (WSIP) that operates in a network of government and NGO-sponsored schools in predominantly rural and remote mountain communities. An international NGO, Save the Children, has sponsored community schools' initiatives in Mali, Malawi, Ethiopia, and Uganda since 1988. In Chile, *La Fundación Chile* has sponsored the implementation of a CSR model called *Mejor Escuela* in about 50 high-poverty low-performing schools with clear gains in student outcomes in participating schools. Farrell (2002) provides a comparative perspective on the emergence of alternative models of schooling that have yielded positive student-learning results in these and other regions of the developing world. In sum, the CSR approach to school improvement represents another active and promising approach to school improvement in the developing world. CSR programs and networks, however, typically depend on external nongovernmental funding sources and technical assistance (even when implemented in publicly funded schools, not just when set up as independent schools). Cooperation and coordination between public school systems and the CSR networks can be politically, financially, and logistically problematic.

Conclusion

During the latter half of the twentieth century, many developing-world countries were just beginning to create mass public-education systems. The predominant initial concern in these contexts has been to develop the material (e.g., school buildings, curriculum, and instructional

materials) and human-resource capacity (e.g., trained teachers, educational managers, and supervisors) to deliver public primary and secondary education on a large scale, and to extend access to that education to all children (e.g., urban and rural, boys and girls, rich and poor, and majority and minority cultural/linguistic groups). Resolution of the fundamental material and human-resource-capacity issues remains an enduring challenge in many areas of the world in the context of ongoing national efforts to extend universal access to primary and secondary education, and in the face of regional conflicts and other humanitarian crises (e.g., the human immunodeficiency virus (HIV) AIDS epidemic in Africa or natural disasters) that disrupt the continuity and provision of basic education to children on a large scale.

In addition to investments in the basic infrastructure for and access to primary and secondary school education, national governments with assistance from international and local stakeholders and donor agencies have undertaken various policies and programmatic approaches to improve the quality of primary and secondary education. This article provides an overview of six common approaches to school improvement in developing countries: basic resource-capacity building, adoption and implementation of changes in curriculum and instruction, changing the support system for innovation, decentralization and SBM, school choice and privatization, and the creation and implementation of CSR models. While these are conceptually distinct approaches to improvement, in practice they frequently overlap. CSR models, for example, require the adoption and new programs and practices (the innovation adoption and implementation approach). School choice and privatization overlap with policy trends toward decentralization. Changes in organizational support systems for change are necessary for effective implementation of programmatic changes in curriculum and teaching, and different strategies may be required to provide effective assistance for continuous improvement in centralized and decentralized systems. While research on school improvement has yielded a substantial knowledge base for how to improve teaching and learning at a classroom and on a school-by-school basis, application of this knowledge at a large scale remains a daunting and ongoing political and practical challenge.

Sustainable Educational Reform

A Hargreaves, Boston College, Chestnut Hill, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

This article discusses the nature and importance of sustainability and unsustainability in primary and secondary education and in educational reform. It provides a definition of sustainability and contrasts it with synonyms and analogs in the field. Three historical and sequential ways of addressing the challenge of sustainability over the past half-century are reviewed – along with their strengths and limitations – and then principles of sustainability that define a fourth age of educational change are defined, described, and exemplified.

Education for Sustainable Development

Sustainability and sustainable development have two prime uses in educational change. The first use – and the chief focus of this article – concerns the sustainability of particular changes and also of broader change processes, especially in terms of whether these changes last or spread. The second use is connected more closely and obviously to the original meanings of sustainability and sustainable development. This section deals with the more obvious aspects of educational and environmental sustainability prior to linking them to the ensuing issues of human and organizational sustainability.

The global crisis of climate change has brought the ecological aspects of sustainability to the forefront of almost everyone's attention (Giddens, 2009). One educational response to these issues has been the emergence of Education for Sustainable Development (ESD). In some respects, ESD is a re-working of environmental or global education – teaching young people about the environment's interconnectedness and how to care for it. It has spawned initiatives in ESD curriculum, and in movements to build sustainable or green schools that promote innovative architecture, prudent and responsible use of energy, and environmental practices such as recycling, throughout the school's community. Influential advocates and intellectuals, such as Senge (forthcoming), point to the necessity of schools and young people engaging in real-world environmental activism to develop the systems-thinking that enables and empowers them to act as informed, concerned, and committed citizens in an imperiled world.

International organizations, such as United Nations Educational, Scientific and Cultural Organization (UNESCO), advocate for an even more inclusive approach to ESD that encompasses the needs of sustainable communities as well as natural environments – communities characterized by

gender equity, multicultural inclusiveness, the rights of basic education for all, elimination of poverty, and so on.

This essential understanding of ESD makes clear that sustainability of the natural environment cannot be disconnected from social justice in the organizational and human environment. ESD is not just a prelude or sidebar to the discussions of organizational sustainability that concern the endurance and spread of reforms. It strikes at the nature and effects of those reforms themselves. Thus, reforms that restrict the curriculum or standardize teaching to such an extent that the enriching, engaging, and empowering elements of ESD are sacrificed to raising test scores in the basics of literacy and numeracy at any cost are inherently unsustainable – whether or not they endure or last – for they transgress the fundamental purposes and principles of sustainable development in learning and life.

In this respect, it is important to recall and renew the ethical and environmental origins of sustainability and sustainable development. In the early 1990s, Lester Brown founded the World Watch Institute and defined a sustainable society as one that is able to satisfy its needs without diminishing the opportunities of future generations to meet theirs. The later idea of sustainable development was historically defined by the Brundtland Report of the World Commission on the Environment and Development as the ability to “meet the needs of the present without compromising the ability of future generations to meet their own needs” (World Commission on Environment and Development, 1987). Adapting this original definition, Dean Fink and this author developed the first body of work that theoretically elaborated and empirically supported a definition and philosophy of sustainability in education and educational change:

Sustainable educational leadership and improvement preserves and develops deep learning for all that spreads and lasts, in ways that do no harm to – and, indeed, create positive benefit for others around us – now and in the future (Hargreaves and Fink, 2003). Michael Fullan's *Leadership and Sustainability* (2004) sees sustainability as the link between systems thinking (grasping the interconnectedness of things) and moral purpose (taking responsibility for the connections) (Fullan, 2004).

The remainder of this article uses these definitions and the associated ideas of ESD as touchstones to review historic changes in educational reform strategy and its varied approaches – and failure – to achieve sustainability. It then identifies and exemplifies seven key principles of

educational sustainability in the emerging reform era and considers their implications for the future of educational change.

Three Ages of Unsustainability

In the 1960s and early 1970s, an age of innovations in curriculum programs, innovative schools, and open classrooms was stimulated by the US response to Sputnik and the need for more advanced teaching and learning in mathematics and science. Research on educational change, during this period, primarily examined what happened to innovations as things, and how they could be spread or diffused from central scholarly experts to educational practitioners. However, it was discovered, knowledge was rarely utilized in a rational way. People assigned their own meanings to innovations depending on the parts of it they experienced and the sense they made of the innovations in relation to their own roles and background experiences. The same innovations were assigned very different meanings according to the characteristics of users (Louis, 1998) and of users' social networks. Innovative schools are subject to the same fate. Typically, innovations fade, lighthouse schools lose their luster, and attempts to spread initiatives across a wider, more skeptical system – scaling them up – meet with little success.

As a result, the focus of educational change shifted from orchestrating the rational mechanics of dissemination and diffusion, to understanding the meaning of change for different participants and finding ways to manage that meaning (Fullan, 1982).

The inconsistencies of the *Age of Innovation* were, therefore, followed by a quest for purpose and coherence, and for managing the meaning of educational change in order to increase commitment to it. Sustainability – as we might now see it – was approached by the attempt to develop common meaning. First, there was an attempt to set out some central principles, parameters, and even broad standards of educational purpose that provided stronger direction while still allowing professionals to exercise discretionary judgment in how these purposes were interpreted.

Second, there were efforts to restructure the roles and responsibilities of schooling to reduce the restrictive effects of bureaucracy, to create more incentives for school-based initiative, and to reconfigure teacher interactions so they crossed traditional boundaries. Decentralized decision making, magnet schools, and charter schools were devised as ways to raise achievement for the children of aspirational families and to release schools from the one-size-fits-all controls of administrative bureaucracies and teacher unions in local school districts.

However – for the classroom teacher – this combination of centralized frameworks and initiatives with

decentralized roles and responsibilities often seemed bewildering. Portfolio assessments were paralleled by standardized tests. Interdisciplinary initiatives ran alongside subject-based report cards. Magnet schools targeted to particular populations also had to include others with special educational needs to meet federal civil rights guidelines. Teachers, in some schools, succeeded in maintaining their missions while still addressing the standards and accommodating to the structures. Many others, however, were fragmented and frustrated. The problem was not the structure, but the culture of teaching.

The third element of educational change in this period, therefore, was one of reculturing the working relationships among teachers, and managing the meaning they attached to teaching, learning, and school reform. In first devising and defining the concept of reculturing, this author contrasted it with restructuring in terms of its focus on rules and relationships rather than roles and responsibilities (Hargreaves, 1994). Reculturing is more about the meaning of change than its technical mechanisms. It is a response to long-standing concerns with the traditional culture of teaching characterized by noninnovative cultures of conservatism, individualism, and presentism – a fixation on the short term (Lortie, 1975).

Reculturing has promoted more teacher collaboration and inquiry. Collaborative cultures are generally associated with increased student success and improved retention among new teachers. They provide the mutual learning and moral support that stimulate teachers and sustain them through the difficulties of change.

In the end, however, reculturing failed to achieve consistent success or sustainability because of inconsistent leadership and insufficient emphasis on results. Under strong and effective leadership, collaborative cultures could make sense of complex purposes together and make sure that joint professional efforts led to improved outcomes in learning and results. Under weak or ineffective leadership, however, collaborative cultures were not always connected to learning and achievement and, under autocratic leadership, mandated coaching and collaboration often turned genuine teacher inquiry into rituals of contrived or enforced collegiality that actually made teachers inclined to collaborate less (Hargreaves, 1994).

Frustrations with the technical strategy of planned diffusion, and the cultural strategy of developing shared meaning, led to a more politically driven *Age of Large-Scale Systemic Reform* characterized by centrally coordinated prescription, control, intervention, and accountability.

Michael Fullan heralded the return of large-scale reform (LSR) at the turn of the century (Fullan, 2000), but it had already had more than a decade's track record in many Anglo-American nations where schools were, increasingly, placed in a competitive system of market choice for students and their parents, in relation to more-and-more detailed standards linked to high stakes

tests that were widely publicized in league tables of performance and, often, combined with weakened levels of resourcing, as well as impossibly accelerated timelines for implementation. This political strategy of educational change was, subsequently, also adopted within the bipartisan, federal No Child Left Behind (NCLB) legislation in the US.

In the Age of LSR, the benefits of sustainability-as-spread were evident in the emergence of clearer focus, greater consistency, and attention to all students with a stronger sense of urgency. However, many negative effects of unsustainability were evident beyond the criterion of spread. Achievement gains often occurred for a year or two in most cases, but then soon reached a plateau. Parents had more choice, but it was the affluent ones who knew how to work the system to advance their interests and protect their privileges. Standards raised the bar but shortfalls of professional support did not help children reach it. As measures of performance rose in tested literacy, rates of reading for pleasure actually fell. The costs to the quality, depth, and breadth of children's learning to increased dropout and reduced innovation, as well as to the caliber of teachers and leaders the profession could recruit and retain, were considerable (Hargreaves, 2003).

In response to these limitations of unsustainability, a revamped version of LSR – or LSR 2.0 – was launched instead (Barber, 2007; Hopkins, 2007). LSR 2.0 is even tighter in its imposition of ends, yet considerably more flexible in the orchestration of means.

In LSR 2.0, government establishes a small number of specific goals – such as the closely specified “Adequate Yearly Progress” indicators in the US, or system-wide literacy and numeracy targets in Ontario and England – and provides greater oversight at every level in their prescription and pacing. Test-score data are the focus of professional learning communities of inquiry in schools and districts that identify gaps and inconsistencies and design interventions accordingly. Collegial coaching and leadership supervision through walk-throughs and other methods provide technical support to teachers while also ensuring they comply with or demonstrate fidelity to the reforms. League tables printed in newspapers and digital media inform the public about student achievement results, and parents in underachieving schools are given opportunities to transfer their children to others with better results. Educators are encouraged to build lateral learning networks to drive change and the public has access to information with regard to teacher quality and student achievement levels. The government sponsors outsourcing of some educational provisions, such as the supplementary educational services provided by NCLB to students in struggling schools. Diverse provider models enable parents and students to shop among a variety of school options. Politically imposed timelines for improvement are linked to short-term election cycles, and the

failure of schools to meet these leads to increasing amounts of intervention, so that, in general, intervention is inversely related to success.

Advocates of LSR 2.0 claim increased standards in measurable improvement, narrowed achievement gaps, enhanced professional quality and motivation, and system-wide impact. In terms of sustainability, they point to depth or penetration of impact on achievement and spread of impact on a large scale.

Critics acknowledge these gains but also highlight significant limitations that create unsustainability such as an overemphasis on tested and targeted basics that marginalizes attention to arts, social studies, innovation, and creativity that are essential for competitive success in twenty-first-century knowledge; an inverse relationship between narrowly tested achievement and the development of the whole child and its overall well-being; a preoccupation with data-driven improvement that distracts teachers from deeper engagements with teaching and learning; a tendency for large-scale changes to lose their sophisticated and deeper qualities when they are hurriedly transplanted from one city or country to another; an overwhelmingly short-term orientation that leads to cynical strategies to improve results that secure only temporary success; and disincentives for schools to assist their weaker neighbors when school-by-school competitiveness persists (summarized in Hargreaves and Shirley, 2009).

Given these weaknesses, LSR 2.0 has difficulties meeting the sustainability criteria of depth, endurance, and benign impact on others in the surrounding environment, even though it might achieve some success in terms of spread.

A Fourth Age of Sustainability

Dean Fink and this author have been the first to develop an integrated theory and evidence-based elaboration of educational sustainability (Hargreaves and Fink, 2003). The theory of sustainability consists of seven interrelated principles that emerged from evidence collected in a study of educational *Change Over Time* funded by the Spencer Foundation (Hargreaves and Goodson, 2006). The study examined the experiences of educational change over more than 30 years in eight US and Canadian secondary schools – four innovative, and four more traditional – through the eyes of teachers and leaders who had taught there since the 1960s and 1970s. It encompassed more than 250 interviews with three cohorts of teachers in these schools who had entered the profession and also these schools at different points in time. It also included ethnographic observations as well as interpretation of detailed archival and demographic data from the schools and their surrounding districts and communities.

Through grounded theorizing, the project identified themes and periods in relation to changes that did and did not persist and why. The existing literature of educational change usually defined these questions of persistence in terms of sustainability, but, in turning to the wider literature of environmental and organizational sustainability, the discovery was that, in education, sustainability was being used as a synonym for maintainability. More detailed and interactive engagement of this wider literature with the evidence of our study then gave rise to our theory of educational and organizational sustainability and the seven essential and interrelated principles that comprise it.

Sustainable improvement, it was found, is characterized by depth of purpose in learning, caring, and real achievement rather than superficially tested performance; length of impact over the long haul – beyond individual leaders and short-term results – through longer-term planning and effectively managed leadership succession; breadth of influence – where leadership and improvement become a distributed responsibility; justice in ensuring that improvement efforts do no harm to, and actively benefit, students in other classes and schools; diversity that replaces monocultural standardization and alignment with networks and cohesion; resourcefulness that conserves and renews teachers' and leaders' energy and does not burn them out; and conservation that builds on the best of the past to create an even better future.

Sustainable Reform in Practice

In recent years, this author's research program has been concentrating on investigating and articulating the basic principles of demonstrably successful and sustainable change and reform in schools, districts, networks, provinces, and countries, as well as other sectors outside education. Two examples of these follow: a report for the Organization for Economic Cooperation and Development (OECD) on the relationship between leadership and school improvement in the world's highest performing country on the Program for International Student Assessment (PISA) tests of educational performance – Finland (Hargreaves *et al.*, 2008); and an ongoing cross-sector project co-directed with Alma Harris on *Performing Beyond Expectations*, in education, health, business, and sport, that includes the London Borough of Tower Hamlets (Hargreaves and Shirley, 2009).

Finland is the world leader on results in PISA tests of sophisticated, applied knowledge in mathematics, science, and literacy, as well as on international ratings of economic competitiveness according to the International Monetary Fund (IMF). This is remarkable given Finland's

economic collapse, in 1992, when unemployment levels reached ~20%.

Finland avoids short-sighted and unsustainable standardization along with national standardized tests altogether and reaches high levels of educational achievement and economic success by attracting highly qualified teachers with supportive working conditions, strong degrees of professional trust, and an inspiring mission of inclusion and creativity. This mission connects back to Finns' understandings of themselves as a creative and craft-like people and is embedded in a curriculum that not only values science and technology but also promotes creative and performing arts for all students until the end of secondary school with musical instruments paid for by the state.

Our OECD research team found that school principals in Finland have been able to lead communities of highly qualified teachers who develop their school curriculum together in each municipality within broad national guidelines. They and their teachers work in cultures of trust, cooperation, and responsibility, seeing themselves as one of a society of experts – who work with fellow professionals and neighboring schools – to achieve compelling and inspiring purposes, together, that rebuild their communities and their nation around knowledge society principles of inclusiveness and creativity. Indeed, in the city of Tampere, high schools principals told us that when they jointly agree on an important initiative for their community, if one school is short of resources, the principal can call the others and one of them will say “We have a little bit extra, would you like some of ours?” Finnish teachers think about more than ‘me and my class.’ In addition, Finnish principals think and act beyond ‘me and my school.’

Finns' inspiring purpose enables them to connect their hi-tech future to their creative past (conservation) and to concentrate on learning and caring for every student rather than boosting scores on testing (depth). Finns are not distracted by the necessity for short-term lifts in test scores to satisfy the temporary demands and transient initiatives of passing governments (endurance). Distributed responsibility among teachers and with principals ensures breadth of impact within and between schools. Schools help their neighbors because of a compelling and transcending commitment to a common community (justice) and they work together in networks of curriculum development and support (diversity). Free school meals and instruments for all children along with sufficient salaries and adequate working conditions give teachers the energy for change that is not sapped by unwanted external interventions (resourcefulness). For 15 years, the Finnish system of improvement and change in education and in the society has not only been successful but also sustainable.

The London Borough of Tower Hamlets with its large Bangladeshi community is an equally compelling example of system-wide sustainable improvement. Tower Hamlets' Bengali community suffered from high unemployment rates and some of the greatest incidences of poverty in the country with more children on free school meals than almost anywhere else. Educators' aspirations for student achievement were startlingly low and, in 1997, Tower Hamlets was proclaimed the country's worst-performing Local Education Authority (LEA), with the lowest performing primary school in the nation.

Ten years later, the transformation of the schools in Tower Hamlets is dramatic. The schools perform around and above the national average. On standardized achievement tests, high school examination results, and rates of students going on to university, the borough ranks as the most improved local authority in England. It has significantly reduced achievement gaps in relation to children with special educational needs, those from cultural minorities, and those on free school meals. These gains have been achieved with, largely, the same population and in comparison with the more modest national gains posted in the same time period.

Refusing to apply punitive interventions or sponsor market competition, Tower Hamlets has had an orderly succession of inspiring district leaders who have communicated high expectations that poverty is not an excuse for poor outcomes, that aspirations should be extremely high, that efforts to meet these aspirations should be relentless, and that everyone should work on this together. These system leaders have developed collaborative and trusting relationships with leaders in their schools. Testing is always on teachers' and leaders' radar but engaging students in their learning definitely comes first. Schools set ambitious performance targets together in a culture of target setting so that everybody owns them and these targets exceed those that are handed down to them by government.

District administrators are very present in the schools. They report that "lots of our schools work very closely together and with the local authority" and inspectors' reports refer to the "enthusiasm and high level of morale among the workforce". This grounds intervention in consistent and direct personal knowledge and communication more than in the numerical data that eventually appear on spreadsheets.

When schools fall behind, others rally round to help. Better teachers are cultivated and kept as a result of positive partnerships with local teacher-training providers. Positive and responsible partnerships have been developed with the corporations in the Docklands development of Canary Wharf, and droves of paid teaching assistants – drawn from the local community – work alongside classroom teachers, easing the workload, and

developing active trust and committed engagement with parents and the community.

In Tower Hamlets, as in Finland, a carefully managed succession of leaders (endurance) with a robust and resilient sense of purpose (depth) work closely with their schools and develop shared targets for improvement (breadth). The local authority has developed a collaborative ethic of schools helping schools and the strong supporting the weak (justice and diversity) even within a national political system that is designed to be highly competitive. Two proud pasts – of Tower Hamlets and its Bengali community – are connected to the borough's inspiring transformation for the future (conservation). These leaders think and work sustainably beyond their isolated schools – with other schools, teacher training-providers, and also the surrounding communities. This not only develops distributed responsibility beyond individual schools and beyond the schools in general, but it also increases the energy, support, and resourcefulness for change. One of Tower Hamlet's leaders sums it up well. It is "not just about the data. It's actually knowing the school, knowing the community, knowing about history, knowing about the staff – all of that."

Conclusion

Sustainability means more than maintainability. It means developing changes that matter, spread, and last and do no harm to others. Three ages of educational reform have failed to achieve sustainability. Innovations as things did not spread or endure. Efforts to reculture the teaching profession were undone by insufficient investment in leadership and insubstantial attention to results. More recent movements toward LSR have achieved greater spread and affected the details of practice, but, oddly, the practice that has been affected and enforced has reinforced traditional practices rather than disrupting them. More than this, LSR 2.0 has typically enjoyed only transient success and, often, at the expense of others.

A deeper philosophy and practice of sustainability returns to and embraces the environmental roots of the concept. It emphasizes, celebrates, and advocates for learning in depth about one's place in and contribution to the world; for developing individual interdependence on each other in cultures of trust and responsibility; for building a lasting legacy beyond short-term cycles of political popularity; for ensuring that competition does not destroy or diminish one's necessary capacity for helping one's neighbors; and for elevating change by professionalism and democracy over reform through market competition and bureaucracy. Our future has to be sustainable. So must our schools be (Havelock, 1971).

The Role of the District in Tri Level Reform

M Fullan, University of Toronto, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

The most distinctive feature of educational reform, over the past decade, has been the increasing focus on system-wide effectiveness. This has been called the tri-level reform: what has to happen at the school and community level, the mid- or district level, and at the state. This new work is not so much about the intralevel developments, but rather about strong multi-way interrelationship across the levels – in other words, systemic reform.

This article focuses particularly on the role of the district – linking both downward (to its schools) and upward to the state. In North America, districts play a more direct line authority role than they do, for example, in England.

The role of local authority in England is more complex with the evolution of the cross-cutting forces of the local autonomy, and more central accountability. The increase in the scope of responsibilities to include all of children's services has further complicated the scene. It is, in this author's view, very difficult at this time to sort out the causal role of local authorities in England. It is too much of a moving and complex target. One empirical study of the role of local authorities in England (the data on which it is based is now 3-years old, which itself is a problem) concluded "the Education Authority attended by pupils has almost no relevance to their progress" (Tymms *et al.*, 208: 261).

The role of the district in North America is more influential. It is true that the impact of the classroom is most important, the school second most, and the district third most, and so on. Nonetheless, this article claims that the infrastructure does matter a great deal.

The main two sections of this article present the case and the data, drawn from this author's own research and the research in the field as a whole. These issues are pursued, first, by considering the role of the district (and its schools), and, second, by placing districts in the context of the state or system as a whole.

The Role of the District

If one takes a quantitative approach, the majority of districts are not effective. To be fair, stimulating, coordinating, and sustaining coherent development across many schools is exceedingly difficult because it requires balancing top-down and bottom-up forces. This article traces the evolution of the role of districts in school reform using informal language to capture the three themes: getting somewhere; not so fast; and what's next?

Getting Somewhere

Since nearly 1990, there has been a growing body of work that points to common characteristics and strategies that successful districts use to raise student achievement. Rosenholtz's (1989) study of 78 elementary schools classified schools as "stuck," "moving," and "in-between." Rosenholtz also found that a disproportionate number of stuck schools came from certain districts; likewise, moving schools were clustered in certain other districts. This prompted her to write a chapter on stuck and moving districts. Rosenholtz comments:

The contrast between stuck and moving districts, nowhere more apparent than here, underscores how principals become helpful instructional advisors or maladroit managers of their schools. It is also clear that stuck superintendents attribute poor performance to principals themselves, rather than accepting any responsibility to help them learn and improve. This again may indicate their lack of technical knowledge and subsequent threats to their self-esteem. If districts take no responsibility for the in service needs of principals, of course, principals become less able colleagues, less effective problem-solvers, more reluctant to refer school problems to the central office for outside assistance, more threatened by their lack of technical knowledge, and, most essential, of substantially less help to teachers. (p. 189)

Anderson (2006), a colleague of mine, reviewed the research on district effectiveness and named 12 key strategic components.

1. District-wide sense of efficacy.
2. District-wide focus on student achievement and the quality of instruction.
3. Adoption and commitment to district-wide performance standards.
4. Development and adoption of district-wide curricula and approaches to instruction.
5. Alignment of curriculum, teaching, and learning materials, and assessment to relevant standards.
6. Multi-measure accountability systems and system-wide use of data to inform practice, hold school and district leaders accountable for results, and monitor progress.
7. Targets and phased focuses of improvement.
8. Investment in instructional leadership development at the school and district levels.

9. District-wide, job-embedded professional development focuses and supports for teachers.
10. District-wide and school-level emphasis on teamwork and professional community (including in several cases positive partnerships with unions).
11. New approaches to board–district relations and in-district relations.
12. Strategic relations with state reform policies and resources.

One would think, then, that there is a growing consensus and that it is just a matter of going to town on what we know. One would be wrong.

Not So Fast

So a district should get the standards right, align curriculum to them, conduct assessments on the new alignment, provide solid and continuous professional development on curriculum and instruction, set up a data system that can be used for both assessment for and assessment of learning, and engage with the local community and state reform policies. It may surprise many readers that these steps, by themselves, are not sufficient and, at best, may represent a waste of resources, and, at worst, do more harm than good.

The experience of the San Diego City Schools District is a good place to start with respect to the not-so-fast theme. Coming off a highly successful experience in District 2 in New York City from 1988 to 1996, Tony Alvarado was hired as Chancellor of Instruction in 1997 to join a new high-profile superintendent – Alan Bersin – in San Diego. In a sense, the question was – if you could take the best knowledge, and add resources and political clout, could you get results in a large urban district within a 4-year period, and then keep going, in this case, moving from success in 45 schools (District 2) to 175 schools (San Diego)? The answer, incidentally, is yes, but it requires good strategies and a good deal of finesse.

The San Diego reform story is probably the most closely watched reform initiative in the history of urban school improvement. Here, this article draws on the excellent account by Hubbard *et al.* (2006). The San Diego strategy was well detailed and explicit from day 1. It consisted of the following three main components:

- Improved student learning: closing the achievement gap.
- Improved instruction: teacher learning through professional development.
- Restructuring the organization to support student learning and instruction.

The focus was on literacy, and the strategies were highly specific. Teachers received support from literacy coaches and principals who were positioned to be leaders of

instruction, with day-to-day support, and monthly full-day in-service sessions by area superintendents whose new roles (and new people) were re-created as instructional leaders.

This article does not provide the space to enter a detailed account of the San Diego experience, but the main outcomes and reasons can be identified (for a full account, see Hubbard *et al.*, 2006). To cut to the chase, literacy achievement increased, somewhat, at the elementary level in the 1997–2001 period, had a limited impact in middle schools, and was a dismal failure in high schools. Momentum was lost by 2001, Alvarado was asked to leave in 2002, and Bersin – after slowing down the nature and pace of reform in 2003–04 – was replaced by the school board when his term expired in June 2005. What happened?

One could say that it was a political problem – the board was divided from the beginning (3:2 in favor of the reform initiative), and the teacher union that opposed the reform from the beginning eventually carried the day. There is some truth to this, but the deeper explanation is closer to the theme of our interest in meaning and motivation relative to pace, the too-tight/too-loose problem, and the depth of instructional change and thinking required to make a difference. Hubbard *et al.* (2006) expressed the basic problem in terms of three challenges that the strategy failed to address: “The need to accomplish deep learning within the constraints of a limited time frame; principals’ and coaches’ limited understanding of the concepts they were trying to teach; and the difficulty of reaching common ground between school leaders and teachers” (p. 128).

All this, despite plenty of classroom visits, walk-throughs involving all schools, frequent problem-solving sessions, and an emphasis on job-embedded professional learning. The San Diego case is an exercise in the dilemmas faced by leaders with an urgent sense of moral purpose and considerable knowledge of what should happen in classroom instruction. However, it also points to how the strategies employed must be much more respectful of how deep change happens. Much good was done in improving literacy achievement in elementary schools, but it was not deep enough or owned enough to go further. The San Diego strategy failed because the pace of change was too fast, the strategy was too unidirectional from the top, relationships were not built with teachers and principals, and, above all, the strategies did not really build capacity – which is the development of the collective knowledge and understandings required for ongoing instructional improvement that meets the needs of each child.

San Diego is also one of the better examples of attempted reform. Most districts do not focus their efforts on district-wide reform. In addition, when they do, they encounter limits to what can be accomplished despite considerable effort and resources.

Another confirmation of our not-so-fast worry comes from the Cross City Campaign for Urban School

Reform (2005), which has been cross-referenced above and examines major reform initiatives in Chicago, Milwaukee, and Seattle. All three school systems had the attention of political leaders at all levels of the system and focused on many of the right things, such as literacy and math; all of the systems used current choice strategies such as concentration on assessment-for-learning data, invested heavily in professional development, developed new leadership, and focused on system-wide change.

In addition, they had money – Seattle had \$35 million in external funds, Milwaukee had extra resources and flexibility, and Chicago had multimillions. There was huge pressure, but success was not expected overnight. Decision-makers and the public would have been content to see growing success over a 5- or even 10-year period. The upfront conclusion of the case-study evaluation was that for many of the principals and teachers interviewed, “the districts were unable to change and improve practice on a large scale” (Cross City Campaign for Urban School Reform, 2005: 4).

The issues in the Chicago, Milwaukee, and Seattle reforms help to identify the missing ingredient, even though those districts appear to have gotten most components right. Chicago, for example, appeared to have an impressive strategy: Academic standards and instructional frameworks, assessment and accountability systems, and professional development for standards-based instruction are among the tools of systemic reform that are used to change classroom instruction (Cross City Campaign for Urban School Reform, 2005: 23).

This appears to be a standards-based, system-wide reform that sounds like it should work. The failure, in this author’s opinion, is that the strategy lacks a focus on what needs to change in instructional practice. In Chicago, teachers did focus on standards, but in interviews, they “did not articulate any deep changes in teaching practice that may have been under way” (p. 23). Furthermore, “instructional goals were articulated more often in terms of student outcomes or achievement levels than in terms of instructional quality, that is, *what the schools do* to help students achieve” (p. 29, emphasis in original). Milwaukee reveals similar problems in achieving instructional improvements while using greater decentralization in the context of system support and competitive choice. The focus was on literacy; a literacy coach was housed in every school in the district and considerable professional development and technical support services were available. Education plans for each school were to focus on literacy standards through (1) data analysis and assessment and (2) subject-area achievement targets – including literacy across the curriculum. Sounds like a convincing strategy. However, what is missing, again, is the black box of instructional practice in the classroom. The case writers observe: “We placed the Education Plan in the indirect category due to its non-specificity regarding regular or

desired instructional content and practices” (Cross City Campaign for Urban School Reform, 2005: 49).

More generally, the report concludes that while these serious district-wide reform initiatives appeared to prioritize instruction, they did so indirectly (through standards, assessment, and leadership responsibilities). However, in the experience of principals and teachers, the net effect was that “policies and signals were non-specific regarding intended effects on classroom teaching and learning” (p. 65).

The third case, Seattle, is a variation on the same theme. The game plan looks good. Standards defined the direction, while the district’s Transformational Academic Achievement Planning Process “was designed as a vehicle for helping schools develop their own strategy for (1) helping all students meet standards, and (2) eliminating the achievement gap between white students and students of color” (p. 66). Similar to Milwaukee, the district reorganized to support site-based management, including the allocation of considerable resources to schools. The case writers observe:

The recent effort to become a standards-based district was one of the first sustained instructional efforts with direct attention to teaching and learning. However, the conversations district leaders had about standards *were rarely connected to changes in instruction.*

(Cross City Campaign for Urban School Reform, 2005: 69; emphasis added)

The report continues: “At the school level, finding teachers who understood the implications of standards for their teaching was difficult” (p. 72).

This article cites one more case, which – in some ways – is more encouraging but still proves this author’s main conclusion that instructional change is going to require different strategies that help develop and shape collective capacity and shared commitment to engage in continuous improvement. Supovitz (2006) conducted an excellent case study of the reform effort in Duval County, Florida. The title of his book captures the emphasis of his analysis – *The Case for District-Based Reform*. Supovitz chronicled the district-wide reform effort from 1999 through 2005. Duval County has 142 schools. The reform strategy is now familiar to us.

1. Develop a specific vision of what high-quality instruction should look like.
2. Build both the commitment and capacity of employees across the system to enact and support the instructional vision.
3. Construct mechanisms to provide data at all levels of the system that will be used both to provide people with information that informs their practices and to monitor the implementation of the instructional vision.
4. Develop the means to help people continually deepen their implementation and to help the district continually refine this vision and understand its implications.

With a sustained 5-year focus on the four strategic components, the district made significant gains in student achievement. For example, the number of schools receiving C or better on the state assessment system went from 87 (of 142) in 1999 to 121 by 2003. In addition – for the first time in a 7-year period, in 2005 – no school in the district received an F on the state accountability system.

The strategy was driven by a strong superintendent who helped to orchestrate the development of district-wide capacity according to the four core components described above. The strategy was enacted with considerable action and focus. As Supovitz reports, “Duval County leaders repeatedly stated their vision and the strategies for achieving it in public venues” (p. 43). Supovitz argues that the spread and deepening of district-wide success is as much “gardening” as it is “engineering” (p. 63). And that the balance requires “advocacy without mandate” (p. 66), “fostering urgency” (p. 68), and “building existing proof” of success (p. 69). One sees a similar array of strategies as in San Diego, but with less heavy-handedness: direct training of teachers, school standards coaches, district standards coaches, principal leadership development, and district leadership development.

With 6 years of consistent effort and with an explicit emphasis on professional learning communities as a strategy, Supovitz comments: “The possibilities of professional learning communities—rigorous inquiry into the problems and challenges of instructional practice and the support of that practice—seemed only to be occurring in pockets of the district” (p. 174). Much was accomplished in Duval County, but it was, by no means, deep or durable after 6 years. So the not-so-fast observation presented above is an apt worry. Even with comprehensive strategies and relentless focus over a 5- or 6-year period, one is still not getting it right.

What’s Next?

It has been seen that even the most ambitious efforts fall short, and these initiatives involve only a small minority of districts. Most are not nearly so active. This author believes that these efforts are on the right track, but the approach needs considerable refinement. To state what is needed upfront, there is need for a focus on instruction, standards, assessment, continuous feedback and use of data, and instructional leadership at the district and school levels. However, also needed is a process of interactive capacity building and commitment building within and among schools, and between schools and the district. Above all, this, increasingly, must de-privatize teaching so that learning in context can occur, and the district must stay the course over a period of 10 or more years. This work does not necessarily require the same superintendent over two or more terms, but does require continuity of good direction over two or three superintendencies. This article

cites three examples, from three different countries, of what this means in practice.

York Region District School Board just outside Toronto, Ontario, is a multicultural district with a growing and diverse population, and over 100 different languages spoken in the schools. There are 145 elementary schools and 30 secondary schools. We have been working in partnership with York for the past 5 years, including monitoring the processes and results as we go (see, e.g., Sharratt and Fullan, 2006). The focus is on literacy in an initiative called the Literacy Collaborative (LC). The basic approach is designed to shape and reshape district-wide continuous improvement – what this author calls “capacity building with a focus on results.” Key features of the approach include:

- A clearly articulated vision and commitment to literacy for all students, which is continually the subject of communication in the district.
- A system-wide comprehensive plan and framework for continuous improvement.
- Using data to inform instruction and determine resources.
- Building administrator and teacher capacity to teach literacy for all students.
- Establishing professional learning communities at all levels of the system and beyond the district.

All schools – including all secondary schools – joined the LC in a phased-in fashion, with school-based teams being the focal point for capacity building. At the elementary level, teams consisted of the principal (always the principal), the lead literacy teacher (a leadership role within the school, with a teacher released for 0.5 to 10 time to work with principals and teachers), and the special education-resource teacher. High school teams were slightly larger and focused on literacy – especially in the ninth and tenth grades. The LC model has evolved to contain 13 parameters, which are not listed here but include embedded literacy teachers, timetabled literacy blocks, a case-management approach focusing on each student, cross-curricular literacy connections, and so on (see Sharratt and Fullan, 2006). There is constant interaction, action research, and capacity building through formal monthly sessions, and many learning-in-context interactions carried out daily by school and district leaders within and across schools.

The results – as measured by province-wide assessments – were significant after a 3-year period (2001–04), but not as substantial as district leaders had hoped. On a closer examination of the initial cohort of 17 schools, it was found that nine of the schools had implemented the 13 parameters more deeply compared with the other eight. When the latter schools were separated, the results showed that the nine schools – despite starting below the York Region and Ontario provincial average in 2001 – had risen above both averages by 2004. In the meantime, the district

was working with all 167 schools. Province-wide results, in 2005, showed that York Region increased by a full 5%, on the average, in literacy across its 140 elementary schools. High schools also did well for the first time on the tenth-grade literacy test.

In terms of what is new, the theory of action reflected in the approach in York Region can be considered. First, we have many of the elements we have seen previously – standards, assessment of and for learning, instructional leadership, and so on – but one also sees two new significant emphases. One is that the leaders have taken a long-term perspective; they realize that it takes a while for change to kick in; they frequently speak of staying the course, and persistence but flexibility; the pace is steady, even pushy, but not overwhelming; they expect results, not overnight, but also not open ended. The other new aspect is that leaders are careful not to judge slow or limited progress in given schools. They take what this author calls a “capacity building first, judgment second” stance. Large-scale change is all about moving the whole system so that more and more leaders permeate the system and take daily actions that build capacity and ownership.

This is an entire district that is on the move. There has been one director (superintendent) – Bill Hogarth – throughout the 8-year process, and a strong rapport between the board and the district leadership. As a strong collaborative culture has been built, the chances of continuing this direction when he leaves are greatly increased. As this author said, one does not need the same superintendent over 8–12 years, but one does need continuity and deepening of good direction.

In further work in the York Region, the Superintendent of Curriculum – Lyn Sharratt – and this author examined the prospects for “sustaining leadership in York Region” (Fullan and Sharratt, 2007). When school principals were asked how they sustain their focus on continuous improvement, five major themes were identified. For effective building for the future, school principals said that they simultaneously focus on five interrelated components:

1. Shared beliefs, goals and vision
2. Distributed leadership and professional learning cultures
3. Data-based decisions/impact measures/celebrating success
4. Mobilization of resources (time, ideas, expertise, money)
5. School/community/home relations. (Fullan and Sharratt, 2007: 126)

While it is observed that sustainability will always be problematic, it can be concluded that York Region has done better than most in establishing the conditions that make sustainability more likely. In particular, four propositions have been formulated:

- Proposition One: Sustainability is not about prolonging specific innovations, but rather it concerns establishing the conditions for continuous improvement.

- Proposition Two: Sustainability is not possible unless school leaders and district leaders are working together on the same agenda.
- Proposition Three: Proposition Two notwithstanding, sustainability is not furthered by school and district leaders simply agreeing on the direction of the reform. Any temporary agreements must be continually tested and extended in the crucible of implementation with school and district leaders being equally influential.
- Proposition Four: Despite the clear signs in York Region and despite being able to identify favorable conditions, we still do not know what will happen when district leadership changes. (Fullan and Sharratt, 2007: 134–135).

A second good example is the decade-long reform initiative of the 58 000 student Boston Public Schools (BPS) under the leadership of Superintendent Tom Payzant. McLaughlin and Talbert (2006) describe the basic plan as based on six essentials: effective instruction as the core essential, student work and data, professional development, shared leadership, resources, and families and community. Again the words are familiar, but it is the theory of action – and careful cultivation over a decade – that is the real story. Professional development, for example, takes place at the school level and features a coaching strategy involving collaborative teaching groups. In collaborative coaching, teachers learn by analyzing one another's work under the guidance of skilled coaches. The idea is not just to observe one another's teaching and share ideas, but to critique lessons in a way that links to improving student learning. As with the York Region, a well supported and easy-to-access database on student learning is used to help teachers examine their teaching in light of ongoing results, integrating data into professional learning. Substantial outreach to parents and community is a major component of teachers' and schools' work.

Education Week published a profile on BPS and Payzant on the occasion of his announcing his retirement, in 2007, following 11 years as superintendent (“Time on his side,” Allen, 2006). In addition to reporting on the activities and approach just described, *Education Week* gets beneath the strategy.

Mr. Payzant did not bring the Boston schools to this point overnight. He rolled out initiatives not all at once, but only when they made sense. The idea was to start small, test things out, and retool them. In addition, he focused on building consensus. All were radical notions in an era of hard-charging, quick turnaround leaders (p. 31).

The impact of the Boston strategy brought significant results in student achievement. In the tenth-grade English language arts and in mathematics, scores have increased steadily since 1999 for all four race and ethnic groups (black, white, Asian, and Hispanic), with some leveling off in the 2004 and 2005 years. McLaughlin and Talbert (2006) summarize the positive impact in these words.

Multiple evaluations show that Boston's approach to instruction [and] to collaborative coaching and learning are benefiting students and teachers. Student outcomes have improved, as have relationships between teachers and students and among teachers. Boston sees other positive system-level consequences of their strategy—enhanced coherence, increased accountability at all levels, and increased buy in from district educators. (pp. 126–127)

Again, one sees a more sophisticated theory of action carrying the day. It is not that one is seeing flawless strategies. The pace of change was, likely, not fast enough in Boston. Put another way, few superintendents would be allowed to take this amount of time in 2009. However, the point remains. Too fast is a more likely negative scenario. Balancing pace – press for improvement with corresponding capacity building – carefully assessed as you go, is required. Payzant's own reflective lessons are revealing. He says he left some areas of work "too much to chance." He said he should have allowed fewer programs for teaching literacy. Likewise, he said it was a mistake to let high schools come up with their own plans for creating more personalized learning environments for students ("Time on his side," Allen, 2006).

The performance in Boston, along with substantial improvements, also reveals a plateauing effect in the last 2 years – a phenomenon that is normal, not to be lamented, but requiring new, deeper strategies. Elmore (2004) and this author (Fullan, 2006) have both commented on the plateau effect as a natural and (depending on what one does next) valuable opportunity to consolidate and then go deeper. In addition, while all four race and ethnic groups have gained, the gap has not closed and, in some cases, has increased. The next critical question for Boston is: who will be Payzant's successor? This author has said that, in these cases of being on the right track, it is crucial for districts to hire for continuity and deepening of good direction.

We move to England for our third example – Knowsley Local Education Authority. Note here, the contrast to the negative findings from Tymms *et al.* (2008), which found that the local authority made little difference in the education lives of students; qualitative case studies are likely to find examples of success (and failure) as opposed to large quantitative studies.

In any case, Knowsley Local Education Authority (called Local Authority, since 2005) is a metropolitan district just east of Liverpool. It is defined as the sixth most-deprived authority in the country. In 1999, Knowsley consisted of 59 primary schools, 11 secondary schools, and seven special schools. The district was audited in that year as part of the national inspection scheme conducted by the Office for Standards in Education (OFSTED). The assessment found serious weaknesses on most basic dimensions of performance: student achievement, capacity to

improve, relationships between the district and the schools, and linkage to the community. A new Director of Education, Steve Munby, was appointed in 1999. A second inspection was conducted in 2003, which found major improvements. What happened in 4 years to transform a very low-performing, disadvantaged, discouraged system into one vastly improved and ready to do more?

One can begin with OFSTED's 2003 findings (OFSTED, 2003).

Recent developments and the implementation of well-thought-through initiatives have resulted in Knowsley establishing itself as a local education authority (LEA) of some significance. It has improved over the past 3 years and has shown how vision and leadership, together with excellent relationships with schools, can revive an education service (p. 2).

As OFSTED further noted, both literacy and numeracy scores increased at a time when national averages were flatlined. OFSTED also observes that "the new administration has taken partnerships and collaborative working to an unusually high level." In addition, "head-teachers of individual schools see themselves as part of a wider team with responsibility for the education service throughout the borough" (p. 2).

Munby (2003) states that the drivers for change are low student performance, new leadership, external funding, and a moral commitment to narrow the gap between the highest and lowest performing schools. Munby then lists what he calls his "priorities for sustainability":

- Establishing an innovative, coherent, and comprehensive policy framework that provides direction for instruction and professional learning
- The training of "lead learners" to support school learning
- Deploying lead learners to work with clusters of schools to embed new practice
- Cluster-based work—action learning, observing and sharing learning, supporting small-scale action research to provide evidence of impact on pupil motivation, and engagement with the learning process
- Encouragement and support of the further development and embedding of a culture of co-planning, co-teaching, co-review, and co-coaching in schools, everyone a leader of learning. (p. 2)

In January 2005, Munby was appointed the chief executive officer (CEO) of the National College of School Leadership. A time for the continuity of good direction. The new director, Damian Allen, was appointed from within Knowsley, having been deputy director. Because Munby had employed a strategy of co-development of leadership, Allen was already immersed in the strategy, and, in fact, had helped shape it. By the time he was appointed in January 2005, the new Every Child Matters agenda had become a reality, with all children's services – including schools – coming

Table 1 A comparison of Knowsley's strategy with the government's white paper

Co-leadership between LA and schools	Vs.	Individual independent specialisms
Collaboration and federation as standard	Vs.	Collaboration and federation as a response to weakness
System performance	Vs.	Individual school performance
Failure driven out by challenge and support	Vs.	Failure driven out by early intervention and closure
Development of co-leadership	Vs.	Schools need autonomy
High support and engagement with schools	Vs.	Light-touch monitoring

under the LA. Allen became the first executive director, Children's Services. Knowsley has continued with the directional strategy of having an ambitious agenda for children, but forging ahead with co-leadership and capacity building. The district proceeded to introduce a remarkable secondary school reform that involved closing all 11 high schools, and reopening them with eight brand-new schools – complete with new state of the art buildings called learning centers. Knowsley did this without any rancor and, indeed, considerable enthusiasm – partly because of the co-leadership strategy, partly because new national money was available for new buildings, and partly because it was already experiencing success (e.g., the percentage of 15-year-olds passing five or more GCSEs – a mark of advanced placement courses for further education – had doubled from 22% in 1998 to 45% in 2005, while the national average moved from 47% to 57%).

Ever conscious of the theory of action that had gotten them there, Allen (2006) made a presentation at a national meeting in which he compared the Knowsley strategy with the strategy embedded in the recent white paper from the government (Department for Education and Skills, 2005). After pointing out the inconsistencies in the white paper, he noted the following comparisons (Knowsley on left; white paper on right, **Table 1**).

What is new, in this author's view, is the creating of partnerships of engagement that mobilize the entire district. It is still early in Knowsley's journey, but one can see a consistent, adaptable strategy in which successive leaders build on good direction, interacting with internal and external contexts.

The District and the State

It is beyond the terms of reference in this article to take up the complex and new emergence in the role of the state/central governments whether they be federal and state/provincial, or single national entities. There is, certainly, a growing focus on system strategies such as Michael Barber's *Instruction to Deliver* in England, and Hargreaves and Shirley's (forthcoming) *The Fourth Way*. Issues of market model, education and citizen empowerment, accountability, the new teacher professionalism are all intermingled in this debate.

For our purposes in this particular context, one can take the narrower question of the implications of the

previous section on the role of the state. The first thing to say is that the district should be focused and proactive in its own right, irrespective of the state's role.

Second, and more directly, this author's conclusion is that there is a direct analogy between the relationship of the schools and their districts, and the relationship between districts and state. In other words, in the same way that schools and the district must work as a single system, so too must the state and its schools/districts.

We have had a direct experience in shaping such a system in Ontario, Canada, since 2003. Ontario has two million students, 4900 schools, and 72 districts. We have focused, with considerable success, on improving literacy, numeracy, and high school graduation. The principles are similar to those that were reviewed in the last section (but obviously more complex, given the increase in size and component parts).

The relevant policies, strategies, and results, so far, are well documented in Levin *et al.* (2008) and Fullan (2008). Thus, Levin *et al.* describe the main sustaining elements as:

- Respect for staff and professional knowledge
- Comprehensiveness (whole system)
- Coherence and alignment through partnership with district and schools.

This author has described the actual action strategy as based on six elements:

1. Direction and sector engagement
2. Capacity-building with a focus on results
3. Supportive infrastructure and leadership
4. Managing the distractors
5. Continuous evaluation and inquiry
6. Two-way communication. (Fullan, 2008: 278)

It is encouraging to find that the same lessons about smaller system effectiveness (districts) apply with respect to whole-system reform. It can safely be predicted that the next phase of reform – assume 2009–14 – will focus deeply on system-wide reform on what this author has called tri-level reform. It is not just that the goal is to achieve new effectiveness across the whole larger system, but rather that the strategies involve system components at all three levels working in two-way and multi-way partnerships. One is, indeed, heading toward greater comprehensiveness, greater focus, more capacity building, and greater precision in zeroing in on core goals of literacy, numeracy, and high

school graduation. The next phase should accelerate our learning and knowledge with regard to school and system effectiveness.

Indeed, we and others are experiencing considerable success in increasing student achievement in literacy and numeracy and high school graduation rates across whole state systems (Fullan, 2010a, b).

Whole School Designs for Enhancing Student Achievement

S Stringfield, University of Louisville, Louisville, KY, USA

Introduction

Change is the normal condition in both the physical and the social world. A generation ago, Toffler (1970) noted that the rate of change in our social world was increasing geometrically, and Freidman (2005, 2008) regularly reminds us of the international implications of these rapidly increasing changes. Increasing changes in the social world are causing a great need for dramatic educational improvements across nations.

Increased education is associated with a wide variety of desirable outcomes, ranging from increased voting rates to the acceptance of leadership in social and religious organizations to income. As an example of the later trend, in the United States the difference in incomes between 25–34-year-old male high school dropouts and 25–35-year-old male college graduates stood at 30% in 1949. In the twenty-first century, it stands at over 150%. Today's young college graduate typically makes over \$2.50 for every dollar earned by a high school dropout, and the gap continues rising. Such changes over time in the impact of education have profound implications for both the economy and civil society. In this rapidly changing environment, with the consequences of educational failure at their highest levels in history, it is hardly surprising that nations are increasingly focusing on improving educational attainments.

The focus of this article is on results from relatively large-scale, multiyear studies of diverse school-reform efforts that include measures of academic outcomes. While individual case studies are interesting and often enlightening, they cannot provide information as to generalizability of findings.

Further, we focus largely on studies conducted in the United States. There are a range of interesting projects in other countries, such as the Improving the Quality of Education for All efforts in diverse countries. However, many such studies have not focused clearly on measures of student achievement. By contrast, the United States offers a deep history and a substantial number of mixed-method, outcome-focused studies. We invite readers to consider the findings and to independently estimate their relevance to their countries' contexts.

The United States as Context

There are several characteristics of US education that make it relevant for study. With over 300 000 000 citizens

from around the world, the United States is both large and diverse. The US education system is unusually decentra-
lized, with 50 state governments and over 15 000 local education authorities (LEAs) governing schools and attempting to hold schools accountable for a wide array of outcomes and measures. On achievement measures ranging from those used for the National Assessment of Educational Progress (NAEP) to the tests of the Third International Math and Science Studies (TIMSS), states and LEAs range from not statistically different from the highest-achieving countries worldwide to achieving at levels comparable to Third World nations.

Throughout America's history it has also been the case that Americans have been perpetually unsatisfied with the *status quo* and hence highly likely to change a broad range of governmental and other social conditions.

More specifically, Americans are perpetually unsatisfied with the quality of their schooling. At the end of the nineteenth century, Harvard's much-admired president C.W. Eliot complained that the main characteristic of instruction in American schools was a lack of stimulating, interesting tasks. Seventy-five years later John Goodlad summarized data from his large-scale studies and concluded that student boredom was the norm of American schooling.

At a policy level, the 30 years following Goodlad's finding have seen repeated large-scale efforts to change core schooling practices. Striking examples include the New American Schools initiative begun by the first President Bush in the early 1990s and the federally funded Comprehensive School Reform program. Given the aforementioned national penchant for change, perhaps it is not surprising that both of those efforts subsequently have been abandoned by the federal government – Americans perpetually change their changes.

The question remains, however, about how to best approach change to produce consistent improvement in adults' educational practices and student outcomes in schools.

Large-Scale School Improvement Studies in the United States

Fortunately, an extensive body of research on large-scale efforts to reform American schools, spanning most of the twentieth century and continuing, has yielded consistent findings regarding key issues in whole-school change.

Several of these findings are robust despite greatly differing historical conditions, reform goals, change strategies, and cultural norms within which the studies were conducted. Several of the most significant of these US studies are briefly described below. These are followed by cross-study findings and implications for future research and achievement-enhancing reform.

The Eight-Year Study of the 1930s employed a quasi-experimental design to examine the impact that substantial high school reforms would have on students' achievement in college. Thirty experimental schools were matched to 30 similar comparison schools, and arrangements were made with 300 colleges and universities to alter their admission standards to allow freedom for the experimental schools to develop local, innovative curricula. External change agents, known as the Curriculum Associates, used the reform goals espoused by the Progressive Education Association to work with the experimental schools to facilitate whole-school reform. In addition to collecting qualitative data regarding the type of reforms attempted and the change process, experimental and comparison student performance in college were examined.

The RAND Change Agent study of the mid-1970s examined implementation of school programs and curricular innovations that received federal support for a trial period of implementation. The first phase of the study examined how the characteristics of the reform interacted with local conditions to affect project initiation and implementation in 293 sites, with a more intensive focus on 29 sites to permit comparisons of similar projects implemented in diverse settings. The second phase investigated project continuation in 100 sites after federal support ended.

The Follow Through Classroom Observation Evaluation (FTCOE) of the 1970s evaluated the implementation and outcomes of seven school restructuring models that had been developed by design teams receiving federal support. The goal of each model was to ameliorate the well-documented fade out of positive effects from federally funded preschool programs. This stoppage of fade was to be achieved by providing continuing intervention for disadvantaged children in the early elementary grades. FTCOE employed a quasi-experimental design, using low-inference classroom observations, cognitive and affective student outcome measures, and teacher questionnaires to determine whether (1) each model was implemented as intended, (2) variability in classroom instruction was a function of which model was implemented, and (3) the models had an impact on student outcomes.

One of the most comprehensive studies of federally supported educational innovation that focused specifically on the relative efficacy of various change

strategies was the Dissemination Efforts Supporting School Improvement (DESSI) from the late 1970s and early 1980s. DESSI was intentionally designed to provide a basis for comparing four fundamental strategies for encouraging innovation:

1. interpersonal linkage of validated practice,
2. commercial distribution of innovative curricula,
3. state-administered programs, and
4. local invention and development.

The DESSI findings were based on observations, interviews, questionnaires, site visits, and analysis of documents gleaned from nearly 5000 participants in 146 project sites.

Like DESSI, the Urban and Suburban/Rural Special Strategies for Educating Disadvantaged Students of the mid-1990s examined implementation of both locally developed and externally developed reforms, but, like FTCOE, also looked at the effectiveness of the strategies in terms of impact on student achievement. The externally developed reforms examined in the Special Strategies study included nationally disseminated whole-school programs that employed very different nationally developed approaches to change ranging from highly specified programs, like Success for All, to such loosely structured reform principals as the Coalition of Essential Schools. The locally developed reforms included school-wide projects (locally developed whole-school change efforts), extended-day and extended-year programs, and peer tutoring.

Special Strategies examined 25 sites that were nominated as exemplary on the basis of their implementation of the various strategies in terms of impact on student achievement, and the perceptions of students, teachers, administrators, and parents. Observations continued for 3 years.

In the last decade, large-scale studies of implementation and effects of the New American Schools designs and reviews of the Comprehensive School Reform literature have provided additional insight into externally facilitated whole-school reform efforts in the United States.

Most recently, efforts have been made to conduct meta-analyses of the effects of diverse reforms on the academic achievements of students. The largest and most thorough of those meta-analyses concluded that there were only three externally developed reform designs which had strong, consistent research support: Success for All, Direct Instruction, and the Comer School Development Program. At least ten other reform designs were producing net positive effects, but that the research bases in support of the designs were not yet strong. The second striking finding from that work was that reforms seemed to get their greatest effects if they persevered in schools for at least 5 years.

Findings from Large-Scale School Improvement Efforts

The previous section has illustrated the historic and intellectual breadth of studies of whole-school reform in the United States. The next section summarizes conclusions that can be drawn from those large-scale and other studies of whole-school reform efforts:

1. Virtually all educational improvement efforts include academic gain as one of their stated goals, but most studies of change efforts fail to find substantial evidence of academic gain resulting from most reform types. This frequent failure to achieve desired outcomes is significant and should receive more discussion. Meaningful improvements evaded the medical field for over 100 years until the majority of researchers concluded that most medicines had yielded no positive benefits. This realization led to a century of fundamental reexamination of what was known, hard research, and our current, often breathtaking, level of research-based medical advances. From the Eight-Year Study through studies of the New American Schools, most studies of most reforms have not yielded intended results. Acknowledging this fact proved greatly energizing in medicine, and we should do the same in education.
2. Externally developed reforms have proven more likely to produce desired outcomes than locally developed reforms. There have been instances in which locally developed innovations have been successfully implemented to good effect, but, at least in the published research, these instances are rare. The US Department of Education's What Works Clearinghouse recently released a report on 'Turning around chronically low-performing schools' in which they sought out strong evidence for turn-around school characteristics. The authors' conclusion was that the evidence for generalizability of any common characteristic of locally developed schools' academic improvement effects was low. This was in part because the What Works Clearinghouse reviewers excluded all externally developed designs from their analyses. By so doing, they left themselves with a least-likely-to-succeed data set. Across over a half-century's research, the best available evidence is that outcomes from reforms conceived and implemented purely locally are more likely to result in changes that are trivial, and often are more costly, than those that are the result of collaboration with external facilitators. Several of the previously noted large-scale studies found that schools were more successful at changing reading practices if they adopted and then adapted external programs. Locally developed programs attempted less-ambitious change, and staff

members became overwhelmed when confronted with the daunting task of development.

There are several possible explanations for this, and they are not mutually exclusive. Locally developed reform efforts tend to spend a year developing the reform. By the time they get to implementation, they may have exhausted their enthusiasm or their leadership may have moved away. Alternately, the group of local educators may choose a set of reform elements that, however attractive in the abstract, do not have track records of producing positive effects. Hence, even when well implemented, the reforms may not produce desired effects. Third, meaningful change is hard, and local educators may not be willing to push one another with sufficient force to cause necessary changes.

A fourth explanation is that the external group has gone through the change process many times in many locations. The processes and stresses of change are familiar to them, and they may have developed time-proven strategies for dealing with large-group change as a part of their job. By contrast, most local educators go through whole-school change efforts once or twice in a career. Regardless of the reasons, in studies over several decades, externally developed designs have proven more likely to produce specific, desired outcomes.

Across studies that included both whole-school and targeted-to-specific-subgroup reforms, whole-school reforms have tended to produce more effects. Pull-out programs, however attractive in the abstract, do not tend to have good track records. Among other plausible explanations for this finding, there is the issue of time for coordination between the regular classroom teacher and the pull-out specialist. US schools allocate precious little teacher time for lesson preparation and student materials development and scoring. They are left with virtually no time for coordination of lessons with pull-out teachers. A student receiving two sets of uncoordinated lessons in one subject area could hardly be blamed for not accelerating his learning.

3. A few specific whole-school reform designs – not all – have produced reasonably consistent evidence of positive effects. In the United States, Success for All, Direct Instruction, and the Comer School Development program have produced the most nearly stable evidence of positive impact on student achievement. Perhaps a dozen other reform designs have produced positive, although less-compelling evidence.
4. To be effective, external reforms and related professional development must have specificity. Multiple studies of the New American Schools redesign models concluded that designs requiring extensive local development were less likely to experience implementation success – typical schools simply did not have the

capacity to do their own development on the scale required for substantive change. Reform approaches that leave the lion's share of development to the school tend to result in increased variability in instructional practices and often result in staff anxiety and burnout.

External assistance in the form of change facilitation, wherein schools still bear the onus of development of specific program components, has not proved sufficient to produce change in most schools. External assistance that focuses on issues such as enhanced collaboration, redistribution of power, and facilitative leadership in the absence of specific guidance relative to curriculum, instruction, and assessment has repeatedly proven unlikely to produce substantive change. Reforms that are highly complex and ill-defined, yet require substantial change, typically result in reduced expectations in terms of goals, behavioral change, and reform outcomes.

Reform strategies that lack specificity and direction regarding instructional practices – such as peer coaching, site-based management, teaching teams, and organizational development models – generally fail to deliver changes in teaching or student outcomes because they are not linked to specific practices and do not link organizational changes to changes in individual teacher behavior.

Follow Through researchers found that the programs that were most likely to be successfully implemented and to have positive effects on student achievement were highly structured or even prescriptive. Likewise, the three corporate social responsibility (CSR) models that a recent meta-analysis indicated most likely to have strong positive effects on student achievement are characterized by high levels of specificity regarding core schooling functions. Both DESSI and Special Strategies researchers found that, although there was variation in implementation both between and within schools, externally developed models could be implemented with fidelity to their key characteristics. Indeed, the authors of DESSI felt that the most robust finding of the entire study was that teaching practices changed substantially in at least 50% of the schools that adopted externally developed programs.

5. In addition to specificity, whole-school change efforts must be accompanied by user-oriented assistance that provides support and guidance to school staffs as they implement the reform. The Rand Change Agent study found a strong relationship between extensive pre-implementation training, ongoing workshops, and locally available technical assistance. Support and assistance that address teachers' specific concerns related to implementing new strategies, delivered by a credible person who has classroom experience with the strategies, provide a powerful inducement to change in teaching behavior.

6. There are many more examples of successful change in classroom processes and student outcomes in the primary grades than in secondary schools. There are several plausible explanations for this finding as well. Secondary schools tend to be substantially larger than primary schools, and it is harder to change large organizations. Secondary students are older and perhaps less open to change. The content of high school instruction is inherently more advanced and more specialized; perhaps this requires more direct instruction. Within the folk wisdom of educators, high school teachers are regarded as having seen a greater range of student behaviors, and as having become more cynical about change in general. For whatever reason, high schools have proven to be particularly challenging environments in which to achieve lasting changes.
