#### STATE SUPPORT

School finance involves the interrelated issues of raising, distributing, allocating, and using revenues for the purpose of educating children. Early in the twentieth century, local school districts were primarily responsible for providing funds—mostly through property taxes—for schools. Considerable disparities in the per pupil property wealth of school districts led to dramatic differences in both local property tax rates and in the amount of money available for schools. It was not uncommon to find districts with very low tax rates and high expenditures as well as districts with high tax rates and low expenditures.

In 1968 plaintiffs in California filed the first successful legal challenge, known as the *Serrano* case, to such school funding systems. The California state supreme court held that such inequities were unconstitutional and ordered the state to equalize spending differences based on property wealth. Challenges have been filed in most other states and have been successful in about half of these cases. In the late 1980s, plaintiffs began to challenge state funding systems by arguing that they do not provide adequate resources for education. These cases have been successful in a number of states, most notably in Kentucky, Ohio, and Wyoming.

Faced with such court rulings, or in many cases simply faced with a legal challenge, states have increased the level of support for schools. Whereas in 1920, local property taxes accounted for nearly 90 percent of school district revenues, by 2001, the federal government provided about 6 percent of school revenues with the remaining 94 percent shared approximately equally between states and local school districts. Although these percentages vary considerably from state to state, the general pattern of in-

creased state involvement in the funding of schools is clear.

States rely on two major types of intergovernmental grants to school districts and use a variety of distribution formulas to actually allocate funds to each district. The two major types of grants are *general aid* and *categorical grants*.

### General Aid

General—or unrestricted—aid represents the largest source of state revenue for local school districts in all of the states. General aid is money distributed to school districts with relatively few strings attached. This money, combined with local resources, usually represents between 70 and 90 percent of a district's budget and is spent for such things as teacher salaries, administrators, operations, and maintenance, instructional support, and the general operations of the schools. Much of this money is distributed to school districts in inverse relation to the local property wealth per pupil, with the intended consequence of equalizing differences in revenue capacity. States use the following mechanisms to allocate general aid to school districts.

**Flat grants.** A flat grant is a fixed amount of money given to each school district regardless of need. Popular in the early twentieth century, flat grants, if they are used at all, are relatively small today. Flat grants have lost favor because of their disequalizing impact and the fact that they provide assistance to districts regardless of local property wealth.

**Foundation programs.** Under a foundation program, the state establishes a base—or foundation—level of revenue that each district should maintain. It also establishes a required tax rate that each district must levy. The state then provides resources to each school district to make up the difference between the foundation level and how much is raised by that school district though the required property tax rate. If a district raises more than the required amount some states take those additional funds and use them to finance the state's share in other districts. This process is known as *recapture*. A foundation program works well in states where the court has ruled that some minimum level of funding is necessary to insure adequate educational opportunities.

**Guaranteed yield.** Another approach is to guarantee each district the ability to raise money as if it had a specified level of property wealth. The state estab-

lishes a guaranteed wealth level and as under the foundation program, districts with per pupil property wealth below that guarantee are given state aid so that at any tax rate they can raise as much revenue as the district whose wealth is equal to the guarantee. As before, wealthy districts are able to raise more than the guarantee. Some states recapture this difference and others do not.

The principle difference between foundation programs and guaranteed yield programs is that under a foundation program all districts are required to level a fixed tax rate and have the same revenue guarantee. This provides for considerable equity across districts, but limits local choices over how much to spend. Districts seeking to spend more than the foundation guarantee must do so with unequalized local property taxes. To the extent that the foundation level defined by the state does not grow as fast as school district revenue needs, larger portions of total revenue will become unequalized. This problem occurred in many states in the last half of the twentieth century.

Guaranteed yield programs specify a wealth guarantee. This gives districts more flexibility in determining how much they wish to spend, and insures that all districts (whose wealth is less than or equal to the guaranteed level) have access to the same level of per pupil revenue with equal tax rates. This approach allows for more local choice, but if the wealth guarantee does not keep up with growth in property values in the state, it too can lead to substantial portions of local revenue not being equalized.

A common solution to this problem is a two-tiered approach to distributing general aid to school districts. The first tier is a traditional foundation program requiring all districts to levy a minimum property tax and guaranteeing funding at a minimum level. The second tier relies on a guaranteed yield system, offering districts an equal amount of revenue per pupil for each increment in property tax rate above the foundation required tax rate. This guarantee often is capped at some level. Some states even allow districts an unequalized property tax above the second tier.

### Categorical Grants

Not all students have the same needs. Some children have disabilities that require special assistance to help them learn. There is also considerable evidence

that children from low-income homes are at a disadvantage in learning compared to children from higher-income families. Therefore, simply providing an equal level of revenue for each child may not offer equal educational opportunities. In addition, the characteristics of school districts may lead to differences in cost structures that must be compensated for if all children are to have equal access to educational services. Categorical grants are generally used by states to compensate for these differences in student and district characteristics. Among the categorical approaches most frequently in place are the following.

**Pupil weighting.** Something of a hybrid between general and categorical aid, the practice of pupil weighting counts students with special needs more than once before general state aid is distributed to school districts. For example, a child with a learning disability may receive an additional weight of one, meaning he or she is counted as two students for the purpose of state aid distribution. This has the effect of reducing the districts per pupil property wealth and hence increasing the state aid per pupil, and of providing that state aid for that child twice. It is assumed that the additional revenues will be used to meet the needs of the children who generate the funds, although not all states actually require that.

**Program-specific grants.** An alternative approach, program-specific grants give districts additional money based on child or district characteristics. For example, grants could be provided to help fund the special educational needs of children with disabilities. This can come in the form of direct reimbursements, or paying a fixed amount of money for each child so identified. In the case of compensatory education (money for children from low-income homes), additional revenue is often provided to enhance educational opportunities. Generally it is required that the funds be spent on the children who generated the funds in the first place.

States also provide categorical funds to assist districts with programs where costs may vary for reasons that are out of the control of the district. For example, geographically large but sparsely populated districts generally have higher transportation costs per pupil than do more densely populated urban districts. Many states provide separate transportation assistance to districts to compensate for these differences.

**Geographic cost differences.** In addition to the cost differences that school districts experience described

above, across most states there are substantial differences in the costs of the personnel, supplies and materials that schools purchase. Some states have begun to make adjustments to state aid formulas to accommodate these differences. For example, the costs of housing may be higher in large urban areas of a state compared to rural areas. In addition, there may be more competition for individuals with high levels of education and training (such as teachers) in some areas of a state. As a result, it may cost a district more to provide exactly the same services different parts of any state. Therefore, a geographic cost adjustment could be included in the state aid formula to adjust for those differences. These adjustments are often controversial and frequently poorly understood by state policy makers. Their intent is to equalize differences in costs faced by school districts that are out of their control. But legislators faced with allocating more money to other parts of the state often have difficulty supporting such adjustments and as a result they are only infrequently used today.

It is likely that over time, as lawsuits focused on school funding adequacy grow in importance, the state share of support for public education will grow. How states elect to distribute funds to local school districts will not only continue to be an important policy issue, but its importance will grow over time.

### FLEXNER, ABRAHAM (1866–1959)

Author of the monumental survey *Medical Education in the United States and Canada* (1910), Abraham Flexner contributed to a period of reform in

American medical education that hastened the closing of commercial medical schools and strengthened university-affiliated institutions adopting scientific approaches. A Louisville, Kentucky, native who earned his A.B. degree at Johns Hopkins University, Flexner established his own preparatory school in Louisville. However, he gained prominence as an educator through his critical essays, surveys, and reports about American educational institutions and practices. Throughout the early twentieth century, Flexner's ideas wielded influence through the sponsorship and largesse of powerful corporate foundations. Finally, from 1930 through 1939, Flexner designed and directed the Institute for Advanced Study at Princeton.

### Early Learning and Teaching Experiences

Born into a poor but ambitious family, Flexner developed an appetite for reading and studying outside of school. The endorsement of a Johns Hopkins alumnus sent Flexner to Baltimore in 1884, and an older brother's modest business income provided funds for his college tuition and expenses. Although inexperienced in the prerequisite studies of Latin and Greek, Flexner exercised industry and gained mastery of the classical languages. Against the norm, Flexner earned his bachelor's degree in two years.

Flexner returned to Louisville and secured employment in the Louisville High School, where he taught primarily Greek and Latin for four years. Supplementing his salary through private tutoring after school proved challenging and lucrative, however, and in 1890 Flexner opened his own school. This endeavor allowed Flexner to practice a rigorous and progressive student-centered pedagogy without the customary rules, tests, and reports. "Mr. Flexner's School" earned the reputation for preparing wealthy and sometimes troublesome boys for college. Furthermore, Flexner's work caught the attention of college presidents in the Northeast, who noticed that Flexner's students outperformed graduates of eastern prep schools. Flexner's pedagogical authority increased through articles he authored about his work in *The Educational Review* and *The International Journal of Ethics*.

### Attaining Status as Educational Expert

In 1904 Abraham Flexner closed his school and left Kentucky with his wife, Anne Crawford Flexner, to pursue advanced study at Harvard University. Despite Flexner's initial enthusiasm, he left the univer-

sity after a year, disappointed in his professors and assistantship. Never to earn an advanced degree, Flexner embarked instead upon an extended period of observation of all types of schools and universities both in New York and Europe. In his study and travel, Flexner benefited from sponsors and social acquaintances, including those of his brother Dr. Simon Flexner of the Rockefeller Institute for Medical Research. Thus, Flexner enjoyed unequalled access to institutions and introductions to professors, researchers, and foreign ministers. Settling at the University of Berlin and later Heidelberg, Flexner penned his first book, *The American College: A Criticism*, an overall critique of Harvard, which was based upon his personal experiences, including a scathing indictment of the elective system. This book, published in 1908 upon Flexner's return to America, received little notice except by the president of the Carnegie Foundation for the Advancement of Teaching, Dr. Henry S. Pritchett. Pritchett soon offered Flexner the opportunity to conduct the survey of medical schools that elevated him to national prominence.

To Henry Pritchett, Abraham Flexner was a "layman educator" capable of completing a key assignment in the Carnegie Foundation's larger institutional classification scheme, (i.e., differentiating colleges from secondary schools; universities from colleges, and accounting for appropriate work at each level). A vanguard force in the early-twentieth-century movement to increase standardization, efficiency, effectiveness, and the use of scientific methods, Pritchett deemed the Carnegie Foundation a champion of the public good. Pritchett presumed that Flexner's exhaustive survey of medical schools would improve American medical care by exposing society's overabundance of poorly trained physicians and the inferiority of its commercial medical schools. In combination with other social trends, Flexner's observations and scathing critique nurtured the scientific and professional practice of medicine. Specifically, schools labeled inferior eventually closed, the competing practice of homeopathy lost momentum, the admissions standards for prospective medical students increased, and the professional authority and status of university-trained physicians soared. Flexner's report earned him accolades and afterward he conducted a complete study of medical education in Europe.

Flexner continued to be a part of the elite circles of foundation administrators and consulted often in

matters of benefaction. In 1913 Flexner's foundation role became formalized through an appointment as assistant secretary to another Rockefeller-funded philanthropy, the General Education Board (GEB). Flexner worked for the GEB until 1929, having advanced to the position of executive secretary and member of the board. Importantly, Flexner's "expertise" as an educational reformer achieved new significance, with the philanthropy of the GEB behind him as a powerful incentive for institutional change. For example, from his studies of medical education Flexner advocated full-time appointments for clinical teachers in medical schools. Thus, those university medical schools first willing to require full-time clinical staffs (e.g. Johns Hopkins, Yale, Chicago, Cornell, Vanderbilt, and Iowa) received large foundation grants.

However, Flexner's GEB work was not limited to medical education. Flexner continued to practice sponsorship by offering financial support to promising scholars for research and travel. Also, Flexner directed extensive surveys and evaluations of public school systems. Maryland, Delaware, North Carolina, Indiana, and Kentucky, to name a few, contracted with the GEB for these services. Finally, Flexner created and established the Lincoln School at Teachers College, Columbia University, through a GEB endowment gift. Highly regarded for its experimental pedagogy, the Lincoln School eschewed the classical curriculum for modern languages, science, and social studies.

#### **Retirement and the Institute for Advanced Study**

Upon his retirement from the GEB, Flexner accepted the prestigious invitation for residence at Oxford for the Rhodes Trust Memorial Lectures, which later he published as *Universities: American, English, German* in 1930. Extolling the intellectual vigor of the German research tradition, this work became institutionalized as Flexner obtained a gift of \$5 million to create and direct the Institute for Advanced Study at Princeton. Ironically, the intellectual life of Flexner's institute benefited from the increasing repression of German universities, as foreign scholars, most notably Albert Einstein, found a place for research in the United States. Flexner left the institute in 1939 to spend his final years producing his autobiography and several other books.

## **FOREIGN LANGUAGE EDUCATION**

---

Foreign language education in the United States at the beginning of the twenty-first century is energized by some of the most dramatic developments in its modern history. Proficiency movement and standards initiatives have changed the focus of language instruction and assessment. Implications of emerging brain research have fueled renewed interest in early and intensive language learning for children in the first years of formal schooling, as well as programwide emphasis on meaningful use of language in authentic contexts. The resources of the Internet and other technology tools provide new opportunities for students to have direct experiences with the target language and its cultures, both within and beyond the school setting.

#### **Proficiency**

The American Council on the Teaching of Foreign Languages (ACTFL) Proficiency Guidelines, first published in 1986, shifted the emphasis in language instructional goals from what learners know *about*

language to what they can *do with* the language they have learned, and at the same time they established a common metric for measuring student performance. The Proficiency Guidelines describe student performance in listening, speaking, reading, and writing at the novice, intermediate, advanced, and superior levels. They were adapted from guidelines developed in U.S. government language schools and have made “proficiency-oriented instruction” a part of the vocabulary of every language teacher. The 1986 guidelines were subsequently reevaluated and revised, beginning with the 1999 document “ACTFL Proficiency Guidelines—Speaking” and with the 2001 document “Preliminary Proficiency Guidelines—Writing.”

### Standards

The *Standards for Foreign Language Learning in the Twenty-First Century*, introduced in 1996 and revised in 1999, created the bold vision of a long sequence of language instruction for all learners, beginning in kindergarten and continuing through grade twelve and beyond. Eleven content standards were clustered within five major goals:

- Communication: Communicate in Languages Other than English
- Cultures: Gain Knowledge and Understanding of Other Cultures
- Connections: Connect with Other Disciplines and Acquire Information
- Comparisons: Develop Insight into the Nature of Language and Culture
- Communities: Participate in Multilingual Communities at Home and Around the World

Sample performance indicators were provided for grades four, eight, and twelve, and sample learning scenarios described classroom activities that reflect the standards. After introduction of the general standards in 1996, supporting documents were developed for nine languages and were included in the 1999 edition.

ACTFL Performance Guidelines for K–12 Learners, devised in 1998, support the content standards with descriptions of student performance. Based on both the Proficiency Guidelines and the *Standards* document, the Performance Guidelines reinforce the vision of the K–12 sequence and dramatize the idea that proficiency development requires time and intensity of language instruction.

### Assessment

The Oral Proficiency Interview (OPI) is the tool by which trained interviewers place foreign language speakers on a proficiency continuum from novice to superior. By focusing on the ability to use the language to accomplish communicative tasks of increasing complexity, the OPI has influenced curriculum, teaching, and assessment, as well as standards for licensure of language teachers.

The application of the proficiency model to the other language skills of writing, reading, and comprehension created a new focus in assessment on performance tasks rather than linguistic manipulation. Teachers create contexts and rubrics for evaluating student performance and portfolios of student work, in addition to more traditional tests of accuracy and grammatical competence.

Because of the usefulness of performance assessments, adaptations of OPI-based assessments have been developed for use in K–8 settings and for articulation between high school and college programs. The Center for Applied Linguistics developed an oral interview for students in immersion and other elementary school language programs called the Student Oral Proficiency Assessment. Similar to the OPI, this test uses contexts and environments more appropriate to the child in grades three to five. Another test, the Early Language Listening and Oral Proficiency Assessment, was subsequently developed for language learners from pre-K to grade two. These tests are intended primarily for program evaluation, although they give teachers feedback on effectiveness of teaching and student progress, as well as tools for constructing their own classroom oral assessments.

### Technology

The growing use of technology throughout society has had an impact on foreign language instruction as well, especially at the middle and high school level. The language labs of the 1960s and 1970s have become multimedia learning laboratories. Students and teachers supplement their textbooks with CD-ROMs, access foreign-language websites, hold online conversations with students in other countries, and interact regularly with their “key pals,” often in the target language. Many students keep electronic portfolios and build culminating projects using Internet resources and multimedia software such as PowerPoint or HyperStudio. They may create individual or class web pages, and outstanding student work may

appear on the school web page. Teachers use the web to post activities and information, to communicate with parents and the community, and to provide resources for students, parents, and other teachers. In many respects the Internet is the realization of a long-held dream: Students can be in regular contact with authentic foreign language resources, both at school and at home, and they can use the target language for meaningful, personal purposes.

Technology can also help teachers and school districts provide foreign language instruction even in remote and isolated settings. Interactive television has made it possible for one Spanish teacher in North Dakota, for example, to reach students in schools many miles away. Interactive television can bring a Russian or a Japanese class to one or two high school students who would otherwise have to wait until college to enroll in the language of their choice. Distance learning is the only option for language education for some rural and isolated school districts. Because of the popularity of distance learning and the special conditions necessary for its success, the National Council of State Supervisors of Foreign Language issued a position paper on the topic in 2002.

### Support for Foreign Language Teachers

K–12 foreign language teachers of the early twenty-first century have unprecedented support and resources available to them. Each of the major languages has a national organization that provides guidelines, resources, and sometimes funding to assist teachers and programs. The American Council on the Teaching of Foreign Languages (ACTFL) serves as an umbrella organization for all languages, and in this role it has initiated major projects such as the ACTFL Proficiency Guidelines, the *Standards*, and the ACTFL Performance Guidelines for K–12 Learners. Teachers also have access to state and national conferences sponsored by these organizations, as well as regional conferences such as the Northeast Conference on the Teaching of Foreign Languages, the Southern Conference on Language Teaching, the Southwest Conference on Language Teaching, and the Central States Conference on Teaching Foreign Languages. Most sessions at these conferences focus on curriculum and pedagogy for the K–12 level.

The Center for Applied Linguistics provides research and information about K–12 language learning, and its Educational Resources Information Center (ERIC) Clearinghouse on Languages and

Linguistics offers a wide range of resources in foreign language education. The language resource centers were established by Congress in 1989 to serve as resources to improve the nation's capacity to teach and learn foreign languages effectively. One of these, the K–12 Foreign Language Resource Center at Iowa State University, is focused specifically on issues of curriculum, assessment, and teacher development for K–12 programs.

Listserves provide teachers with the opportunity to post questions about programs, materials, or methodology and share their ideas with colleagues from all over the country. Two of the most popular are FLTeach, used especially by middle and high school teachers, and Nandu, the early language listserv for K–8 teachers. Many other listservs address the needs of specific languages and topic areas.

### Elementary School Foreign Language Programs

Paul Garcia, then president of the ACTFL, was asked in a 2000 interview in *Curriculum Technology Quarterly* about new trends in foreign language education. He identified the continuing growth of foreign language programs for primary school learners as the most important trend and made special note of immersion education within that development. After a surge in the 1960s and a steep decline in the 1970s and early 1980s, interest in early language learning accelerated and sustained momentum through the turn of the century.

National reports played a strong role in this re-awakening of interest. These reports included:

- *Strength through Wisdom*, a 1979 report of the President's Commission on Foreign Language and International Studies, which specifically recommended that language learning begin in the elementary school and continue throughout a student's schooling.
- *A Nation at Risk*, a 1983 report of the National Commission on Excellence in Education, which ranked foreign language education at the same level as the "basic academic fields."

Such reports emphasized the national and economic importance of attaining a level of proficiency in a foreign language that could only be accomplished over a long period of study.

Further impetus for early language learning came from results and interpretation of brain research, brought to popular awareness through reports in *Newsweek* in 1996 and *Time* in 1997. In the

*Time* article, J. Madeline Nash wrote, "The ability to learn a second language is highest between birth and the age of six, and then undergoes a steady and inexorable decline. . . . What lessons can be drawn from the new findings? Among other things, it is clear that foreign languages should be taught in elementary school, if not before" (p. 56).

A number of states responded with mandates for teaching languages at the elementary school level, in some cases without funding to support the new programs. By 2002 there were mandates for foreign languages in the elementary school curriculum in at least eight states: Arizona, Arkansas, Louisiana, Montana, New Jersey, North Carolina, Oklahoma, and Wyoming. Other states worked without a mandate to increase and promote elementary school foreign language offerings.

In 1997 there were foreign language programs in 31 percent of all public and private elementary schools surveyed by the Center for Applied Linguistics, up from 22 percent in 1987. Spanish was taught in 79 percent of the programs, followed by French at 27 percent. Programs in German, Latin, Japanese, and Spanish for Spanish speakers were also well represented.

Elementary school foreign language programs generally fit into three major categories: immersion, FLES (foreign languages in elementary schools), and FLEX (foreign language exploration or experience).

**Immersion education.** Foreign language immersion programs, in which the content of the school curriculum is taught in the foreign language, are among the most influential innovations of the final decades of the twentieth century. Immersion goals are twofold: fluency in the foreign language and mastery of the content of the school curriculum. Most immersion programs begin in kindergarten or grade one, and many continue through the middle and high school levels. The first North American public school immersion program began in 1965 with a kindergarten in St. Lambert, a suburb of Montreal, Canada. Supported and advised by researchers from McGill University in Montreal, this French program was shaped by sound professional advice and carefully researched as it progressed from one grade to the next. Longitudinal research validated the effectiveness of immersion in meeting both language and content goals and served to inspire new immersion programs across Canada and in the United States.

The first U.S. immersion program was established in Spanish in Culver City, California, in 1971.

In 1974 a total immersion program in French began in Montgomery County, Maryland, and partial immersion programs in French, Spanish, and German began in Cincinnati, Ohio. Other programs soon followed, and by 1993 approximately 28,200 students were enrolled in nine languages in 139 programs, in twenty-five states and Washington, DC. Spanish was the most frequently taught language, followed by French, Japanese, and German. By 1999 the total number of immersion schools had risen to 278, with approximate 46,000 students enrolled, in eleven languages. More than half the programs were in Spanish.

In *total immersion* programs all instruction during the school day is conducted in the target language, beginning with four- or five-year-olds in kindergarten, and children learn to read first in their new language. English language instruction is usually introduced in grade two or three, commonly for a half hour per day, and is gradually increased each year until by grade five or six, 20 to 40 percent of the day is taught in English.

*Partial immersion* programs deliver the curriculum in the English language for approximately half the school day and in the foreign language for the other half of the day. Children learn to read in both languages simultaneously or in English first and then in the new language. This balance of English and foreign language instruction continues from the beginning of schooling until grade five or six.

Both total immersion and partial immersion are designed primarily for native speakers of English, although native speakers of other languages are also successful immersion students. In most cases the teacher is the only fluent language model for the students in the classroom. *Two-way immersion*, or *bilingual immersion*, is a model that grew rapidly after its introduction in 1963. In this approach, native speakers of English and the target language learn together, half a day in one language and half a day in the other. Each group of students is learning in its new language during half the school day, and student native speakers serve as language models for one another. By 2000 there were 260 programs in twenty-three states, most of them in Spanish. This model depends on the presence of a stable population of native speakers of both languages, and the growing Spanish population in the United States creates ideal conditions for two-way Spanish immersion programs.

**FLES (foreign languages in elementary schools) programs.** FLES programs have a long history in the

United States, with a notable surge in popularity in the 1960s and a resurgence in the late 1980s. As generally defined, FLES programs are part of a long sequence of language study, beginning before middle school, that lead to continuing courses at the middle and high school levels. The programs of the late 1980s emphasized integrated, thematic planning and a close connection with the general elementary school curriculum. Some “content-based” or “content-related” programs make a special effort to reinforce student learning in other content areas. Class periods range from ten to forty minutes in length, from once to five times per week.

This variability of starting points, instructional time, and degree of content orientation has made it very difficult to evaluate the overall results of FLES programs. The task force that developed the “ACTFL Performance Guidelines for K–12 Learners” addressed this problem by recommending that “the accomplishment of such content standards (in the ACTFL *Standards* document) required students to be enrolled in elementary programs that meet from 3–5 days per week for no less than 30–40 minutes per class” (Swender and Duncan, p. 482).

The Georgia ESFL (elementary school foreign language) model programs, established in 1992 with state funding, provide a clear picture of what is possible in a FLES program. Georgia model programs were designed to provide optimum conditions for language learning and to serve as a case study for the amount of language proficiency children can attain after six years of language study. Program guidelines require participating schools to offer a foreign language for thirty minutes per day, five days per week, beginning in kindergarten and continuing at least through grade five. Instruction is delivered in the target language, and teachers are expected to teach no more than eight classes per day. Testing in 1996, 1998, and 2001 by the Center for Applied Linguistics affirmed the outstanding results of these programs in all the languages represented—French, German, Japanese, and Spanish—and the 2001 report commended the program as a model for the entire United States.

**FLEX programs (foreign language exploration or experience).** Some school districts that find it impossible to fund more intensive foreign language programs for all students offer short-term programs that give learners a sample of one or more languages over a limited period of time. In 1994 Helena Curtain and Carol Ann Bjornstad Pesola characterized

FLEX programs as “frequent and regular sessions over a short period of time or short and/or infrequent sessions over an extended period of time” (p. 30). These programs have limited goals, usually stated in terms of interest and awareness, and in some cases they are taught mostly in English. Sometimes FLEX programs are offered as a way of helping students choose which language they will later study in depth. When carefully designed and well taught, FLEX programs can serve to enhance cultural awareness and motivate future language study, but they do not claim measurable language skills as an outcome.

### Middle School Programs

Middle school programs face several major challenges. The first is the learners themselves, who have developmental characteristics that require instructional materials and strategies that are different both from those appropriate for the elementary school and from those effective with high school students. These needs are not adequately met by simply extending textbook instruction over two years instead of one, a typical program format. Second, as elementary school programs continue to grow, the middle school is literally caught in the middle of the long sequence, with a responsibility to coordinate with both elementary school and high school programs. Experienced language learners need continuation courses in the same language learned in the elementary school, and they also benefit from the option to begin a third language in the middle school. Middle schools that receive students from immersion programs or K–5/6 FLES programs sometimes offer content courses taught in the target language, especially mathematics and social studies. Third, middle schools have very limited time available for electives, and so long as foreign language classes are viewed as electives, they are often in competition with such attractive options as music, art, and applied arts.

Exploratory programs, long a popular approach for the middle school, fit well with the philosophy of exploration that has been a hallmark of the middle school curriculum. While FLEX programs may equip students to make an experience-based choice of a language for further study, they do not fit well with the projected K–12 sequence of the *Standards* document, nor with the recommendations of the task force for the ACTFL Performance Guidelines, which call for “middle school programs that meet daily for no less than 40–50 minutes” (Schwender and Duncan, p. 482). These programs also do not

meet the needs of learners who have spent four to seven years in an elementary school FLES or immersion program.

A typical middle school format before the advent of proficiency and the *Standards* document included one semester to one year of the language in grade seven, followed by one semester to one year in grade eight, both considered to be “Level One.” Students entering grade nine would then be eligible to enroll in “Level Two” of the language. This format, often preceded by a one-semester or one-year exploratory program, continues to be typical at the beginning of the twenty-first century.

Clearly the variety of programs at the middle school level, ranging from nothing to a continuation of an effective elementary school program, made the *Standards* vision of a K–12 foreign language sequence difficult to attain. As Myriam Met pointed out in 1996, “Foreign language instruction in middle schools will be critical to the success of long sequences in the coming years” (p. 1).

### High School Programs

The curriculum at the high school level has continued to be textbook-driven, although proficiency and the *Standards* have had a growing impact on textbooks, methodology, and student success. Teachers use partner and group work to help students develop strong communication skills. Influenced by the *Standards*, many teachers build units thematically, focus them on culminating projects, and integrate content from the general curriculum.

As with the middle school level, there is a vast variability across the country in terms of access to foreign language instruction at the high school level. Students in districts with well-developed K–12 programs emerge with impressive levels of proficiency from full five- to six-year programs spanning middle school and high school. At the same time there are other students, often in rural areas, who have virtually no access to foreign language instruction. Some schools have addressed the problem of access through the use of interactive television or by encouraging summer enrollment in various college or camp offerings.

Block scheduling in many schools has challenged teachers to rethink how they involve students with learning over class periods lasting ninety minutes and longer. Lack of continuity in language study, common in block scheduling, can create ob-

stacles to the attainment of proficiency goals and place added stress on students and teachers.

In years three to five of the high school curriculum, a number of programs offer courses leading to the International Baccalaureate (IB), a schoolwide program that entitles graduates to enter universities around the world. Other programs offer Advanced Placement (AP) classes, which prepare students to take examinations that can result in college credit. Both IB and AP classes tend to focus on literature. Some states offer college-in-the-schools programs that allow advanced students to take college courses in their high school environment.

Many schools offer travel programs for foreign language students, often during spring or summer breaks, and in some cases a partner school in the target culture also sends students to the United States. These opportunities for authentic language practice are popular with students and teachers. Even short programs help to solidify language skills and motivate further language study. Other authentic language opportunities are found in popular weekend and summer language camps, such as the Concordia Language Villages in northern Minnesota.

### Foreign Language Programs in Other Countries

A study of nineteen countries on six continents completed by the Center for Applied Linguistics in 2000 identified a number of contrasts between U.S. programs and those elsewhere. Most of the countries surveyed require the study of at least one foreign language, beginning in elementary grades. Some countries require two languages in the course of schooling, and Israel requires three languages—Hebrew plus two others. In countries of the European Union, foreign language study is moving earlier and earlier in the curriculum, and many countries begin in first grade.

Another contrast with the United States is the presence of strong language policy in many of the surveyed countries. Such policies include compulsory foreign language education, a national curriculum or curriculum framework, and designated amounts of time required for foreign language instruction. In many of the countries surveyed foreign languages are considered to be core subjects. In Germany, for example, languages command the same status and time commitment as mathematics, reading, and social studies. All of these policies stand in sharp contrast to the U.S. school setting.

The influence of immersion education and content-based instruction is notable in Europe and Australia, as increasing numbers of programs use the target language as a tool and not only a focus of instruction. Canada continues to show leadership in the development of and research into immersion programs, mainly for English-speaking learners of French. Two-way immersion programs are proliferating in Germany and Australia.

Communicative language teaching methods have been increasingly evident in Europe. As political and economic barriers among European countries have dropped away, the need to function in several languages has increased sharply, and priority has been placed on proficiency in written and spoken language. These priorities are reflected in both materials and teaching approaches. The Goethe Institute, a German government organization that provides German language instruction throughout the world, has been a leader in the development and dissemination of communicative teaching methodologies.

### Challenges for K–12 Foreign Languages

As teachers work toward the vision of K–12 language programs and performance-based curriculum and instruction, several major challenges await them. First, developing smooth transitions from elementary to middle to high school, and then from high school to colleges and universities, will be a high priority. Making time for languages in the crowded middle school curriculum will be a major obstacle. Using the resources of technology to stretch the potential of the language classroom will be a constant challenge, especially as the technology continues to provide new opportunities. Teachers continue to be in short supply at all levels. Finally, there is the fundamental challenge: claiming a secure place in the school day and in the K–12 curriculum for foreign language instruction.

## FREIRE, PAULO (1921–1997)

Paulo Reglus Neves Freire was a Brazilian educator whose revolutionary pedagogical theory influenced educational and social movements throughout the world and whose philosophical writings influenced academic disciplines that include theology, sociology, anthropology, applied linguistics, pedagogy, and cultural studies. He was born to a middle-class family in Recife, in the state of Pernambuco in the northeast of Brazil. His early work in adult literacy—the most famous being his literacy experiments in the town of Angicos in Rio Grande do Norte—was terminated after the military coup in 1964. That year he went into exile, during which time he lived in Bolivia; then Chile where he worked for the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the Chilean Institute for Agrarian Reform, and where he wrote his most important work, *Pedagogy of the Oppressed* (1970); Mexico; the United States where he held a brief appointment at Harvard University's Center for

Studies in Development and Social Change; and Switzerland where he worked for the World Council of Churches as the director of their education program. He also served as an adviser for various governments, most notably the government of Guinea-Bissau. In 1980 he returned to Brazil to teach and later to serve as secretary of education for São Paulo. He worked as a consultant for revolutionary governments such as the New Jewel Movement in Grenada, the Sandinista government in Nicaragua, and the government of Julius K. Nyerere in Tanzania. From 1985 until his death in 1997, Freire served as the honorary president of the International Council for Adult Education. Freire's conception of education as a deeply political project oriented toward the transformation of society has been crucial to the education of revolutionary societies and societies undergoing civil war, as well as established Western democracies. Freire's work has exercised considerable influence among progressive educators in the West, especially in the context of emerging traditions of critical pedagogy, bilingual education, and multicultural education.

Freire's revolutionary pedagogy starts from a deep love for, and humility before, poor and oppressed people and a respect for their "common sense," which constitutes a knowledge no less important than the scientific knowledge of the professional. This humility makes possible a condition of reciprocal trust and communication between the educator, who also learns, and the student, who also teaches. Thus, education becomes a "communion" between participants in a dialogue characterized by a reflexive, reciprocal, and socially relevant exchange, rather than the unilateral action of one individual agent for the benefit of the other. Nevertheless, this does not amount to a celebration of the untrammelled core of consciousness of the oppressed, in which the educator recedes into the background as a mere facilitator. Freire conceived of authentic teaching as enacting a clear authority, rather than being authoritarian. The teacher, in his conception, is not neutral, but intervenes in the educational situation in order to help the student to overcome those aspects of his or her social constructs that are paralyzing, and to learn to think critically. In a similar fashion, Freire validated and affirmed the experiences of the oppressed without automatically legitimizing or validating their content. All experiences—including those of the teacher—had to be interrogated in order to lay bare their

ideological assumptions and presuppositions. The benchmark that Freire used for evaluating experiences grew out of a Christianized Marxist humanism. From this position, Freire urged both students and teachers to unlearn their race, class, and gender privileges and to engage in a dialogue with those whose experiences are very different from their own. Thus, he did not uncritically affirm student or teacher experiences but provided the conceptual tools with which to critically interrogate them so as to minimize their politically domesticating influences.

### Conceptual Tools

**Banking education.** Freire criticized prevailing forms of education as reducing students to the status of passive objects to be acted upon by the teacher. In this traditional form of education it is the job of the teacher to deposit in the minds of the students, considered to be empty in an absolute ignorance, the bits of information that constitute knowledge. Freire called this *banking education*. The goal of banking education is to immobilize the people within existing frameworks of power by conditioning them to accept that meaning and historical agency are the sole property of the oppressor. Educators within the dominant culture and class fractions often characterize the oppressed as marginal, pathological, and helpless. In the banking model, knowledge is taken to be a gift that is bestowed upon the student by the teacher. Freire viewed this false generosity on the part of the oppressor—which ostensibly aims to incorporate and improve the oppressed—as a crucial means of domination by the capitalist class. The indispensable soil of good teaching consists of creating the pedagogical conditions for genuine dialogue, which maintains that teachers should not impose their views on students, but neither should they camouflage them nor drain them of political and ethical import.

**Problem-posing method.** Against the banking model, Freire proposed a dialogical *problem-posing method* of education. In this model, the teacher and student become co-investigators of knowledge and of the world. Instead of suggesting to students that their situation in society has been transcendently fixed by nature or reason, as the banking model does, Freire's problem-posing education invites the oppressed to explore their reality as a "problem" to be transformed. The content of this education cannot be determined necessarily in advance, through the expertise of the educator, but must instead arise

from the lived experiences or reality of the students. It is not the task of the educator to provide the answer to the problems that these situations present, but to help students to achieve a form of critical thinking (or *conscientization*) that will make possible an awareness of society as mutable and potentially open to transformation. Once they are able to see the world as a transformable situation, rather than an unthinkable and inescapable stasis, it becomes possible for students to imagine a new and different reality.

In order, however, to undertake this process, the oppressed must challenge their own internalization of the oppressor. The oppressed are accustomed to thinking of themselves as "less than." They have been conditioned to view as complete and human only the dominating practices of the oppressor, so that to fully become human means to simulate these practices. Against a "fear of freedom" that protects them from a cataclysmic reorganization of their being, the oppressed in dialogue engage in an existential process of dis-identifying with "the oppressor housed within." This dis-identification allows them to begin the process of imagining a new being and a new life as subjects of their own history.

**Culture circle.** The concrete basis for Freire's dialogical system of education is the *culture circle*, in which students and coordinator together discuss generative themes that have significance within the context of students' lives. These themes, which are related to nature, culture, work, and relationships, are discovered through the cooperative research of educators and students. They express, in an open rather than propagandistic fashion, the principle contradictions that confront the students in their world. These themes are then represented in the form of codifications (usually visual representations) that are taken as the basis for dialogue within the circle. As students decode these representations, they recognize them as situations in which they themselves are involved as subjects. The process of critical consciousness formation is initiated when students learn to read the codifications in their situationality, rather than simply experiencing them, and this makes possible the intervention by students in society. As the culture circle comes to recognize the need for print literacy, the visual codifications are accompanied by words to which they correspond. Students learn to read these words in the process of reading the aspects of the world with which they are linked.

Although this system of codifications has been very successful in promoting print literacy among adult students, Freire always emphasized that it should not be approached mechanically, but rather as a process of creation and awakening of consciousness. For Freire, it is a mistake to speak of reading as solely the decoding of text. Rather, reading is a process of apprehending power and causality in society and one's location in it. Awareness of the historicity of social life makes it possible for students to imagine its re-creation. Literacy is thus a "self-transformation producing a stance of intervention" (Freire 1988, p. 404). Literacy programs that appropriate parts of Freire's method while ignoring the essential politicization of the process of reading the world as a limit situation to be overcome distort and subvert the process of literacy education. For Freire, authentic education is always a "practice of freedom" rather than an alienating inculcation of skills.

### Philosophy of Education

Freire's philosophy of education is not a simple method but rather an organic political consciousness. The domination of some by others must be overcome, in his view, so that the humanization of all can take place. Authoritarian forms of education, in serving to reinforce the oppressors' view of the world, and their material privilege in it, constitute an obstacle to the liberation of human beings. The means of this liberation is a *praxis*, or process of action and reflection, which simultaneously names reality and acts to change it. Freire criticized views that emphasized either the objective or subjective aspect of social transformation, and insisted that revolutionary change takes place precisely through the consistency of a critical commitment in both word and deed. This dialectical unity is expressed in his formulation, "To speak a true word is to transform the world" (Freire 1996, p. 68).

Freire's educational project was conceived in solidarity with anticapitalist and anti-imperialist movements throughout the world. It calls upon the more privileged educational and revolutionary leaders to commit "class suicide" and to struggle in partnership with the oppressed. Though this appeal is firmly grounded in a Marxist political analysis, which calls for the reconfiguring of systems of production and distribution, Freire rejected elitist and sectarian versions of socialism in favor of a vision of revolution from "below" based on the work of autonomous popular organizations. Not only does

Freire's project involve a material reorganization of society, but a cultural reorganization as well. Given the history of European imperialism, an emancipatory education of the oppressed involves a dismantling of colonial structures and ideologies. The literacy projects he undertook in former Portuguese colonies in Africa included an emphasis on the reaffirmation of the people's indigenous cultures against their negation by the legacy of the metropolitan invaders.

Freire's work constitutes a rejection of voluntarism and idealism as well as determinism and objectivism. The originality of Freire's thought consists in his synthesis of a number of philosophical and political traditions and his application of them to the pedagogical encounter. Thus, the Hegelian dialectic of master and slave informs his vision of liberation from authoritarian forms of education; the existentialism of Jean Paul Sartre and Martin Buber makes possible his description of the self-transformation of the oppressed into a space of radical intersubjectivity; the historical materialism of Karl Marx influences his conception of the historicity of social relations; his emphasis on love as a necessary precondition of authentic education has an affinity with radical Christian liberation theology; and the anti-imperialist revolutionism of Ernesto Che Guevara and Frantz Fanon undergird his notion of the "oppressor housed within" as well as his commitment to a praxis of militant anticolonialism.

Freire's pedagogy implies an important emphasis on the imagination, though this is not an aspect that has been emphasized enough in writings about him. The transformation of social conditions involves a rethinking of the world as a particular world, capable of being changed. But the reframing proposed here depends upon the power of the imagination to see outside, beyond, and against what is. More than a cognitive or emotional potential, the human imagination, in Freire's view, is capable of a radical and productive envisioning that exceeds the limits of the given. It is in this capacity that everyone's humanity consists, and for this reason it can never be the gift of the teacher to the student. Rather, educator-student and student-educator work together to mobilize the imagination in the service of creating a vision of a new society. It is here that Freire's notion of education as an ontological vocation for bringing about social justice becomes most clear. For Freire, this vocation is an endless struggle because critical awareness itself can only be a neces-

sary precondition for it. Because liberation as a goal is always underburdened of a necessary assurance that critical awareness will propel the subject into the world of concrete praxis, the critical education must constantly be engaged in attempts to undress social structures and formations of oppression within the social universe of capital without a guarantee that such a struggle will bring about the desired results.

### Criticism

Since its first enunciation, Freire's educational theory has been criticized from various quarters. Naturally, conservatives who are opposed to the political horizon of what is essentially a revolutionary project of emancipation have been quick to condemn him as demagogic and utopian. Freire has faced criticism from the left as well. Some Marxists have been suspicious of the Christian influences in his work and have accused him of idealism in his view of popular consciousness. Freire has also been criticized by feminists and others for failing to take into account the radical differences between forms of oppression, as well as their complex and contradictory instantiation in subjects. It has been pointed out that Freire's writing suffers from sexism in its language and from a patriarchal notion of revolution and subjecthood, as well as a lack of emphasis on domination based on race and ethnicity. Postmodernists have pointed to the contradiction between Freire's sense of the historicity and contingency of social formations versus his vision of liberation as a universal human vocation.

Freire was always responsive to critics, and in his later work undertook a process of self-criticism in regard to his own sexism. He also sought to develop a more nuanced view of oppression and subjectivity as relational and discursively as well as materially embedded. However, Freire was suspicious of postmodernists who felt that the Marxist legacy of class struggle was obsolete and whose antiracist and anti-sexist efforts at educational reform did little to alleviate—and often worked to exacerbate—existing divisions of labor based on social relations of capitalist exploitation. Freire's insights continue to be of crucial importance. In the very gesture of his turning from the vaults of official knowledge to the open space of humanity, history, and poetry—the potential space of dialogical problem-posing education—Freire points the way for teachers and others who would refuse their determination by the increasingly enveloping inhuman social order. To believe in that

space when it is persistently obscured, erased, or repudiated remains the duty of truly progressive educators. Freire's work continues to be indispensable for liberatory education, and his insights remain of value to all who are committed to the struggle against oppression.

## FROEBEL, FRIEDRICH (1782–1852)

The German educator Friedrich Froebel is significant for developing an Idealist philosophy of early childhood education and establishing the kindergarten, a school for four- and five-year-old children that is found worldwide.

## Biography

Friedrich Wilhelm August Froebel was the youngest of five sons of Johann Jacob Froebel, a Lutheran pastor at Oberweissbach in the German principality of Schwarzburg-Rudolfstadt. Froebel's mother died when he was nine months old. When Friedrich was four years old, his father remarried. Feeling neglected by his stepmother and father, Froebel experienced a profoundly unhappy childhood. At his father's insistence, he attended the girls' primary school at Oberweissbach. From 1793 to 1798 he lived with his maternal uncle, Herr Hoffman, at Stadt-Ilm, where he attended the local town school. From the years 1798 to 1800 he was as an apprentice to a forester and surveyor in Neuhaus. From 1800 to 1802 Froebel attended the University of Jena.

In 1805 Froebel briefly studied architecture in Frankfurt. His studies provided him with a sense of artistic perspective and symmetry he later transferred to his design of the kindergarten's gifts and occupations. In 1805 Anton Gruener, headmaster of the Pestalozzian Frankfurt Model School, hired Froebel as a teacher. To prepare him as a teacher, Gruener arranged for Froebel, now twenty-four years old, to take a short course with Johann Heinrich Pestalozzi at Yverdon. Froebel believed Pestalozzi's respect for the dignity of children and creation of a learning environment of emotional security were highly significant educational elements that he wanted to incorporate in his own teaching. He also was intrigued by Pestalozzi's form, number, and name lessons, which would form a basis for his later design of the kindergarten gifts. After his training with Pestalozzi, Froebel taught at Gruener's Model School until he returned to Yverdon in 1808 for two more years of study with Pestalozzi.

From 1810 to 1812 Froebel studied languages and science at the University of Göttingen. He hoped to identify linguistic structures that could be applied to language instruction. He became particularly interested in geology and mineralogy. From 1812 to 1816 Froebel studied mineralogy with Professor Christian Samuel Weiss (1780–1856) at the University of Berlin. Froebel believed the process of crystallization, moving from simple to complex, reflected a universal cosmic law that also governed human growth and development.

In 1816 Froebel established the Universal German Educational Institute at Griesheim. He moved the institute to Keilhau in 1817 where it functioned

until 1829. In 1818 Froebel married Henrietta Wilhelmine Hoffmeister (1780–1839), who assisted him until her death. In 1831 Froebel established an institute at Wartensee on Lake Sempach in Switzerland and then relocated the school to Willisau. Froebel next operated an orphanage and boarding school at Burgdorf.

Froebel returned to Germany, where in 1837 he established a new type of early childhood school, a child's garden, or kindergarten, for three- and four-year-old children. Using play, songs, stories, and activities, the kindergarten was designed as an educational environment in which children, through their own self-activity, could develop in the right direction. The right direction meant that, in their development, children would follow the divinely established laws of human growth through their own activity. Froebel's reputation as an early childhood educator increased and kindergartens were established throughout the German states.

In 1851 Karl von Raumer, the Prussian minister of education, accused Froebel of undermining traditional values by spreading atheism and socialism. Despite Froebel's denial of these accusations, von Raumer banned kindergartens in Prussia. In 1852, in the midst of the controversy, Froebel died. Although kindergartens existed in the other German states, they were not reestablished in Prussia until 1860. By the end of the nineteenth century, kindergartens had been established throughout Europe and North America.

## Froebel's Kindergarten Philosophy

Froebel shaped his educational philosophy during the high tide of German philosophical Idealism that was marked by the work of Johann Gottfried Herder (1744–1803), Immanuel Kant (1724–1804), and Georg Wilhelm Hegel (1770–1831). In the *Education of Man* (1826), Froebel articulated the following idealist themes: (1) all existence originates in and with God; (2) humans possess an inherent spiritual essence that is the vitalizing life force that causes development; (3) all beings and ideas are interconnected parts of a grand, ordered, and systematic universe. Froebel based his work on these principles, asserting that each child at birth has an internal spiritual essence—a life force—that seeks to be externalized through self-activity. Further, child development follows the doctrine of preformation, the unfolding of that which was present latently in the individual. The kindergarten is a special educational environ-

ment in which this self-active development occurs. The kindergarten's gifts, occupations, and social and cultural activities, especially play, promote this self-actualization.

Froebel was convinced that the kindergarten's primary focus should be on play—the process by which he believed children expressed their innermost thoughts, needs, and desires. Froebel's emphasis on play contrasted with the traditional view prevalent during the nineteenth century that play, a form of idleness and disorder, was an unworthy element of human life.

For Froebel, play facilitated children's process of cultural recapitulation, imitation of adult vocational activities, and socialization. He believed the human race, in its collective history, had gone through major epochs of cultural development that added to and refined its culture. According to Froebel's theory of cultural recapitulation, each individual human being repeated the general cultural epoch in his or her own development.

By playing, children socialize and imitate adult social and economic activities as they are gradually led into the larger world of group life. The kindergarten provided a milieu that encouraged children to interact with other children under the guidance of a loving teacher.

### The Kindergarten Curriculum

Froebel developed a series of gifts and occupations for use in kindergartens. Representing what Froebel identified as fundamental forms, the gifts had both their actual physical appearance and also a hidden symbolic meaning. They were to stimulate the child to bring the fundamental concept that they represented to mental consciousness. Froebel's gifts were the following items.

- Six soft, colored balls
- A wooden sphere, cube, and cylinder
- A large cube divided into eight smaller cubes
- A large cube divided into eight oblong blocks
- A large cube divided into twenty-one whole, six half, and twelve quarter cubes
- A large cube divided into eighteen whole oblongs: three divided lengthwise; three divided breadthwise
- Quadrangular and triangular tablets used for arranging figures
- Sticks for outlining figures

- Whole and half wire rings for outlining figures
- Various materials for drawing, perforating, embroidering, paper cutting, weaving or braiding, paper folding, modeling, and interlacing

As a series, the gifts began with the simple undifferentiated sphere or circle and moved to more complex objects. Following the idealist principle of synthesis of opposites, Froebel's cylinders represented the integration of the sphere and the cube. The various cubes and their subdivisions were building blocks that children could use to create geometrical and architectural designs. Using the sticks and rings to trace designs on paper, children exercised the hand's small muscles, coordinated hand and eye movements, and took the first steps toward drawing and later writing.

The occupations were items such as paper, pencils, wood, sand, clay, straw, and sticks for use in constructive activities. Kindergarten activities included games, songs, and stories designed to assist in sensory and physical development and socialization. Froebel published *Mutter-und-Kose-lieder*, (Mother's songs, games, and stories), a collection of kindergarten songs, in 1843.

### Diffusion of the Kindergarten

Kindergartens were established in Europe and North America. In the United Kingdom, Bertha Ronge, a pupil of Froebel's, established several kindergartens. In the United States, German immigrants introduced the kindergarten. In Watertown, Wisconsin, Margarethe Meyer Schurz established a kindergarten for German-speaking children in 1856. In New York, Matilda H. Kriege introduced and marketed kindergarten materials imported from Germany.

Henry Barnard, the first U.S. Commissioner of Education, popularized Froebel's philosophy in his *Common School Journal*. Elizabeth Palmer Peabody (1804–1894) established a kindergarten in Boston, translated several of Froebel's books into English, organized an educational organization called the Froebel Union, and established an institute to train kindergarten teachers.

Superintendent of Schools William Torrey Harris, (1835–1909) incorporated the kindergarten into the St. Louis, Missouri, public school system in 1873. Harris was assisted by his associate, Susan Elizabeth Blow (1843–1916), a dedicated Froebelian, who wrote *Letters to a Mother on the Philosophy of Froebel* in 1899 and *Kindergarten Education* in 1900.

In the early twenty-first century, kindergarten teachers continue to emphasize Froebel's ideas of developing the social side of a child's nature and a sense of readiness for learning. The important outcome for the kindergarten child is readiness for the intellectual learning that will come later in his educational career.

## FULL-SERVICE SCHOOLS

According to David Tyack, writing in 1992, there is a long history in the United States of providing remediation services to children in a school setting. Early programs attempted to provide health and so-

cial services in the school setting. The intent of these early efforts was to assist immigrant children in adjusting to their new culture. Locating these services in the school changed the focus from serving the family to serving the individual child.

The following quote, from social reformer Robert Hunter, writing in 1904, is indicative of the environment in which full-service schools have evolved:

The time has come for a new conception of the responsibilities of the school. The lives of youth are desperate, parents bring up their children in surroundings which make them in large numbers vicious and criminally dangerous. Some agency must take charge of the entire problem of child life and master it. (Kronick, p. 23)

In a similar vein, William Wort, the superintendent of schools in Gary, Indiana, in 1923 stated:

The school should serve as a clearinghouse for children's activities so that all child welfare agencies may be working simultaneously and efficiently, thus creating a child's world within the city wherein all children may have a wholesome environment all of the day and everyday. (Kronick, p. 23)

The modern history of full-service schools must be traced to Joy Dryfoos. Her work is one of central importance for all who want to understand and implement full-service schools. Her 1994 book *Full-Service Schools: A Revolution in Health and Services for Children, Youth, and Families* is a landmark piece on the concept of full-service schools. She continues to write and advocate for full-service schools, and her writings and presentations are a critical force in the history and continued development of full-service community schools. According to Dryfoos, what is important in the historical evolution of full-service schools is that many disparate groups were working toward the goal of creating such schools, but they did not know what each other was doing. These groups include the Charles Stewart Mott Foundation, the Children's Aid Society, Communities and Schools, and the Tennessee Consortium for the Development of Full Service Schools. The following definition of a full-service school evolved out of discourse between Dryfoos and those working with her to try to develop full-service schools.

A full-service school is a school that has broadened its mission and vision to meet the needs of all

of its students. The school is where health, mental health, and other services are provided. The emphasis is on *prevention*. The full-service school is a new environment where a *systems* approach to change is used. It is not a school where human services are an add-on. Collaboration thus becomes a key process in the school. Input from the community determines what special services will be provided. By meeting the noncurricular needs of children and families, the full-service school ensures that learning will happen for all students in the school.

### Community

Full-service schools have been around conceptually for quite some time. After all, the American philosopher and educator John Dewey (1859–1952) talked about the school as the community and the community as the school. Thus, community has been at the heart of full-service schools from the beginning. The concept of community is important to full-service schools in several ways. First, the school is a piece of real estate the community owns. This leads to the importance of building use after the end of the school day. The idea is that the sense of community increases as schools become better, and as schools improve the sense of community becomes stronger. At the same time each local community determines the needs for each school. Hence, the after-school needs may range from adult education to laundry services.

The importance of community is why full-service schools are often called full-service community schools. Other names include “lighted schools” and “beacons.” The central idea, regardless of name, is that all children have the right to learn and the right to the best curriculum feasible. No learning will go on, however, if the children and their families’ noncurricular needs are not met first. These needs might include alcohol and drug counseling, conflict resolution, general mental health issues, and many others. Research has found that the main need for the children and families is mental health care. It is impossible for children to learn when they come to school tired, hungry, and/or abused. Full-service schools support the notion that it is not whether the school will be a parent or not, but whether it will be a good parent.

### Prevention

Along with community, prevention is another central tenet of full-service schools. Keeping students in

school and learning is clearly a way of preventing them from going on welfare or becoming incarcerated in a correctional or mental health facility. In her 1994 book, Dryfoos asserted that one in four children in America drinks or does drugs, has early unprotected sex, and/or drops out of school. This statistic alone should make prevention a priority.

In many states corrections and mental health consume an undue amount of the state budget because not enough time, money, and effort has been spent on prevention. The best place for conducting prevention programs is in schools, because that is where the children and the families are. Full-service schools, by working to meet the ecological needs of children and families, begin prevention and intervention at an early age and seek to diminish the inequities that exist between the haves and the have-nots.

The philosophy of starting full-service schools is to begin where the need is the greatest. The thought is that if those who are on the bottom move up, all will benefit. The rising boat benefits all. In some schools, 90 percent of the students qualify for the free and reduced lunch program. The mobility of these students and their families is very high, resulting in a high turnover rate. Oftentimes the whereabouts of these people is unknown. More is known about migratory birds than is known about migratory people.

### Collaboration

Dryfoos noted that a universal call has been issued for one-stop, unfragmented, health and social service systems that are consumer oriented, developmentally appropriate, and culturally relevant. Full-service schools can be seen as central institutions in the community to provide an important if not critical organizing focus for the coordination and integration of service.

Full-service schools are seamless organizations in which educators and human service workers work collaboratively. The goal is to meet the needs of the child. Collaborators must set aside their own agendas and work for the benefit of the child. Collaboration as a bare minimum requires communication, trust, and clear agreements. It is much more complicated than coordination or cooperation.

### Systems Change

The full-service school is a new environment in which a systems approach to change is used. Full-

service schools collaborate with human service agencies in a systems approach. Blaming the child for not being able to learn appropriately is replaced by a problem-solving approach that does not seek to push the child out of school. A focus on systems emphasizes the interconnection of health, welfare, and educational forces in the child's life. The full-service school program watches for and tries to prevent push-outs and dropouts. There is a definite difference between the two.

The focus on systems emphasizes the importance of education and human service collaboration. This focus strongly asserts that human services cannot be add-ons at the school. Add-ons ensure only failure. Tinkering with schools but not making thoroughgoing changes courts failure. The full-service school is thus about thoroughgoing change.

### Controversies

Current controversies address the following issues: (1) Should the services be school based or school linked? (2) How should these services be integrated so that they are more than add-ons? (3) How can turfism be addressed? and (4) Do these support services water down academics?

**School-based versus school-linked services.** School-based or school-linked services are concerned with colocation of services as well as pay and the sources of pay. School-based services have the advantage of immediacy of response, collegiality, and teamwork. They have the disadvantage of being associated negatively with the school if the child and parent have a bad perception of the school. School-based services help deal with the problems of transportation and fragmentation of services.

**Integration of the services.** One of the strongest arguments for full-service schools is that they will cut down on the fragmentation of existing services. In one full-service school project, which was launched in 1999, this proved to be the case within three years of launching. Helping professionals and educators, who at most schools normally do not work with each another, are sharing and collaborating. This school's experiences with school-linked services is that they are nothing more than what currently exists. The coordinator of services has reduced fragmentation.

There must be collaboration between schools and human service personnel. School principals play a critical role in this process. Schools that operate in a human relations frame, where communication is

bottom up, horizontal, and top down, are more successful than those that are bureaucracies where communication is top down only. When people actually know each other they are more likely to trust one another.

**Turfism.** In dealing with a complex issue such as interprofessional collaboration, turfism arises as one of the thorniest issues to try to solve. The first problem here is responsibility. How do teachers and human service workers, who have historically not collaborated, work together harmoniously? This collaboration is well beyond the traditional working relationships between teachers and school social workers, school counselors, or school psychologists. The human service workers who are working in full-service schools are community personnel, and the collaboration with them is much more complex than those same professionals who are employed by school systems. Thus the second major issue of pay arises. Who is this worker actually working for, the school or the community agency? Is this worker a school system employee or a community service employee? This issue will be continually debated for quite some time. At the same time it is not an unsolvable problem.

**Do these services water down academics?** The final controversy is whether these services should be provided at the school, and if so, how will these services affect academics? Research answers the question in such a way that for a certain portion of school-age children, these support services must be offered for these children to have any chance at all for learning. To not provide these services yields the onerous option of the creation and continuation of a permanent underclass.

A related question, however, is what happens to the gifted child, in comparison to the average child? The money for education is fixed and not likely to expand. Thus the perennial question remains, can excellence and equity coexist? Excellence and education are not mutually exclusive. No, the idea is that full-service schools will not require education moving, but rather the moving of human service workers into school.

### Evaluation

To those familiar with full-service schools it is not news that the evaluation process is lacking. Evaluation of the programs is essential in order to acquire funding, grants, and community support. Past at-

tempts at documentation of success of the full-service school model have fallen drastically short of their goals because of poor planning and lack of data regarding the programs that constitute the school. Record-keeping may be the key to a successful school evaluation. This is a difficult task, especially so for the full-service school, because of the nature of the model. Because a full-service school consists of multiple components, such as a health clinic, after-school programs, adult education classes, and mental health services, an evaluation of the whole model must include all of the subcomponents. Turnover of students also affects the evaluation process. In many inner-city schools student turnover is upwards of 30 percent each school year. It is impossible to get an accurate reading of school improvement with such a loss of data.

Finally, time should be considered when evaluating a full-service school. These programs develop slowly and improve and change based on school and community needs. Therefore, it may take several years for the full effects on students and their families to become evident. Consequently a one- or two-year evaluation may not leave sufficient time for all the benefits to manifest. All these factors should be considered before an evaluation of a full-service school can take place.

One way to control many of the problems that will be encountered is for the evaluators to be involved from the conception of the program. Therefore they can establish the criteria for an evaluation and determine what data need to be tracked and for how long. Working intimately with the principal is essential to evaluation success. Also helpful is to employ an activities coordinator to oversee and keep documentation on all components of the school. This responsibility is too cumbersome for the principal to undertake and should not be pushed off onto already overworked teachers. Making good use of the position of activities coordinator will help the full-service school be seen as a unified institution, thereby making evaluation more effective.

### The Future

In the early twenty-first century, democratic communities are needed more than ever. The schoolhouse can be the place for discourse on important international events that will affect the educational system for many years to come. The schoolhouse, as stated at the outset, belongs to the community. The full-service school has not been used a great deal in-

ternationally, but at the Community Schools Conference (March 2001, Kansas City, Missouri) there were architects from Japan present. Japan is very interested in learning how architects can help develop schools that can be used by students for both academic and nonacademic pursuits. Urban/city planners are also coming into the planning and development of full-service schools. Hence, nontraditional professionals are now entering the fray, trying to see that all children are educated, and the full-service school is certainly one way to do this.

## FUTURE FACULTY PREPARATION PROGRAMS

---

Future faculty preparation programs provide a smooth transition between graduate school and faculty positions by preparing graduate students to meet the demands and expectations they will face as faculty members in U.S. colleges and universities. By examining the multiple roles and responsibilities that faculty hold—including research, teaching, and service—these programs extend beyond the parameters of standard graduate education, which empha-

sizes research, and teaching assistant (TA) development or graduate teaching certification programs, which emphasize present or future teaching alone. Instead, future faculty preparation programs view graduate school as a time for professional development in all areas and emphasize the need for finding and maintaining balance among the wide range of roles future faculty will encounter. At core, these programs share a commitment to cooperatively supporting graduate education in a more holistic way, giving graduate students firsthand experience with appropriate mentoring. This process relies on cooperation and effective communication between diverse institutions, between institution and faculty, and between faculty and graduate students. Most importantly, future faculty preparation programs offer a new model of graduate student development—one not merely supplementary to existing graduate student education or TA development, but one that considers professional development as inherent to graduate schooling.

### **Impetus and Development**

Future faculty preparation programs evolved from the TA training programs that proliferated between 1960 and 1990. Prior to the 1960s no formal training for teaching assistants existed; however, as colleges and universities began to depend on TAs more regularly to teach introductory courses, and as students, as well as the general public, began criticizing the resulting quality of their undergraduate educations, higher education institutions responded by organizing the first formal TA training programs. TA development programs were initially departmental in scope and designed to help TAs perform their graduate teaching tasks effectively, but they were not necessarily designed to equip students for their future roles as faculty members.

The 1986 National Consortium on Preparing Graduate Students as College Teachers initiated a public dialogue focusing on both the important role TAs played in undergraduate education and the lack of formal training to prepare them for faculty positions. This and subsequent biannual conferences provided a forum for new research on TAs' developmental stages and encouraged the proliferation of campus-wide, centralized training programs. By the mid-1990s, after legislators, public officials, and investigative reporters entered the conversation about TA training, the conference began to include broader issues of professional development for graduate students.

These conferences, together with Ernest Boyer's publication of *Scholarship Reconsidered: Priorities of the Professoriate* (1990), served as the real impetus for the development of future faculty preparation programs as entities distinct from TA training programs. The conferences prompted further inquiry into the state of TA training, and Boyer's book provoked discussion and debate about the meaning of scholarship and the relationship between teaching and learning. Both encouraged a deliberate focus on the issue of preparing graduate students to meet future professional challenges, "not as a by-product of TA development, but rather as an integral part of their doctoral studies" (Tice et al., p. 276). As this statement attests, although many future faculty programs developed out of TA training programs, they differ from them in their effort to prepare participants for the professoriate by exposing them to all aspects of their future occupations.

Future faculty preparation programs developed as an outgrowth of the public conversations about academic work introduced by Boyer and these TA conferences; this dialogue primarily addressed the frequently reported discrepancy between graduate training and the duties of junior faculty, particularly as many graduate students assumed jobs with very different responsibilities than those at the research university where they received their degree. By providing holistic professional development, early future faculty preparation programs also acknowledged that faculty at most institutions were increasingly expected to demonstrate both strong teaching skills as well as continued research. Growing dissatisfaction with the job readiness skills of doctoral students led to the recognition that graduate students were being trained for research but not for the multiple demands of teaching, research, and the administrative tasks accompanying academic jobs at various institutions. In 1996, for example, fewer than 10 percent of new Ph.D.s received faculty positions at research universities while the majority of the recipients of doctoral degrees took teaching jobs at institutions having very different combinations of mission, student populations, and expectations for faculty.

The launching of the Preparing Future Faculty (PFF) program in 1993 marked, according to its website, the first sustained "national initiative to transform doctoral education." The PFF program began as a collaboration between the Association of American Colleges and Universities (AACU), the

Council of Graduate Schools (GSC), and Pew Charitable Trusts. PFF programs bring “the *consumers* of Ph.D. programs into contact with the *producers* and provide opportunities for graduate students to gain personal experience with different types of institutions, faculty cultures, and student bodies” (Gaff and Pruitt, p. 1). PFF programs orchestrate this cooperation between the “consumer” (hiring institutions) and “producers” (doctoral degree-granting programs) by organizing partnerships, or *clusters*, between doctoral-granting institutions and diverse partner institutions or departments. These partners often include public and private four-year baccalaureate colleges, comprehensive state universities, and community colleges to give graduate students a sense of the different roles and responsibilities faculty have at these various institutions.

The explosion of future faculty preparation programs established in the late 1990s could only have happened because of the programs funded as part of PFF. The seventeen clusters of eighty-eight institutions funded in 1993 grew to seventy-six clusters at forty-six doctoral-granting institutions with more than 295 partner institutions by 2000. PFF programs funded between 1993 and 2002 developed in four distinct phases. The first two phases focused on developing model programs (1993–1996) and institutionalizing and spreading these as part of a national initiative (1997–2001). The next two phases shared an emphasis on discipline-specific future faculty preparation primarily through the provision of grants for disciplinary associations and professional groups to form departmentally based PFF programs. With support from the National Science Foundation and a private donor, AACU and GSC collaborated with disciplinary associations and professional groups to develop model programs in the sciences and mathematics (1998–2000) and in the humanities and social sciences (1999–2002).

Since 1993 many institutions have created future faculty preparation programs similar to the PFF model. These programs emphasize that graduate education should provide opportunities for graduate students to learn about and experience all aspects of faculty responsibilities: teaching, research, and service. As with the PFF model, which allows participating institutions to create their own programs to meet graduate student needs and relative stages of development, these programs attempt to anticipate changing faculty needs and expectations, to provide graduate students with training and professional de-

velopment to help them meet these needs and expectations, and to heighten awareness among established faculty about the changing expectations for faculty and graduate students.

### Characteristics of Programs

While they share a common mission, future faculty preparation programs vary in structure, as diverse models have arisen in response to differing participant needs and institutional climates. The impetus for developing the future faculty preparation program, whether as an outgrowth of a TA development program or an initiative to redefine graduate education, often dictates where the program is administered and how it is funded. Future faculty preparation programs are commonly developed and supported in one of three locations: graduate schools, academic departments, or TA development centers. On many campuses, these three units work in concert to offer a combination of centralized and departmentally based activities. Regardless of where they are housed, having a programmatic or financial connection to the graduate school or graduate dean generally fosters support among faculty on the home campus and helps to build collaborations with partner institutions. Many programs further expand their support base through advisory committees consisting of faculty and graduate students.

Where and how the future faculty preparation program is administered usually determines variables such as participant eligibility and length of time to complete activities. Some programs admit students only from certain participating departments, while others enroll participants from across the university. A few also include postdoctoral fellows. In some faculty preparation programs, students go through an application/selection process and participate in the program for a defined time period—often one to two semesters. Upon completion, they earn a graduate teaching certificate or some other honor. Other programs have structured activities that participants complete in stages as part of their graduate education and some allow participants to engage in various components of the program at any time during their graduate career. These latter models tend to have an open enrollment and do not selectively admit candidates to the program. Time commitments typically range from attendance at various short workshops to enrollment in a semester-long course or frequent travel to partner institutions.

While no generic faculty preparation program template exists, many programs offer some combination of the following components.

**Courses, seminars, and workshops.** These may last a few hours or a semester, with the longer ones often receiving course credit. Topics include comprehensive surveys of teaching techniques, specific pedagogical issues, academic job-market information, professional development tips, and issues in higher education. Some programs offer a cognate in college teaching, a master of science degree for teachers, or a graduate teaching certificate upon completion of certain courses or activities.

**Development of materials.** Materials for a teaching portfolio and/or web page showcasing their research and teaching are often required of participants. These materials usually include a curriculum vitae, cover letters, and other documents necessary for an academic job search, along with course syllabi, lesson plans, and various materials used to teach a course.

**Collaborations with partner institutions.** Collaborations are a key feature of many future faculty preparation programs, since they provide opportunities for participants to meet faculty at other institutions. Opportunities range from a one-day visit to shadowing a professor for a day, guest lecturing, or teaching a course at the partner institution. In some cases, participants can sit in on departmental and school committee meetings. These collaborations allow participants to experience the diversity of faculty roles and responsibilities that exist at different types of institutions.

**Experiential activities.** These provide opportunities for participants to get hands-on practical experience teaching, giving job talks, serving on committees, working with undergraduates, or networking with colleagues. These experiences take place on both the home campus and at the partner institutions.

**Mentoring opportunities.** These programs give graduate students the opportunity to work with a variety of mentors so that they learn about the varied duties of faculty. Mentors can include faculty and staff at the home campus and partner institution, recent alumni, and experienced future faculty preparation program participants.

**Coverage of contemporary issues in higher education.** Contemporary issues are often addressed through various activities and usually include a focus on the use of technology in teaching, increasing stu-

dent diversity, university governance, or changing trends in higher education.

### Future Trends

In general, faculty preparation programs encourage a more holistic approach to graduate education. Ideally, the mission and goals of these programs will eventually become part of the ethos of departments and institutions, particularly as the distinct activities and opportunities they provide become fundamental to the graduate curriculum, rendering separate faculty preparation programs obsolete. This transformation depends on the participation of all members of the academic community—from senior faculty and staff to undergraduates—as well as the strengthening of collaborations among diverse institutions so that hierarchical divisions fade away.

The development of future faculty preparation programs signals the beginning of a movement to re-examine, if not radically alter, graduate education. Program directors are beginning to think broadly about the set of skills that future faculty need in order to meet the changing demands of higher education institutions and to create opportunities for them to develop these skills and be leaders in this change. At the same time, many faculty preparation programs now realize that their responsibilities may lie outside the narrow scope of preparing graduate students to be faculty, and instead encompass a broader range of career options for graduate students, both within and outside of academia.

## GARY SCHOOLS

---

The Gary, Indiana, public schools, founded in 1906, were developed by Superintendent William A. Wirt from 1907 to 1938 and quickly expanded into an illustrious example of Progressive education through the 1920s. Born on a farm in eastern Indiana in 1874, Wirt attended nearby Bluffton High School, graduated from DePauw University, and returned to Bluffton as school superintendent in 1899. His school innovations, particularly a more diversified elementary curriculum and flexible schedule, as well as improved facilities, paved the way for his selection as Gary's first professional superintendent. Founded by U.S. Steel Corporation in 1906, Gary grew quickly and attracted a heterogeneous population. Heavily influenced by the ideas of the American philosopher and educator John Dewey, as well as his own rural, Protestant background, Wirt believed that public schools should provide salvation for the children as well as the community.

The Gary Plan, Work-Study-Play, or Platoon School Plan, as it was variously known, focused on establishing two central characteristics in the elementary grades. First, because of a concern for efficiency, Wirt believed in maximizing school facilities by constant use of all classrooms, including nights (for adults), weekends, and summers. Second, he expanded the curriculum to include manual training (numerous shops for the boys and cooking for the

girls, for example), recreation, nature study, daily auditorium activities (including public speaking, music lessons, and movies), and other subjects beyond traditional academic concerns. The plan theoretically organized students into two platoons. During the morning, Platoon A students occupied the specialized academic classrooms (mathematics, science, English, history, etc.), while Platoon B students were in the auditorium, shops, gardens, swimming pools, gym, or playground. They switched facilities during the afternoon. The students, busy every day, were supposed to develop their mental, social, cultural, and physical abilities. Gary's large schools, first Emerson, then Froebel, and a few others built in the 1920s and 1930s, were unique because they were unit schools including all grades, K–12, which allowed for a more efficient use of space and building funds. By the late 1920s about half of the system's 22,000 students were attending such schools, with the remainder in the smaller elementary buildings.

The Gary Plan, highly developed by World War I, quickly attracted national publicity because of its apparent efficiency and diversified curriculum. By 1929, now promoted by the National Association for the Study of the Platoon or Work-Study-Play School Organization, 202 cities had over 1,000 platoon schools. It also generated much controversy, with New York City, for example, rejecting it in 1917 after a three-year experiment. While the Gary schools, in many ways, captured the positive spirit of Progressive education, they also incorporated some troubling aspects. There was the perception in New York and elsewhere that the inclusion of manual training classes was designed to channel the working classes (the majority of Gary's students) into vocational

trades; while the high school enrollment increased, most students did not graduate. The schools were also racially segregated, closely following the northern urban model. The 2,759 black children in 1930 mostly attended all-black elementary schools or the integrated (but internally segregated) Froebel School. The situation worsened as black enrollment increased to 6,700 by 1949 (34% of the student population), despite the school board's attempt in 1946 to promote building integration. By 1960, 97 percent of the 23,055 black pupils (over half of the 41,000 students) were in eighteen predominantly or exclusively black schools, with primarily black teachers and administrators, and the trend would continue as the black population increased and the white population decreased over the following decades.

The Gary work-study-play schools barely survived the depression years, when budgets were severely cut (and most platoon schools were abandoned throughout the country), and then Wirt's death came in 1938. Following an external study in 1940, which recommended dismantling the system, now considered old-fashioned and academically weak, the Gary schools began the slow process, not completed until the 1960s, of instituting the contained classroom, single-teacher model in the elementary grades (which were separate from the eight high schools by 1960). For the remainder of the century, with the mass exodus of whites, along with much of the business community, Gary's troubled schools managed to survive. They had long since lost their progressive luster, as the 25,000 African-American students (there were few others by 1990) from struggling families, an aging teacher corps, and shrinking federal dollars meant that the schools faced numerous problems into the foreseeable future.

## GAY AND LESBIAN STUDIES

Gay and lesbian studies are academic programs dedicated to the study of historical, cultural, social, and political issues of vital concern to lesbian, gay, and, increasingly, bisexual and transgendered individuals. The focus of such programs is on lesbian and gay lives and social institutions, as well as about homophobia and oppression related to sexual orientation. Gay and lesbians studies programs have encouraged many traditional disciplines to reassess their theoretical and political grounding and to consider sexuality and sexual diversity as critical facts determining social behaviors and political structures.

### Goals

The goals of gay and lesbian studies programs are as varied as the programs themselves. The general goals include discovering and recovering the history and culture of homosexuality and bringing homosexuality to the forefront of academic studies, away from being an unspeakable or untouchable subject. The existence of gay and lesbian studies programs helps to challenge the invisibility of homosexuality in society and to expose students to gay and lesbian oppression as it has existed historically. Another goal of lesbian and gay studies is to explore the lives of lesbian and gay people through investigation of identity issues, experiences of oppression, and struggles for recognition. The programs seek to find a common understanding and language in which homosexuals and heterosexuals can better understand gay and lesbian lives. Many programs have an activist agenda that includes such goals as critiquing and transforming the social, political, cultural, economic, ethnic, and gender situations that continue to oppress gay and lesbian people.

In 2000 Jeffery Weeks, a professor of sociology at the University of London, identified five additional goals for gay and lesbian studies. The first is to find ways for society to learn to live with differences in sexual orientation and to provide a forum for discussing differences. The second is to adopt political and cultural stances that work toward sexual justice,

which involves seeking fairness and equity in the treatment of all sexual orientations. The third goal is to challenge heterosexual norms that have been created throughout history. By addressing the second and third goals, homosexuality can be validated and affirmed while heterosexual norms are questioned so that equality of sexual orientations can be reached. The fourth goal is to question the existing body of knowledge related to sexual orientation, especially addressing who has the right to speak authoritatively on gay and lesbian issues. The fifth goal is to create spaces for debate, analysis, negotiations, disagreements, and finding common ground regarding issues of sexual orientation.

### History

Gay and lesbian studies emerged from the civil rights movement, yet the roots of this discipline stretch back to the middle of the twentieth century. The Kinsey studies of human sexuality in the 1940s and 1950s challenged scientific assumptions related to sexuality and, by raising the visibility of homosexuality, provided a platform for gay and lesbian studies. Gay and lesbian studies, although taking place in academia, have been strongly influenced by the political and cultural development of gay and lesbian communities, especially in urban areas throughout the United States. As the political and cultural environment within society changed during the latter half of the twentieth century, so too did the frameworks in which gay and lesbian intellectuals and scholars worked. Specifically, during the 1950s and 1960s the homophile movement, combined with the gay liberation and lesbian feminism movements that began after the riots at the Stonewall Inn in 1969, helped to create the political climate that allowed for the development of the early stages of lesbian and gay studies in the 1970s. Additionally, the AIDS crisis in the 1980s added yet another layer that helped mature gay and lesbian studies. In 1991 the Center for Lesbian and Gay Studies (CLAGS) was founded at the City University of New York Graduate School. CLAGS is the first and only university-based research center in the United States dedicated to the study of historical, cultural, and political issues of concern to lesbian, gay, bisexual, and transgendered individuals.

Another way of understanding the historical development of gay and lesbian studies is to consider the focus of scholarly activity and its diversification during the last three decades of the twentieth century.

Jeffrey Escoffier, deputy director for policy and research of the Office of Gay and Lesbian Health in New York City, in 1992 identified several different interdisciplinary paradigms that arose during that period. The first, "Search for Authenticity, 1969–1976," was formed by the Stonewall generation as an effort to encourage research and writing from gay liberation and feminist perspectives. For example, during this period the Gay Academic Union was formed in New York City with the goal of confronting homophobia in academia. Although the union lasted only a short while, it did provide a forum for academics interested in issues related to sexual orientation and led to further organizing and eventually to program development.

"Social Construction of Identity, 1976–present" focuses on homosexual identity and how this identity is shaped and formed not only by homosexual behavior but also by cultural and societal action. "Essentialist Identity: Lesbian Existence and Gay Universals, 1975–present" is the complement to the socially constructed aspect of identity and concentrates on the structures and similarities in the gay and lesbian experience that span historical periods. "Difference and Race, 1979–present" addresses how culture, ethnicity, and race combine with homosexuality. One of its many concerns is that gay and lesbian studies and scholarship not remain focused on white culture, but rather emphasize the diversity of experience in gay and lesbian lives. The final paradigm, "The Pursuit of Signs: The Cultural Studies Paradigms, 1985–present," builds on the social construction of identity paradigm to include all forms of texts, cultural codes, signifying practices, and modes of discourse that form attitudes toward homosexuality.

### Current Configurations

At the beginning of the twenty-first century, gay and lesbian studies programs vary widely in terms of focus, structure, and connections with other academic units. Most programs are at large institutions, both public and private, and most of these institutions are in urban areas. There are few programs at small, private, rural liberal arts colleges. Most programs are gay and lesbian specific while some also include the general categories of gender and sexuality. Others have expanded to include emphases on bisexuality, transgender issues, and queer theory. The majority of the lesbian and gay studies programs offer undergraduate minors or certificate programs.

Few institutions offer undergraduate majors or graduate degrees strictly in gay and lesbian studies. Some institutions offer undergraduate programs in which lesbian and gay studies can be combined with a traditional major (e.g., a major in history with a focus on gay and lesbian studies); others offer the opportunity to create degree programs through individualized learning or liberal studies programs; and some institutions offer dual or integrated graduate degree programs where lesbian and gay studies can be combined with programs in other disciplines.

Because lesbian and gay studies focuses on a group of subjects instead of a concept, it is difficult to place the field within a specific academic discipline. Therefore, virtually all programs are interdisciplinary in nature, working with other departments on campus covering a wide span of disciplines including biology, anthropology, anatomy, cultural anthropology, English, literature, film and video, history, art history, political science, psychology, religion, sociology, ethnic studies, and women's studies. Additionally, lesbian and gay studies programs are most often linked to or coupled with women's studies or gender studies.

The disadvantages of interdisciplinarity include diffused academic power and influence, constrained resources, and a lack of a disciplinary home. The advantage of interdisciplinarity is that once established, lesbian and gay studies programs are difficult to isolate and sequester. Interdisciplinary study then results in a change in how gay and lesbian lives, experiences, and reality are experienced, studied, and understood. It forces scholars to integrate the often-fragmented disciplines into which the academic experience has been sorted. Scholarship and study in separate disciplines makes it easier to ignore diversity and complexity and allows important questions to go unasked, a few chosen issues to be raised, select individuals to be studied, and leaves a large portion of the lesbian and gay population ignored. Interdisciplinarity reinforces the fact that no longer are there only the categories of heterosexual and homosexual, but that there are many variations in between. Interdisciplinary study encourages a constant questioning of the assumptions underlying theories that are being used and why they are being used.

Two growing areas under the rubric of lesbian and gay studies are lesbian studies as a self-contained unit and queer theory. There have been some efforts to separate lesbian studies from gay studies and women's studies because of concerns about sexism

(in gay studies) and heterosexism and homophobia (in women's studies). The argument is that lesbian oppression has been ignored and needs to be investigated from the perspective of multiple disciplines separate from gay studies.

The category of queer theory first appeared in the early 1990s. Teresa de Lauretis is the theorist often credited with inaugurating the phrase. Queer theory expands the focus of lesbian and gay studies from socially constructed or essentialist identities to sexual practices and sexual representations. Queer theorists view sexuality along a continuum and question whether it is ever fixed at one point. Queer theory challenges all identity categories, such as heterosexual, homosexual, male, and female and analyzes the power imbalances that are inherent in them.

## GENDER ISSUES, INTERNATIONAL

Many benefits accrue to investments in women's schooling, which range from social payoffs (such as lower fertility rates, improved children and women's health, greater life expectancy for women and men, and higher schooling attainment by new generations) to individual improvements (such as older age at marriage, reduced teen pregnancy, greater participation and productivity into the labor force, and a greater sense of independence in economic and political decisions). For education to have a positive effect, particularly in wages, it appears that women must reach a threshold of attainment between four years of primary-level schooling and completion of primary schooling.

### Access to Schooling

Women's access to schooling is far from equal to that of men, with considerable variation among developing regions. Official statistics for enrollment tend to underestimate the dimension of this problem; nonetheless they indicate that there are between 120 million and 150 million children ages six to eleven out of school. This group is mostly poor, and about two-thirds are girls. In South Asia, the Arab region, and sub-Saharan Africa, about 600 million boys and girls attend school, but 42 million fewer girls than boys are enrolled at the primary level and 33 million fewer at the secondary school, as reported in 1999 by Shanti Conly and Nada Chaya. Due to low access to basic education when young, two-thirds of the 900 million illiterates are women. The literacy gender gap has been narrowing over time, except in South Asia.

If educating girls is such a win-win proposition, why are there not more girls in school? Cultural factors such as notions of a girl's proper age for marriage, anxiety about the sexuality and sexual safety

of daughters, and the division of labor at home (with women in charge of domestic and childcare tasks) affect girls' enrollment and both primary and secondary school completion. In India and many sub-Saharan countries, where strong cultural norms require early marriage, parents often consider puberty as the cutoff for schooling.

Many countries in the developing world face heavy external debts, which forces governments to give priority to economic matters (industrial or manufactured production) over welfare or social justice. Across countries, completion of girls' schooling is at risk because poor parents are more willing to invest in boys since boys (when adults) will be expected to support parents while girls will follow their husbands' families. Another economic factor of importance is the immediate value of girls through their domestic work. Since parents tend to withdraw daughters from school when they do not perform well, girls are not allowed to repeat school as boys would, especially in sub-Saharan Africa. About 150 million of those currently enrolled in primary school will drop out before completing four years of education according to Kevin Watkins's 1999 study. The losses are greatest among girls who belong to poor families or marginalized ethnic groups. Finally, political factors also intervene when governments find it is easier to maintain the status quo than to risk antagonizing opposing groups.

### What Is Learned in School

In developing countries some rural families are reluctant to send their daughters to school for fear they will learn new values, becoming less inclined to accept domestic work and more interested in joining salaried occupations. But formal education—both in developing and industrialized countries—tends to convey messages and experiences that reproduce traditional views of femininity and masculinity, with the consequence that girls do not acquire knowledge that makes them question the status quo and boys do not learn to appreciate girls' needs and conditions. The school curriculum in some subject areas avoids dealing with issues considered social taboos. Thus, sexual education does not consider the social relations of sexuality but emphasizes knowledge of reproductive organs and, now that AIDS has become an illness of major proportions, information about avoiding risky sexual practices, primarily via sexual abstinence. Discussion of sexual orientation, a major concern in adolescence, is especially avoided for fear

of promoting homosexuality. Serious and widespread issues such as domestic violence and rape are usually sidestepped in the school curriculum.

Activism by the women's movement and some research about textbooks led to the improvement of content of many school materials. Most of the changes have dealt with incorporating a more inclusive language (referring not only to men but also to women), including more balanced roles between women and men, and displaying a greater presence of women as examples or significant historical actors. Yet, although studies of current textbooks are limited, evidence indicates that the changes do not question the existence of sexism in society, nor challenge girls and boys to confront everyday practices at home, school, and other institutions that sustain conventional gendered ways in which society is organized.

A major weakness in the efforts to make schools become venues for gender contestation has been the limited provision of teacher training (either in institutions that prepare new teachers or through in-service training) on issues of gender in society and education. As a result, teachers—many of whom are women—do not have a solid understanding of how gender operates in their lives and in the lives of others. Classroom behaviors by teachers favoring the intellectual development of boys and fostering the compliance of girls go unchecked. Outside the classroom, spaces where the reproduction of prejudicial gender beliefs and norms occurs, such as sports, the playground, and extracurricular activities, are seldom considered for examination and transformation.

### **Public Policies on Gender and Equity**

Many governments have made public commitments to increasing the access of girls to schooling, reducing the gap in schooling between girls and boys, and reducing illiteracy, especially among women. Such commitments are seldom met. For example, the Education For All (EFA) initiative sought to provide universal education for all by the year 2000. By 2000 this goal had been deferred to 2015, with no firm promise that previous obstacles to policy implementation would be removed. Major international assistance agencies (notably the World Bank and the U.S. and Japanese bilateral development agencies) continue to justify support for girls' education for its value as an economic investment, downplaying reasons of social justice and individual autonomy. A

number of pilot studies attempted in several developing countries have demonstrated the power of interventions such as the provision of tuition subsidies or scholarships for girls to offset their economic value to families. Unfortunately, only a handful of countries have brought these interventions to nationwide application (scholarships for secondary schoolgirls in Bangladesh, family stipends to families with daughters in primary school in Guatemala, and subsidies to rural families in Mexico). Most governments are willing to uphold the importance of girls' and women's education, but fail to acknowledge the impact of ideological factors shaping definitions of masculinity and femininity, which in turn determine men's and women's unequal roles in society. When women shy away from male-dominated fields of study and occupations (particularly in science and technology), and as they give priority to family over professional or occupational responsibilities, their decisions are interpreted as entirely individual choices.

Schools throughout the world are undergoing major structural and substantive reforms. Efforts to decentralize the public school system and to foster the creation of private schools abound. It is not clear how community participation in the decentralized schools will favor gender equity if the parents themselves are not educated to understand the dynamics of gender reproduction and transformation. Privatization may further constrain girls' participation if the economic conditions of families do not improve. Substantive reforms of schools are focused on improving quality, but this objective is defined in narrow terms, emphasizing the preparation of future workers, rather than future citizens. Math and science are seen as the key curriculum subjects to the detriment of other disciplines. Evidence from Latin America indicates that current reforms express concern for issues of "productivity" and "competitiveness" but much less so for those of equity and social justice (Task Force on Education Reform in Central America, 2000). They seek to promote decentralization and nationwide assessments of student achievement to compare their performance within and across countries. They also seek differentiated pay for teachers on the basis of their performance, which will act as a mechanism to further concentrate on math and reading.

Concerned with the slow progress to improve education in general and the education of girls in particular, a number of nongovernmental organiza-

tions (NGOs) in developed countries have become active in advocating major financial resources for education in the Third World. It is estimated in Watkins's 1999 study that closing the gender gap by 2005 would require U.S. \$9.5 billion in recurrent expenditures in the fifty-one countries with the largest gender differentials. As of the early twenty-first century, the quantity and content of girls' education is best described as being at an impasse, in which forces capable of implementing nationwide action are concentrating on the economic ends of schooling and seeing it as a gender-neutral institution, while forces for transformation, particularly those that could be carried by women's groups, are not receiving the support they need.

## GENERAL EDUCATIONAL DEVELOPMENT TEST

The General Educational Development Test (GED) is a battery of tests designed to measure the educational level of people who did not formally complete high school. Candidates who successfully pass the five subject area tests are awarded a high school equivalency certificate recognized by state education departments. The American Council on Education (ACE) offers the GED and preparation guidance across the United States and worldwide. Other organizations, such as the National Institute for Literacy, also offer Adult Basic and Secondary Education programs designed to aid adults in completing the GED successfully. Developed during World War II to assist veterans who had left high school before graduation to enlist in the military, the GED test battery underwent revisions for 2002, which were designed to make the test comparable to standards-of-learning tests compulsory in most states since the mid-1990s.

### History

After World War I, veterans who had left high school to enlist in the armed services were awarded diplomas in exchange for their service to the nation. After World War II, however, returning soldiers were required to pass a test before being given their high school equivalency certificates. The U.S. Armed Forces Institute examination staff first constructed the GED test in 1942. In 1945 ACE established the Veterans' Testing Service (VTS), and beginning in 1947 tests were distributed to civilian institutions where veterans were applying for employment or college admission. By 1959 more civilians than veterans were being given the GED test, and in 1963 the VTS changed its name to the General Educational Development Testing Service to reflect this shift in test-taking populations. Early tests were designed so that most veterans would pass, and more than 90 percent did. The test was revised in 1988 to include an essay section, and remained essentially unchanged until January 2002, when a series of revisions went into effect. At the turn of the twenty-first

century, more than 860,000 people take the tests annually, and one in seven people who finish high school earns the credential by passing the GED test. High school graduation rates published by the U.S. Census Bureau include GED holders, and the certificate is seen as interchangeable with a high school diploma for most employers and colleges. Although researchers debate the success of the GED in helping individuals attain meaningful careers, it is clear that the GED is an important part of the American educational landscape.

### Changes at the Start of the Twenty-First Century

The General Educational Development test questions and norms have been revised beginning in 2002 as a response to the standards movement in American secondary education. The overall impact of the revisions is to make the test more difficult. The previous test was structured to provide a failure rate of about one in three; however, revised cutoff scores are now designed so that 40 percent of high school seniors would not pass. The designers of the revised GED tests responded to complaints from colleges and employers about poorly educated GED holders by developing questions geared to identify and measure practical knowledge and life skills. Information sources such as product labels and legal documents are used to generate questions and answers. The revised GED tests are designed to be an improved measurement of a student's practical skills, dispositions, and abilities.

### Test Description

Like other standardized tests, the GED is primarily a multiple-choice test in each content area. The General Educational Development questions fall into five test areas similar to those of public secondary standards-based assessments: writing skills, literature and arts, mathematics, social studies, and science. The writing test is divided into two sections: the first presents sentences that may or may not include errors that require correction. These questions are similar to those of the SAT Test of Standard Written English (as administered prior to 1994) and the Test of English as a Foreign Language (TOEFL). The second writing skills test is to construct an essay of about 200 words on one of several topics provided by the test makers.

Like the PSAT and SAT essays, the GED writing test is holistically scored on a scale from one to six. Graders emphasize clarity of composition, support

for ideas, and sentence mechanics. The revised, two-part mathematics section tests skills in arithmetic operations, algebra, and geometry. Test takers respond to equations, word problems, and data displayed on charts and graphs. Sample questions provided by ACE emphasize real-world numeric texts, such as federal tax allocations, personal earnings, and nutritional values charts. All mathematics questions were formerly in the multiple-choice form; in 2002, 20 percent require fill-in responses and students are allowed to use calculators. The social studies section tests knowledge in economics, political science, geography, and the behavioral sciences (anthropology, psychology, sociology). Social studies questions are different in Canadian versions of GED tests than in the United States. Science questions are based on information typically taught in earth science, biology, physics, and chemistry. Students are asked to analyze charts, graphs, drawings, or questions, and identify the best solution to the practical problems presented. Sample GED science question topics include the principles of buoyancy, displacement, spectrum heat absorption comparison, and chart-reading skills. The literature and the arts section of the test once emphasized reading comprehension only in the areas of popular and classical poetry, fiction, nonfiction prose, and drama. The revised test includes passages from other real-world text sources such as tax documents and commentaries.

### Resources

The American Council on Education provides test preparation materials and sample questions in each content area, as well as a comprehensive preparation guide. The GED Testing Center also includes a directory of adult education and GED prep classes. The GED tests are available in Spanish and French for qualified applicants, and special accommodations are available for candidates with disabilities. Accommodations include an audiocassette edition, large-print edition, braille edition, extended time, use of a scribe, talking calculators, private room use, one-on-one testing at a candidate's home, vision-enhancing technologies, video equipment, sign-language interpreter, or other accommodation in cases where circumstances warrant.

JAMES B. TUTTLE

## GENERAL EDUCATION IN HIGHER EDUCATION

---

As American higher education moved from institutions that promoted learning for learning's sake to institutions that prepare individuals for work and careers, new approaches in college and university curriculum development became necessary. One significant evolution was the movement away from the classical, European model of liberal education to the development of a narrower, more selective model of liberal studies, that has become known in American colleges and universities as *general education*.

### The Difference between Liberal Education and General Education

The original mission of American higher education was to provide a liberal education based on the European model of classical education. In the liberal education model, college students became well versed in classic literary works, philosophy, foreign languages, rhetoric, and logic. This model stressed the importance of a broad base of education that encouraged an appreciation of knowledge, an ability to think and solve problems, and a desire to improve society. American liberal arts colleges and universities most closely resemble this traditional model of liberal education.

In the late eighteenth century, however, social forces in American society began calling for a more

utilitarian and practical education that would prepare students for work upon graduation. State normal schools emerged to prepare teachers for jobs in American schools. In addition, business schools and other vocational preparation programs became more popular. In 1862 the Morrill Act further pushed this utilitarian model by providing federal money to land-grant institutions chosen to develop agricultural and technical programs. By the late 1800s, students on many campuses had the ability to choose courses freely, without requirements, and could now choose a concentration, or major, in one particular field of study. By the late nineteenth and early twentieth centuries, many work-oriented fields such as teaching, business, engineering, and nursing had made their way into the four-year college and university curriculum. Vocational and practical education was now a major component of American higher education.

In the mid-twentieth century, a new movement for the revitalization of liberal education began. A great debate emerged between those in higher education who supported the movement toward specialized and vocational preparation and those who felt that this push to focus on a particular field was leading to overspecialized and narrow areas of study that would be of little use as careers and technology changed. Many supporters of liberal education also argued that specialized study did not contribute positively to the development of society. In 1947, as the debate became more heated, the President's Commission on Higher Education called for the development of a balance between "specialized training on the one hand, aiming at a thousand different careers" and a general curriculum that fosters "the transmission of a common cultural heritage toward common citizenship on the other" (p. 49).

Recognizing the importance of vocational training but still valuing the significance of classical education, many colleges and universities began to develop a series or set of courses that all students attending their institution would take prior to graduation. This set of courses became known as general education, sometimes referred to as a core curriculum. This model of curriculum has come to exist as a fundamental component of American higher education. According to Joan Stark and Lisa Lattuca, the American Council on Education found that in 1990 over 85 percent of American colleges and universities required all students to complete some sort of general education requirements.

## The Goals of General Education

General education emerged in response to changing societal needs and the tension between classical liberal education and more practical or specialized education. The primary goal of general education is to provide a broad, yet focused, survey of courses that will promote critical thinking and increase students' awareness of the world around them. On many campuses, general education's purpose serves as a foundation for technical or vocational training, fostering in students the ability to think beyond their areas of specialization. Many faculty members and administrators on college and university campuses hope that requiring a set of specific courses will encourage students to make connections across disciplines and between formal course instruction and informal learning experiences outside the classroom.

General education requirements vary significantly from one institution to another. These expectations, however, often stem from the way in which different institutions answer the same guiding questions, such as: ideally, what knowledge, skills, values, and attitudes should graduates of the institution possess upon completion of their degree? And, how should the curriculum be designed to meet this goal? The variation in general education requirements stems from the broad array of institutional missions and goals and, accordingly, the many ways these broad questions are answered by the hundreds of American colleges and universities.

More important than specific requirements for general education is the time given by institutions to intentional thought, discussion, and development of general education curriculum. Ernest T. Pascarella and Patrick T. Terenzini (1991) affirmed this notion when they discovered that the greatest gains in students' ability to think critically were found at institutions with courses specifically designed to meet general education requirements. Even knowing this, however, extensive disagreement continues to exist among members of college and university communities regarding the identification of fundamental components and requirements of a general education curriculum. This continuing disagreement can lead to a tedious and lengthy debate, resulting in slow and difficult change on most campuses. The importance of general education was affirmed in a national study conducted by Ernest Boyer for the Carnegie Foundation for the Advancement of Teaching (1987). Boyer and his colleagues found that approximately 75 percent of undergraduates in

American colleges and universities felt that general education courses "added to the enrichment of other courses" and "helped prepare [them] for life-long learning" (p. 85).

A final goal, espoused by many supporters of general education, is that all students should have a common experience or be exposed to a particular set of knowledge. It is not uncommon in the early twenty-first century to find colleges and universities that provide required reading lists to all incoming students. These readings are often incorporated in the general education curriculum and provide a common foundation and experience for that cohort of students. These common learning experiences often emerge in discussions throughout students' experiences at that institution and continue into their lives beyond the collegiate experience. This approach to general education relates to the primary goal of general education stated earlier: to make connections between formal course instruction and informal learning experiences outside the classroom.

## Typical Characteristics of General Education

Although specific requirements may vary among American colleges and universities, there are characteristics common to general education across institutions. Typically, general education does not emphasize practical knowledge or research skills. The emphasis of general education is to help students understand that they are not individuals who stand apart from society but rather one person living in community with others in a greater society. As Boyer eloquently wrote, general education "is significant when it shows us who we are as individuals and as citizens, and touches the hopes and fears that make each of us both unique beings and a part of corporate humanity" (p. 98). This level of understanding is often achieved through the weaving of courses across a variety of disciplines.

In order to foster this understanding of a broad picture of society and to lay a foundation upon which all else is built, general education requirements are often taken during the first few semesters of the college experience. Students on many campuses are given a set of courses from which they can choose specific classes that will fulfill specific requirements. Some general education requirements, however, become prerequisites for upper level courses so that students enter these classes with a common level of knowledge and understanding. An additional benefit of general education courses is

that students tend to recognize others taking the same courses and establish friendships during those first few semesters that extend beyond the classroom and often last a lifetime.

With an increasing number of students attending two-year institutions and more students transferring to and among four-year colleges and universities, it has become more critical for colleges and universities to recognize and identify courses that fulfill general education requirements. Usually, courses such as English, mathematics, and foreign languages are transferable across institutions. Some courses directly align with and meet general education requirements, while other courses are accepted as electives but still count toward graduation credit. This change has made it easier and more financially possible for students to move among institutions without penalty. Many colleges and universities, however, do limit the total number of credits that they allow to transfer in order for students to receive the quality education desired by the institution.

### Typical Requirements

A broad array of choices exist in general education across American colleges and universities. Some institutions follow a very prescribed and specific set of courses, whereas many others offer a broad spectrum of courses from which students select “some of these and some of those,” a method often referred to as *cafeteria-style*.

One specific requirement that tends to remain constant across most institutions is a proficiency in English. Most colleges and universities agree that a fundamental component of being well educated is the ability to read and write. Thus, regardless of students’ chosen fields, almost every college and university requires coursework in English literature and composition. Even professors of mathematics and engineering have stressed the importance of students being able to express themselves in the written and spoken word. Beyond this one component, requirements do vary with some overlapping expectations among colleges and universities.

According to Stark and Lattuca, by the mid-1980s most students in American colleges and universities (over 60%) were required to take courses in English and mathematics. Additionally, 45 percent of all institutions require courses in Western or world civilizations. Beyond these more common requirements, some institutions also require course-

work, at least at an introductory level, in laboratory sciences such as biology or chemistry, and in social sciences such as psychology, sociology, or political science. Some also require the study of a foreign language.

As noted earlier, over 85 percent of American colleges and universities have some sort of general education requirements for their undergraduate students. Stark and Lattuca noted that typical students at four-year institutions spend 33 to 40 percent of their studies meeting general education requirements. And, although debate continues regarding which courses should be considered critical in the development of educated graduates prepared for life beyond college, general education itself is firmly grounded in the modern American collegiate experience. Some colleges maintain a broad array of choices that satisfy general education requirements, whereas others are very specific with their curriculum. Many institutions have also been very successful at creating interdisciplinary courses that incorporate material and perspectives from a wide variety of disciplines; some of these courses have become quite popular and successful at institutions across the United States. Regardless of institutional choice, with such varying expectations from one institution to another, it is critical that students understand what is expected of them in order to develop a successful approach to their college studies.

## **GEOGRAPHY, TEACHING OF**

Geography, like history, is not defined by the uniqueness of its content; rather, both gain their distinction by the way in which they organize and analyze the data they collect regarding particular aspects of the human experience. History compares and contrasts information within the framework of chronology, while geography organizes its information within the context of the spatial environment. Today, the focus of geographic inquiry is generally conceded to be on spatial interactions, that is, the geographer seeks to understand the significance of human activity within a spatial framework. Where historians report their findings primarily through written narratives, geographers present their data primarily through the construction of maps.

Until the advent of the Progressive movement in American life, beginning in the decades following the Civil War, geography was taught as a separate subject. Memorization of the names of important cities, physical features, and relational facts dominated instruction. Recognition of the temporary shelf life of that kind of information taught in rote fashion led Progressive educators to deemphasize the acquisition of facts and to instead emphasize the role of reasoning and problem solving in learning. Under this program, the traditional subjects of geography, history, and civics were fused. In this context the teaching of geography began to lose its identity as a unique area of study.

### **Effectiveness of Instruction**

Whether taught as a separate subject or fused in some way with subject matter drawn from other fields of the natural and social sciences, there is a long history of ineffectiveness of instruction in the teaching of geography. From the first attempt to assess the effectiveness of instruction in geography, in the 1840s in Boston's public schools, to the most recent efforts, notably the National Assessment of Educational Progress (NAEP), there is a continuing record of what most consider to be substandard results. A much more sophisticated assessment tool than those of past years, the NAEP results have shown, for example, that secondary students learn more geographic information in history classes than in those classes devoted exclusively to the study of geography. Although one can decry such a seeming incongruity, the historical knowledge displayed by students on these tests was equally dismal.

How is it that geographic instruction appears to be so ineffective? One reason may be that teachers generally are not themselves geographically literate. One teaches what one knows, and today's teachers are as much a product of their schooling as anyone else. It might be hoped that professional geographers would be able to communicate the nature of geographic literacy and would be effective in educating teachers for the task of teaching geographic concepts. Unfortunately, the number of professional geographers is limited—hardly a drop in the bucket when compared to the number of professional historians, for example—so it is to be expected their ability to help teachers will also be limited. However, there are many geographers who are devoted to the task of teacher education and are actively involved in remediating this problem, which is coordinated to the extent possible through a professional organization, the National Council for Geographic Education.

A second reason that geographic instruction is not as effective as it might be is because not enough is known about how students acquire geographic concepts. There is, however, a body of information that is suggestive of that process. Swiss psychologist Jean Piaget (1896–1980) is the towering figure in the development of research techniques and in broadening understandings about the fashion in which spatial concepts develop. Rather than being interested in a child's ability to give a correct response to direct questions, he sought to understand the reasoning process that led children to give incorrect answers to the broader tasks he set before them to solve. As well, instead of attempting to secure answers in a third-person setting in which the correct answers were foretold—the paper-and-pencil test so familiar in American schools—he asked youngsters to talk their way through the solution to a particular spatial problem irrespective of “correctness.”

Piaget's pioneering research, and that of many researchers who followed his lead in exploring the emergence of spatial concepts, tells us that the intellectual progression in the ability to comprehend spatial properties moves from perceived space to conceived space, from experiencing space only in the most direct sense to conceptions of space in which the child's thoughts, at first quite primitive, gradually become abstract and based on Euclidean (mathematical) conceptions. The development of a reasonably mature ability to comprehend spatial interactions appears not to be available to the student

until early adolescence. If this is so, then the importance of providing direct environmental experience, especially in the elementary school, would be required for the development of the kind of thinking that is basic to the mature comprehending of spatial interactions. That school environments largely preclude direct experiencing of the spatial environment means that the development of geographic literacy faces some significant hurdles, and it also explains why the focus on “where-is-it,” “what-is-it” kinds of questions persist in the school curriculum.

### Maps and Spatial Concepts

Since the map provides the basic tool for reporting spatial interactions, the ability to read maps meaningfully is a primary objective of instruction. Map reading can be viewed as a more complex form of print reading—the reading of books, newspapers, and so forth—in which the number of symbols and their positions in relation to one another are both consistent and limited. Map reading, in contrast, requires the reader to develop meanings for a wide variety of symbols, some conventional print but others of varying degrees of abstraction, all arranged in a relational two-dimensional environment. The reading process, regardless of the symbol systems employed, requires the creation of meanings, which in turn are dependent upon the reader’s conceptual base, that is, what the reader understands the symbols are intended to represent. There has long been controversy over how the reading process, regardless of the complexity of the symbol system involved, is initiated. Many believe that initial skills should be taught in a more or less arbitrary fashion and that the development of meanings follows. Others, and that is the argument here, believe that form follows function, that concepts, in this case of spatial relationships, are basic to the process of creating meanings in response to apprehending textual material.

As in learning to read conventional print, it is argued that the most constructive route to fluent reading involves much writing based on one’s own experience. If map reading is, as it appears, similar to reading print in its more conventional form, but complicated by the presence of a variety of symbols representing different sets of meanings arranged in a two-dimensional plane (as well as an abstraction of the world’s three-dimensional reality), then learning to read maps with some degree of sophistication must depend upon prior experiences in constructing maps out of one’s personal experience. Taking this

view, an important activity throughout the school curriculum for both elementary and secondary schools should entail an emphasis on a developmental sequence that takes the student from first creating maps directly out of one’s own experience and going onward from there toward learning how the mathematics of map making results in the kind of representations seen in classrooms and the world at large.

Studies of children’s conceptions of spatial interactions indicate the progression toward some degree of intellectual maturity in this regard is much slower than commonly perceived. For example, concepts of political entities (towns, states, nations, etc.), notions of boundary lines, slope, and elevation seem to commence their emergence late—in early adolescence at best. The argument that television and various forms of virtual reality, abstractions even at their best, have expanded student’s views such that they are much more aware of the world they live in begs further examination. It is to be regretted in this regard that Piagetian research protocols have not been updated and applied to furthering our knowledge. The admittedly little evidence we do have suggests that we be cautious in coming to any conclusions about the efficacy of media, including the Internet, in promoting geographic understandings because the emergence of mature geographic understanding appears to be so highly dependent upon prior firsthand experiencing of the immediate environment.

### Evaluating Geographic Learning

How, then, does one evaluate geographic learning? Geographers are not in agreement regarding the approach instruction should take and, consequently, how to judge whether significant learning has occurred. The major traditions of geographic inquiry, which might be used as the basic framework for making such judgments, have been defined as the *spatial tradition*, the *areas studies tradition*, the *man-land tradition*, and the *earth science tradition*. These are the traditional categories employed in developing college curricula. Geographers more interested in defining geography appropriate to elementary and secondary schools have argued for what they call the *five themes of geography*: location, place, relationships within places, movement over the earth, and regions.

Whichever set of criteria one uses for developing test items, and despite the popularity of paper-and-pencil multiple-choice questions, easily evaluat-

ed by mechanical means, it is now widely accepted that evaluation procedures, to be valid, must include questions requiring the student to demonstrate reasoning abilities for reaching a particular conclusion about spatial interrelationships. Evaluating responses that demonstrate reasoning powers along with knowledge of specifics requires more time than current test practice provides and will, therefore, not be widely used until there is a broader acceptance of in-depth analyses of knowledge as the better indicator of students' progress toward geographic literacy.

## G.I. BILL OF RIGHTS

On June 22, 1944, U.S. President Franklin D. Roosevelt signed into law the Servicemen's Readjustment Act of 1944, also known as the G.I. Bill of Rights. The purpose of the act was to help the nation reabsorb millions of veterans returning from overseas who had been fighting in World War II. During the decades since its enactment, the law and its amendments have made possible the investment of millions of dollars in education and training for a vast number of veterans. The nation has earned many times its investment in return, through increased tax revenues and a dramatically changed society.

A myriad of forces converged to bring about the successful passage of the G.I. Bill. The end of the war brought reduced demand for the production of wartime goods and fueled fears of the type of economic slowdown that followed previous wars. The influx of potential laborers created apprehension regarding job security and economic stability. The bill addressed these and other problems by providing six benefits, the first three of which were administered by the Veterans Administration (VA).

- Education and training
- Loan guarantees for a home, farm, or business
- Unemployment pay of \$20 per week for up to fifty-two weeks

- Job-location assistance
- Building materials for VA hospitals as a priority
- Military review of dishonorable discharges

In enacting the legislation, lawmakers demonstrated that they had learned from the mistakes made by the United States government during the period following the World War I, when war veterans marched on the nation's capital in a crusade for increased compensation from the government. During the last years of World War II, the federal government began a period of activity designed to smooth the transition of society as a whole, and individual veterans in particular, to the postwar era. The economic stability provided by these federal efforts, the centerpiece of which was the G.I. Bill of Rights, boosted Americans' confidence and changed the way individuals lived, worked, and learned.

Initial expectations for the number of veterans who would utilize the educational benefits offered by the G.I. Bill were quite inaccurate. Projections of a total of several hundred thousand veterans were revised, as more than 1 million veterans were enrolled in higher education during each of 1946 and 1947, and well over 900,000 during 1948. Veterans represented between 40 and 50 percent of all higher education students during this period.

The increasing numbers of veterans in higher education created several changes on American college and university campuses. New facilities were constructed to accommodate the surging enrollments. New programs evolved, ones that were geared to the vocational and professional emphases that veterans sought from the classroom. The veteran was among the most successful of all college students academically, and this phenomenon generated a psychological shift for many within American society: no longer was the college campus seen as the exclusive preserve of elite sons and daughters. Once veterans were welcomed inside the college classroom, the irreversible trend began of more and more people, from all groups within society, being able to secure a stable and successful future through the pursuit of higher education and training.

Out of more than 15 million American veterans from World War II, more than 7,800,000 used the G.I. Bill to receive education in the years after the war. One primary reason for the program's success is the flexibility that it gave to veterans, who were able to spend their annual tuition stipend on a wide range of options, ranging from training in specific vocations to enrollment on Ivy League campuses.

This younger generation of Americans aspired to a way of life that was considerably different from that of their parents. Coupled with assistance for housing costs, the educational benefits of the G.I. Bill made possible a middle-class lifestyle that was characterized by white-collar work, home ownership, and life in the suburbs. War-weary citizens were finished with the sacrifices that had been necessary during both depression and wartime; the savings that had accumulated during the war could be spent without reservation, for the financial stability offered by the G.I. Bill's provisions allayed fears of postwar economic disruptions.

The empowerment of the individual veteran by the G.I. Bill helped to create the expectation that all Americans can and must have an opportunity to share in the dreams of a college education and a successful, middle-class lifestyle. In the decades following World War II, the federal government pursued initiatives designed to extend this opportunity to minorities, to women, and to the disabled within American society. The successes of the G.I. Bill encouraged legislators to create educational opportunities for individuals in these groups as a means of redressing past social and economic inequities.

This emphasis on advanced education and training for the masses has facilitated the development of America's knowledge-based economy and society. More than ever, Americans see knowledge and training as vital to each individual's future economic success and position within society. Though not entirely eradicated, barriers to accessing this knowledge and training have diminished in many areas of American society, due in large part to the efforts of the federal government. The G.I. Bill proved the ability of the federal government to promote social and economic advancement through educational attainment and training, and millions of veterans can attest to the importance in their own lives of the opportunities that welcomed them following the completion of their military service.

Subsequent legislation includes the following.

- The Veterans Readjustment Act of 1952, approved by President Truman on July 16, 1952, for those serving in the Korean War
- The Veterans Readjustment Benefits Act of 1966, signed into law by President Lyndon B. Johnson on March 3, 1966, for post-Korean War veterans and Vietnam-era veterans
- The Post-Vietnam Era Veterans' Educational Assistance program (VEAP) for individuals that

entered active duty between December 31, 1976, and July 1, 1985

- The Montgomery G.I. Bill for individuals initially entering active duty after June 30, 1985
- The Montgomery G.I. Bill: Selected Reserve Educational Assistance Program for members of the Selected Reserve, including the national guard
- The Survivors' and Dependents' Educational Assistance Program, the only VA educational assistance program for spouses and children of living veterans

## GIFTED AND TALENTED EDUCATION

---

The term *gifted and talented* is often used in tandem to describe both a wide range of human exceptional

performance, and people who display such high levels of competence in culturally valued domains or socially useful forms of expression. For children to be identified as gifted and talented, they need to demonstrate outstanding potential or promise rather than mature, expert performance. Thus different standards are used when the term is applied to children as opposed to adults. The term *gifted children* has a connotation that the outstanding potential they demonstrate is largely a natural endowment. However, the term *gifted* as used in educational contexts (e.g., gifted child or gifted performance) is descriptive rather than explanatory. Although efforts have been made to differentiate the two terms, with giftedness referring to natural (spontaneously demonstrated) abilities, and talents referring to systematically developed abilities, such differentiation proves difficult, if not impossible, in practice, as no reliable measures exist to tease apart the constitutional and acquired parts of individual differences in human abilities.

#### The Nature and Identification

The phenomenon of gifted and talented children is easier to describe than explain. Some scholars in the field attribute children's outstanding performance on IQ or culturally defined domains largely to their constitutional makeup (e.g., a neurological advantage), reminiscent of the position of Francis Galton (1822–1911), an early pioneer of behavioral genetics and intelligence testing. Other scholars are more cautious about bestowing the title of *gifted and talented* for some children by mere virtue of their test performance while treating the rest as nongifted. Rather, they emphasize the emergence of gifted and talented behaviors among children in more authentic contexts as a result of both genetic and environmental influences, involving motivational as well as cognitive processes. Still others point out that, to the extent that the phenomenon of the gifted and talented is subject to different interpretations and assessment strategies based on one's values and beliefs, consequently with different criteria and outcomes, it reflects a social construction rather than an objective reality.

One way of analyzing the research underlying conceptions of giftedness is to review existing definitions along a continuum ranging from conservative to liberal. Conservative and liberal are used here not in their political connotations, but rather according to the degree of restrictiveness that is used in deter-

mining who is eligible for special programs and services.

Restrictiveness can be expressed in two ways. First, a definition can limit the number of specific performance areas that are considered in determining eligibility for special programs. A conservative definition, for example, might limit eligibility to academic performance and exclude other areas such as music, art, drama, leadership, public speaking, social service, and creative writing. Second, a definition can limit the degree or level of excellence that one must attain by establishing extremely high cutoff points.

At the conservative end of the continuum is Lewis Terman's 1926 definition of giftedness as "the top 1 percent level in general intellectual ability as measured by the Stanford-Binet Intelligence Scale or a comparable instrument" (p. 43). In this definition, restrictiveness is present in terms of both the type of performance specified (i.e., how well one scores on an intelligence test) and the level of performance one must attain to be considered gifted (top 1 percent). At the other end of the continuum can be found more liberal definitions, such as the following one by Paul Witty in 1958: "There are children whose outstanding potentialities in art, in writing, or in social leadership can be recognized largely by their performance. Hence, we have recommended that the definition of giftedness be expanded and that we consider any child gifted whose performance, in a potentially valuable line of human activity, is consistently remarkable." (p. 62)

Although liberal definitions have the obvious advantage of expanding the conception of giftedness, they create two dilemmas. First, they introduce a values issue by forcing educators to delineate potentially valuable lines of human activity. Second, they introduce even greater subjectivity in the measurement and assessment of children's potentialities.

In recent years the values issue has been largely resolved. There are very few educators who cling tenaciously to a "straight IQ" or purely academic definition of giftedness. Multiple talents and multiple criteria are almost the byproduct words of the present-day gifted education movement, and most people would have little difficulty in accepting a definition that includes almost every socially useful form of human activity.

The problem of subjectivity in measurement and assessment is not as easily resolved. As the defi-

nition of giftedness is extended beyond those abilities that are clearly reflected in tests of intelligence, achievement, and academic aptitude, it becomes necessary to put less emphasis on precise estimates of performance and potential and more emphasis on the opinions of qualified judges in making decisions about admission to special programs. The crux of the issue boils down to a simple and yet very important question: How much are we willing to sacrifice purely objective criteria in order to allow recognition of a broader spectrum of human abilities? If some degree of subjectivity cannot be tolerated, then our definition of giftedness and the resulting programs will logically be limited to abilities that can be measured only by objective tests. A balance between the reliance on measurement technology and expert judgment seems to be the most reasonable course of action.

### Goals and Purposes

Although Lewis Terman launched the first large-scale effort to identify gifted children in the United States, it was Leta Stetter Hollingworth in 1942 who shifted the focus of the gifted child movement to educational issues. However, a full-fledged gifted education movement was rather triggered by the launching of the satellite *Sputnik* by the Soviet Union in 1957 and the ensuing space race. The ensuing decline of targeted services in the second half of the twentieth century was closely related to political and economic circumstances and apparently inadequate educational conditions, as reflected in the reports by the National Commission on Excellence in Education 1983 (*A Nation at Risk*) and by the U.S. Department of Education in 1993 (*National Excellence: A Case for Developing America's Talent*). For example, by citing evidence of declined academic achievement and poor showing of American students compared to other industrialized nations, Joseph Renzulli and Sally Reis in 1991 proposed that a major goal of gifted education was to "provide the best possible education to our most promising students so that we can reassert American prominence in the intellectual, artistic, and moral leadership of the world" (p. 26). The general education curriculum, which is tailored to average students, is inadequate to provide such an education, thus necessitating special educational provisions for gifted and talented students.

Other educators and researchers of the gifted and talented have advanced an alternative argument for a special service for the gifted and talented. In

line with Hollingworth, they emphasize the uniqueness of gifted and talented students' cognitive development, social-emotional experiences, and corresponding educational needs. Therefore, gifted and talented education is aimed not at advancing national or societal interests but at promoting individual gifted children's welfare, academically as well as socially and emotionally, not unlike special provisions for the mentally retarded or learning disabled.

A more recent approach to gifted and talented education focuses on talent development. This movement is largely a result of dissatisfaction with the notion of giftedness as unidimensional (i.e., high general intelligence) and the traditional gifted programs that are frequently short-term based, limited to school subjects, and typically do not address individual children's unique strengths, interests, and long-term development. The talent development approach, based on related psychological research that cumulated in the 1980s and 1990s, attempts to nurture talents among a more diverse group of children and address their unique needs with their long-term talent development in mind.

There are two main strategies to serve gifted children: acceleration and enrichment. With accelerated curriculum, gifted children can learn at a pace commensurate with their learning ability. This allows them to progress to high-level materials much faster for their age norms or grade levels. The constant challenges not only suit these advanced learners' intellectual levels, but also keep them motivated. Enrichment activities, on the other hand, provide gifted children with opportunities to explore topics and issues from (or beyond) regular curriculum in greater breadth and depth, to engage in independent or collaborative inquiry that cultivates their problem solving abilities, research skills, and creativity, and inspire their desire for excellence. Acceleration and enrichment, facilitated by various forms of grouping arrangement, constitute the core instructional adaptations to meet the educational needs of gifted and talented children. From a talent development perspective, both acceleration and enrichment can be used to provide individualized educational programs that aim at promoting long-term development and accomplishment in one's chosen area of human endeavor.

### **Programs and Their Effectiveness**

Specific programs for the gifted and talented can be conceptualized as a continuum from activities that

can be arranged in regular classrooms, sometimes with the participation of all students, to arrangements that are exclusively tailored to the needs of the gifted and talented. These programs encompass enrichment and acceleration services that take place (1) within regular classrooms or clusters from one or more grade levels; (2) during special grouping arrangements within classrooms, across grade levels, or in after-school and out-of-school programs; (3) in special schools such as magnet schools or high schools that focus on advanced learning opportunities in particular curricular areas; and (4) through arrangements made for individual students at colleges, summer programs, internship opportunities, or mentorship programs. Age and grade levels play a role in making decisions about special services. Students' abilities, interests, and learning styles tend to become more differentiated and more focused as they grow older. There is, therefore, more justification for interest and achievement level grouping as students progress through the grades. The nature of the subject matter and the degree to which classroom teachers can reasonably differentiate instruction also play a role in making decision about differentiation. For example, acceleration is a more viable option for subjects that are highly structured and linear-sequential in content (e.g., algebra, chemistry, physics). Within-class differentiation in literature is easier to accomplish at the elementary or middle school levels, but an advanced literature class is a more specialized option at the high school level.

With respect to the issue of effectiveness, gifted students in pull-out, separate class, and special school programs performed better than their gifted peers in the within-class arrangements or in schools without gifted programs. Academic gains from acceleration and various benefits regarding content, process and product aspects of objectives as well as positive affective and motivational effects are also reported for enrichment programs. Meta-analyses of the outcomes of these programs reveal quite compelling positive effects. Among other issues, concerns about social-emotional adjustment for students accelerated to higher grade levels or college, about the impact of the gifted label on social interaction, and about self-concept change when placed with equally competent peers, have also been addressed in research.

The effectiveness of gifted and talented programs is not easy to determine for many reasons. Difficulty in finding appropriate control groups, as

well as in controlling extraneous variables, poses many threats to internal validity. Ceiling effects constitute another problem. In addition, some criteria (e.g., problem solving, creativity) for evaluating the effectiveness of gifted programs are not as amenable to reliable measurement as those typically used in general education. Because of these difficulties, there is a lack of high-quality research on the effectiveness of various gifted and talented programs. More systematic, methodic (instead of piecemeal) program evaluation is sorely needed.

Two issues about the effectiveness and equity of gifted programs remain controversial. The first one involves the argument that what is good for gifted students is good for most students. Such an argument is a double-edged sword. On the one hand, gifted education can be and has been a viable laboratory for educational experimentation. What is shown to be effective in gifted education may inform and facilitate reform in general education. On the other hand, however, it is preposterous to assume that only gifted children would benefit from such an education. Many critics who argue that gifted education is elitist hold such a view. Two responses have been advanced to address this concern. First, some components of gifted programs may indeed be applicable to general education, such as enrichment or inquiry-based learning, while other components are only suitable for gifted children, such as acceleration and some high-level curricular materials. Second, even though instructional principles and strategies appropriate for gifted learners may also be appropriate for other learners, there are differences in the pace and levels of learning and understanding that impose constraints on the effectiveness of implementation of these principles and strategies. In 1996 Carol A. Tomlinson identified nine dimensions along which to differentiate curriculum and instruction: foundational to transformational, concrete to abstract, simple to complex, few facets to multifacets, smaller leap to greater leap, more structured to more open, clearly defined or fuzzy, less independence to greater independence, slower to quicker.

The second issue is whether gifted education is nothing but “fluff,” with fancy rhetoric but not much substance. This concern reflects the fact that the quality of gifted programs varies from school district to school district and that programs meet the needs of their constituents. There are many factors contributing to effectiveness or ineffectiveness of gifted programs, such as administrative support and

staff training. In general, gifted education needs to continue to develop and implement individualized programs rather than a one-size-fits-all gifted curriculum, integrating what students receive from regular classrooms and what they get from pull-out programs. Based on their extensive review of the literature, Bruce Shore and Marcia Delcourt in 1996 suggested that effective gifted programs (1) congregate gifted children at least part of the time; (2) address children at a high intellectual level; (3) use acceleration when warranted; (4) address real and challenging problems; (5) include well-supervised independent study; (6) place educational experiences in a life-span context for the learner; (7) build substantially upon opportunities for individualization; (8) include well-trained and experienced teachers; and (9) support the cognitive and affective needs of all gifted students.

### Issues, Controversies, and Trends

Because the term *gifted and talented* is an umbrella concept meant to encompass various facets of excellence or potential for excellence, its meaning is an object of constant debate within and outside of the field. What is the basis for the phenomenon of gifted and talented performance: general mental power or highly specific abilities or talents, or both? Even though most experts in the field accept the notion of diverse expressions of excellence, they have their own leanings, ranging from the most traditional conception of giftedness as high general intelligence as indicated by IQ test scores, to the most pluralistic definition that defies any terms of psychometric measurement.

A related question is do gifted and talented manifestations reflect fundamental attributes of some children (hence gifted children) that set them apart from other children, or emergent developmental qualities of the child as a result of interaction with the environment? Is it a fixed or fluid condition? Major ideological differences exist in the field between those who believe that gifted children are a distinct group of exceptional children who share certain unique cognitive and social-emotional characteristics (i.e., being gifted made them different from the rest of children), and those who believe that gifted and talented performance or behavior should be understood in a more dynamic context in which it occurs, and can be attributed to contextual influences as much as personal characteristics. These differences have profound implications for identifi-

cation. Should we develop a fixed formula for finding the right gifted child or should we instead focus on nurturing and facilitating the emergence of gifted behaviors among children, while holding flexible but “soft” identification criteria?

From an assessment perspective, the traditional approach, deeply rooted in the intelligence testing movement, focused on a set of static attributes or traits. On the other hand, a dynamic assessment approach affords a closer look at processes, strategies, insights, errors, and so on, and is thus more informative and explanatory. A contrast has been made between a static (trait) approach and a dynamic (process) approach that involves micro-level analysis and clinical insights regarding children’s superior performance. This reinforces the issue of subjectivity in measurement and assessment. Time will tell whether a dynamic assessment will supplement, or even replace, the traditional way of identifying gifted and talented children. A better understanding of the nature and improved assessment of potential for talent development will also help address other derivative issues such as multipotentialities, multiple exceptionalities, and underachievement among highly able children.

Because of different understandings of the phenomenon in question and concerns about equity, some experts suggest that we abandon the term *gifted* altogether to avoid the arbitrary bifurcation of the gifted and nongifted, and that we should label services instead of labeling the child, whereas others view this movement as abandoning the very *raison d’être* for gifted programs. The social-emotional impact of labeling aside, the issue is also that of restrictiveness discussed earlier: how inclusive and flexible gifted programs can be. On the one hand, programs such as Talent Search are highly selective in nature; some cutoffs (e.g., ninety-ninth percentile) are necessary to determine one’s qualification, and intensive programs can be implemented with relatively high efficiency. On the other hand, various forms of enrichment and high-end learning can be open to a larger pool of able students, even to all students, and qualification can be determined in a flexible manner to maximize opportunities for participation, with gifted programs justified on the basis of needs (e.g., substituting regular curriculum with more advanced materials) rather than status (being identified as gifted), as is the case with the Revolving Door Identification Model.

As mentioned above, various forms of grouping are necessary to provide special services for gifted and talented children. It is not difficult to justify grouping as a way of providing an optimal educational environment for gifted and talented children. The challenge is justifying the services within the context of the whole educational system. Ability grouping practices are vulnerable to charges such as favoritism or elitism in a democratic society and egalitarian culture. The problem is exacerbated by the fact that ethnic minority (except Asian-American) students and students from families of low social economic status are underrepresented in gifted education programs in the United States. Until gifted education is well integrated into the whole education system, its identity and functions become better defined, and its pursuit of excellence is balanced with concerns over equity, it will continue to be the target of criticism.

On a positive note, gifted education has proven to be a vital force in American education. In many respects, programs for the gifted have been the true laboratories of our nation’s schools because they have presented ideal opportunities for testing new ideas and experimenting with potential solutions to long-standing educational problems. Programs for high potential students have been an especially fertile place for experimentation because such programs usually are not encumbered by prescribed curriculum guides or traditional methods of instruction. It was within the context of these programs that the thinking skills movement first took hold in American education, and the pioneering work of notable theorists such as Benjamin Bloom, Howard Gardner, and Robert Sternberg first gained the attention of the education community in the 1980s. Other developments that had their origins in special programs are currently being examined for general practice. These developments include a focus on concept rather than skill learning, the use of interdisciplinary curriculum and theme-based studies, student portfolios, performance assessment, cross-grade grouping, alternative scheduling patterns, and perhaps most important, opportunities for students to exchange traditional roles as lesson-learners and doers-of-exercises for more challenging and demanding roles that require hands-on learning, first-hand investigations, and the application of knowledge and thinking skills to complex problems.

Research in a variety of gifted education programs has fostered the development of instructional

procedures and programming alternatives that emphasize the need (1) to provide a broad range of advanced level enrichment experiences for all students, and (2) to use the many and varied ways that students respond to these experiences as stepping stones for relevant follow-up on the parts of individuals or small groups. These approaches are not viewed as new ways to identify who is or is not gifted. Rather, the process simply identifies how subsequent opportunities, resources, and encouragement can be provided to support continuous escalations of student involvement in both required and self-selected activities. This orientation has allowed many students opportunities to develop high levels of creative and productive accomplishments that otherwise would have been denied through traditional special program models. Practices that have been a mainstay of many special programs for the gifted are being absorbed into general education by reform models designed to upgrade the performance of all students. This integration of gifted program know-how is viewed as a favorable development, since the adoption of many special program practices is indicative of the viability and usefulness of both the know-how of special programs and the role gifted education can and should play in total school improvement. This broader and more flexible approach reflects a democratic ideal that accommodates the full range of individual differences in the entire student population, and it opens the door to programming models that develop the talent potentials of many at-risk students who traditionally have been excluded from anything but the most basic types of curricular experiences. This integration of gifted and talented education into the general education system is beginning to redefine the ways in which we develop the many and various potentials of the nation's youths.

## GLOBALIZATION OF EDUCATION

---

In popular discourse, *globalization* is often synonymous with *internationalization*, referring to the growing interconnectedness and interdependence of people and institutions throughout the world. Although these terms have elements in common, they have taken on technical meanings that distinguish them from each other and from common usage. Internationalization is the less theorized term. Globalization, by contrast, has come to denote the complexities of interconnectedness, and scholars have produced a large body of literature to explain what appear to be ineluctable worldwide influences on local settings and responses to those influences.

Influences of a global scale touch aspects of everyday life. For example, structural adjustment policies and international trading charters, such as the North American Free Trade Association (NAFTA) and the Asia-Pacific Economic Cooperation (APEC), reduce barriers to commerce, ostensibly promote jobs, and reduce the price of goods to consumers across nations. Yet they also shift support from "old" industries to newer ones, creating dislocations and forcing some workers out of jobs, and have provoked large and even violent demonstrations in several countries. The spread of democracy, too, is part of globalization, giving more people access to the political processes that affect their lives, but also, in many places, concealing deeply rooted socioeconomic inequities as well as areas of policy

over which very few individuals have a voice. Even organized international terrorism bred by Islamic fanaticism may be viewed as an oppositional reaction—an effort at *deglobalization*—to the pervasiveness of Western capitalism and secularism associated with globalization. Influences of globalization are multi-dimensional, having large social, economic, and political implications.

A massive spread of education and of Western-oriented norms of learning at all levels in the twentieth century and the consequences of widely available schooling are a large part of the globalization process. With regard to the role of schools, globalization has become a major topic of study, especially in the field of comparative education, which applies historiographic and social scientific theories and methods to international issues of education.

### Globalization Theory

Globalization is both a process and a theory. Roland Robertson, with whom globalization theory is most closely associated, views globalization as an accelerated compression of the contemporary world and the intensification of consciousness of the world as a singular entity. Compression makes the world a single place by virtue of the power of a set of globally diffused ideas that render the uniqueness of societal and ethnic identities and traditions irrelevant except within local contexts and in scholarly discourse.

The notion of the world community being transformed into a *global village*, as introduced in 1960 by Marshall McLuhan in an influential book about the newly shared experience of mass media, was likely the first expression of the contemporary concept of globalization. Despite its entry into the common lexicon in the 1960s, globalization was not recognized as a significant concept until the 1980s, when the complexity and multidimensionality of the process began to be examined. Prior to the 1980s, accounts of globalization focused on a professed tendency of societies to converge in becoming modern, described initially by Clark Kerr and colleagues as the emergence of *industrial man*.

Although the theory of globalization is relatively new, the process is not. History is witness to many globalizing tendencies involving grand alliances of nations and dynasties and the unification of previously sequestered territories under such empires as Rome, Austria-Hungary, and Britain, but also such events as the widespread acceptance of germ theory

and heliocentrism, the rise of transnational agencies concerned with regulation and communication, and an increasingly unified conceptualization of human rights.

What makes globalization distinct in contemporary life is the broad reach and multidimensionality of interdependence, reflected initially in the monitored set of relations among nation-states that arose in the wake of World War I. It is a process that before the 1980s was akin to *modernization*, until modernization as a concept of linear progression from traditional to developing to developed—or from *gemeinschaft* to *gesellschaft* as expressed by Ferdinand Toennies—forms of society became viewed as too simplistic and unidimensional to explain contemporary changes. Modernization theory emphasized the functional significance of the Protestant ethic in the evolution of modern societies, as affected by such objectively measured attributes as education, occupation, and wealth in stimulating a disciplined orientation to work and political participation.

The main difficulty with modernization theory was its focus on changes within societies or nations and comparisons between them—with Western societies as their main reference points—to the neglect of the interconnectedness among them, and, indeed, their interdependence, and the role played by non-Western countries in the development of the West. Immanuel Wallerstein was among the earliest and most influential scholars to show the weaknesses of modernization theory. He developed *world system theory* to explain how the world had expanded through an ordered pattern of relationships among societies driven by a capitalistic system of economic exchange. Contrary to the emphasis on linear development in modernization theory, Wallerstein demonstrated how wealthy and poor societies were locked together within a world system, advancing their relative economic advantages and disadvantages that carried over into politics and culture. Although globalization theory is broader, more variegated in its emphasis on the transnational spread of knowledge, and generally less deterministic in regard to the role of economics, world system theory was critical in shaping its development.

### The Role of Education

As the major formal agency for conveying knowledge, the school features prominently in the process and theory of globalization. Early examples of edu-

cational globalization include the spread of global religions, especially Islam and Christianity, and colonialism, which often disrupted and displaced indigenous forms of schooling throughout much of the nineteenth and twentieth centuries. Postcolonial globalizing influences of education have taken on more subtle shapes.

In globalization, it is not simply the ties of economic exchange and political agreement that bind nations and societies, but also the shared consciousness of being part of a global system. That consciousness is conveyed through ever larger transnational movements of people and an array of different media, but most systematically through formal education. The inexorable transformation of consciousness brought on by globalization alters the content and contours of education, as schools take on an increasingly important role in the process.

**Structural adjustment policies.** Much of the focus on the role of education in globalization has been in terms of the structural adjustment policies of the World Bank and other international lending organizations in low-income countries. These organizations push cuts in government expenditures, liberalization of trade practices, currency devaluations, reductions of price controls, shifts toward production for export, and user charges for and privatization of public services such as education. Consequently, change is increasingly driven largely by financial forces, government reliance on foreign capital to finance economic growth, and market ideology.

In regard to education, structural adjustment policies ostensibly reduce public bureaucracies that impede the delivery of more and better education. By reducing wasteful expenditures and increasing responsiveness to demand, these policies promote schooling more efficiently. However, as Joel Samoff noted in 1994, observers have reported that structural adjustment policies often encourage an emphasis on inappropriate skills and reproduce existing social and economic inequalities, leading actually to lowered enrollment rates, an erosion in the quality of education, and a misalignment between educational need and provision. As part of the impetus toward efficiency in the expenditure of resources, structural adjustment policies also encourage objective measures of school performance and have advanced the use of cross-national school effectiveness studies. Some have argued that these studies represent a new

form of racism by apportioning blame for school failure on local cultures and contexts.

**Democratization.** As part of the globalization process, the spread of education is widely viewed as contributing to democratization throughout the world. Schools prepare people for participation in the economy and polity, giving them the knowledge to make responsible judgments, the motivation to make appropriate contributions to the well being of society, and a consciousness about the consequences of their behavior. National and international assistance organizations, such as the U. S. Agency for International Development and the United Nations Educational, Scientific and Cultural Organization (UNESCO), embrace these objectives. Along with mass provision of schools, technological advances have permitted distance education to convey Western concepts to the extreme margins of society, exposing new regions and populations to knowledge generated by culturally dominant groups and helping to absorb them into the consumer society.

A policy of using schools as part of the democratization process often accompanies structural adjustment measures. However, encouraging user fees to help finance schooling has meant a reduced ability of people in some impoverished areas of the world to buy books and school materials and even attend school, thus enlarging the gap between rich and poor and impeding democracy. Even in areas displaying a rise in educational participation, observers have reported a reduction in civic participation. Increased emphasis on formalism in schooling could plausibly contribute to this result. An expansion of school civics programs could, for example, draw energy and resources away from active engagement in political affairs by youths, whether within or outside of schools. Increased privatization of education in the name of capitalist democratization could invite greater participation of corporate entities, with the prospect of commercializing schools and reducing their service in behalf of the public interest.

**Penetration of the periphery.** Perhaps the most important question in understanding how education contributes to globalization is, what is the power of schools to penetrate the cultural periphery? Why do non-Western people surrender to the acculturative pressure of Western forms of education?

By mid-twentieth century, missionaries and colonialism had brought core Western ideas and practices to many parts of the world. With contemporary

globalization, penetration of the world periphery by means of education has been accomplished mainly in other ways, especially as contingent on structural adjustment and democratization projects. Some scholars, including Howard R. Woodhouse, have claimed that people on the periphery are “mystified” by dominant ideologies, and willingly, even enthusiastically and without conscious awareness of implications, accept core Western learning and thereby subordinate themselves to the world system. By contrast, there is considerable research, including that of Thomas Clayton in 1998 and Douglas E. Foley in 1991, to suggest that people at the periphery develop a variety of strategies, from foot dragging to outright student rebellion, to resist the dominant ideology as conveyed in schools.

Evidence on the accommodation of people at the periphery to the dominant ideology embodied in Westernized schooling is thus not consistent. Erwin H. Epstein, based on data he collected in three societies, proposes a *filter-effect theory* that could explain the contradictory results reported by others. He found that children in impoverished areas attending schools more distant from the cultural mainstream had more favorable views of, and expressed stronger attachment to, national core symbols than children in schools closer to the mainstream. In all three societies he studied, globalization influences were abrupt and pervasive, but they were resisted most palpably not at the remote margins, but in the towns and places closer to the center, where the institutions representative of the mainstream—including law enforcement, employment and welfare agencies, medical facilities, and businesses—were newly prevalent and most powerfully challenged traditional community values.

Epstein explained these findings by reasoning that it is easier for children living in more remote areas to accept myths taught by schools regarding the cultural mainstream. By contrast, children living closer to the mainstream cultural center—the more acculturated pupils—are more exposed to the realities of the mainstream way of life and, being more worldly, are more inclined to resist such myths. Schools in different areas do not teach different content; in all three societies, schools, whether located at the mainstream center or periphery, taught an equivalent set of myths, allegiances to national symbols, and dominant core values. Rather, schools at the margin are more effective in inculcating intended political cultural values and attitudes because they

operate in an environment with fewer competing contrary stimuli. Children living in more traditional, culturally homogeneous and isolated areas tend to be more naive about the outside world and lack the tools and experience to assess objectively the political content that schools convey. Children nearer the center, by contrast, having more actual exposure to the dominant culture, are better able to observe the disabilities of the dominant culture—its level of crime and corruption, its reduced family cohesion, and its heightened rates of drug and alcohol abuse, for example. That greater exposure counteracts the favorable images all schools convey about the cultural mainstream, and instead imbues realism—and cynicism—about the myths taught by schools.

In other words, schools perform as a filter to sanitize reality, but their effectiveness is differential; their capacity to filter is larger the farther they move out into the periphery. As extra-school knowledge progressively competes with school-produced myths, the ability and inclination to oppose the dominant ideology promoted by schools as part of the globalization process should become stronger. This filter-effect theory could clarify the impact of schools as an instrument of globalization and invites corroboration.

## GOALS 2000: EDUCATE AMERICA ACT

*See:* EDUCATION REFORM; SCHOOL REFORM; STANDARDS FOR STUDENT LEARNING; STANDARDS MOVEMENT IN AMERICAN EDUCATION.

### GODDARD, HENRY H. (1866–1957)

Director of research at the New Jersey Home for the Education and Care of Feeble-Minded Children in Vineland, Henry H. Goddard used and elaborated Alfred Binet’s intelligence tests for use with American students. Goddard made a number of important contributions in special education, including his guiding role in the establishment of the first state law mandating special education services. He is remembered, however, primarily for his work in popularizing Alfred Binet’s approach to psychological testing in the United States and studying the hereditary roots of feeble-mindedness in his book, *The Kallikak Family: A Study in the Heredity of Feeble-Mindedness* (1912).

#### Background and Education

Goddard grew up in a devout Quaker family, and his initial educational experiences occurred at Haverford College, a Quaker institution in Pennsylvania. At various points during his education, he took teaching and administrative positions in Quaker schools. At one point, he lectured at the newly founded University of Southern California—where he held the distinction of being that university’s first football coach. But Goddard’s interests in psychology lured him to Clark University to study with G. Stanley Hall, where Goddard gained an appreciation for scientific approaches to studying human behavior.

Upon graduation with his doctorate, Goddard worked for several years at a teacher’s college in Pennsylvania, where he became frustrated by the lack of emphasis on scientific psychology and peda-

gogy. As a result, in 1906 he accepted the position of director of research at the New Jersey Home for the Education and Care of Feeble-Minded Children in Vineland, a small town in the southern, rural part of the state. Although Goddard is best known for his work at the Vineland School, he also held two major positions in Ohio before his retirement.

#### Intelligence Testing

Early in the twentieth century, Goddard was concerned with separating, in his terms, the retarded—who suffered from poor health or environment and required remedial help—from the feeble-minded—who suffered from decreased mental capacity and required a special curriculum. Goddard believed that the Binet-Simon intelligence tests, recently developed in France, could aid in assessing the nature of this problem and began to advocate for the use of the scales in the United States.

About this time, American educators became concerned with the percentage of students who were older than would be expected given their grade. When the question of grade versus age became a major issue in American education, Goddard saw that the Binet scales with which he was already working could be used to study this issue. Goddard’s advocacy for the Binet tests was enthusiastic and exhaustive. Well-connected in areas as diverse as medicine, education, psychology, and law, he championed the use of the tests in several venues. For example, he taught or organized courses for teachers on administration of the Binet tests at several institutions. These teachers proceeded to use the tests in educational settings throughout the United States. In addition, he advocated the value of test results as legal evidence. Goddard was also highly involved in the U.S. army psychological testing program during World War I, further legitimizing this particular approach to mental testing.

Goddard’s advocacy of the Binet tests had two important outcomes. The mental testing approach gained popularity relative to the qualitatively different techniques used by Francis Galton and others who relied upon physical and physiological measures to estimate intelligence. Also, various forms of the Binet test, primarily revisions by Goddard and especially Lewis Terman, remain in use, and a majority of contemporary intelligence tests are based on similar methodologies. Without Goddard’s influence, early-twenty-first century testing and related educational practices might look quite different.

## The Kallikak Family Study

Goddard's other major contribution was his study of feeble-mindedness. Goddard's field-based research resulted in many publications, with the best known being *The Kallikak Family: A Study in the Heredity of Feeble-Mindedness*. Although Goddard and his assistants studied hundreds of families, the Kallikak family remains the most famous. The family was that of a Vineland student, Deborah. The name *Kallikak* is actually a pseudonym created from the Greek words *kallos* (beauty) and *kakos* (bad). The Kallikak family was divided into two branches—one "good" and one "bad,"—both of which originated from Deborah's great-great-great grandfather, Martin Kallikak. When Kallikak was a young soldier, he had a liaison with an "unnamed, feeble-minded tavern girl." This tryst resulted in the birth of an illegitimate son, Martin Kallikak Jr., from whom the bad branch of the family descended. Later in his life, Martin Kallikak Sr. married a Quaker woman from a good family. The good branch descended from this marriage.

Goddard's genealogical research revealed that the union with the feeble-minded girl resulted in generations plagued by feeble-mindedness, illegitimacy, prostitution, alcoholism, and lechery. The marriage of Martin Kallikak Sr. to the Quaker woman yielded generations of normal, accomplished offspring. Goddard believed that the remarkable difference separating the two branches of the family was due entirely to the different hereditary influences from the two women involved with the senior Kallikak.

Goddard's work had a powerful effect. Scholars were generally impressed by the magnitude of the study, and *The Kallikak Family* became very popular. Critical reaction in the popular press was positive, with more muted reaction within the scientific community. For example, James McKeen Cattell praised the contribution and conclusions but criticized the research design. The Kallikak study was a powerful ally to eugenicist movements, including that of the Nazi party, and contributed to the atmosphere in which compulsory sterilization laws were passed in many states.

## Controversy

Controversy followed Goddard throughout his career. However, the Kallikak study and Goddard's eugenicism in the 1910s created the most serious problems. For example, Goddard concluded *The*

*Kallikak Family* with recommendations of forced sterilization and segregation of the feeble-minded in isolated colonies. His work also had a strong anti-immigrant tone at a time when immigrants were seeking citizenship in record numbers. Goddard later admitted that many of his recommendations on social policy had been misguided, but his controversial role earlier in the twentieth century helped to place his work in low regard by the 1940s.

By the end of the twentieth century, Goddard's research once again came under fire. A photographic expert suggested that some of the Kallikak photographs—those of the bad branch of the family—were retouched. Critics charged that the modifications were made by Goddard to give a more disturbing appearance. However, several researchers have concluded that fraud appears to be unlikely. As Leila Zederland noted, a main thrust of Goddard's work was to show that feeble-minded people looked normal and were often quite attractive; he was advocating for mental testing, not visual inspection, to determine feeble-mindedness.

## Contribution

Henry Goddard made substantial contributions to American education, including the popularizing of mental testing, compulsory special education, and gifted education. His research into the hereditary nature of feeble-mindedness and related eugenicist activities, however, has helped to paint the rather negative picture many people continue to hold of Goddard and his work.

## GOODMAN, PAUL (1911–1972)

Social and educational critic Paul Goodman was referred to by his biographer, Taylor Stoehr, as a "prophet." Revered by the youth movement in the 1960s, his ideas on education and youth were extremely appealing to many people on the political left.

Goodman was born in New York, and raised amid the urban, Jewish intellectual community. He graduated from City College of New York in 1931. Goodman earned his Ph.D. at the University of Chicago, but moved back to New York and lived with his wife Sally until his death. His major works on education were *Growing Up Absurd*, *Community of Scholars*, and *Compulsory Mis-Education*, but he also wrote many articles that dealt with de-schooling, alternative education, mini-schools, and free universities.

The publishing of *Growing Up Absurd* in 1960 brought Goodman to the public as a social/educational critic. The book was rejected seventeen times before a publisher accepted it, after Norman Poderhotz serialized it in the then leftist *Commentary*. Goodman spent the last twelve years of his life teaching courses at universities in New York, speaking on campuses throughout the country, and as a visiting professor at San Francisco State University and the University of Hawaii. Goodman never held a tenure track appointment. *Growing Up Absurd* was adopted in education and sociology courses throughout the country. The book was read as a condemnation of the alienation and oppression in American society and schools, and was a forerunner

to the educational criticism of John Holt, Herb Kohl, Jonathan Kozol, and Edgar Friedenberg. For sixties activists, as well as liberal educators, the book provided an analysis of the wrongs of American society and education.

Goodman published *Compulsory Mis-Education* and *Community of Scholars* as a single volume in 1962. The books were assigned reading in education courses and initiated thoughtful educational criticism. *Compulsory Mis-Education* became somewhat of a blueprint for de-schoolers as well as for the alternative school movement in the late 1960s and 1970s. Critical of education from kindergarten through the university, the work led seamlessly into *Community of Scholars*, which emphasized Goodman's endless quest for community while criticizing the status quo. Goodman spent much of his time in his final years bringing his philosophy on education to college campuses. He was actively antiwar, but he warned student activists of the danger in "action for the sake of action." He continued to write, mostly about educational criticism.

*Decentralizing Power*, Taylor Stoehr's biographical work on Goodman, is a collection of Goodman's writing on social and educational criticism. The general theme of the work is community life. Goodman's initial discussion of the issues and problems of youth analyzes the youth movement—both idealism and alienation—with the latter being predominant. He speaks of power-beating community, coining the phrase "school monks." The theme of community is also prevalent in his important essay on children's rights. Goodman laments the lack of community and gently criticizes both Maria Montessori and A. S. Neill for educational practices that ask children to become adults too quickly.

At the same time, he lauds Neill's school, Summerhill, for delaying socialization and protecting the wildness of childhood. Goodman discusses schools as therapeutic communities, where children can escape from bad homes and bad cities. Goodman also offers a plan to abolish high schools and to replace them with apprenticeships, academies, youth houses, and therapeutic free schools—in fact, it is a de-schooling plan that preceded Ivan Illich's book, *De-schooling Society*.

Although Goodman was philosophical, and asked searching questions about people's relationship with the world, his educational proposals were practical and simple. As a teacher, his classroom was

an interactive laboratory. His proposals asked that education allow the same for young children, adolescents, and adults.

### GOSLIN, WILLARD E. (1899–1969)

A nationally acclaimed school superintendent, Willard E. Goslin became a symbol of the end of educational progressivism, when he was forced to resign from the Pasadena, California, schools in November 1950. Goslin's ouster was a victory for citizens' groups that deemed his support of racial understanding, outdoor education, child guidance, and mental health as evidence of subversive, un-American values.

Goslin was raised on a Missouri farm. He began teaching in the rural schools of Boone County, Missouri, in 1916. After receiving a B.S. degree from Northeast Missouri State Teachers College (later, Truman State University) in 1922, he was appointed principal (1922–1923) and superintendent (1923–1928) in Slater, Missouri. He earned an M.A. degree from the University of Missouri in 1928 and served as superintendent of Webster Groves, Missouri, from 1930 to 1944. In 1944 Goslin was named superintendent of Minneapolis schools. During his tenure there he was named one of the five outstanding public school administrators in the country. In 1948, while serving as Minneapolis's superintendent, he concurrently held the office of president of the American Association of School Administrators. That year he also accepted the superintendency of the Pasadena (California) Public Schools, a move

that was to bring him considerable fame as well as disappointment.

As a Progressive educator, he soon found himself the center of criticism from a vigorous and reactionary minority of Pasadena's residents, who criticized him not only for his advocacy of Progressive education, but also for his "ideological" support of the United Nations Educational, Scientific and Cultural Organization (UNESCO), his inclusion of sex education in the curriculum, his concern for African Americans, and his advocacy of racial integration of the schools.

In June 1950 Goslin and the Pasadena School Board proposed an increased tax levy, which was soundly defeated by a two-to-one vote. From then on, both the board and the superintendent experienced increasing difficulties. Goslin endeavored to prune the budget and carry on. The forces that, in the closing hours of the tax election campaign, had indulged in a number of misrepresentations and attacks on the superintendent, had created a rupture between the administration and the lay board. Early in November the board asked for his resignation. After a few weeks of discussion, private and public, which David Hulburd describes as "Turmoil in Pasadena," Mr. Goslin resigned from his position.

Although public criticism ultimately forced him to resign from his position, an action that stunned professional educators throughout the country, it was the lack of press support that became an important factor in his eventual ouster from the school board. Educators' interest in such an event is obvious, but the situation offered enough drama to stimulate a great deal of interest for the public as well. The forced resignation of Willard Goslin as superintendent of Pasadena schools had enough appeal to warrant prominent attention in the national press as in, for example, *Life* magazine.

At least two careful investigations found Goslin's dismissal to result largely from the demands of a comparatively small but very vocal group of critics. Goslin had received a warm welcome as the new superintendent. The end of the honeymoon period began with the defeat of a tax proposal to provide additional educational funds. The organization that had spearheaded the campaign to defeat the tax proposal went on to denounce as leftist and educationally unsound the "Progressive Education" that Goslin was alleged to represent. Among the charges hurled at Goslin by the Pasadena unit of Pro-

America and others were his association with W. H. Kilpatrick and the "Columbia [Teachers College] cult of progressive educators," and his support of a program alleged "to sell our children on the collapse of our way of life" (Hulburd, p. 89).

Despite untruths and what appears to be an absence of justice, the Goslin case involved events that transpired while he was superintendent. Not all attacks on schools of the day reached such a dramatic and pronounced climax, but even in more typical cases, where school personnel were not threatened to such an extent, intense assaults had widespread ramifications among school employees. For instance, a severe undermining of teachers' morale during the attack on Goslin took place in Pasadena. A 1955 survey conducted by the National Education Association's Defense Commission substantiated the effects of attacks on schools of the day. The study noted "various morale problems, and numerous resignations by teachers as well as by administrators" (p. 20).

Responding to criticisms of the public schools during this period, educators faced a familiar dilemma. On the one hand, the public schools belong to the people and should never be exempt from critical examination and appraisal by the people; nor should educators be unduly defensive or smug about claimed achievement for schools. On the other hand, the attacks on the schools were incited and supported by a minority and were often manifestly unfair and distorted.

Following the Pasadena crisis, Ernest O. Melby, dean of the School of Education at New York University, wrote *American Education under Fire: The Story of the 'Phony Three-R Fight*. Issued as one of the Freedom Pamphlets of the Anti-Defamation League of B'nai B'rith and sponsored by the American Education Fellowship, the John Dewey Society, and two constituent bodies of the National Education Association, this publication analyzed the methods used by the organizations that systematically attacked public schools of the day, particularly Allen Zoll's National Council for American Education. Over and above this Melby's discussion focused on identifying the characteristics of a "good education" and outlining procedures by which critics and criticism may be properly answered. His concluding section demonstrates how educators and interested citizens can cooperate to secure better schools.

In September 1951 Goslin became head of the Division of School Administration and Community

Development at George Peabody College for Teachers. The National Education Association gave him their American Education Award for 1952. In 1953 Goslin contributed a chapter to the Association for Supervision and Curriculum Development's 1953 yearbook, *Forces Affecting American Education*. His chapter, titled "The People and Their Schools," drove home the idea that the success with which public schools do their job depends upon the interest, support, and participation of all the citizens of every community and their understanding of educational principles and practices. In 1961, Seoul University awarded Goslin an honorary doctorate for his work as coordinator of a Korean teacher education project, hailing him as "the father of modern education in Korea" (*New York Times*, p. 27).

Goslin's work with Peabody College's "Multi-Year Project" in Korea was a capstone of his professional activities at Peabody. However, his seminars and regular classes were his true love. He specialized in teaching "foundations of education" and history of education, as well as teaching a colloquium on the superintendency each semester. It has been reported that his classes sometimes reached 80 to 100 students. Students and colleagues remember him as an excellent orator, having a "Will Rogers" kind of demeanor. He retired from teaching in 1966 at the age of sixty-seven, but remained actively involved with his students on a daily basis until his death in 1969.

ROBERT C. MORRIS

## GOVERNANCE AND DECISION-MAKING IN COLLEGES AND UNIVERSITIES

There is no single or generally accepted definition of governance, as it has been described as structures, legal relationships, authority patterns, rights and responsibilities, and decision-making patterns. One commonly given definition of governance is the way that issues affecting the entire institution, or one or more components thereof, are decided. It includes the structure and processes, both formal and informal, of decision-making groups and the relationships between and among these groups and individuals. What distinguishes governance from administrative decisions is that governance tends to be early on in the process and establishes policies. Much of what happens later is administration.

Governance of higher education institutions around the world varies from nation to nation, ranging from direct and detailed control by the central government to *laissez-faire*, private profit-making enterprises, with many other arrangements in between. This entry will focus on governance patterns of colleges and universities that have emerged in the United States. One of the distinctive features of U.S. governance is the great diversity of forms that have emerged in contrast to other countries, which tend to have great uniformity. Each governance pattern reflects the unique history of the sector and the needs of those specific institutional types. There are several reasons for this diversity within the governance system, which include the absence of a centralized authority for education, strong public and private interests, a lay citizen governing board, and responsibilities that vary for trustees, presidents, and departments among institutions. The distinctive feature of governing boards has allowed for a decentralized system of governance where power and autonomy is distributed. Also, the U.S. governance

system has followed the general societal patterns for governance in a democracy—representative or collective decision-making often termed *shared governance*.

### Shared Governance

The definition of shared governance has changed slightly over time, but the commonly accepted definition is from the 1966 Statement on Government of Colleges and Universities. It identified governance as the joint efforts in the internal operations of institutions, but also characterized certain decisions as falling into the realm of different groups. This statement was jointly formulated by the American Association of University Professors (AAUP), the American Council on Education (ACE), and the Association of Governing Boards of Universities and Colleges (AGB).

The statement, although not intended to serve as a blueprint for institutional decision-making, outlines roles for the president, faculty, administrators, and trustees in academic governance decisions. For example, it suggests that issues such as managing the endowment fall to the trustees, maintaining and creating new resources to the president, and developing the curriculum to the faculty. Not all decisions neatly fall into the domain of one of the three groups. It notes that much of governance is (or should be) conducted jointly. In other words, the statement argues that multiple members of the campus should have input on key decisions, a process termed *shared governance*. Questions over general education policy, the framing and execution of long-range plans, budgeting, and presidential selection should be decided jointly.

This open definition of shared governance is meant to respect the wide differences in history, size, and complexity of American higher education. For example, governance processes at liberal arts colleges are distinctive in that the whole faculty is often involved in governance; at larger institutions such as doctoral- and masters-granting institutions, governance tends to be a representative process through a faculty senate and joint committees. At community colleges, unions are also a key factor in the process. Although academic governance has changed over time, becoming highly participatory in the 1960s and more hierarchical in the 1980s, it has historically retained the notion of the importance of consultation and participation of campus constitu-

ents in major decision-making, reflecting democratic principles.

### Governance Structure

The governance process is complex and includes many different layers (or groups). Each group differs in levels of responsibility by type of institution, culture of the campus, and historical evolution. Thus, there is no single organizing approach for governance. Trustees and boards have been delegated authority by college and university charters from the state legislature for oversight and decision-making. The legal requirements for boards are typically very loose; they need to assemble with a quorum periodically and oversee certain broad responsibilities. In the eighteenth and nineteenth centuries, boards dominated decision-making, and faculty had little involvement. However, as faculty professionalized in the late 1800s, there was a concerted effort among faculty to obtain greater authority within the decision-making process. As Robert Birnbaum notes, “the reality of governance today is much different than the strict legal interpretation would suggest” with boards having total authority (p. 4).

Even though governance is shared, trustees, governors, boards, or visitors play a significant role. Although holding different titles, these individuals maintain a similar function: to protect and ensure the interest and trust of the institution for the public or for a private group such as a church. The differing names reflect the different sectors and regional traditions. Trustees are more likely to play a custodial role over property and funds, being less involved with academic matters. Governors’ roles tend to be more comprehensive and include academic matters. In general, board (this generic term will be used throughout the entry to designate these several different authority groups) responsibilities vary from clarifying mission, assessing president’s performance, fund-raising, ensuring good management, and preserving institutional independence. Many boards have authority for ratifying institutional decisions, which can allow them to become involved in administrative details. Board authority varies by institution; thus to understand a particular campus it is necessary to obtain their charter and by-laws. Also, board members can be elected in public institutions or appointed in private institutions. Boards of private institutions tend to be larger than public ones.

Most boards report to another entity; for example, boards of trustees might report to a church while regents report to the legislature of a state. Today, most states have a system-wide coordinating board that campus governors or regents report to rather than directly to the legislature. Up until World War II, 70 percent of public colleges reported to their own board. However, when enrollments increased and there was major growth in the number of higher education institutions, state systems of governance developed. By the mid 1970s, only 30 percent of public colleges answered only to their governing boards.

Boards, trustees, and regents can be made up of very different types of individuals. Trustees are often alumni of the institution, whereas regents are often elected officials representing political party or district interests. Therefore, the perspective brought to the task of governing can vary greatly.

Another key player in governance is the president, who administers the policies set by the board. Presidents’ and other administrators’ role in governance is to make recommendations to the board and to implement policies. Faculty members, as noted above, became an integral part of governance around the turn of the twentieth century. In 1915 the American Association of University Professors developed a set of principles related to faculty rights, one of which is the right to offer input concerning institutional governance on matters related to academic decisions. Faculty members typically have input on decisions in such areas as employment, research, degrees and degree requirements, courses, evaluating programs, evaluation of faculty, admission, advising, and criteria for obtaining degrees.

Students’ involvement in governance also varies by institution. Some boards have student membership. Some states, such as California, now have a law providing for student board membership. Also, most campuses have a student assembly or senate in which members are chosen by election. This body can operate as a governance body, providing recommendations to the president, administration and board. But it is rare for student assemblies to have any formal authority; rather, they are considered as part of the shared governance process.

Campus senates are the most common mechanism for faculty involvement in governance in a systematic way. Senators are elected to their positions from each college or school, making the campus sen-

ate a representative body. Most campus senates operate primarily through committees, and are only allowed to make recommendations to the president/administration and board about institutional matters. Several campuses have developed other formal governance structures in order to codify decision-making processes and input. Some campuses have developed joint committees of faculty, students, and administrators that develop recommendations for action on key institutional issues.

What are the areas in which governance decisions tend to be made? Policy setting areas tend to include mission, strategic direction, and selection processes for administrators, faculty, and staff; budgeting and expending funds; procedures related to construction of buildings; academic programs including degrees, course, admission, and graduation; promotion, tenure and salary increments; athletic programs; student matters; research, grants, and contracts; parking, security, and other services; and public relations.

### **External Influences**

Although not formally part of campus governance, outside forces such as state governments, alumni, donors, federal government, accreditors, and associations often affect governance processes through funding, persuasion, policy, and guidelines. These other groups are important to acknowledge, even if their influence is infrequent and not formally defined by a charter, statement, or set of principles. Legislatures use budget allocation as a way to influence campus decision-making outside the formal governance processes. Individual donors might ask to have a say in certain institutional decisions in exchange for a monetary contribution to the institution. The federal government can establish rules and regulations that indirectly affect campus decision-making. For example, regulations about affirmative action have had an effect on campus admissions decisions and policies. Accreditors and associations probably have the least direct influence on campus governance. Accreditors, for example, can define requirements for a certain field of study. These requirements influence the decision-making processes at campuses that want to retain their accrediting status.

### **Trends in Governance**

There are several trends in governance that are important to highlight: (1) the growth of external influ-

ences; (2) inability to respond to external challenges; (3) the lack of prominence and move away from shared governance; and (4) decreasing participation. These forces are related: The growth of external influences is coupled with institutions' trying to alter decision-making processes that were originally internally oriented to be more externally oriented. The lack of participation, among faculty in particular, is related to a move away from the tradition of shared governance.

Many commentators have noted that external agents are less reluctant to enter the decision-making process than in the past, even at the final stages. In addition, higher education is in the midst of a shift from its tradition of informal, consensual judgments to standardization, litigation, and centralization. Societal and legislative expectations have been altered, focusing more on accountability, quality, and efficiency. As Kenneth Mortimer and Thomas McConnell note, "the increased influence of state coordinating boards and system level administration in the last twenty years has moved decisions further away from campus based constituents." (p. 165). Boards and presidents now find themselves acting more as buffers to outside forces than in the past.

The intense environmental demands on higher education place great responsibility and strain on institutional leaders to make difficult decisions in a timely manner. The substance of academic governance has changed; traditional "maintenance" decisions, which include items such as the allocation of incremental budgets, modifications to the curriculum, and issues of faculty life, are being replaced with "strategic policy-making" decisions. These new decisions are high stakes challenges related to the changing nature of scholarship, prioritizing among programs, choosing among new opportunities, and reallocating either shrinking or unchanging (not growing) budgets. Current decision-making systems (e.g., academic senates) were not created to cope with these types of decisions and demands. These traditional academic governance structures are facing a cascade of criticism, describing them as being slow and ineffective. Campus senates and other joint administrative-faculty committees need to design processes to resolve unprecedented problems from the changing environment.

Although shared governance has been the norm for the last century, several commentators have noted that there are problems with shared governance that can no longer be ignored, including the

following: (1) it does not actually represent or describe governance patterns in the majority of institutions; (2) it ignores the conflict of interests and adversarial decision-making practices inherent in a major new governance structure—collective bargaining; and (3) it takes in little account of the external forces. It is noted that shared authority only exists at a few elite institutions with powerful faculty, and that administrative authority is foremost at most institutions. Also, it is noted that there are few shared goals at most institutions, the principle that shared governance is built upon. Faculty and students are divided into different interest groups, making self-governance difficult with minimal consensus on issues. Thus, in practice, shared governance is usually not possible.

At the same time, academic governance is becoming less participatory, as fewer individuals care about or are involved in academic governance. Current trends work against widespread academic governance participation—fewer full-time faculty are employed, participation is not rewarded, other demands take precedence, and faculty allegiances favor disciplines rather than institutions. There is concern about institutional effectiveness, morale, and the quality of decision-making. Because of the complexity of institutional issues, well-considered decisions should be based on a high degree of input and thought, usually achieved through participation of multiple constituents. Institutions may jump to poor conclusions since decisions do not benefit from a thorough examination of the issues or multiple perspectives.

There are many challenges in governance that need to be resolved in the twenty-first century: perhaps new structures and governance forms will be applied to higher education, as developed in the last century, with the emergence of shared governance, campus senates, and state-wide coordinating boards.

## GOVERNMENT AND EDUCATION, THE CHANGING ROLE OF

---

Since about 1990 the assumption that the public sector should be responsible for all aspects of education has been increasingly questioned, in both developed and developing countries, for four main reasons. First, there have been doubts about the effectiveness and efficiency of public education. Second, there are doubts about the equity and accountability of public education, which particularly affect the poor. Third, there is an increasing awareness of initiatives by educational entrepreneurs, and evidence to suggest that competitive pressures can lead to significant educational improvements. Fourth, there has been a need to restrain public expenditure in order to reduce budget deficits and external debts, and, consequently, a need to find alternative sources of educational funding.

About the fourth reason little more can be said, apart from the fact that this has motivated governments and international agencies to look to the possibility of an increasing private sector role. But potentially countering each of the other three reasons is the notion that education is a public good, and hence requires government intervention for its provision. Before reviewing relevant arguments, it is important to stress that the whole issue is controversial. Consequently, it is worth noting at the outset some recent overviews of the whole debate.

Largely unsympathetic to an increasing role for the private sector are philosopher Harry Brighouse, sociologists such as Stephen Ball, the Karl Mannheim professor of sociology of education at the University of London, and the journalist Alex Molnar. Brighouse, who is affiliated with both the American and the British reform movements, presents philosophical arguments against extending educational choice, particularly stressing how they will promote inequity. He is, however, sympathetic to some arguments about the way private sector could raise standards and be more efficient. Ball and his colleagues

have explored the way market reforms have occurred in to England, and they suggest the evidence points to a deleterious impact on equality of opportunity. Finally, Molnar has explored the increasing commercialization of American schools, and he argues that the profit motive and education should not be allowed to mix.

For the alternative perspective, a good place to start is with the economic historian Edwin G. West's seminal work *Education and the State* (1994), followed by the work of Andrew Coulson and James Tooley. West suggests that before the government got involved in education in England and Wales and the United States, there was widespread private provision of education, which was crowded out by the intervening state. Coulson takes up the historical case in ancient Greece (among other places), and providing detailed economic and conceptual arguments to support the case for markets in education, and he challenges the idea that public education can promote social cohesion and equality of opportunity. Tooley takes up similar themes, conducting a thought experiment to explore historical, philosophical, and economic arguments that suggest the desirability for an increased role for the private sector in education—including addressing the objections to for-profit education.

Playwright George Bernard Shaw once quipped that the Americans and the British are divided by a common language. Nowhere is this more obvious than when we speak of the role of government in education. The British, for reasons buried in historical time, call their most elite private schools *public schools*, and other countries such as India followed this usage. To avoid confusion, this article will follow the more logical American usage, where *public schools* are those funded by government, and *private schools* are those that are not.

### Education As a Public Good

It is often argued that education is a *public good*, and that this implies a particular role for government. Economists define a public good as satisfying up to three conditions: (1) indivisibility, (2) nonrivalry, and (3) nonexcludability. Indivisibility can be illustrated by the example of a bridge over a river, which can be used by anyone without extra costs being incurred. Nonrivalry is virtually the same, except that it is the benefits available to every member of the public that are not reduced, rather than the amount of the good. For example, the good of hiking in the

Grand Canyon could be, to a large extent, indivisible, in that many millions of people could do it without thereby hindering others also doing it. However, the greater the number of people who hike, the lower the enjoyment of those who wish to be in an empty wilderness—in which case the good is not nonrival. Finally, nonexcludability pertains when it is not feasible to exclude any individual members of the group from consuming the good. The classic economic example is of a lighthouse.

It would seem that education satisfies none of these conditions. It is clearly not nonexcludable, for a particular child can be excluded from a classroom or any other educational opportunity. The situation is similar for nonrivalry and indivisibility, for it is the case that if some children have the attention of an excellent teacher, then that teacher has less time for others, who therefore can obtain less benefit from the teacher. Indeed, it seems likely that it was precisely because of this nonrivalry or indivisibility that reformers wanted government to intervene in education—to alleviate this inequality of access.

However, if it is not a public good in this sense, education does seem likely to have *neighborhood effects*, or *externalities*—defined by economists as when an activity undertaken by one party directly affects another party's utility. That is, there are likely to be benefits to the community or society at large (if there are educational opportunities available) in terms of equality of opportunity, social cohesion, democratic benefits, law and order, economic growth, and so on. Crucially, these externalities are likely to exhibit a large degree of nonexclusion (it is costly to exclude people from these benefits or costs) and there are usually considerations relating to nonrivalry or indivisibility (the external benefits or costs are likely to be available to all with near zero marginal costs). For example, a society lacking in equality of opportunity could be a dissatisfied, lawless society. One could exclude oneself from the problems of such a society, but only at the expense of burglar alarms, bodyguards, high fences, or by restricting one's movements. It is in this sense that education could be referred to as a public good; and it is in this sense that it could legitimately be argued that education needs government intervention to ensure its provision and obtain these externalities.

From these considerations, the discussion would need to focus on the perceived effectiveness, efficiency, and equity of public education, and the presence, or lack, of private initiatives. These con-

cerns bring us squarely back to the major reasons adduced earlier for questioning the role of government in education. So, what of these reasons?

### Standards and Efficiency

As far as the first reason is concerned, while doubts have arisen in many countries about standards in public schools, it is not until comparisons are made with private schools in the same countries that the role of government is significantly questioned. This comparative approach started with an 1982 American study by James Coleman, Thomas Hoffer, and Sally Kilgore, which predicted the score on a standardized test for an average public school student if he or she were to attend a private school. The study found that private schools were more effective at developing the cognitive abilities of students. After responding to criticisms that innate ability had not been controlled for, a follow-up study substantially confirmed the results.

Numerous studies since then have been carried out across a wide range of middle- and lower-income countries, all of which have found that private schools not only are more effective educationally (when controlled for socioeconomic factors), but are also more efficient. For instance, studies from the World Bank began by looking at achievement in verbal ability in Thailand, following up with studies of achievement in language and mathematics in Colombia, the Dominican Republic, the Philippines, Tanzania, and Thailand again. The studies explored the proportional gain in achievement score if a randomly selected student, with the characteristics of an average public school student, were to attend a private rather than a public school, holding constant the student's socioeconomic background. While there was a large range, the studies all showed the superiority of private education in terms of raising these cognitive abilities. In Colombia the results showed that private schools were 1.13 times more effective than public schools, averaging for verbal and mathematical achievement. In the Dominican Republic private schools were about one-and-a-half times more effective in raising achievement in mathematics; and in Thailand, again for mathematics, private schools were 2.63 times more effective than the public schools.

One obvious objection was that private schools can succeed where public schools cannot because of increased resources. However, when the same researchers probed this issue, they found the opposite

to be the case. Comparing the cost per student in a private and a public school gave results ranging from a low of 39 percent in Thailand to a high of 83 percent in the Philippines. Combining these two sources of information, the researchers were then able to gain an answer to the question: “For the same per-pupil cost, how much more achievement would one get in private than in public schools?” The answer ranged from 1.2 times (Philippines) to a massive 6.74 times more achievement (Thailand) in the private than in the public schools.

Finally, Geeta Kingdon’s evidence from India reveals similar findings. Kingdon controlled for twenty-one potentially confounding variables—including parental and family income, number of years of mother’s education, number of books in the home, and student aptitude—for her study of a stratified random sample of schools in urban Lucknow, Uttar Pradesh. She found that the (unaided) private schools were 27 percent more effective at teaching mathematics, and slightly more effective at teaching language, than the public schools. But when per-pupil costs are brought into the equation, the results become quite striking. In the (unaided) private schools the per-pupil cost was less than half that in the public schools (38 rupees compared to 80 rupees).

### Equity and Accountability

Doubts about public education that inform the debate about the role of government in education also focus on the fairness of public provision, although this is countered by doubts that privatization could be more equitable. In many countries, however, it has been observed that, despite public expansion of funding and provision, the expansion has not reached all members of society equally. Particularly acute is the wide gap in terms of educational provision offered to urban and rural populations. In Indonesia, for instance, only 3 percent of urban children of primary school age did not receive any schooling; while in the rural areas this figure rises to 10 percent. These comparison figures also obscure the fact that gender disparities in rural areas are even more severe. In Pakistan, for instance, while 73 percent of urban females age seven to fourteen have ever attended school, this figure plunges to 40 percent for rural females in the same age group.

In the poorest countries, it might be thought that spending on basic education would be a government priority, since these have yet to achieve univer-

sal primary-school enrolment. However, this often does not happen. In Africa, for instance, per-student spending on higher education is about forty-four times higher than on primary education. In most African nations, the poorest 20 percent of the population get significantly less than 20 percent of public education subsidy, while the richest 20 percent receive significantly greater than 20 percent. Most dramatically, in Nepal, the richest quintile gets almost half of total public spending on education.

Some of the most dramatic evidence of the inequity of public provision, which also raises the issue of accountability, comes from India. The PROBE Team’s *Public Report on Basic Education in India* (1999) looked at primary education in four states, where it surveyed a random sample of villages in which there were a total of 195 government and 41 private schools. The report outlines some of the “malfunctioning” that is taking place in government schools for the poor in these four states. The schools suffer from poor physical facilities and high pupil-teacher ratios, but what is most disturbing is the low level of teaching activity taking place in them. When researchers called unannounced, only in 53 percent of the schools was there any teaching activity going on. In fully 33 percent, the head teacher was absent. The PROBE survey reported many instances of “plain negligence,” including “irresponsible teachers keeping a school closed or non-functional for months at a time” and a school where “only one-sixth of the children enrolled were present” (p. 63). Significantly, the low level of teaching activity occurred even in those schools with relatively good infrastructure, teaching aids, and pupil-teacher ratios. Even in such schools, “teaching activity has been reduced to a minimum, in terms of both time and effort. And this pattern is not confined to a minority of irresponsible teachers—it has become a way of life in the profession” (p. 63).

These problems highlight the “deep lack of accountability” in the public schools, for these problems were not found in the private schools. The PROBE Team found a considerably higher level of teaching activity taking place in the private schools, even though the work environment is not better in these schools. For the researchers, this “brings out the key role of accountability in the schooling system. In a private school, the teachers are accountable to the manager (who can fire them), and, through him or her, to the parents (who can withdraw their children). In a government school, the chain of ac-

countability is much weaker, as teachers have a permanent job with salaries and promotions unrelated to performance. This contrast is perceived with crystal clarity by the vast majority of parents” (p. 64).

All of this evidence is leading some governments and international agencies to wonder whether or not public education can reach the poorest in society, or whether some form of public-private partnership—perhaps with publicly funded vouchers being available for use at any school, public or private—would be a better role for government to play if reaching the poor is its aim.

### Private Sector Alternatives

The existence of private schools for the poor in India might come as a surprise. In fact, this is a growing phenomenon throughout the developing world, and relates to the third major reason for the growing questioning of the role of government in education, the emergence of apparently viable private-sector alternatives. Schools for the poor are commonplace across a range of countries, including in India, where recent research has revealed a whole range of schools charging about \$10 to \$20 per year for each student, run on commercial principles and not dependent on any government subsidy or philanthropy. These fees are affordable by families headed by rickshaw pullers and market-stall traders. Even so, many of these schools also offer significant number of free places (up to 20 percent) for even poorer students, allocated on the basis of claims of need checked informally in the community. Similar schools have been reported in many African countries as well.

The emergence of private education alternatives is not only about the poor, of course. Recent research has uncovered a whole range of interesting examples of educational entrepreneurs who are creating innovative and effective private alternatives. The International Finance Corporation found for-profit education companies in developing countries that had created chains of schools and colleges, often operated on a franchise basis, with strict quality control procedures in place (including using the international standards of ISO 9000 series). These companies invest in research and development to explore new ideas in pedagogy and curriculum. Examples include Objetivo/UNIP in Brazil, which has over half a million students from kindergarten to university level across its 500 campuses around Brazil; and NIIT, based in New Delhi, which offers computer education and training in its forty owned

centers in the metropolitan areas, and about 1,000 franchised centers across India. It also has a global reach, with centers in the United States, Europe, Japan, Central Asia, Africa, and the Asia-Pacific region.

Notably, private entrepreneurs have harnessed information technology to the learning process. There has been a rapid growth of for-profit private-sector providers in education at all levels, creating e-learning opportunities in developing as well as developed countries. Many of these are in direct competition with traditional public-sector providers, such as the University of Phoenix, with 90,000 students across thirty-two campuses and seventy-one learning centers. However, many traditional universities have also responded to the challenge by either creating for-profit subsidiaries themselves—New York University, for instance, set up its NYOnline arm, and Columbia University created a for-profit arm, Fathom Knowledge Network Inc., in partnership with Cambridge University Press, the New York Public Library, and the University of Chicago. Other for-profit companies are emerging to provide e-learning for the K–12 market, including the appropriately named k12.com, led by William J. Bennett, the secretary of state for education during the Reagan administration.

The emergence and strength of these private-sector alternatives has impressed many governments looking to improve the quality and efficiency of public schooling. The British government is currently engaged in a process of contracting out failing schools and local education authorities to the private sector, trying to find best-value service wherever it can be found. But this process is not confined to developed countries. One notable example comes from India, where the Tamil Nadu state government wanted computer education in all high schools. Significantly, although allocating extra funds to this endeavor—about U.S. \$22 million over five years—it didn’t look to the public sector to provide this, but instead developed a model to contract out the delivery to private companies, who provide the software and hardware, while the government provides an electricity supply and the classroom. Significantly, companies that have won these contracts, such as NIIT, can also use the classroom as a franchised center, open to the school children and teachers during the day and open to the general public in the evenings and on weekends. The contracting out of curriculum areas such as this represents an important

step forward in relationships between the public and private sectors, and provides an interesting model worth watching and emulating.

## Conclusion

The debate will continue about the changing role of government in education, but there is considerable practical innovation and experimentation taking place globally that points to an acceptance of the changing role for government in educational delivery. Three types of reform can usefully be distinguished.

The first is the *contracting out* model, in which a state school has some or all of its educational functions contracted out to the private sector under accountability guidelines established by the local and/or central government. Education management companies such as Edison Schools in the United States and 3Es in England fit into this model, where all of the educational functions—pedagogy, curriculum, school management and improvement—are taken over by the private company.

Second, there is the *demand-side financing* model, which allows students to exit state schools—often when these are failing—and move to private schools through state-funded vouchers. Such schemes are found all around the world, including in the United States, Chile, Colombia, and the Ivory Coast, to name a few.

Third, there is the *state-funded private school* model, where either private schools are allowed to opt-in to state funding (as in Denmark and Holland), or new independent schools are specially created under government regulations to receive state funding, (as with charter schools in America, Canada, and China, and City Academies in England and Wales).

In Denmark for instance, the first private schools gained state subsidies in 1899. Now, any group of parents can claim the right to create a private school. Once established and running, the state guarantees to provide 80 to 85 percent of expenditures in the school. Some of these free schools are religious schools, but the majority are not: instead they are Rudolf Steiner schools, German minority schools, or simply independent academically-minded schools. Such private schools are becoming increasingly attractive to parents, with enrollments rising from 8 percent in 1982 to 12 percent in 1998.

## SCHOOL

Few issues have created more controversy among educators than those associated with grading and reporting student learning. Despite the many debates and multitudes of studies, however, prescriptions for best practice remain elusive. Although teachers generally try to develop grading policies that are honest and fair, strong evidence shows that their practices vary widely, even among those who teach at the same grade level within the same school.

In essence, grading is an exercise in professional judgment on the part of teachers. It involves the collection and evaluation of evidence on students' achievement or performance over a specified period of time, such as nine weeks, an academic semester, or entire school year. Through this process, various types of descriptive information and measures of students' performance are converted into grades or marks that summarize students' accomplishments. Although some educators distinguish between *grades* and *marks*, most consider these terms synonymous. Both imply a set of symbols, words, or numbers that are used to designate different levels of achievement or performance. They might be letter grades such as *A, B, C, D, and F*; symbols such as  $\sqrt{+}$ ,  $\sqrt{}$ , and  $\sqrt{-}$ ; descriptive words such as *Exemplary, Satisfactory, and Needs Improvement*; or numerals such as *4, 3, 2, and 1*. Reporting is the process by which these judgments are communicated to parents, students, or others.

### A Brief History

Grading and reporting are relatively recent phenomena in education. In fact, prior to 1850, grading and reporting were virtually unknown in schools in the United States. Throughout much of the nineteenth century most schools grouped students of all ages and backgrounds together with one teacher in one-room schoolhouses, and few students went beyond elementary studies. The teacher reported students' learning progress orally to parents, usually during visits to students' homes.

As the number of students increased in the late 1800s, schools began to group students in grade levels according to their age, and new ideas about curriculum and teaching methods were tried. One of these new ideas was the use of formal progress evalu-

ations of students' work, in which teachers wrote down the skills each student had mastered and those on which additional work was needed. This was done primarily for the students' benefit, since they were not permitted to move on to the next level until they demonstrated their mastery of the current one. It was also the earliest example of a narrative report card.

With the passage of compulsory attendance laws at the elementary level during the late nineteenth and early twentieth centuries, the number of students entering high schools increased rapidly. Between 1870 and 1910 the number of public high schools in the United States increased from 500 to 10,000. As a result, subject area instruction in high schools became increasingly specific and student populations became more diverse. While elementary teachers continued to use written descriptions and narrative reports to document student learning, high school teachers began using percentages and other similar markings to certify students' accomplishments in different subject areas. This was the beginning of the grading and reporting systems that exist today.

The shift to percentage grading was gradual, and few American educators questioned it. The practice seemed a natural by-product of the increased demands on high school teachers, who now faced classrooms with growing numbers of students. But in 1912 a study by two Wisconsin researchers seriously challenged the reliability of percentage grades as accurate indicators of students' achievement.

In their study, Daniel Starch and Edward Charles Elliott showed that high school English teachers in different schools assigned widely varied percentage grades to two identical papers from students. For the first paper the scores ranged from 64 to 98, and the second from 50 to 97. Some teachers focused on elements of grammar and style, neatness, spelling, and punctuation, while others considered only how well the message of the paper was communicated. The following year Starch and Elliot repeated their study using geometry papers submitted to math teachers and found even greater variation in math grades. Scores on one of the math papers ranged from 28 to 95—a 67-point difference. While some teachers deducted points only for a wrong answer, many others took neatness, form, and spelling into consideration.

These demonstrations of wide variation in grading practices led to a gradual move away from per-

centage scores to scales that had fewer and larger categories. One was a three-point scale that employed the categories of *Excellent*, *Average*, and *Poor*. Another was the familiar five-point scale of *Excellent*, *Good*, *Average*, *Poor*, and *Failing*, (or *A*, *B*, *C*, *D*, and *F*). This reduction in the number of score categories served to reduce the variation in grades, but it did not solve the problem of teacher subjectivity.

To ensure a fairer distribution of grades among teachers and to bring into check the subjective nature of scoring, the idea of grading based on the normal probability, bell-shaped curve became increasingly popular. By this method, students were simply rank-ordered according to some measure of their performance or proficiency. A top percentage was then assigned a grade of *A*, the next percentage a grade of *B*, and so on. Some advocates of this method even specified the precise percentages of students that should be assigned each grade, such as the 6-22-44-22-6 system.

Grading on the curve was considered appropriate at that time because it was well known that the distribution of students' intelligence test scores approximated a normal probability curve. Since innate intelligence and school achievement were thought to be directly related, such a procedure seemed both fair and equitable. Grading on the curve also relieved teachers of the difficult task of having to identify specific learning criteria. Fortunately, most educators of the early twenty-first century have a better understanding of the flawed premises behind this practice and of its many negative consequences.

In the years that followed, the debate over grading and reporting intensified. A number of schools abolished formal grades altogether, believing they were a distraction in teaching and learning. Some schools returned to using only verbal descriptions and narrative reports of student achievement. Others advocated *pass/fail* systems that distinguished only between acceptable and failing work. Still others advocated a *mastery* approach, in which the only important factor was whether or not the student had mastered the content or skill being taught. Once mastered, that student would move on to other areas of study.

At the beginning of the twenty-first century, lack of consensus about what works best has led to wide variation in teachers' grading and reporting practices, especially among those at the elementary level. Many elementary teachers continue to use tra-

ditional letter grades and record a single grade on the reporting form for each subject area studied. Others use numbers or descriptive categories as proxies for letter grades. They might, for example, record a 1, 2, 3, or 4, or they might describe students' achievement as *Beginning*, *Developing*, *Proficient*, or *Distinguished*. Some elementary schools have developed *standards-based* reporting forms that record students' learning progress on specific skills or learning goals. Most of these forms also include sections for teachers to evaluate students' work habits or behaviors, and many provide space for narrative comments.

Grading practices are generally more consistent and much more traditional at the secondary level, where letter grades still dominate reporting systems. Some schools attempt to enhance the discriminatory function of letter grades by adding pluses or minuses, or by pairing letter grades with percentage indicators. Because most secondary reporting forms allow only a single grade to be assigned for each course or subject area, however, most teachers combine a variety of diverse factors into that single symbol. In some secondary schools, teachers have begun to assign multiple grades for each course in order to separate achievement grades from marks related to learning skills, work habits, or effort, but such practices are not widespread.

### Research Findings

Over the years, grading and reporting have remained favorite topics for researchers. A review of the Educational Resources Information Center (ERIC) system, for example, yields a reference list of more than 4,000 citations. Most of these references are essays about problems in grading and what should be done about them. The research studies consist mainly of teacher surveys. Although this literature is inconsistent both in the quality of studies and in results, several points of agreement exist. These points include the following:

**Grading and reporting are not essential to the instructional process.** Teachers do not need grades or reporting forms to teach well, and students can and do learn many things well without them. It must be recognized, therefore, that the primary purpose of grading and reporting is other than facilitation of teaching or learning.

At the same time, significant evidence shows that regularly checking on students' learning prog-

ress is an essential aspect of successful teaching—but checking is different from grading. Checking implies finding out how students are doing, what they have learned well, what problems or difficulties they might be experiencing, and what corrective measures may be necessary. The process is primarily a diagnostic and prescriptive interaction between teachers and students. Grading and reporting, however, typically involve judgment of the adequacy of students' performance at a particular point in time. As such, it is primarily evaluative and descriptive.

When teachers do both checking and grading, they must serve dual roles as both advocate and judge for students—roles that are not necessarily compatible. Ironically, this incompatibility is usually recognized when administrators are called on to evaluate teachers, but it is generally ignored when teachers are required to evaluate students. Finding a meaningful compromise between these dual roles is discomforting to many teachers, especially those with a child-centered orientation.

**Grading and reporting serve a variety of purposes, but no one method serves all purposes well.** Various grading and reporting methods are used to: (1) communicate the achievement status of students to their parents and other interested parties; (2) provide information to students for self-evaluation; (3) select, identify, or group students for certain educational paths or programs; (4) provide incentives for students to learn; and (5) document students' performance to evaluate the effectiveness of instructional programs. Unfortunately, many schools try to use a single method of grading and reporting to achieve all of these purposes and end up achieving none of them very well.

Letter grades, for example, offer parents and others a brief description of students' achievement and the adequacy of their performance. But using letter grades requires the abstraction of a great deal of information into a single symbol. In addition, the cut-offs between grades are always arbitrary and difficult to justify. Letter grades also lack the richness of other, more detailed reporting methods such as narratives or standards-based reports.

These more detailed methods also have their drawbacks, however. Narratives and standards-based reports offer specific information that is useful in documenting student achievement. But good narratives take time to prepare and as teachers complete more narratives, their comments become increas-

ingly standardized. Standards-based reports are often too complicated for parents to understand and seldom communicate the appropriateness of student progress. Parents often are left wondering if their child's achievement is comparable with that of other children or in line with the teacher's expectations.

Because no single grading method adequately serves all purposes, schools must first identify their primary purpose for grading, and then select or develop the most appropriate approach. This process involves the difficult task of seeking consensus among diverse groups of stakeholders.

**Grading and reporting require inherently subjective judgments.** Grading is a process of professional judgment—and the more detailed and analytic the grading process, the more likely it is that subjectivity will influence results. This is why, for example, holistic scoring procedures tend to have greater reliability than analytic procedures. However, being subjective does not mean that grades lack credibility or are indefensible. Because teachers know their students, understand various dimensions of students' work, and have clear notions of the progress made, their subjective perceptions can yield very accurate descriptions of what students have learned.

Negative consequences result when subjectivity translates to bias. This occurs when factors apart from students' actual achievement or performance affect their grades. Studies have shown, for example, that cultural differences among students, as well as their appearance, family backgrounds, and lifestyles, can sometimes result in biased evaluations of their academic performance. Teachers' perceptions of students' behavior can also significantly influence their judgments of academic performance. Students with behavior problems often have no chance to receive a high grade because their infractions overshadow their performance. These effects are especially pronounced in judgments of boys. Even the neatness of students' handwriting can significantly affect teachers' judgments. Training programs help teachers identify and reduce these negative effects and can lead to greater consistency in judgments.

**Grades have some value as rewards, but no value as punishments.** Although educators would undoubtedly prefer that motivation to learn be entirely intrinsic, the existence of grades and other reporting methods are important factors in determining how much effort students put forth. Most students view

high grades as positive recognition of their success, and some work hard to avoid the consequences of low grades.

At the same time, no studies support the use of low grades or marks as punishments. Instead of prompting greater effort, low grades usually cause students to withdraw from learning. To protect their self-image, many regard the low grade as irrelevant and meaningless. Other students may blame themselves for the low mark, but feel helpless to improve.

**Grading and reporting should always be done in reference to learning criteria, never “on the curve.”** Although using the normal probability curve as a basis for assigning grades yields highly consistent grade distributions from one teacher to the next, there is strong evidence that it is detrimental to relationships among students and between teachers and students. Grading on the curve pits students against one another in a competition for the few rewards (high grades) distributed by the teacher. Under these conditions, students readily see that helping others threatens their own chances for success.

Modern research has also shown that the seemingly direct relationship between aptitude or intelligence and school achievement depends on instructional conditions. When the quality of instruction is high and well matched to students' learning needs, the magnitude of this relationship diminishes drastically and approaches zero. Moreover, the fairness and equity of grading on the curve is a myth.

Relating grading and reporting to learning criteria, however, provides a clearer picture of what students have learned. Students and teachers alike generally prefer this approach because they consider it fairer. The types of learning criteria teachers use for grading and reporting typically fall into three general categories:

1. *Product criteria* are favored by advocates of standards-based approaches to teaching and learning. These educators believe the primary purpose of grading and reporting is to communicate a summative evaluation of student achievement and performance. In other words, they focus on what students know and are able to do at a particular point in time. Teachers who use product criteria base grades exclusively on final examination scores, final products (reports or projects), overall assessments, and other culminating demonstrations of learning.

2. *Process criteria* are emphasized by educators who believe product criteria do not provide a complete picture of student learning. From this perspective, grading and reporting should reflect not just the final results but also how students got there. Teachers who consider effort or work habits when reporting on student learning are using process criteria. So are teachers who count regular classroom quizzes, homework, class participation, or attendance.
3. *Progress criteria*, often referred to as *improvement scoring*, *learning gain*, or *value-added grading*, consider how much students have gained from their learning experiences. Teachers who use progress criteria look at how far students have come over a particular period of time, rather than just where they are. As a result, grading criteria may be highly individualized. Most of the research evidence on progress criteria in grading and reporting comes from studies of differentially paced instructional programs and special education programs.

Teachers who base their grading and reporting procedures on learning criteria typically use some combination of these three types. Most also vary the criteria they employ from student to student, taking into account individual circumstances. Although usually done in an effort to be fair, the result is a “hodgepodge grade” that includes elements of achievement, effort, and improvement.

Researchers and measurement specialists generally recommend the use of product criteria exclusively in determining students' grades. They point out that the more process and progress criteria come into play, the more subjective and biased grades are likely to be. If these criteria are included at all, they recommend reporting them separately.

### Conclusion

The issues of grading and reporting on student learning continue to challenge educators. However, more is known at the beginning of the twenty-first century than ever before about the complexities involved and how certain practices can influence teaching and learning. To develop grading and reporting practices that provide quality information about student learning requires clear thinking, careful planning, excellent communication skills, and an

overriding concern for the well-being of students. Combining these skills with current knowledge on effective practice will surely result in more efficient and more effective grading and reporting practices.

## HIGHER EDUCATION

Over the course of an academic career the average student will be exposed to a variety of grading systems and procedures. Although some of these systems may be qualitative in nature, such as an annual or semiannual written narrative, the vast majority are quantitative and depend upon numerical or alphanumerical metrics. Perhaps the most familiar of these involves the letters “A” through “F,” where “A” is usually given a value of 4.0 and is characterized in words as *outstanding* or *excellent* and “F” is given a value of 0.0 and is described as *unsatisfactory* or *failing*. The grades of A through F are usually derived from some more differentiated quantitative value such as test score, in which the specific nature of the relationship between grade and test score may take a variety of different forms: (e.g., an A is defined by a score of 90% or better or by a value that falls in the top 5–10% of scores independent of absolute value, and so on). Regardless of the specific translation of test performance into letter grade, the point to keep in mind is that the A–F scale defines the most frequent grading system used in higher education over the past half century or more.

### Variations in the Grading System

Like all prototypes, the A–F system admits many variations. These often take the form of pluses and minuses, thereby producing a scale having the possibility of fifteen distinct units: A+, A, A–, B+, B, . . . F–. In actual practice, the grade of A+ is scarcely ever used and the same is true for D+ and D– and F+ and F–, thereby yielding a scale of between eight to ten units. Generally speaking, the greater the number of units in the grading system the more precisely does it hope to quantify student performance. What is interesting in this regard are fluctuations in the actual number of units used in different historical eras. Without going too deeply into the relevant historical facts, it is clear that certain historical periods, such as the 1960s, reduced the grading system to two or so units—Pass, No Credit (P/NC)—whereas other periods, such as the 1980s, expanded it to ten, eleven or twelve units.

Variations in the breadth of the grading system would seem to have significant educational implications. At a minimum, these differences may be taken to imply that scales having a large number of units indicate a relative comfort in making precise distinctions, whereas those having fewer units suggest a rel-

ative discomfort in making such distinctions. In the case of more differentiated systems, distinctions and rankings are significant, and individual achievement is emphasized; in the case of less differentiated systems, distinctions and rankings are de-emphasized and interstudent competition is minimized. To some degree, it is possible to view fluctuations in American grading systems as reflecting a more general ambivalence the society has in regard to competition and cooperation, between individual recognition and social equity. Educational institutions sometimes emphasize strict evaluation, competition, and individual achievement, whereas at other times they emphasize less precise evaluation, cooperation, and sympathetic understanding for students of all achievement levels.

Another property of grading systems is that individual class grades often are combined to produce an overall metric called the grade point average or GPA. Unlike its constituent values, which usually are carried to only one (or no numerically significant places), the GPA presents a metric of 400 units yielding the possibility that a GPA of 3.00 will locate the student in the category of “good” whereas a value of 2.99 will exclude him or her from this category. In the same way, honors, admission to graduate school, preliminary selection for interviews by a desirable company, and so forth, may be defined by a single point difference on the GPA scale (e.g., 3.50 versus 3.49 for Phi Beta Kappa, etc.).

Because GPAs are significant in categorizing student performance, a number of evaluations have been made of their reliability and validity. One issue to be addressed here concerns field of study, where it is well documented that classes in the natural sciences and business produce lower overall grades than those in the humanities or social sciences. What this means is that it is unreasonable to equate grade values across disciplines. It also suggests that the GPA is composed of unequal components and that students may be able to secure a higher GPA by a judicious selection of courses.

Although other factors may be mentioned aside from academic discipline (such as SAT level of school, quality and nature of tests, etc.) the conclusion must be that the GPA is a poor measure and should not be used by itself in coming to significant decisions about the quality of student performance or differences between departments and/or educational institutions. The GPA is also a relatively poor basis on which to predict future performance, which

perhaps explains why such attempts are never very impressive. In fact, a number of meta-analyses of this relationship, conducted every ten years or so since 1965, reveals that the median correlation between GPA and future performance is 0.18; a value that is neither very useful nor impressive. The strongest relationship between GPA and future achievement is usually found between undergraduate GPA and first-year performance in graduate or professional school.

Despite such difficulties in understanding the exact meanings of grades and the GPA, they remain important social metrics and sometimes yield heated discussions over issues such as grade inflation. Although grade inflation has many different meanings, it usually is defined by an increase in the absolute number of As and Bs over some period of years. The tacit assumption here seems to be that any continuing increase in the overall percentage of “good grades” or in the overall GPA implies a corresponding decline in academic standards. Although historically there have been periods in which the number of good grades decreased (so-called grade deflation), significant social concerns usually only accompany the grade inflation pattern. This one-sided emphasis suggests that grade inflation is as much a sociopolitical issue as an educational one and depends upon the dubious equating of grades with money. What really seems of concern here is a value issue, not a cogent analogy that reveals anything significant about grades or money.

### How Grades Are Produced

Grading systems represent just one aspect of an interconnecting network of educational processes, and any attempt to describe grading systems without considering other aspects of this network must necessarily be incomplete. Perhaps the most important of these processes concerns the procedures used to produce grades in the first place, namely, the classroom test. Here, of course, are purely formal differences; for example, between multiple choice and essay tests, or between in-class and take-home tests or papers. Also to be included are the quality of test items themselves not only in terms of content but also in terms of the clarity of the question and, in the case of multiple choice tests, of the distractors.

One way to capture the complexity of possible ways in which grades are produced is to consider the set of implicit choices that lie behind an instructor’s use of a specific testing and/or grading procedure.

Included here are such questions as: What evaluation procedure should I use? Term papers, classroom discussions, or in-class tests? If I choose tests, what kind(s)? Essay, true/false, fill-in-the-blank, matching, or multiple-choice? If I choose multiple-choice, what grading model should I use? Normal curve, percent-correct, improvement over preceding tests? If I choose percent-correct, how many tests should I give? Final only, two in-class tests and a final, one midterm and one final? How should I weight each test if I choose the midterm-final pattern? Midterm equals final, midterm is equivalent to twice the final exam grade, final equals twice the midterm grade? What grade report system should I use? P/F; A, B, C, D, F; or A+, A, A–, B+, . . . F? An examination of this collection of possible choices suggests that instructors have a large number of options as to how to go about testing and grading their students.

Any consideration of the ways in which testing and grading relate to one another must also deal with the ways in which one or both of these activities relate to learning and teaching. The relationship between learning and testing is a fairly direct (if neglected) one, especially if tests are used not only to evaluate student achievement but also to reinforce or promote learning itself. Thus it is easy to develop a classroom question or exercise that requires the student to read some material before being able to answer the question or complete the exercise. Teaching, on the other hand, would seem to be somewhat further removed from issues of testing and grading, although the specific testing and grading plan used by the instructor does inform the student as to what constitutes relevant knowledge as well as what attitude he or she holds toward precise evaluation and academic competition.

Students are not immune to testing and grade procedures, and educational researchers have made the distinction between students who are grade oriented and those who are learning oriented. Although this distinction is surely too one-dimensional, it does suggest that for some students the classroom is a place where they experience and enjoy learning for its own sake. For other students, however, the classroom is experienced as a crucible in which they are tested and in which the attainment of a good grade becomes more important than the learning itself. When students are asked how they became grade (or learning) oriented, they usually point to the actions of their teachers in emphasizing grades as a signifi-

cant indicator of future success; alternatively, they describe instructors who are excited by promoting new learning in their classrooms. When college instructors are asked about the reason(s) for their emphasis on grades, they report that student behaviors—such as arguing over the scoring of a single question—make it necessary for them to maintain strict and well-defined grading standards in their classrooms. The ironic point is that both the student and the instructor see the “other” as emphasizing grades over learning, and neither sees this as a desirable state of affairs. What seems missing in this context is a clear recognition by both the instructor and the student that grades are best construed as a type of communication. When grades (and tests) are thought about in this way, they can be used to improve learning. As it now stands, however, the communicative purpose of grading is ordinarily submerged in their more ordinary use as a means of rating and sorting students for social and institutional purposes not directly tied to learning. Only when grades are integrated into a coherent teaching and learning strategy do they serve the purpose of providing useful and meaningful feedback not only to the larger culture but to the individual student as well.

## GRADUATE RECORD EXAMINATION

Every year, thousands of students prepare for, and take, the Graduate Record Examination (GRE)—a standardized test that measures the aptitude of promising graduate students. In 1998, 364,554 potential graduate students, a number that includes one-third of all bachelor degree recipients, took the GRE, according to the National Center for Education Statistics. Why does this test draw thousands of students? GRE scores are required for acceptance into most graduate programs. As a result, the exam, designed to assist graduate schools with their admissions decisions, also succeeds in sending would-be graduate students into a panic, raises questions of the efficacy of standardized testing, and funds a lucrative “test-prep” industry. Despite such side effects, it has proven useful to those it intends to serve—graduate schools. The GRE provides these institutions with a universal ruler against which applicants can be measured.

Administered by the Educational Testing Service (ETS), the GRE takes three basic forms: the General Test, Subject Tests, and the Writing Assessment. The General Test, most often referred to as the GRE, measures verbal, quantitative, and analytical reasoning skills. The Subject Tests measure achievement in eight disciplines. The Writing Assessment

consists of two analytical writing tasks. Graduate institutions and departments independently determine which GRE test, or combination of tests, will be required for admission.

### Genesis of the GRE General Test

Created in the early 1930s, the Graduate Record Examination General Test has been assessing college student aptitude for nearly seven decades. The Carnegie Foundation for the Advancement of Teaching funded the project, unaware of the vital part the test would soon play in graduate education. Widespread use of the GRE General Test began after World War II, when colleges and universities selected the test to help in the evaluation of the larger, more diverse pool of students applying to graduate programs. From this point forward, GRE test results have been used to evaluate students' capacity to succeed in graduate programs. Today, the Educational Testing Service and the GRE Board define the test as "a measure of knowledge and skills that members of the graduate community have identified as important for graduate study" (GRE 2001a, p. 2).

### General Test

The Graduate Record Examination General Test's three parts—verbal, quantitative, and analytical—are designed to measure examinees' reading comprehension, mathematical, interpretative, and logical reasoning skills. Taken in a timed, proctored setting, the multiple-choice written test causes stress for many students. Though anxiety over the test has not changed, the format has. On April 11, 1999, the option to take the exam in written form was eliminated (except in developing countries). Today, the Computer Based Test (CBT), which replaces the pencil and paper version, is offered daily in centers around the world. Soon-to-be test-takers, and GRE test preparation companies, such as Kaplan Incorporated and The Princeton Review, have had to adjust to the features of the new design. In the past, paper-based GRE questions were identical: presented and weighted equally for all test-takers. Now, the "adaptive" CBT presents students with unique combinations of questions tailored to their skill level. Students complain about early questions on the computer-based test having greater bearing on their final scores and about the inability to answer questions out of sequence. Many agree, however, that the benefits of CBT, including instant scoring, continuous availability, and better data analysis capabilities,

far outweigh the disadvantages. Research indicates that scores from the paper-based tests are comparable to those of the computer-based test. Each section of the test yields a separate score ranging from 200 to 800. Scoring may change in October 2002 when one of the multiple-choice analytical sections will be replaced by a writing component.

### Subject Tests

The GRE Subject Tests, offered in both paper and computer-based formats, are designed to help graduate school admission committees and fellowship sponsors assess applicants' preparation for graduate work in specific disciplines. The Subject Tests, offered in Biochemistry, Cell and Molecular Biology; Biology; Chemistry; Computer Science; Literature in English; Mathematics; Physics; and Psychology are required by select programs. Subject Test scores can range from 200 to 990.

### The Writing Assessment Test

Launched in 1999, the Writing Assessment comprises two analytical writing tasks: one an opinion piece on an issue of the Educational Testing Service's choosing, the other a critique of a presented argument. The "tasks" are meant to complement each other, providing evidence of the examinees' ability to both make and analyze arguments. Like the Subject Test, this test can be taken on paper or electronically. Writing assessment scores range from 0 to 6.

### Use of GRE Scores in Graduate Program Admissions Decisions

At every education level, controversy surrounds the use of standardized tests. According to the Business Council for Effective Literacy "objections [to standardized tests] tend to fall into two broad categories: their intrinsic defects and their misuse" (p. 6). At the turn of the twenty-first century national attention has turned to the Education Testing Service's GRE, with questions about GRE scores' assumed correlation with success in graduate school and issues of test fairness.

According to ETS, the Graduate Record Examinations measure general skills acquired over time. The scores have been validated for use in graduate admissions, fellowship selection, and other assessments related to graduate study. When interpreted and applied properly, GRE test scores can be helpful in admissions decisions. In the United States, master's and doctoral level admissions decisions are

often based on a number of factors, including grade point averages (GPAs), transcripts from previously attended higher education institutions, GRE General Test scores, letters of recommendation, personal statements, self-reported information, and in some cases GRE Subject Tests, Writing Assessments, and personal portfolios. Problems arise when departments and colleges heavily rely on GRE scores, rather than considering all the information available on the student. As Judith Toyama states, “All too often, [GRE] scores, because they are numerical, [thus quantifiable], are given more importance” (p. 34). As a result of this pervasive misuse, the GRE is seen as a “gatekeeper” of minority and female—typically lower-scoring groups—access to graduate education. Many graduate schools use a combination of the verbal and quantitative section scores when considering applicants. How well does this composite predict academic success in graduate school? Peter Sacks, using data compiled by ETS, states, “Data from 1,000 graduate departments covering some 12,000 test-takers show that GRE scores could explain just 9 percent of the variation in grades of first year graduate students.” Some studies have shown, however, that a combination of GRE scores and grade point averages can be indicative of student success.

Another controversial aspect of the GRE is that disparity in scores between ethnic groups points to the possibility of an intrinsic bias, or unfairness, in the General Test. Data analysis of GRE General Test scores reveals differences in the mean scores earned by racial, ethnic, and gender groups. According to the Graduate Record Examination Board, data from the 1999–2000 testing year shows the following: (1) white men scored at least 100 points higher, on average, than minority men and both minority and non-minority women; (2) self-classified whites, Asian/Pacific Islanders, and “others” received higher scores on the verbal and analytical sections than other ethnic groups; and (3) within ethnic groups, men scored higher than women. In response to concerns over such performance gaps, the Educational Testing Service and the GRE Board instituted practices to reduce GRE test bias. Faculty have been included in the test design, review process, and analysis of differential item functioning (DIF) when the percentage of correct answers on the same test question differs between groups. Despite these efforts, differences still occur along ethnic and minority lines. ETS stresses, however, that differences

should be expected as “test results cannot be judged in isolation from the unequal outcomes produced by our educational, economic, and social systems” (2001a, p. 2).

### Evaluation

Within our culturally, economically, and socially diverse population, no one measure could equitably evaluate individuals’ promise. Even the GRE, a vetted, long-standing standardized test, has difficulty producing a fair measure of the diverse students that flock to test-taking centers each year. Moreover, when admissions committees make GRE scores the primary basis for their decisions, they overlook many characteristics and qualifications that are not measured on the test and are proven factors in student success, such as drive, passion, determination, and charisma. The use of GRE scores in the appraisal of students’ ability in the tested areas is merited. The scores are inadequate, however, when applied as sole predictors of success. Students, scholars, and the ETS agree, the Graduate Record Examinations are valuable, as long as graduate school admissions committees exercise good judgment, and use the scores to supplement other admissions criteria.

LORI J. CAVELL

## GRADUATE SCHOOL TRAINING

Graduate and professional education is the continuation of academic study beyond the baccalaureate degree. Graduate education is distinguished from professional education in that the graduate student is preparing for a career in academia, the government, or other professions. Those continuing in professional education are in degree programs that will prepare them for work in law, medicine, or other professional fields. Both graduate and professional education have been well established in the United States for over 100 years; however it was only in the latter part of the twentieth century that the face of graduate education began to change as the higher educational system became more diversified through such developments as the proliferation of women and minority graduate students.

In the early nineteenth century, German universities were the leading force of graduate education. Leadership in this area passed to the United States in the twentieth century as American universities advanced their programs. Three universities—Harvard, Yale, and Johns Hopkins—are credited with the adaptation of post-baccalaureate education. While Harvard took the lead, in 1847 Yale developed a model that made the distinction between undergraduate and graduate education. Johns Hopkins University was the first institution to be founded primarily as a graduate education institution.

## The Master's Degree

Graduate education is divided into two main areas: the master's degree and doctoral study. Obtaining a master's degree typically requires a minimum of thirty credit hours past the baccalaureate degree, although some programs may require more or less depending on the university and discipline requirements. At the completion of class work, either a comprehensive exam is administered or a written thesis is submitted, and either of these may be followed by an oral defense where the student is posed questions by the department faculty. This is the typical pattern of master's degree study, with most programs requiring two years of coursework. However, there are hundreds of different types of master's degrees offered in the United States and it is not unusual for each program to have unique characteristics and requirements.

The traditional master's degrees grounded in the arts and sciences curriculum are the master of arts (M.A.) and the master of science (M.S.). Examples of other master's degrees that have a more practical or professional approach are the master of business administration (M.B.A.), the master of education (M.Ed.), and the master of engineering (M.Eng.). While there are still a significant number of students who attend graduate school immediately following their undergraduate experience, more students are choosing to return for a master's degree several years after entering the work force. For these more mature students, the master's degree is considered a stepping-stone for career advancement. Many individuals have the added bonus that more businesses now make it possible for their employees to attend graduate school by offering tuition reimbursement and time off from work for educational purposes. At the same time, universities are offering more options for students who choose to remain employed while pursuing their master's degree. Examples include offering evening or weekend classes and conducting classes in the work environment rather than on the college campus.

Additionally, the proliferation of master's programs being offered by colleges and universities is increasing the options of those who choose to re-enter academia. Rather than graduate education being offered only at universities, liberal arts colleges are adding one or more master's programs to their curriculum. At the same time, they are targeting the more mature student as well as the student who would prefer the liberal arts college environment to

the larger university. With the increased availability and visibility of master's education, the number of master's degrees awarded in the United States continues to grow each year.

### The Doctoral Degree

A doctoral program is considered the basis for socialization into the professoriate. It has always been regarded as a beginning for developing skills, knowledge, and competencies associated with teaching and research. For this reason, there are some general requirements for doctoral degrees that apply to most institutions in the United States. While there are differences with course requirements and completion rates, the basic doctoral degree begins with one to two years of course work and ends with the oral defense of the dissertation. Some students, particularly those who enter a doctoral program without a master's degree, will earn their master's degree while pursuing the doctorate. In this case, course work could take more than two years to complete. In addition to these basic requirements, many doctoral students hold research or teaching assistantships in addition to taking classes. Likewise, faculty members are encouraged to and often include doctoral students in research projects. Both the assistantships and the mentor relationships with faculty are preparation not only for the dissertation but for the professorial role many will enter into upon completion of their degrees.

Allen R. Sanderson and Bernard Dugoni identified fifty-two different research doctorates in their 1997 summary report of doctoral recipients from United States universities. Traditionally, the non-professional doctoral degree most often awarded is the doctor of philosophy (Ph.D.), although other degrees such as the doctor of education (Ed.D.), doctor of arts (D.A.), and the doctor of science (D.Sc. or Sc.D.) are now being offered in greater numbers. Professional doctoral degrees such as the jurist doctorate (J.D.) and the medical doctorate (M.D.) also indicate that ending of advanced education but the requirements for these doctoral degrees differ from the Ph.D. and its equivalent.

Course work for a doctoral degree is most often individually tailored based on the student's background, interests, and professional goals. In addition to completing class work prior to the dissertation, doctoral students are required to take comprehensive exams. Depending on the program, a student may be required to take more than one comprehen-

sive exam throughout the course of study. Typically, a comprehensive exam is administered immediately following completion of course work and the exam itself may take various forms such as a day-long session where students answer questions based on knowledge obtained in their studies. In most circumstances this is a closed book exam and, after faculty members have had the opportunity to grade the exam, doctoral students must defend their responses orally before a faculty panel.

The dissertation is an original body of research conducted by a student in her final years as a doctoral student. A typical dissertation completed by a Ph.D. candidate will include five chapters: the first is a general introduction, the second chapter is a thorough literature review of the subject, the third chapter contains the methodology or how the research is to be conducted, the fourth chapter shows the findings from research, and the final chapter is a discussion of the findings with suggestions for possible future research.

Prior to conducting the dissertation research, the graduate student must defend his proposal to a dissertation committee which is generally made up of three to five members. The proposal is typically the first three chapters of the dissertation. After the proposal is approved the doctoral student may begin their research and move to completing the dissertation. After the research has been conducted and data analyzed, doctoral students must again orally defend the dissertation before their committee. Each Ph.D. candidate must show a thorough knowledge of the subject being studied along with the presentation of original research and findings that add to the body of knowledge for their discipline.

The Ph.D. (doctor of philosophy) is the typical doctoral degree awarded at universities although the areas of study range from the basic humanities to the sciences and education. Those receiving Ph.D.s have traditionally gone on to faculty positions at colleges or universities. It is not uncommon today, though, for Ph.D. recipients to go immediately into careers outside of academia. Not only do many choose to forego teaching or research opportunities, many are forced to look elsewhere for work due to the lack of available faculty positions. With the proliferation of doctoral recipients, it is natural to assume that not all Ph.D.s will find the ideal job at a college or university.

Other doctorates are available for those selecting a course of study that leads to careers outside ac-

## GRADUATE STUDY IN EDUCATION

---

ademia. Some examples are the educational doctorate, which may be pursued by those with careers in K–12 classroom teaching or school administration, and the doctor of engineering, for candidates working in areas of technology or applied sciences. It is normal for these graduate students to focus their studies and dissertations on practical topics, rather than theoretical ones, that have immediate relevance to their field of work.

### Professional Graduate Education

Professional doctoral education, as previously mentioned, is post-baccalaureate study in the professions. Two of the most established professional education fields are medicine and law. The requirements for obtaining an M.D. or J.D. are rigid and do not vary greatly at different universities, unlike programs for research doctoral programs, which offer more flexibility to students in their individual courses of study. Professional doctoral students enter their graduate program as a cohort, take the same classes as others who entered the program with them, and graduate within the recommended time period, unless serious circumstances delay their progress. The curriculum focuses on applied areas of study. Unlike a Ph.D., where the dissertation is the culmination of study, often after the professional doctoral education is completed, graduates are required to take state-regulated exams in order to practice their professions, as in medicine, law, or nursing.

PATRICIA A. HELLAND

Graduate programs in the field of education are offered in U.S. colleges and universities at the master's, specialist, and doctoral levels. Like graduate programs in other disciplines and fields of study, graduate programs in education require baccalaureate degrees as a prerequisite. Degrees are typically awarded after students complete specified program requirements.

From 1997 to 1998 education was the most popular field of study at the master's and doctoral level. According to the U.S. Department of Education, slightly more than one-quarter (114,691) of the 430,164 master's degrees awarded in 1997 to 1998 were in the field of education, and at the doctoral level, approximately 15 percent (6,729) of the 46,010 doctoral degrees awarded were in education. Men earned slightly fewer than one-quarter of the master's degrees (24%) awarded in 1997 to 1998 and at the doctoral level men earned 37 percent of the degrees. Whites represented 77 percent of the master's degree recipients in 1997 to 1998, followed by black non-Hispanics (9%), Hispanics (4%), non-resident aliens (3%), Asian or Pacific Islanders (2%) and American Indian/Alaskan Natives (1%), with students who did not report their race/ethnicity representing 5 percent of master's degree recipients. At the doctoral level, whites earned 71 percent of the doctoral degrees, followed by black non-Hispanics (11%), nonresident aliens (8%), Hispanics (4%), Asian or Pacific Islanders (2%), American Indian/Alaskan Natives (1%) and students who did not report their race/ethnicity represented 3 percent.

### Education Degrees

Similar to psychology and social work, but unlike many other graduate-level fields of study, students who enroll in education graduate programs choose between a research path and a professional practice path and in some cases, a path that combines research and practice. Traditionally, the research path is designed for people who want to examine and evaluate educational practices and research, with the goal of preparing students to become college faculty or researchers, while the professional path is designed for people who wish to practice in the field in positions such as school principal, school superintendent, chief financial officer within a primary or secondary school, a dean of admissions, or a dean of

student affairs at a college or university. This difference between the applied and the research-oriented degree is reflected in the types of degrees. The master of education (Ed.M.), the specialist in education (Ed.S), a degree intended for teachers, counselors, and administrators who wish to pursue graduate study beyond the master's level, and the doctor of education (Ed.D.) programs prepare students to apply knowledge and scholarship toward addressing problems in educational settings. In contrast the master of arts (M.A.), the master of science (M.S.), the master of arts in teaching (M.A.T), the master of science in education (M.S.Ed.), the doctor of arts (D.A.), which is intended to develop pedagogical skills along with scholarly achievement and research excellence, and the doctor of philosophy (Ph.D.) programs prepare students to engage in research and scholarship on education to create knowledge.

Certificate programs are yet another post-baccalaureate educational option. Examples of some of the certificates include a post-baccalaureate certificate program (nondegree) and a Certificate of Advanced Graduate Study (CAGS). Most candidates for the CAGS have earned a master's degree. The CAGS often serves one of the following two purposes: (1) an end goal for individuals who seek advanced training without having the pressure or the time commitment of a doctoral degree program or (2) an intermediary step before students formally apply to a doctoral program.

Graduate education instructional programs cover the spectrum of the educational landscape from pre-kindergarten to adult education. The National Center for Education Statistics Classification of Instructional Programs has classified fifteen program of instruction areas in education:

- education, general
- bilingual, multilingual, and multicultural education
- curriculum and instruction
- educational administration and supervision
- educational/instructional media design
- educational assessment, evaluation, and research
- international and comparative education
- social and philosophical foundations of education
- special education and teaching
- student counseling and personnel services

- teacher education and professional development: specific levels and methods
- teacher education and professional development: specific subject areas
- teaching English or French as a second or foreign language
- teaching assistants/aides
- education, other

Within each of these sixteen categories are finer classifications of areas of instruction.

### Admission to Education Graduate Programs

Unlike undergraduate admissions in which students apply to a college or university's central admissions office, which then reviews all students' application materials, admissions decisions at the graduate level are usually handled by a faculty committee at the education graduate school or the specific graduate program within the school (e.g. curriculum and instruction, or educational administration and planning). The typical application materials submitted for admission include the following: (1) academic transcripts from all prior colleges or universities attended; (2) an application for admissions; (3) an essay or statement of purpose and goals (4) an application fee; (5) letters of recommendation; and (6) admissions test scores.

There are three primary admissions tests accepted by graduate schools of education: Graduate Record Examination (GRE), Miller Analogies, and the Test of English as a Foreign Language (TOEFL). The GRE General Test has three parts: verbal, quantitative, and analytical. These parts are not related to any specific field of study, but rather are intended to assess the abilities of applicants to graduate school in mathematical reasoning, literacy, and analytical thinking. Scores for each section of the GRE General Test range from 200 to 800. A two-part writing assessment is also available to measure student abilities to articulate complex ideas clearly and effectively and to support their ideas with relevant reasons and examples. The writing assessment has one combined score. The GRE also includes eight subject area tests. Some graduate programs require students who are applying to educational psychology programs to take the GRE psychology test, which measures the extent of knowledge of psychology that would be acquired primarily in undergraduate psychology curricula. Subject test scores range from 200 to 990. The Miller Analogies Test consists of 100 partial analogies that

are completed in fifty minutes. Miller Analogy score reports present three MAT Scores: a student's raw score (the number answered correctly), the percentile based on intended major, and the percentile based on the general population of MAT examinees. The TOEFL measures the ability of nonnative speakers of English to use and understand North American English.

Graduate school admission committees typically review several parts of an applicant's admission record:

- the reputation of their undergraduate institution
- undergraduate grade point average (UGPA), both overall and in some instances their GPA in their undergraduate major
- admission test scores
- personal statement
- work history if applicable
- letters of recommendation
- how student's research interests match faculty research interests.

The weight that each graduate program assigns to these components varies from program to program. Particularly at the doctoral level, admissions decisions may also be based on the amount of funds that are available to support students who are applying. Some programs do not admit more students than they anticipate being able to fully fund for the duration of their graduate career, while others seek to provide initial support to attract students, and assume that students will find a niche along with support after they are engaged in the process.

Students apply for financial aid for graduate school simultaneously with their application for admission. There are three primary types of financial assistance at the graduate level. The first is a fellowship. When a student receives a fellowship, she/he typically receives money without an obligation to perform any work in exchange for the money. Assistantships are the second form of financial assistance. There are three types of assistantships: teaching, research and administrative. Teaching assistantships usually require students to perform teaching duties in exchange for tuition and a stipend. Research assistantships usually require students to work with faculty on their research in exchange for tuition and a stipend. Administrative assistantships require students to work with administrative offices

on programs or projects in exchange for tuition and a stipend. In both the cases of fellowships and assistantships, students may or may not receive health benefits. The third form of financial assistance is a loan. Loans require students to repay the money typically with interest. The exact terms of the loans vary depending upon the originating source of the loan. A less prevalent form of paying for graduate school is the use of employer tuition assistance plans. Graduate level financial aid awards may be made on the basis of academic credentials (e.g., test scores, undergraduate grades, if a an applicant's area of interest is related to one of the faculty's areas of interest), academic promise, or on the basis of financial need.

### Degree Requirements

Students may be enrolled either full-time or part-time. Graduate programs may offer classes during the traditional academic year, during the summer, or in a two-day weekend format offered monthly throughout the calendar year. Graduate education programs are typically delivered in two formats. The traditional delivery method is in person where faculty meet students at the main campus or at a satellite campus location. Satellite locations may be either in-state or out-of-state. The other medium involves distance education technology.

Graduate degrees in education are typically awarded after students complete specified program requirements. Course work requirements are a basic degree requirement. Course requirements may include a set number of courses or credit hours as well as a distribution requirement. The distribution requirement may include courses within the education graduate program as well as courses in other related disciplines or fields of study offered at the institution. At the master's level students may be required to complete a culminating exercise ranging from creative projects to a master's thesis. Master's students may also be required to complete a field experience practicum.

At the doctoral level, students complete a qualifying or preliminary examination at the end of their course work. The structure of the exercise will vary from program to program and may be dependent upon whether the student is pursuing an Ed.D. or a Ph.D. After passing the qualifying or preliminary examination, the doctoral student is typically required to write and defend a dissertation. The requirements of the dissertation may vary depending upon the terminal degree. The Ed.D. dissertation

may require doctoral students to examine an issue in education, while the Ph.D. dissertation requires the doctoral student to pursue original research.

## GRADUATION CEREMONY

*See:* COMMENCEMENT.

### GRAY, WILLIAM SCOTT (1885–1960)

William S. Gray, as author of the popular “Dick and Jane” series, arguably helped to define the field of reading education in the United States. Gray received a bachelor’s degree from the University of Chicago in 1913, a master’s degree from Teachers College, Columbia University, in 1914, and a Ph.D. from the University of Chicago in 1916. He was associated with the University of Chicago from the time he became an instructor in 1915 to his retirement as professor emeritus in 1950. Always interested in the education of teachers, he was dean of the college of education from 1917 to 1930 and head of the university’s teacher preparation committee from 1933 through 1945.

Conducting and analyzing research studies to improve reading instruction was Gray’s passion, and his work impacted virtually every aspect of the field. During his lifetime he authored more than 500 publications that examined the characteristics of all ages

of readers, from young children to adults, as well as teaching procedures appropriate for the characteristics. He also developed a standardized reading test in 1915, which continues to be used into the twenty-first century, and he pioneered the diagnostic/remedial approach to reading difficulties.

#### Influence of Reform Movements

The underpinnings of Gray’s approach to research and practice were formed in the first two decades of the twentieth century when his work and education brought him into contact with the reform movements transforming American education. In 1908, to prepare to become a teacher, he entered the Illinois State Normal School, the center of the Herbartian movement in North America: Charles De Garmo and Frank and Charles McMurry were among those who had taught or studied there. Herbartianism at the turn of the century was a scientific approach to education based on principles of learning. Gray adopted Herbartian principles and had the opportunity to apply them when he became principal of the training school at Illinois Normal following his graduation in 1910. The experience led to Gray’s first publications: twelve articles on the teaching of geography, based on the principles of Herbartianism, which appeared in *The School Century* from May 1911 through June 1912.

Gray’s incipient interest in a scientific approach to education was nurtured at the University of Chicago, where he worked primarily with Charles Judd, head of the department of education. Judd was a psychologist as well as educator who utilized scientific methods and measurement techniques to study education. While at Teachers College Gray worked with Edward L. Thorndike, who, even more so than Judd, was applying scientific principles, measurement techniques, and statistical procedures to education. Gray’s life-long interest in reading assessment began to focus at this time. Thorndike was developing achievement scales in various subject areas, and Gray, for his master’s thesis, developed a scale for reading. The test, *Standardized Oral Reading Paragraphs, Grades 1–8*, was published in 1915. This test continued to be used with only minor revisions until 1963; in 2001 the fourth edition of the *Gray Oral Reading Test* was issued.

Gray returned to the University of Chicago to study for a Ph.D. and immediately began to work for Judd, who was participating in a survey of the Cleveland schools. The survey was a major reform effort

to bring scientific principles to bear on school improvement, and Judd asked Gray to assess reading achievement in the Cleveland schools. The experience gave Gray the opportunity to observe reading instruction in many classrooms and to refine his skills in reading assessment. He received his Ph.D. degree with a dissertation entitled "Studies of Elementary School Reading through Standardized Tests." His dissertation was published in 1917 as the first number in the *Supplementary Educational Monographs of the University of Chicago*.

During the "Economy of Time" reform movement in the second decade of the twentieth century, Gray, by then dean of the college of education at the University of Chicago, used scientific methods to determine the most successful method of teaching reading. Gray identified the following components: (1) selecting content of interest and significance to students; (2) developing independent word-recognition skills by word study and phonetic analysis after the student has acquired a basic vocabulary through content reading; and (3) providing a system of phonics that will naturally lead to accurate analysis of longer words encountered past the second grade. Gray became an advocate of the sight method of teaching reading, and had the opportunity to directly impact classroom practice in 1930 when he became a coauthor, with William H. Elson, of a popular basal reading series titled the *Elson Basic Readers*, published by Scott, Foresman and Company. In 1936 these became the *Elson-Gray Basic Readers*; in 1940 he became first author of the renamed *Basic Readers*. These "Dick and Jane" readers became widely used throughout America.

### Literacy Efforts

Gray's assessment experience made him aware of student reading difficulties and the necessity to fit instruction to the perceived weaknesses of students. In 1922 this led to an influential book titled *Remedial Cases in Reading: Their Diagnosis and Correction*. This book marked the beginning of a diagnostic/prescriptive approach to individual differences that remained in practice at the beginning of the twenty-first century.

Gray had a continuing interest in adult literacy, publishing *The Reading Interests and Habits of Adults* in 1929 and *Maturity in Reading: Its Nature and Appraisal* in 1956. He was also involved with literacy on an international level, working particularly with the United Nations Educational, Scientific and Cultural

Organization (UNESCO). This led to *The Teaching of Reading and Writing: An International Survey*, first published in 1956. He was also a founder of the International Reading Association, serving as its first president in 1955–1956.

Biographical information and a complete list of Gray's publications are included in a 1985 publication of the International Reading Association: *William S. Gray: Teacher, Scholar, Leader*, edited by Jennifer A. Stevenson. This document is also available as ERIC No. ED255902.

GERALD W. JORGENSEN

## GROUPING PATTERNS AND PRACTICES

*See:* SOCIAL ORGANIZATION OF SCHOOLS.

## GROUP PROCESSES IN THE CLASSROOM

Classrooms are social settings; teaching and learning occur through social interaction between teachers

and students. As teaching and learning take place, they are complicated processes and are affected by peer-group relationships. The interactions and relationships between teachers and students, and among students, as they work side by side, constitute the group processes of the classroom.

Group processes are especially significant in twenty-first century schools. Group projects and cooperative teamwork are the foundations of effective teaching, creative curriculum, and positive classroom climate. Interpersonal skills, group work, and empathy are important ingredients of modern business, where employees must communicate well for their business to be productive and profitable. Group processes are also significant in modern global communities, where citizens must work together for a safe and secure world. Thus, along with teaching academic curriculum, teachers are expected to help students develop the attitudes, skills, and procedures of democratic community.

### Classroom as Group

A group is a collection of interdependent, interacting individuals with reciprocal influence over one another. *Interdependent* means the participants mutually depend on one another to get work done; the teacher's part is to teach as the students strive to learn. *Reciprocal influence* refers to mutual effects exchanged and felt by the same people. In classrooms as few as two people can form groups, as long as the paired individuals have reciprocal influence through communication and mental contact. When the teacher engages the whole class in a learning activity common to all, then everyone forms into a single group, or as Herbert A. Thelen wrote, a "miniature society." Although the teacher and students of one class can be a whole group or from time to time many subgroups, groups are not simply people in proximity, such as a host of screaming students at a concert, or categories of individuals with something in common, such as the blondes and redheads of a school.

A group is also defined by its goals and structures. Goals are jointly held outcomes toward which group members work; structures are group roles taken regularly by members as they carry out the work. Groups seek to accomplish task or work goals and social-emotional or morale goals. Classroom groups become more successful as they pursue both task and social-emotional goals.

In most classrooms learning academic subject matter is a valued task goal, while developing a positive climate is a valued social-emotional goal. The class that accomplishes both is stronger than the class that reaches only one. In a parallel way group structures are made up of formal or official roles and informal or unofficial roles. Many classrooms have the formal roles of teacher, aide, student, administrative supporter, and parent helper along with the informal roles of leader, follower, friend, isolate, and rejectee. Classes with clear and understandable formal roles and nurturing and supportive informal roles are stronger than classes with just one or the other.

### A Social-Psychological View

Social-psychological research helps one form an understanding of the place of group processes in the classroom. The students of a class form a miniature society with peers, teacher, and aides in which they experience interdependence, interaction, common striving for goals, and structure. Many subgroups in the class affect how the larger classroom society works and how individuals relate to one another. Students interact, formally and informally, with teachers, aides, and one another. The informal interactions usually are not discussed even though they can be very important to everyone. Students work on the curriculum in the physical presence of one another to grow intellectually, behaviorally, and emotionally. Their informal roles of friendship, leadership, prestige, and respect affect how they carry out formal aspects of the student role. The informal relationships among students can be charged with emotion; an interpersonal underworld of peer-group affect is virtually inevitable for all students.

While the class develops, informal relationships with peers increase in power and poignancy; the students' definitions and evaluations of themselves become more vulnerable to peer-group influence. Each student's self-concept is susceptible to change within the classroom society, where informal peer interactions can be either threatening or supportive. In particular, the social motives of affiliation, achievement, and power have to be partly satisfied for each student to feel comfortable and secure. The negative conditions of loneliness and rejection, incompetence and stupidity, powerlessness, and alienation arise when these three motives are frustrated. The more supportive peer relations are in satisfying these motives, the more likely students' learning and behavior

will be enhanced. Having students work interdependently toward jointly established goals in supportive, cooperative learning groups can increase their compassion for one another, self-esteem, positive attitudes toward school, and academic learning.

### **Classroom Climate**

Classroom climate refers to the emotional tones associated with students' interactions, their attitudinal reactions to the class, as well as to students' self-concept and their motivational satisfactions and frustrations. Climate is measured by observing physical movements, bodily gestures, seating patterns, and instances of verbal interaction. Do students stand close or far away from the teacher? Are students at ease or tense? How frequently is affective support communicated by smiles, winks, or pats on the back? Do students move quietly with measured steps to their desks, or do they stroll freely and easily, showing the class feels safe? Are students reluctant to ask the teacher questions? How do students relate to one another? Are they quiet, distant, and formal, or do they walk easily and laugh spontaneously? How often do students put a peer down or say something nice to one another? Do students harass or bully other students? How often does fighting erupt? How often does peacemaking occur? Are sessions run primarily by the teacher or do students also take the lead? Do seating patterns shift from time to time, or do they remain the same, regardless of the learning activity? Are students working together cooperatively?

A positive climate exists when the following are present: (1) leadership occurs as power-with rather than power-over; (2) communication is honest, open and transactional; (3) high levels of friendship are present among classmates; (4) expectations are high for the performance of others and oneself; (5) norms support getting academic work done well and for maximizing individuals' strengths; and (6) conflict is dealt with constructively and peacefully. Although each of these six properties of climate can be important by itself, positive climate is an ensemble of all of them. Climate describes how each property is integrated with the others. It summarizes group processes that a teacher develops when interacting with students and how the students themselves relate with one another. Climate is what the behavioral actions are in working toward curriculum goals; it is how curriculum materials are used through human exchange; and it is styles of relating among members

of the classroom group. In classrooms with positive climates we find students and teachers collaborating to accomplish common goals along with feelings of positive self-esteem, security, and warmth. We also find students influencing the teacher and their peers, high involvement in academic learning, and strong attraction for one's classmates, curriculum, and school.

### **Teaching Strategies**

Ronald Lippitt and Ralph White, with guidance from Kurt Lewin, observed effects on youth of three leadership styles: autocratic, democratic, and laissez faire. Autocratic leaders made all decisions about group goals and work procedures. Democratic leaders specified group goals, but urged group members to decide among alternative ways of working. Laissez-faire leaders abdicated authority, permitting youth to work as they pleased. Groups with democratic leaders performed best with high quality work output and high morale. Autocratically lead groups had high quality work output, but low morale. Groups with laissez-faire leaders performed worst overall. Classroom research has shown that although autocratic teachers can get students to accomplish high amounts of academic work, they also create conformity, competition, dependency, and resentment. Students of democratic teachers accomplish both a great deal of excellent academic work, and establish positive social climates.

Effective communication is key in understanding differences between autocratic and democratic teachers. Autocratic teachers use one-way communication in persuading students to accept learning goals and procedures as well as rules for classroom behavior; such unilateral direction giving is often an ineffective way of transmitting information. Democratic teachers use two-way communication often to encourage students to participate in making decisions for themselves and in establishing group agreements for classroom procedures. By using transactional communication whereby students and teachers reciprocate in trying to understand one another, democratic teachers help build a climate that is participatory, relaxed, personal, and supportive. Attributes of democratic teachers who are effective transactional communicators are receptiveness to students' ideas, an egalitarian attitude, openness, warmth, respect for students' feelings, sensitivity to outcasts, a sense of humor, and a caring attitude.

Such participatory teachers understand that friendships in the classroom peer group cannot be separated from teaching and learning; friendly feelings are integral to instructional transactions between teachers and students and among students. Students who view themselves as disliked or ignored by their peers often have difficulty in performing up to their academic potential. They experience anxiety and reduced self-esteem, both of which interfere with their academic performance. As outcasts they might seek revenge, searching for ways to be aggressive toward teachers and peers. By watching their teacher interact with the class, students learn who gets left out and who gets encouragement and praise. Teachers can help rejected students obtain peer support by giving them an extra amount of encouragement and praise in front of their peers, and by assigning them to work cooperatively with popular classmates. Teachers with friendly classes see to it that they talk and attend to every student rather than focusing on a few, and often reward students with specific statements for helpful and successful behavior; they seek to control behavioral disturbances with general, group-oriented statements.

Also central to positive climate are the expectations that teacher and student hold for one another. Teachers' expectations for how each student might behave are particularly important because they affect how teachers behave toward that student. Thus, teachers should engage in introspection and reflection to diagnose their expectations, and obtain feedback from colleagues about how they are behaving toward particular students. Teachers should also use diverse information sources to understand what makes their students behave as they do. In particular, teachers should reflect on their expectations and attributions toward blacks and whites, girls and boys, students of different social classes and ethnic groups, and at-risk or students with disabilities. Teachers should deliberately seek new information about student strengths in order to free themselves of stereotypes.

Classroom norms form when most students hold the same expectations and attitudes about appropriate classroom behaviors. Although norms guide students' and the teacher's behavior, they are not the same as rules. Rules are regulations created by administrators or teachers to govern students' behavior; they might or might not become group norms. Student norms frequently are in opposition to teachers' goals, and can become counterproduc-

tive to individual student development. Teachers should strive to help students create formal group agreements to transform preferred rules into student norms. In particular, cooperative peer-group norms enhance student self-concept and academic learning more than do norms in support of competition.

Conflict, natural and inevitable in all groups, exists when one activity blocks, interferes, or keeps another activity from occurring. Conflicts arise in classrooms over incompatible procedures, goals, concepts, or interpersonal relationships. The norms of cooperation and competition affect the management of conflict differently. With cooperative norms students believe they will obtain their self-interest when other students also achieve theirs. Teachers should strive, therefore, to build a spirit of teamwork and cooperation in their classes, so that students will feel that it is in their self-interest to cooperate with their peers. When a competitive spirit exists, particularly when students are pitted against each other to obtain scarce rewards, a student succeeds only when others lose. In the competitive classroom, interpersonal conflict will arise frequently between students.

For teachers to build and maintain successful classrooms with high student achievement and positive social climate, they should attend to their leadership style, communication skills, friendliness and warmth, expectations and stereotypes of students, tactics for establishing student group agreements, and their skills in managing conflict.

## GUIDANCE AND COUNSELING, SCHOOL

---

School counselors help to make learning a positive experience for every student. They are sensitive to individual differences. They know that a classroom environment that is good for one child is not necessarily good for another. Counselors facilitate communication among teachers, parents, administrators, and students to adapt the school's environment in the best interests of each individual student. They help individual students make the most of their school experiences and prepare them for the future.

### A Brief History of School Guidance and Counseling in the United States

The history of school counseling formally started at the turn of the twentieth century, although a case can be made for tracing the foundations of counseling and guidance principles to ancient Greece and Rome with the philosophical teachings of Plato and Aristotle. There is also evidence to argue that some of the techniques and skills of modern-day guidance counselors were practiced by Catholic priests in the Middle Ages, as can be seen by the dedication to the concept of confidentiality within the confessional. Near the end of the sixteenth century, one of the first texts about career options appeared: *The Universal Plaza of All the Professions of the World*, (1626) written by Tomaso Garzoni. Nevertheless, formal guidance programs using specialized textbooks did not start until the turn of the twentieth century.

The factors leading to the development of guidance and counseling in the United States began in the 1890s with the social reform movement. The difficulties of people living in urban slums and the widespread use of child labor outraged many. One of the consequences was the compulsory education movement and shortly thereafter the vocational guidance movement, which, in its early days, was concerned with guiding people into the workforce to become productive members of society. The social and political reformer Frank Parsons is often credited with being the father of the vocational guidance movement. His work with the Civic Service House led to the development of the Boston Vocation Bureau. In 1909 the Boston Vocation Bureau helped outline a system of vocational guidance in the Boston public schools. The work of the bureau influenced the need for and the use of vocational guidance both in the United States and other countries. By 1918 there were documented accounts of the bureau's influence as far away as Uruguay and China. Guidance and counseling in these early years were considered to be mostly vocational in nature, but as the profession advanced other personal concerns became part of the school counselor's agenda.

The United States' entry into World War I brought the need for assessment of large groups of draftees, in large part to select appropriate people for leadership positions. These early psychological assessments performed on large groups of people were quickly identified as being valuable tools to be used in the educational system, thus beginning the standardized testing movement that in the early twenty-first century is still a strong aspect of U.S. public education. At the same time, vocational guidance was spreading throughout the country, so that by 1918 more than 900 high schools had some type of vocational guidance system. In 1913 the National Vocational Guidance Association was formed and helped legitimize and increase the number of guidance counselors. Early vocational guidance counselors were often teachers appointed to assume the extra duties of the position in addition to their regular teaching responsibilities.

The 1920s and 1930s saw an expansion of counseling roles beyond working only with vocational concerns. Social, personal, and educational aspects of a student's life also needed attention. The Great Depression of the 1930s led to the restriction of funds for counseling programs. Not until 1938, after a recommendation from a presidential committee

and the passage of the George Dean Act, which provided funds directly for the purposes of vocational guidance counseling, did guidance counselors start to see an increase in support for their work.

After World War II a strong trend away from testing appeared. One of the main persons indirectly responsible for this shift was the American psychologist Carl Rogers. Many in the counseling field adopted his emphasis on “nondirective” (later called “client-centered”) counseling. Rogers published *Counseling and Psychotherapy* in 1942 and *Client-Centered Therapy* in 1951. These two works defined a new counseling theory in complete contrast to previous theories in psychology and counseling. This new theory minimized counselor advice-giving and stressed the creation of conditions that left the client more in control of the counseling content.

In 1958 the National Defense Education Act (NDEA) was enacted, providing aid to education in the United States at all levels, public and private. Instituted primarily to stimulate the advancement of education in science, mathematics, and modern foreign languages, NDEA also provided aid in other areas, including technical education, area studies, geography, English as a second language, counseling and guidance, school libraries, and educational media centers. Further support for school counseling was spurred by the Soviet Union’s launching of *Sputnik* and fears that other countries were outperforming the United States in the fields of mathematics and science. Hence, by providing appropriate funding for education, including guidance and counseling, it was thought that more students would find their way into the sciences. Additionally, in the 1950s the American School Counselor Association (ASCA) was formed, furthering the professional identity of the school counselor.

The work of C. Gilbert Wrenn, including his 1962 book *The Counselor in a Changing World*, brought to light the need for more cultural sensitivity on the part of school counselors. The 1960s also brought many more counseling theories to the field, including Frederick Perl’s gestalt therapy, William Glasser’s reality therapy, Abraham Maslow and Rollo May’s existential approach, and John Krumboltz’s behavioral counseling approach. It was during this time that legislative support and an amendment to the NDEA provided funds for training and hiring school counselors with an elementary emphasis.

In the 1970s the school counselor was beginning to be defined as part of a larger program, as opposed to being the entire program. There was an emphasis on accountability of services provided by school counselors and the benefits that could be obtained with structured evaluations. This decade also gave rise to the special education movement. The educational and counseling needs of students with disabilities was addressed with the passage of the Education for All Handicapped Children Act in 1975.

The 1980s saw the development of training standards and criteria for school counseling. This was also a time of more intense evaluation of education as a whole and counseling programs in particular. In order for schools to provide adequate educational opportunities for individuals with disabilities, school counselors were trained to adapt the educational environment to student needs. The duties and roles of many counselors began to change considerably. Counselors started finding themselves as gatekeepers to Individualized Education Programs (IEP) and Student Study Teams (SST) as well as consultants to special education teachers, especially after passage of the Americans with Disabilities Act in 1990.

The development of national educational standards and the school reform movement of the 1990s ignored school counseling as an integral part of a student’s educational development. The ASCA compensated partially with the development of national standards for school counseling programs. These standards clearly defined the roles and responsibilities of school counseling programs and showed the necessity of school counseling for the overall educational development of every student.

### Major Roles and Functions for School Counselors

The roles of a school counselor are somewhat different at various grade levels.

**Elementary school level.** In elementary schools, counselors spend their time with children individually, in small groups, or in classrooms—thus having some connection with every student in the school. With the advent of systems thinking, the elementary school counselor now has a working relationship with students’ families and with community social agencies. Although the roles of school counselors vary among settings, common tasks include individual counseling, small-group counseling, large-group or classroom presentations, involvement in school-

wide behavior plans for promoting positive and extinguishing negative behaviors, and consulting with teachers, parents, and the community. Additional duties might include developing classroom management plans or behavior plans for individual students, such as conducting SST and IEP meetings.

**Middle and high school level.** Like elementary school counselors, the roles of middle and high school counselors vary depending on the district and the school administrators. Counselors deal with a vast array of student problems—personal, academic, social, and career issues. Typically, these areas get blended together when working with a student on any one topic; hence, it is impossible to separate the duties of a counselor on the basis of a particular problem. Counselors in middle and high school have experience with all these areas and work with others in the school and community to find resources when a need arises. It is common for a school counselor to be the first person a student with a difficulty approaches. The school counselor then assesses the severity of the problem in order to provide appropriate support. School administrators sometimes assign counselors such responsibilities as class scheduling, discipline, and administration. These tasks can be integrated with the goals of school counseling but can also dilute the time available for helping individuals.

### Training Requirements

The requirements for the credentialing (in some locations called certification, licensure, or endorsement) of professional school counselors vary from state to state. All states and the District of Columbia require a graduate education (i.e., completion of some graduate-level course work), with forty-five states and the District of Columbia requiring a master's degree in counseling and guidance or a related field. A majority of states also require that graduate work include a certain number of practicum hours, ranging from 200 to 700, in a school setting. Additionally, a majority of states require applicants to have previous teaching experience. Some of these states allow students to gain experience through the graduate program by means of internships.

Half of the states require standardized testing as part of the credentialing process. Many of these tests simply cover basic mathematics, writing, and reading skills, while some states require more specialized tests covering the field of guidance and counseling. Nineteen states require a minimum number of

course credit hours specifically related to guidance and counseling. Fourteen states require students to take courses in other subject areas, such as education of children with disabilities, multicultural issues, substance abuse, state and federal laws and constitutions, applied technology, and identification and reporting of child abuse. Thirty-eight states recognize credentials from other states. Another thirty-eight states require applicants to undergo a criminal background check.

### Major Trends, Issues, and Controversies

Among the many issues facing the school counseling profession are the following three: what the professional title should be, how counselors should be evaluated, and to what extent counselors should work on prevention instead of remediation.

**Professional title.** Some professionals in the field prefer to be called *guidance counselor*, while an increasing number prefer the term *school counselor*. The growing trend is for counselors to be seen as professionals in a large system, working fluidly with all aspects within the system. The expected duties are more extensive than those practiced by vocational guidance counselors of the past, hence the feeling of many school counselors that the name of the profession should reflect its expanded roles.

**Evaluation.** A major trend in education is the demand for accountability and evaluation. School counselors have not been immune to this demand. Since the early 1970s there has been a growing concern with this issue and numerous criteria have been developed to help school counselors evaluate their specific intervention techniques.

The National Standards for Professional School Counselors was adopted by ASCA in 1997. Similar to the academic standards used nationally by state departments of education, the counseling standards provide a blueprint of the tasks of and goals for school counselors. The standards have not been adopted by every state. The average state student-counselor ratio varies from a high of about 1,250 to a low of about 400, so the evaluation of counselor performance with different workloads is a difficult undertaking.

**Prevention versus remediation.** A growing trend in the field of counseling is the focus on prevention instead of remediation. In the past it was not uncommon for counselors to have interactions with students only after some crisis had occurred. There

is now a shift for school counselors to intercede prior to any incidents and to become more proactive in developing and enacting schoolwide prevention plans. The schools, community, and families are requesting assistance in preventing students from being involved with many difficulties, such as participating in gangs, dropping out of school, becoming a teenage parent, using drugs, and participating in or becoming victims of acts of violence.

**Gangs.** Students as early as third grade are being taught gang-type activities. Students are more likely to end up in a gang if family members and peers are already involved in gang activity. It is difficult for children to leave a gang once they have been actively involved. Antigang resources are often focused on fourth and fifth graders—an age before most students join a gang. Counselors are in a position to ascertain whether a child is “at risk” of gang-type activity. The counselor can also be influential in working with the family to help the child avoid gang activity.

**Dropouts.** In many large metropolitan school districts, over 25 percent of students do not complete their high school education. Premature school termination is becoming an increasingly more difficult problem as more careers require education well beyond the high school level. Counselors are in a unique position to assist students with career guidance and help them establish meaningful goals including the completion of a basic education.

**Teen pregnancy.** Teen pregnancy continues to be a societal concern. Precipitating factors are visible prior to middle school. Counselors are often the liaison with community agencies that work to prevent student pregnancy and assist with students who do become pregnant.

**Substance abuse.** Drugs, including alcohol and tobacco, continue to be a serious problem for youth. Despite national efforts to eradicate these problems, many students still find their way to these mind-altering chemicals. Counselors are trained to understand the effects of different drugs and can assist with interventions or community referrals. The counselor is also essential in developing substance abuse prevention programs in a school.

**School violence.** School violence can range from bullying to gunfire. Counselors have training to assist teachers and students in cases of violence and to establish violence prevention programs. Counselor leadership in making teasing and bullying unaccept-

able school behaviors is a powerful way to provide a safer and more inclusive environment for students.

**Diversity.** Tolerance of diversity is an important goal in a multicultural society. School counselors help all students to be accepting of others regardless of sex, age, race, sexual orientation, culture, disability, or religious beliefs.

**Child abuse.** Many states have mandatory reporting laws concerning child abuse. Students in all grades are susceptible to abuse by others, and the counselor is often the first person to discover these deplorable acts and then report them to the proper authorities.

**Terrorism.** Terrorism is becoming an increasingly difficult problem in the world of the early twenty-first century. Children are affected, directly and indirectly, by both massive and small-scale acts of terrorism. Counselors are able to ascertain the extent to which a student or teacher may be adversely affected by terrorist acts. In these cases the counselor can either intervene or direct the person to more intensive interventions.

### School Counseling around the World

How are other countries providing counseling? It is clear that school counseling has made significant progress in the United States. Political, social, and cultural factors are deeply embedded in the way a given country addresses the educational needs of its populace. Following are brief examples of how school counseling is practiced in some other countries.

In Japan, the goal of high school counseling is to “help every student develop abilities of self-understanding, decision-making, life planning, and action-taking to be able to adjust in the career options he or she decides to pursue” (Watanabe-Muraoka, Senzaki, and Herr, p. 101). In France, secondary school counseling was started in 1922 and by the late 1930s was adopted by the educational system and seen as a necessary part of the institution. School counselors assist students with vocational guidance.

In Thailand, school counseling often incorporates advice-giving by teachers. In Israel, school counselors devote one-third of their time to classroom instruction and the rest to personal and social counseling. Career counseling is somewhat curtailed because students are required to enlist with the armed services after high school. In Hong Kong, school counseling and guidance is becoming more

of a service that is incorporated into the whole school with an emphasis on prevention. Turkey has a fifty-year history of counseling development. There is a professional association that publishes a journal and sponsors conferences. Many secondary schools have counseling services and receive support from the Ministry of National Education.

All countries benefit from professional dialogue and a continual exchange of information. In Europe the Transnational Network of National Resource Centres for Vocational Guidance was established to share information, include businesses and social agencies, and improve counseling methods and materials. The Internet is being used widely as a mechanism for disseminating information. Spain, Portugal, Denmark, Belgium, Finland, France, Italy, the Slovak Republic, and Norway are among many countries using the web to make career and counseling information available to guidance experts. As school counseling continues to define itself as a profession and to show its usefulness empirically, counseling services in schools are likely to expand worldwide in an effort to improve everyone's life satisfaction.

## HAHN, KURT (1886–1974)

Progressive educator Kurt Hahn established a system of international schools and programs that even after his death are alive and expanding.

Hahn, a German of Jewish origin who subsequently became a Christian and naturalized English citizen, was born in Berlin as son of a wealthy industrialist. After graduation from the Royal Wilhelm gymnasium in Berlin (1904), he studied philosophy and the classics at Christ Church College, Oxford, and at the universities of Berlin, Heidelberg, Freiburg, and Göttingen with the firm intention of becoming an educator and school reformer in the tradition of Cecil Reddie and Hermann Lietz. In 1910, Hahn published a novel *Frau Elses Verheissung* (Mrs. Else's promise) in which he pondered his experiences as a schoolboy. Another book *Gedanken über Erziehung* (Ideas on education) drew heavily on Plato, Kant, and William James, but was never finished.

Unfit for military service, Hahn served during World War I as specialist for English affairs in the German foreign office and in the political office of the German High Command under General Ludendorff. He wrote commentaries, held lectures, attended international conferences to strive for the democratization of the German political system and for the termination of the unnecessary war at acceptable conditions for all. When Prince Max of Baden was appointed the first parliamentarian German prime minister, Hahn became his private secretary and closest political advisor. After the war, he initiated the "Heidelberger Vereinigung," an association of influential politicians, scientists, industrialists (among them Max Weber), to promote a "peace of

justice and agreement." At the Peace Conference in Paris, Hahn served as secretary and ghost writer for the German minister of foreign affairs, Graf Brockdorff-Rantzau.

In 1919 Hahn moved to Salem castle near Lake Constance in order to realize his educational dream. Together with Prince Max, he founded a *landerziehungsheim* (boarding school), which soon became the largest and most prominent boarding school in Germany. Still politically active, Hahn supported the foundation of the German Institute of International Affairs (1923), wrote the main parts of the *Memoirs* of Prince Max of Baden (1927), and voiced his opposition to Hitler and the rising national socialism. When Hitler came to power, Hahn was imprisoned, but released through the intervention of influential British friends—among them Prime Minister Ramsay Macdonald. Nevertheless Hahn was dismissed as principal of Salem, banned from the state of Baden, and forced to emigrate to the United Kingdom. In 1934 he founded a new public school called British Salem Schools at Gordonstoun, near Elgin in Scotland, which flourished as quickly as its sister school had done. As political refugee Hahn wrote articles, memoranda, and letters to oppose the appeasement policy of the British government, publicize the horrors of the concentration camps, and organize support for the resistance movement in Germany. During World War II he served as translator and advisor for the British foreign office.

Hahn believed that young people are exposed to six declines: (1) the decline in fitness due to modern methods of locomotion; (2) the decline in initiative and enterprise due to the widespread disease of "spectatoritis"; (3) the decline in memory and imagination due to the confused restlessness of Western

civilization; (4) the decline in skill and care due to the weakened tradition of craftsmanship; (5) the decline in self-discipline due to the ever present availability of stimulants and tranquilizers; and (6) the decline in compassion due to the unseemly speed with which modern life is conducted. To counter these social diseases, Hahn conceived a preventive cure called *Erlebnistherapie* (experience therapy) which offered listless and lawless adolescence the opportunity to discover healthy passions, like the zest for exploration and the love for art and music, that would absorb the child completely. Hahn's experiential education program consisted of four elements: (1) physical fitness—exercising the body and keeping free from cigarettes, alcohol, and drugs; (2) expedition—exploring the world by sea and land under difficult conditions, alone or in groups; (3) project work—planning and executing an enterprise in research, art, or construction; and, most important, and (4) social service—helping the injured, sick, old, and handicapped in hospitals, homes, and rescue stations.

Hahn wanted his educational program to develop active citizenship, social responsibility, and international understanding, and he wanted his experience therapy to be available for every boy and girl, whatever their age, social background, and national origin. Thus he provided for scholarships, initiated courses for short-term and long-term education, and founded institutions which are operating on all five continents. The schools and schemes Hahn originated can be arranged into four categories: (1) boarding schools (since 1920, united in the Round Square Conference, about twenty worldwide by 2002); (2) Outward Bound Schools (since 1941, short-term schools of three to four weeks for students and young workers; about thirty by 2002, many of them in the United States); (3) International Award for Young People (since 1956, the most well known is the Duke of Edinburgh Award, about 100,000 boys and girls of 14 to 25 years of age participate in more than 100 countries each year experiencing the fourfold program in their spare time); (4) United World Colleges (since 1962, international two-year colleges in England, Canada, the United States, Italy, Germany, Venezuela, Swaziland, Singapore, Hong Kong).

Hahn received many honors for his political and educational activities. After his death several prizes were instituted to his memory: the Kurt Hahn Award of the American Association for Experiential

Education (since 1983); the Kurt Hahn Scholarships of the University of Cambridge (since 1986); and the Outward Bound Award of the University of Lüneburg (since 1990).

MICHAEL KNOLL

### HALEY, MARGARET (1861–1939)

Margaret Angela Haley was the formative leader of America's first teacher union. In her forty years of leadership with the Chicago Teachers Federation, Haley advocated teachers' right to be involved in school decision-making, the promotion of Progressive educational practice, and the expansion of protective legislation for teachers.

Margaret Haley was born in Joliet, Illinois, of working-class Irish immigrant parents and she attended local rural schools. She developed an early interest in politics from her father, who was a labor activist in the Knights of Labor and the Farmers' Grange. At age sixteen, as she recalled in her autobi-

ography, she was “catapulted” into teaching by her father’s persistent financial troubles, and she began to teach at local country schools. She continued her education at local teacher training institutes where she learned principles of the “new education” that rejected old-fashioned rote memory learning and promoted problem solving and close analytical work.

### Early Career

At the end of her fifth year of teaching, Haley made a further commitment to her education by registering for a four-week summer session at the Normal School at Illinois State University where she studied under leading proponents of Herbartian curriculum theory. But indicative of Haley’s emerging interest in school politics, her favorite class at Illinois was not about pedagogy but about political economy. Her favorite teacher was Edmund Janes James, a scholar of education and economics whose research interests included the labor movement, tax reform, and school finance. In James’s economics class, Haley read Henry George’s recently published *Progress and Poverty* (1879), a book that was revolutionizing liberal American economic theory with its proposal for a single tax system that would allow a more egalitarian and benevolent operation of the capitalist system. George’s theory, Haley recalled, opened up to her “a wide world” of economic restructuring for social improvement and helped her develop her own ideas about teachers’ responsibility to engage in social change.

In 1883 Haley moved with her family to Chicago, and from 1884 to 1900 she taught sixth grade in an elementary school in the Stockyards district. During this time, she studied Progressive child-centered education under Francis Parker at the Cook County Normal School, where she paid particular attention to Parker’s ideas about the role of the teacher. Along with his influential ideas about pedagogy, Parker believed that the individual classroom teacher needed to have the authority of a policymaker—a novel role for female elementary schoolteachers. In later years, Haley studied Progressive pedagogy again at the Buffalo School of Pedagogy in New York State, where she heard William James deliver his “Talks to Teachers on Psychology.” In another summer, she attended a Catholic summer school in Wisconsin that was part of the liberal social movement of the American Catholic church designed to expose parochial and public school teachers to contemporary social prob-

lems and secular intellectual debates. From these varied educational experiences in different parts of the Progressive education movement, Haley learned about the importance of academic freedom, the professional role of the teacher, and the value of shaping the school as a community.

Contrasting with these ideals was Haley’s experience as a teacher in one of Chicago’s poorest school districts. For sixteen years, Haley taught sixth grade in the Hendricks school in the heart of the poverty-stricken meatpacking district of Chicago. Her students were the poorest of the city’s immigrant children, and her classrooms were crowded, underserved, and for most of her students, the last education they would ever experience. By her late thirties, Haley had merged her Progressive educational training with her readings in labor and political theory to develop a strong belief about teachers’ right to shape and control their own workplace, and about the responsibility of the state to support public schools.

### The Chicago Teachers Federation

In 1897 Haley joined the Chicago Teachers Federation, which was recently organized by a group of women elementary teachers to defend a legislative attack on a newly instituted pension law. She quickly rose to district vice president of the federation and began an investigation of the board of education’s claim that a shortage of school funds necessitated a freeze on a promised salary increase for teachers. Haley found that the shortage was due to the tax underassessment of a number of Chicago’s largest corporations, and she led a successful lawsuit in state courts to assess the corporations their full value and assure the promised salary increase. Haley’s leadership of the tax equity battle gained national attention, drawing the praise of a wide variety of social, political, and educational reformers. The fight also spurred teacher membership to the federation so that by 1900 more than half of all Chicago elementary school teachers were members of the federation, making it the largest women’s union in the country.

Haley quickly molded the federation into a powerful political force in Chicago politics. She shared the leadership with another Irish-American elementary teacher, Catharine Goggin, who balanced Haley’s aggressive and legalistic mind with more politic organizing skills. Under their leadership, the federation developed a weekly news bulletin, teacher education programs, and a well-oiled

political organization of teachers across the city. With the federation, Haley consistently advocated for a stable pension plan and tenure laws, arguing that the single women who made up the bulk of the elementary teaching staff were in particular need of job and pension security. She battled repeated attacks on federation authority in the state house, and directed a relentless publicity campaign that kept the federation in the public eye.

### **American Federation of Teachers**

To strengthen the federation's authority, she negotiated an unprecedented affiliation with organized labor by joining the predominately female federation with the industrial Chicago Federation of Labor in 1902. In 1916 the federation became Local 1 of the newly formed American Federation of Teachers.

Haley also fought for women teachers' rights in the National Education Association (NEA), which she accused of being administratively biased, excluding the voice and interests of elementary teachers. In 1901 she became the first woman and first elementary school teacher to speak at a public forum of the NEA, and she promoted the reorganization of NEA elections to facilitate the election of candidates who were women classroom teachers. In her notorious 1904 speech before the NEA, "Why Teachers Should Organize," Haley laid out her reform proposals not only for the organization of protective unions for teachers, but also for an expanded notion of teacher professionalism that included the opportunity to develop progressive pedagogy, improve educational practice, and promote the democratic participation of teachers in school administration. In 1910 she orchestrated the election of Chicago school superintendent Ella Flagg Young as the first woman president of the NEA.

### **Politics**

Haley's individual politics took her across a wide spectrum of the American Left. She supported women's suffrage, child labor laws, direct primaries, and tax reform, and was a member of the Women's Trade Union League. She lived and worked in a wide circle of women political leaders, including Ella Flagg Young, Jane Addams, and Catharine Goggin. A self-educated legal scholar and political tactician, Haley was a popular consultant to fledgling teachers' organizations and women's groups.

Yet Haley's persistent commitment to women teachers' rights kept her on the margins of other so-

cial reform movements. She was excluded from much of middle-class Protestant women's reform because of her class and religious background, and because of her staunch affiliation to labor. Yet male-dominated labor groups also marginalized Haley and her teachers, holding them out as white collar feminized workers who threatened the solidarity of the industrial working class. Haley's refusal to align with more radical groups, including socialists, anarchists, and African Americans, also limited her power. Furthermore, Haley's strong identification of the federation as an elementary teachers' group for women kept her apart from newer organizations. As a broader teacher union movement grew in the 1920s, Haley was left behind by other groups that sought to include secondary teachers, male teachers, and teachers of color.

### **Haley's Contribution**

Haley's federation was at its peak influence between 1909 and 1915 when federation friend Ella Flagg Young was superintendent of the Chicago schools. In 1915 a city law prohibiting teachers from joining labor unions forced Haley to withdraw the federation from the Chicago Federation of Labor. In 1916 her long-time colleague Catharine Goggin was killed in a traffic accident. Through the antilabor 1920s the federation declined in power, and Haley's influence faded through the 1930s as a new generation of teacher union leaders joined the American Federation of Teachers. Jealously guarding the authority of the federation, Haley refused to merge with the new groups. Her strong and opinionated character furthered her marginalization during the difficult economic years of the Great Depression, when she opposed the militant street tactics of the striking teachers in Chicago's American Federation of Teachers. To younger teachers, she may have appeared an outdated bossy spinster of a previous century.

Although Haley was a swaggering giant in Chicago and educational politics, in physical appearance she was a petite and stylishly attired woman. Haley could disarm her opponents by her quick wit and charm that she used to maneuver loyalties among city, labor, and education officials. Margaret Haley never married, and she left almost no personal records with which historians could describe her private life. Clearly, however, she led an intense and peripatetic life in which her professional life doubled as her private life. Throughout her career with the

Teachers Federation, she lived with various women federation members, including Goggin. Her few recorded words of personal affection are about her parents and her five younger brothers and sisters, with whom she felt a deep affection and almost mystical connection throughout her life. She died January 5, 1939, at age 77. She is buried next to her sister Eliza, a fellow teacher and federation member, in Joliet.

### HALL, G. STANLEY (1844-1924)

The "father of adolescence," G. Stanley Hall is best known for his prodigious scholarship that shaped adolescent themes in psychology, education, and popular culture. Granville Stanley Hall was born in a small farming village in western Massachusetts, and his upbringing was modest, conservative, and puritan. He began his scholarly work in theology,

but traveled to Germany to study physical psychology. He would produce over 400 books and articles and become the first president of Clark University, in Worcester, Massachusetts, but his greatest achievement was his public speaking about child-centered research, education, and adolescence to a society in transition.

With the 1883 publication of "The Contents of Children's Minds," Hall established himself as the leader of the "child-study" movement, which aimed to utilize scientific findings on what children know and when they learn it as a way of understanding the history of and the means of progress in human life. Searching for a source of personal and social regeneration, Hall turned to the theory of evolution for a biologically based ideal of human development, the optimum condition of which was health. His pure and vigorous adolescent countered the fragmented, deadening, and routinized qualities of urban industrial life. Hall theorized adolescence as the beginning of a new life and welded this vision to a scientific claim that this new life could contribute to the evolution of the race, if properly administered.

Hall's work lent scientific support to the "muscular Christian" approach to education, an intersection of morals, physical health, and economic productivity that was popular among the reformers who started the Young Men's Christian Association (YMCA), Boy Scouts, and other character-building organizations. Central to this view of health attainment was a rational inventory and investment of limited energies in profitable activities. The reformers of boys were vigilant in their denunciation of masturbation as wasteful sexual activity. As president of Clark University, Hall sponsored Freud's visit to the United States in 1909 and likely accepted Freud's ideas about sexuality, motivation, and the problems of repression. However, Hall also believed that freely expressed sexuality would too often lead to debauchery, so the sexualized energies of boys needed to be promoted yet protected, managed, and channeled.

Fittingly, Hall recommended schooling that mixed Rousseau's emphasis on covert control of male pupils with a strict social efficiency attachment to education for future lives and roles. Hall's educational prescriptions for adolescents emphasized the following six areas:

- Differentiated curricula for students with different futures, that is, an efficient curriculum, in-

cluding an education for girls that emphasized preparation for marriage and motherhood

- The development of manhood through close supervision of the body, emphasizing exercise and team sports and minimizing draining academic study
- An education that drew upon and utilized the expression of (boy-stage) emotions through emphases on loyalty, patriotism, and service
- A curriculum sequence informed by recapitulation theory or cultural epochs (i.e., study of the stages believed to have been key developmental points of the race. A cultural epochs curriculum focused upon “great scenes”: sacred and profane myths and history, from folklore and fairy tales to Robinson Crusoe and bible studies, ending with St. Paul and Luther and the powerful stories of reformation and nationalization. Stories of great men would be used throughout to draw boys into the tales and to build on their natural interest.)
- A school program that kept boys as boys and discouraged precocity or assuming sexual adult roles at a young age
- An administrative gaze schooled to watch youthful bodies

Hall and other “boyologists” identified play as central to creating young men who had disciplined spirit and would obey superiors. Play was revered for making children and adolescents moral and strong via direct and efficient processes, unlike the passive, unfocused, and feminized school curriculum. Cognitive approaches to civilized behavior were deemed unsatisfactory. Play invoked muscles directly, and muscles were believed to be the location of automatic, instinctual morality. Muscles, if properly prepared, carried civilized morality, instantly accessible. Expertly organized play would promote discipline and control, qualities lacking in the immigrant children who were the play reformers’ main targets. The play reformers, like the Boy Scouts, consciously nurtured peer relations to replace “unsatisfactory” families and extend expert influence by promoting boys watching over other boys.

At the beginning of the twentieth century, public schools, private philanthropic endeavors, Boy Scouts, Girl Guides, and juvenile courts participated in an enlarged and intensified discourse about adolescence. Modern facts of adolescence, produced by G. Stanley Hall and his colleagues and students,

emerged in a social context of worries over degeneracy and progress. Although adolescence had been demarcated before the late 1800s, the youth/adult boundary became sharper, more intently watched, and democratically applied to all youth. Hall emphasized adolescence as a new birth and the last chance for race improvement. Slow, careful development at adolescence must be vigilantly guarded; precocity had to be prevented. He and his colleagues issued “pedagogical imperatives,” that is, disciplinary and instructional techniques that were essential for each stage of boyhood and adolescence. Thus, laissez-faire approaches to youth were deemed likely to lead to moral anarchy, and the administrative gaze of teachers, parents, psychologists, play reformers, scouting leaders, and juvenile justice workers was cultivated everywhere.

Hall’s work has commonly been assessed as discredited and outdated, buried along with recapitulation theory by the 1930s. However, Hall’s ideas and their applications in education, scouting, and team sports remain foundational. Hall’s work defined adolescents in modern, scientific terms, that is, as natural and outside of social relations and history. The shapers of the modern, scientific adolescent made growing bodies and sexuality primary foci and the measures to prevent precocity enhanced youth’s economic dependence. At a time when movie theaters, dance halls, and other new, urban pleasures beckoned, public focus on youth revolved around misuse of leisure time. Finally, Hall contributed to scientific knowledge about adolescents that catapulted youth ever more firmly into their peers’ company (expertly guided by psychologists, social workers, and teachers). Hall’s ideas continue to shape contemporary discussions of adolescent biology, growing bodies, peer-orientation, and problematic leisure time.

## HANDWRITING, TEACHING OF

Since the advent of the typewriter, penmanship has been increasingly devalued, even ignored, in the curriculum. Despite the ubiquity of computers, handwriting is still an important means of note taking and communication. Bad handwriting, it has been shown, leads to lower grades in school. Bad handwriting skills may cause the writer physical pain and mental distress. An inappropriate grip on the writing instrument may lead to cramps and an inability to write with speed. This inability to keep up with one's thoughts leads to frustration, which may, in turn, inhibit a child's learning to compose. Illegible handwriting is a failed attempt at communication.

Qualities sought in penmanship are legibility, speed, ease, and individuality. Handwriting is a physical skill that is best learned early, and requires "a competent level of instruction in the components of the physical task." (Alston and Taylor, p. 2). Extra help given to those having trouble at an early stage can often prevent failure in later years. Unfortunately, modern teachers are not usually taught how to teach handwriting. Nor do they have enough class time to work with children individually, which is the proper way to diagnose individual problems and counter them.

Penmanship was, with the rising importance of commerce in the eighteenth century, and before typewriters, an essential job skill. The teaching of handwriting was a major task of education. It is helpful to look at the changes in styles, materials, and teaching methods over time to see the evolution of the current state of handwriting in American education.

### The Eighteenth Century

Early colonists brought with them the hands and teaching methods of their native lands. A variety of hands were taught to be used in various occupations (e.g. law, accounting), or by different groups of people (e.g. university students, women, gentlemen, clerks). Instruction in reading came first; for many who came to the New World, the ability to read the Bible was necessary for all. The ability to write was required only of professionals, the well-born and their secretaries, and merchants and their clerks.

Teaching was accomplished by the rote copying of exemplars set for each student by the writing master. As demand for training increased with the burgeoning economy, a lack of skilled masters led to the use of printed exemplars.

Late in the eighteenth century, a backwoods American teacher named John Jenkins revolutionized the teaching of handwriting by breaking all lower case letters down into six principal pen strokes, which were learned separately and then combined into letters. This method, plagiarized and modified, was used for decades, both in the United States and in Europe. The hand was still the basic English Round hand (often termed *copperplate*), used throughout Europe for commercial purposes since the mid-seventeenth century.

Jenkins's analytical system also required the student to memorize a dialogue about the principal strokes and the letters formed from them before actually writing letters with ink on paper. This memorization persisted through much of the nineteenth century; decades later, Platt Rogers Spencer would still require students to memorize an oral analysis of letters. Another of Jenkins's innovations was the inclusion in his writing manuals of detailed recommendations on teaching methods.

### The Nineteenth Century

Copy slips, with each exemplar printed on a separate piece of paper, grew into copybooks, with blank lines

below the text for the student to imitate the exemplar, thus requiring a new book for each student. By the 1870s there were graded series of books, with accompanying teacher's manuals, wall charts, and other teaching aids. Competition intensified in the nineteenth century, as city, town, or state school boards began selecting textbooks, including penmanship systems, for entire school systems.

An ever-increasing emphasis on speedy handwriting for commercial needs was met by modifications to the letterforms taught and the introduction of new methods of movement. Fewer hands were being taught by the beginning of the century. By 1805 beginners started with a large-sized Round hand, then moved into a *running hand*, similar to the Round hand but faster, because every letter within words was joined. Also offered was a miniaturized version of the cursive, thought suitable for girls.

The letterforms would degenerate throughout the century in two conflicting streams: the stronger current moving toward simpler, faster, more colorless letterforms; and a contradictory cross-current created by the exploration of the decorative possibilities inherent in the use of the flexible steel pen point. These pens, which replaced quills for general use in the 1830s, made possible the extreme thick-and-thin lines in mid-century letterforms. Spencer was the most famous exponent of these attenuated forms.

B. F. Foster introduced "muscular movement," derived from Joseph Carstairs in England, into the classroom in the 1830s. This technique depended on forearm movement, although finger movement was allowed after the student reached a certain level of proficiency. From this point, handwriting practice became more group-based, involving classroom drills.

The famous Spencerian handwriting and the similar system of Spencer's main competitors, Payson, Dunton, and Scribner, returned to the more logical combined use of arm, forearm, and hand movements. These systems still relied heavily on classroom drills and timed instruction.

All the eighteenth- and nineteenth-century systems were taught by copying and correction, so that each student would achieve an exact imitation of the style being taught. Teaching individual handwriting style was not an issue until the typewriter took over business writing and made handwriting newly personal.

Toward the end of the nineteenth century, doctors in Europe, concerned about what would now be called the ergonomics of writing, grew disturbed with the postures and methods of penmanship. A new style, Vertical Writing, unslanted and with simplified letterforms, was introduced to the United States from England and widely adopted by all the publishers of penmanship manuals, including the heirs of Spencer. The copybooks claimed that it was natural and more like print, and so it served as a foreshadowing of manuscript writing.

### The Twentieth Century

The Palmer Method was the dominant system of the twentieth century. A. N. Palmer introduced his system in the 1880s; by 1928, three-quarters of all schoolchildren in the United States were being taught by the Palmer method. The simple, unshaded letterforms were built for speed, taught by drill to establish "kinesthetic memory," and written with a new technique based on arm movement alone (i.e., no finger movement). Unfortunately, while the students remembered the drills all their lives, their handwriting was not particularly successful. Tamara Thornton suggests that the penmanship drill was used especially in cities as lessons in conformity, to assimilate immigrants into mainstream citizenry.

### Manuscript Writing and Other Systems

In 1913 the English calligrapher Edward Johnston gave a lecture at a teachers' conference in which he recommended that the student use a broad-nibbed pen and, starting from simple, rounded, Roman letterforms, achieve a formal italic hand, which would develop into a decent, useful, everyday handwriting. Inspired by the lecture, a group of educators developed *manuscript writing* (also known as *ball-and-stick* or *print-script*), simplified letterforms based on circles and straight lines. This system was, however, not quite what Johnston had in mind.

Until this time, it should be emphasized, children started writing a cursive script from the beginning. Marjorie Wise, an English educator, brought manuscript writing to the United States in 1922, where it was first adopted by progressive schools, and rapidly increased in popularity to the extent that manuscript writing was included in the Palmer company materials. A major advantage of the system was that children could start learning to write at a younger age, with less developed motor skills. With manuscript writing, reading and writing were taught

in parallel for the first time. Also, the introduction of manuscript writing was associated with the idea that children want to learn to write to communicate, although creative writing would not be standard until the 1950s.

There is still controversy over manuscript writing in the early twenty-first century; advocates say it is closer to modern type styles and so easier for the beginner to learn; critics point out the difficulty of transition from print-script to cursive, or the disadvantages of never taking up cursive at all, a system which also has its advocates. There is a wide variety of manuscript writing programs and styles. The early ones had the disadvantage of pairing their geometric print-scripts with contemporary cursives (Palmer in the United States and Vere Foster in Britain), which were quite different. Schemes were developed with more developmental logic between print and cursive, including Marion Richardson's in the United Kingdom and Donald Neil Thurber's D'Nealian in the United States.

Some advocate starting with cursive, citing advantages for early writers in not needing to think where to start each letter, and a clearer division between words. This new idea (which is, of course, an old one) is the standard method in France and Germany. In France's carefully thought-out system, children start preparatory exercises at age three, and are surrounded by signs and texts in a nationally standardized script, all of which help the student learn handwriting earlier and with more success (but less individuality) than American practices.

Calligraphers and other historians of letterforms, including Alfred Fairbank in England, Paul Standard in New York, and Lloyd Reynolds in Oregon, have been advocating italic forms since the 1930s. Italic forms have the simplest transition from basic letterforms to mature cursive writing, and allow for considerable individualization.

Participants in the debate over handwriting education in the twentieth century included not only calligraphers and publishers of the educational materials, but also academics, including statisticians and psychologists. The scientists developed quantitative handwriting scales to evaluate handwriting starting in 1909, but their advice that handwriting required the use of not just Palmerian arm movements, but also the coordinated movements of finger, hand, and wrist, were ignored for decades.

Throughout the twentieth century, both publishers and researchers concentrated on reading

rather than writing. Classroom teachers, often left with little official encouragement and training, pursued their own ways.

Contemporary handwriting research has focused on issues such as type of script, the use of evaluative scales, handedness, ergonomics (grip and posture), tools (writing instrument and paper), and, occasionally, teaching methods, including teacher training and use of pre-writing activities. While no one writing style or approach has been shown to be "the best," consistency of model through early grades does appear to be important, as long as the system is well thought-out.

Left-handedness is no longer disapproved of; instruction in this field concentrates on the different techniques needed to aid the left-handed writer, especially with appropriate grip and paper position. Some individual variation in grip is now considered appropriate for both right- and left-handed writers; however, it is important for the teacher to know which grips will lead to handwriting dysfunctionality, including cramps and lack of speed.

A variety of writing implements is also now considered appropriate, with the student and teacher choosing the one that feels best. Fat pencils used by early writers may lead to an inappropriate grip. Rubber or other pencil prosthetics may help students trying to overcome a bad grip.

Much work has centered on the use of lined versus unlined paper; there is some suggestion that first writers work best with unlined, but there are a variety of research results supporting other opinions.

A variety of pre-writing activities have been recommended, including drawing, painting, threading beads, building blocks, and play dough, aimed at encouraging better pencil hold, and helping to develop isolated finger movements, kinesthetic memory, and upper limb muscle tone. Montessori methods, including writing in sand, tracing letters on sandpaper, and other sensory techniques, have also proved useful.

Much attention has been paid to the handwriting training of dyslexic and learning disabled (LD) students, who need more early intervention to prevent formation of bad writing habits. It has been suggested that it might be easier for these students to start with cursive rather than manuscript writing, both because it is easier physically to write joined letters, and to forestall the switchover from print to cursive. Inconsistent models and teaching methods

within a school make progress particularly difficult for less able children.

Handwriting continues to be an important skill, a building block for success in personal expression. Teaching the teacher to diagnose and remedy problems is vital. Individual attention to students, although often difficult or impossible given large classes, is necessary to achieve good results—pupils with writing that is legible, flowing, and individual.

### HANNA, PAUL R. (1902–1988)

An educator initially trained in elementary education, Paul R. Hanna gained his greatest fame in both social studies and international education.

Hanna was born in Sioux City, Iowa, his father a Methodist minister and his mother the daughter of Swiss immigrants. He entered Hamline College (now Hamline University), and upon graduation in 1924 he enrolled at Teachers College, Columbia, from which he earned an M.A. in 1925 and a Ph.D. in 1929. He served as superintendent of schools in West Winfield, New York, from 1926 through 1927. On the faculty of Teachers College from 1929 through 1934, Hanna then joined the Stanford University School of Education, from whence he retired in 1967, having served a brief term as acting dean in 1963. After retiring he was a senior research associate at the Stanford-based Hoover Institution for War, Revolution and Peace and he continued his extensive work in international education, which he had begun while at Stanford.

Hanna was a pioneer in a number of areas of school curriculum. In the 1930s he explored the notion of the expanding environments model for elementary social studies, and beginning in the 1950s he popularized this model through his editing and writing of the Scott Foresman social studies textbook series. Hanna initiated a strong research component that focused on generalizations identified from the social sciences that could be used as a content base for the series. This was an issue first broached by the American Progressive educator Harold Rugg in the 1920s and reappears today in the demands for curricular standards in history and the various social sciences. He explored the notion of what is now called *service learning* for young people. With his wife, Jean, Hanna also produced some of the most popular spelling series for school use. These books were based on research that Paul and Jean Hanna did within and outside schools. Hanna's elementary social studies periodical series, *Building America* (coproduced and written with James Mendenhall),

was revolutionary in its approach to topics, reflecting contemporary social concerns. These monthly picture magazines attempted to present what made such issues so important to Americans. Late in life Hanna returned to the social studies as the topic of his writing.

Hanna was also committed to and instrumental in developing international education. Hanna pursued understanding of international issues through education, serving in Latin America in 1940 through 1941 within the Coordinator of Inter-American Affairs Office. Following World War II he was one of a team of educational experts that served in Germany to advise the Office of Military Government for Germany on educational affairs. Hanna was appointed in 1948 as an elementary education and teacher education specialist with the United Nations Educational, Scientific and Cultural Organization's educational mission to the Philippines, ending his term in the summer of 1949. He returned in 1952 as a director of education for the Mutual Security Agency's mission to that country, serving to June of 1953. He also traveled on missions to Burma, the Canal Zone, and Yugoslavia, eventually becoming the founder of a degree program in international education in 1952. This later evolved into the Stanford International Development Education Center (SIDECE), which includes many of the world's educational leaders as alumni.

In his last years Paul Hanna became more active with the Hoover Institution, and he and his wife founded the Paul and Jean Hanna Collection on the Role of Education in the Twentieth Century with a large financial gift in the late 1970s. They continued to add to the gift, and Hanna traveled across the country soliciting materials for the collection. The collection publishes periodic guides and thus is accessible to scholars worldwide.

MURRY NELSON

## HARPER, WILLIAM RAINEY (1856–1906)

The first president of the University of Chicago, William Rainey Harper was a leading figure in the development of the modern university in the United States. He was born in New Concord, Ohio, and was considered an academic prodigy, enrolling at age ten as a freshman at Muskingum College where he studied language and music. After graduation at age fourteen, he went to Yale and earned a Ph.D. in Philology in three years. While in graduate school he courted Ella Paul, daughter of the president of Muskingum College. They were married a few months after Harper completed his Ph.D.

Following his advanced studies at Yale, Harper was a teacher and principal in Tennessee and Ohio before accepting an instructorship in Hebrew Theology at the original University of Chicago. He became a full professor of divinity in 1880. In 1886 he was named president in the university's final year.

Upon the closing of the university he went to Yale as professor of Semitic languages in the graduate department and instructor in the divinity school. He taught Hebrew, Assyrian, Arabic, Aramaic, and Syrian. He continued to oversee his summer schools, journals, correspondence school, and printing office. Soon he branched out into lecturing, and began giving courses on the Bible to the public, finding a new means by which he could expound on its origins.

## The University of Chicago

Harper's reputation as a prodigious scholar of religion, combined with his Baptist affiliation, attracted the attention of John D. Rockefeller, who was making plans and generous donations for the founding of a university. Harper accepted Rockefeller's invitation to be the first president of the new University of Chicago in 1891, and served fourteen years until his death in 1906 at the age of forty-nine.

Although Harper was impressive as a scholar, his enduring contribution to American higher education was as an organizational genius and innovative leader. He was gregarious, and worked well with civic leaders and donors in Chicago. Harper was unabashedly ambitious in his plans for the new University of Chicago, and transformed that zeal into successful and even ruthless recruitment of talented faculty, students, and administrators. He gained the envy and scorn of college presidents across the nation when he "raided" the faculty of Clark University in order to enhance the behavioral sciences and psychology departments at Chicago. In concert with Professor Albion Small of the sociology department, whom Harper named dean, the University of Chicago pioneered such innovations as an elaborate bureaucracy of academic departments and ranks. In sum, Harper housed a modern, innovative university in the historic motifs of a monumental Gothic Revival campus that was the pride of the city.

Harper was known as Chicago's "Young Man in a Hurry." As president of the University of Chicago, Harper understood and thrived in the setting of a complex, multipurpose institution. He added new features such as a two-year junior college and an extensive summer school. He planned and obtained generous funding for scientific laboratories, an observatory, a university press, a graduate school with numerous Ph.D. programs, research institutes, and a library. At the same time he also emphasized intercollegiate football with a magnificent stadium geared to a large spectator audience. His hiring of Yale's Amos Alonzo Stagg as football coach and athletic director was instrumental in making the University of Chicago Maroons the dominant champions of the Western (Big Ten) conference. And Stagg, with Harper's approval, created the prototype for the highly commercial athletic department that had direct access to the president and the board of trustees, with little accountability to faculty governance.

Although Harper was an historian of religion, as a campus leader he felt no deference to academic tra-

ditions, whether in admissions examinations or degree requirements. He endorsed the coeducation of men and women. He relied on advertising, billboards, and mass mailings to promote all facets of campus programs and activities. He was committed to systematic public relations and fund raising. He served on numerous boards and committees in the city and nation. The University of Chicago was to be a young, modern university that was central to a dynamic metropolitan area, and that created the national prototype for a truly great American university.

## Contribution to Academia

In 1905 Harper's doctors discovered that he had cancer. In his final months he published a book about education; revised two scriptural articles; published a biblical text; and finished his greatest piece of scholarly work, his *Commentary on Amos and Hosea*. With his characteristic energy, Harper even on his death bed was busy making plans for his elaborate funeral procession, including detailed instructions for Chicago faculty to march wearing full academic regalia.

JASON R. EDWARDS  
JOHN R. THELIN

## **HARRIS, WILLIAM T. (1835–1909)**

An important educational philosopher and statesman of the late nineteenth century, William Torrey Harris served as the chief administrator of the St. Louis Public Schools from 1868 to 1880 and as the United States Commissioner of Education from 1889 to 1906.

Beginning his career in 1857 as an elementary school teacher in the St. Louis public school system, Harris progressed through the ranks, becoming superintendent in 1868. During this same period, his life as a philosopher flourished. He founded the *Journal of Speculative Philosophy* in 1867, and became an important part of a small group of scholars and educators who studied the German philosopher Georg William Friedrich Hegel, a community that would become known as the St. Louis Philosophical movement.

Like Horace Mann, Harris was an advocate of the free common public school. He was an egalitarian who helped to extend the reach of the school, and provided a national model in St. Louis for the kindergarten in the school system. He believed in the separation of church and state in public schooling and reinvented the nature of school discipline by criticizing corporal punishment and favoring self-discipline that was based on internalized moral values. He made the library a normal feature of the school's infrastructure, expanded foreign language education in the curriculum, defended the importance of coeducation, was open minded about new pedagogical ideas (including Pestalozzi's object teaching), and emphasized the importance of perpetual self-education. He worked to universalize public education across class, gender, and racial lines, seeing the school as fundamentally a child-saving agency, and served under four different U.S. presidents during his seventeen-year tenure as Unit-

ed States Commissioner of Education. Many of his views on schooling can be discerned from the twelve annual reports he wrote for the St. Louis public schools during his time in the superintendent's office and from the various reports he authored as U.S. Commissioner of Education.

His philosophical life overlapped with his actions as a school leader. A dutiful follower of Hegel, Harris's philosophy of education elevated the importance of freedom and reason—and self-direction as it was guided by the institutions of civilization. Schooling was one of the processes that allowed youth to rise above their inborn savagery and to participate in a civilizing life. The school was supposed to bring students face-to-face with the accumulated wisdom of humanity and to teach them to find their place in the spiritual nature of all existence. The core philosophical tenets in Harris's life not only played a significant role in his handling of school matters, but also kept him quite busy with philosophical disquisitions, writing essays such as "Goethe's Theory of Colors," "The Phenomenology of Spirit," and "Aristotle's Teleology." These were certainly not typical writings for a professional school administrator. The *Journal of Speculative Philosophy*, which Harris founded and edited, produced a very real contribution to philosophical discourse, highlighting the work of various important thinkers over its twenty-one year run, including John Dewey, William James, Charles Pierce, Josiah Royce, G. Stanley Hall, and George S. Morris. It also featured much of Harris's most gritty philosophical essays, an output of more than 35 articles over the life of the journal. In 1879, Harris became a faculty member at A. Bronson Alcott's Concord School of Philosophy, where he taught primarily on the topic of Hegel. He stayed there until 1888, when the school closed because Alcott died.

Harris sided squarely with a subject-centered view of learning, believing that the wisdom of humanity resided in modern academic subjects and that, for democracy to flourish, public schools had to bring this civilizing insight to the experience of all American youth. This was a prejudice reflected in Harris's influence over the Committee of Ten and the Committee of Fifteen reports, which both helped to crystallize the subject curriculum in the school. Harris, in fact, established the foundational principle of bringing the common academic curriculum to the common school, not for preparation for college but for life in a self-governing democracy.

To Harris, the nature of course study in the public school was largely reducible to what he saw as the five great divisions in the life of civilization, which he labeled “the five windows of the soul.” Two of the windows (or areas of inquiry), mathematics and geography, were committed to humanity’s conquest and comprehension of nature. The other three, literature, grammar, and history, were more connected to human life: literature speaking to literary works of art; grammar, to the study and the use of language; and history, to a multifaceted understanding of the nation’s institutions. Harris reflected these ideas in his various circles of influence. He was, for instance, the main author of the Committee of Fifteen 1895 report, which was designed to offer a course study blueprint for the American elementary school. Harris maneuvered against the American Herbartians, who sought to unify the course work in the elementary school around German philosopher Johann Herbart’s idea of curriculum concentrations, where one subject, usually literature, is made the central core of the learning experience, and other subjects are organized around on the basis of their interrelations to the core’s main features. Harris did not accept this idea of concentration, believing that the five windows of the soul would be weakened when made subordinate to one core area. Instead, he called for a kind of coordination, where each subject is given a definite place and equal attention. The Committee of Fifteen report bears the unmistakable stamp of Harris’s five windows of the soul and is an early example of the kind of subject-centeredness that would mark Harris’s ideas on the curriculum.

Harris’s dedication to the common cultural canon eventually earned him the tag of conservative among some historians, a label that some modern-day scholars have found to be unnuanced and not nearly appreciative enough of the many progressive ideas that Harris also supported. Yet, Harris was undoubtedly among the most effective critics of educational progressivism in his day. He was especially critical of ideas that failed to capture what he believed to be the intellectual and civilizing qualities of the subject curriculum. Harris held in low regard the Progressive ideas embodied in the American child study movement, American Herbartianism, and the expansion of the curriculum into manual or vocational arts instruction. For him they were essentially anti-intellectual endeavors largely wasted on youth. In this sense, Harris became the subject-centered foil

to the prevailing child-centered views favored by Progressives at the turn of the nineteenth century.

## HARVARD UNIVERSITY

Harvard University, the oldest educational institution in the United States, was founded sixteen years after the arrival of the Pilgrims at Plymouth, Massachusetts. Established by the Massachusetts Bay Colony in 1636 and later chartered in 1650 in what is now the oldest corporation in the Western Hemisphere, Harvard University was named for its first benefactor, John Harvard of Charlestown, Massachusetts, who, on his death in 1638, left his library and a portion of his estate to the school. In 1640 Henry Dunster became the first president and also constituted the entire faculty. For more than fifty years Harvard remained the only college in America.

It has been said that “when Harvard speaks, the country listens,” and throughout its history Harvard, as the country’s premier university, shaped the direction of education in the United States. John Harvard’s bequest was the first of the private gifts for education in America, and the act of the colony in 1636 marks the beginning of state aid to higher education in the United States. *New England’s First Fruits*, an anonymous tract celebrating the establishment of higher education in the colonies, was published in London in 1643. Among the influential colonists were a number of Cambridge (hence Harvard’s city name) and Oxford graduates who were eager to replicate the English college in the American frontier. During its early years, Harvard College offered a classic academic course based on the English university model merged with the prevailing Puritan philosophy of the early colonists. Harvard College was loosely affiliated with the Congregationalist church; not surprisingly most of its first graduates became ministers throughout New England, while other graduates entered government service or private business.

### Curriculum

Harvard College’s course of study was similar to the curricula of Cambridge and Oxford universities. Unlike the English model, Dunster first created a curriculum for Harvard that only lasted three years, but in 1652 a fourth year was added. The Harvard core curriculum became a model for American education institutions to follow, not only colleges but also grammar schools and academies that prepared students for higher learning and collegiate studies. The curriculum from its founding through the eighteenth century was theological; early nineteenth-century studies expanded the curriculum to include Latin, Greek, mathematics (including astronomy), English composition, philosophy, theology, natural philosophy, and either Hebrew or French. This prescribed course of study established a pattern for American liberal arts colleges. The most common forms of instruction were oral exercises—the lecture, the declamation, and the disputation.

Charles W. Eliot, who served as president from 1869 to 1909, transformed the college into a modern university, a feat accomplished primarily by transforming the curriculum. Although course electives existed at Harvard throughout the nineteenth century, Eliot became an unrelenting advocate of the elective system, which in turn permitted him to initiate

institutional reform where college studies could accommodate broader as well as more specialized interests of students. The elective system permitted Harvard to become more responsive to the many evolving democratic, technological, and vocational needs of society. By the turn of the twentieth century, Harvard’s elective system was the freest in the country with no subject requirements for studies beyond the first year.

### Faculty

With the expansion of the curriculum, Eliot increased the Harvard faculty from 60 to 600 members. During Eliot’s administration Radcliffe College was established for women. Eliot and others refused to admit women to Harvard but were willing to create a coordinate college that would provide a similar education for women. In 1894 the Commonwealth of Massachusetts chartered Radcliffe College; Elizabeth Cary Agassiz served as this institution’s first president. She was followed by LeBaron Russell Briggs, the former dean of students and a professor of rhetoric at Harvard.

President Abbott Lawrence Lowell, who served from 1909 to 1933, refocused the undergraduate course of study to ensure that a liberal education would include concentration on a single field as well as a distribution of course requirements among other disciplines. James Bryant Conant, who served as Harvard president from 1933 to 1953, initiated the examination of general education, which in turn served to redefine the concept of *core curriculum*, a course of study that delineated breadth in interdisciplinary fields outside the student’s major field of study. Conant’s General Education Committee, which released in 1945 the legendary Harvard Redbook, *General Education in a Free Society*, set the direction for American college and secondary curriculum for the later part of the twentieth century. Under Conant’s leadership, in 1943 Harvard and Radcliffe agreed to enroll women students in Harvard classrooms for the first time. But women would not earn Harvard degrees until the 1970s.

Recent presidents Nathan M. Pusey, Derek Bok, and Neil L. Rudenstine have each contributed significantly toward strengthening the quality of undergraduate and graduate education at Harvard while at the same time maintaining the university’s role as a preeminent research institution. “Harvard has shaped the world of higher education,” said the late Ernest Boyer, president of the Carnegie Foundation

for the Advancement of Teaching. "It's the cathedral that provides inspiration for all the others."

ROBERT A. SCHWARTZ  
CRAIG KRIDEL

## HAVIGHURST, ROBERT J. (1900–1991)

Best known for his conceptualization of human development as mastery of a series of age-related cultural tasks, Robert J. Havighurst was an avid researcher, a prolific writer, and a civil rights activist. As a researcher, he conducted cross-sectional and longitudinal studies of the social, emotional, and moral development of children and adolescents in

various American subcultures (including Native Americans) as well as in several other countries. To illustrate his writing proficiency, a student pushed a large wheelbarrow filled with Havighurst's publications into the banquet hall during a celebration of his sixty-fifth birthday. His 1964 survey of the Chicago public schools drew national attention for its far-sighted yet controversial plan for school and community integration. Many of the twenty-two recommendations offered by the committee concerned the need for organizational and structural changes in the Chicago public schools. A key recommendation called for extensive decentralization of authority; another, for the creation of the modern day equivalent of "schools-within-schools."

A member of a distinguished academic family, Robert J. Havighurst was born the son of Freeman Alfred Havighurst, who was on the faculty of Lawrence College, and Winifred Weter Havighurst, who had been on the faculty until her marriage. He was the oldest of five children—four boys and one girl—and attended public schools in college towns in Wisconsin and Illinois. Following high school he attended Ohio Wesleyan University, receiving his B.A. degree in 1921. He enrolled at Ohio State University, receiving his Ph.D. in chemistry in 1924. Following receipt of his Ph.D., he went to Harvard University as a postdoctoral fellow, studying the structure of the atom and publishing papers in journals of physics and chemistry. He then spent a year on the faculty of chemistry at Miami University.

In 1928, he accepted a position as assistant professor of physics at the University of Wisconsin. He also served as an adviser in the Experimental College there. Largely as a result of his experience with the Experimental College, his interest in the problems of adolescents grew, eventually surpassing his interest in teaching the natural sciences. He left the University of Wisconsin in 1932, taking a faculty position in education at the Ohio State University Laboratory School.

In 1934 he became the assistant director for programs in science education for the General Education Board of the Rockefeller Foundation. It was here, under the guidance of Lawrence Rank, that he became involved in the study of children and adolescents. Within three years, Havighurst became the director of the board. In that role he was instrumental in the funding of research programs in child development at major universities and research centers in the United States. He was also able to provide funds

to enable refugee European scholars to resettle in the United States. Among those assisted were Bruno Bettelheim, Peter Blos, Erik Erikson, and Fritz Redl.

In 1941 Havighurst was appointed professor of education and executive secretary of the Committee of Human Development at the University of Chicago. For the next forty years, Havighurst conducted research and wrote on a variety of topics and issues.

From 1948 to 1953 he developed his highly influential theory of human development. The centerpiece of this theory was the developmental task. He defined a developmental task in the following manner:

A development task is a task which arises at or about a certain period in the life of the individual, successful achievement of which leads to his happiness and to success with later tasks, while failure leads to unhappiness in the individual, disapproval by society, and difficulty with later tasks. (1953, p. 2)

As a concept development tasks were able to merge the relative influences of nature and nurture. As Havighurst wrote:

Nature lays down wide possibilities in the developing of the human body, and which possibilities shall be realized depends on what the individual learns. This is true even of such crude biological realities as feeding habits and sexual relations, while the more highly social realities of language, economic behavior, and religion are almost completely the product of learning at the hands of society. (1953, p. 1)

To foster development, then, educators had to introduce students to these critical tasks at the "right time." This "right time" was described as the "teachable moment." "When the body is ripe, and society requires, and the self is ready to achieve a certain task, the teachable moment has come" (1953, p. 5).

In the 1950s and 1960s Havighurst directed a decade-long study of middle and old age. The results of this study, combined with his subsequent research, altered conventional wisdom about the aging process. His interest in life-span development continued throughout his life. He studied changes in the sex role behavior of men and women over fifty, the adaptation to the retirement process by male sociologists and psychologists, and alternative work schedules for older workers.

From 1967 through 1971, Havighurst directed the National Study of Indian Education, which was funded by the U.S. Office of Education. Native Americans were involved in planning the study as well as in the field work and data analysis. The results indicated that education for Indian youth across the United States varied widely according to numerous factors such as sources of funding, location, curriculum, faculty, degree of isolation, and cultural differences. Recommendations included finding ways for Indians to have an increased voice in their education and the establishment of a national Commission on Indian Education.

In the late 1960s and 1970s, Havighurst focused his attention on the problems of urban education. He conducted a study of public high schools in the forty-five largest cities in the United States, examining educational goals, school structure and organization, staff characteristics, curriculum, student activities, student activism, and school-community relations. He concluded that there was more and deeper segregation and separation of high school students of different socioeconomic and ethnic groups in 1969 to 1970 than there was ten or twenty years before. In 1977, at age seventy-seven, he coedited a book in which he developed a series of policies and practices for the improvement of big-city schools based on his research.

Havighurst continued to engage in research and writing well into his eighties, publishing six journal articles between 1980 and 1986. In his last published article, "The Challenge: 1985–2000," he argued that the challenge for the future of a democratic society is to develop educational programs that foster development in the areas of race and ethnic relations, civil rights, international relations, and gender role. At age eighty-six, there were still new developmental tasks. And, at age eighty-six, Havighurst was still looking toward the future.

## HEAD START

See: COMPENSATORY EDUCATION, *subentry on* UNITED STATES.

## HEALTH AND EDUCATION

The twentieth century saw extraordinary and dramatic improvements in human health. Life expectancy more than doubled, with most of the increase within the century's second fifty years. Improved income, higher levels of education, more and better food, better sanitation, public sewage systems, and new knowledge underpin these gains. This entry focuses on the effect of male and female education levels within the context of this broader range of determinants. The general discussion is illustrated with a more specific treatment of the child mortality rate across countries for the three decades from 1960 to 1990. Child mortality rate is defined as the number of deaths per 1,000 live births between birth and exact age five years; at the start of the twenty-first century the rate varies from less than 10 per thousand for high income countries to over 200 in some poor countries.

Education level has been constantly found to be related to the health status at the levels of individual, household, and country, usually with a stronger effect than that of income. Based on Jia Wang and Dean Jamison's 1997 estimations, one additional year of education for the female population can avert six deaths per thousand in child mortality rates. John Peabody and colleagues found that child

mortality rates in 1993 and 1994 Bangladesh varied across the mothers' education level: 134 deaths per thousand for mothers with some primary education; 105 for mothers who completed primary education; and 90 for mothers with secondary or higher education.

In consequence, one way governments can improve health is to expand investment in schooling, particularly for girls. The World Bank's 1993 World Development Report concluded that education increases the opportunities for households, particularly for mothers, to seek access to information and to make better use of the financial resources to shape the diets, fertility, health care, and other lifestyle choices that have a crucial impact on the health of household members. Children's health is affected much more by the mother's education level than the father's. Educated mothers tend to marry and start families later, factors that diminish the child health risk associated with early pregnancies. Educated mothers are also more likely to use preventive care and delivery assistance, maintain better household hygiene, seek immunization more frequently, and have better use of medical services. According to the World Bank study, a 10 percent increase in female literacy rates in thirteen African countries in the period of 1975 through 1985 reduced child mortality rates by 10 percent, while a 10 percent increase in male literacy rates had little to no effect in decreasing child mortality (p. 42).

To give a sense of the methods and recent results of analyses of education's impact at the country level, it may be valuable to provide a brief illustration. Improved data sets now exist that include the following variables on individual countries at different points in time:

- Child mortality rates for all children, for girls, and for boys
- Real gross domestic product (GDP) per capita adjusted for purchasing power parity, expressed in 1985 U.S. dollars
- Education level for the female population and for the male population, calculated as the average number of years of education for the population aged 15 and over, according to Robert Barro and Jong-Wha Lee.

These variables are measured at a five-year interval for the period of 1960 through 1990 and they are available for 94 countries. The average years of education for the female and male population are 4 and

4.9 years for the period of 1960 to 1990. The mean child mortality rate is 75 deaths per 1,000 live births for boys, 69 deaths for girls, and 63 for both boys and girls. The income per capita has a mean of \$2,368.

Education, income, and time (as a proxy for technical progress) are used by Anthony Bryk and Steve Raudenbusch as determinants of child mortality measures using hierarchical linear modeling (HLM). Jamison and Wang's 2001 study gives detailed information on data and methodology.

Three sets of analyses, with male education, female education, and both female and male education levels as the education measure, were done to assess gender differences in the effect of education on child mortality. Jamison and Wang found that an additional year of male education level is associated with a 3 to 4 percent reduction in child mortality. But the magnitude of the effect is statistically insignificant, whether it is child mortality for the whole population, for girls only, or for boys only. Female education level, on the other hand, has a statistically significant effect on all three measures of child mortality rates. The effect is about a 10 to 11 percent reduction in child mortality. Interestingly when the effect of time (or technical progress) is allowed to be country-specific the estimated effects of income and education on child mortality decline. That said, there is historical evidence to suggest that prior to major gains in medical science in the twentieth century, education had much less of an effect on mortality than today. The effects of new knowledge and of education appear to work together to contribute to the decline in child mortality.

This example confirms the existing literature on health and education in finding that higher education levels are associated with better health. A more careful look, however, finds that female education level has a much stronger effect in reducing child mortality rates than male education level, independent of whether it is the child mortality for boys only, for girls only, or for both.

## HEALTH CARE AND CHILDREN

The United States has the most sophisticated and advanced medical care in the world, attracting people from around the globe for treatment of complex and difficult health conditions. The extent to which individuals living in this country benefit from this care, however, depends to a great degree on whether they have health insurance. Studies consistently show that persons without health insurance are far less likely to use health services than those with health insurance. In addition, the number of people without health insurance is on the rise, providing more cause for concern. More than 42 million Americans under the age of sixty-five were completely uninsured in 1999.

While children's access to care is a function of a wide range of factors, including family characteristics and the organization of the health system, financial barriers such as lack of health insurance play a significant role. Health insurance is by far the most important predictor of whether children will receive needed health care. Uninsured children receive fewer aggregate annual physician visits than their insured counterparts, and they are significantly less likely than publicly insured poor children to identify a usual source of routine care.

Despite the predominant role of health insurance in access to health care, sizable numbers of children in this country are uninsured. While no age group is immune from the threat of losing health insurance, children make up a significant proportion of the uninsured. In 1999, 10 million children, nearly 14 percent of all children in the United States, were uninsured.

### The Importance of Access

Most children are healthy. Some may ask, therefore, why it is important for children to have access to health care. In fact, despite relatively good health, children do need access to regular health care, as well as access to special services when acute or chronic conditions occur. Moreover, children are distinct from other age groups in several important ways. For one thing, they are entirely dependent on their adult caregivers for health services. Children are incapable of making decisions about health care, purchasing services or insurance, or making judgments about the appropriateness of services. Children are also unable to voice preferences or to influence decisions made on their behalf. Thus, it is the responsi-

bility of adults to represent their interests and to ensure that their needs are met.

Children's health needs are also significantly different from those of adults. By nature, children grow and develop at rapid rates, placing them at special risk of being affected by illness and injury. If health problems are not identified and treated, they can affect a child's cognitive, physical, behavioral, and emotional development. It is therefore essential to identify and treat health conditions early to prevent or minimize the impact on overall growth and development.

Finally, the type, severity, and frequency of health conditions that children experience also differ from adults. Children generally experience a wider variety of health problems, but of less severity. Conversely, adults are more likely to have chronic degenerative conditions than children. But certain childhood conditions, though relatively mild in single instances, have the capacity to lead to long-term disabilities in children. For example, chronic otitis media (ear infections), if unchecked, can lead to hearing loss, and possibly learning disabilities. Other rare but severe conditions, such as spina bifida and sickle cell disease, manifest themselves early and require ongoing monitoring and expensive, tertiary care.

### The Role of Insurance

The groups most at-risk of being uninsured are adolescents, minorities, children living with a single parent, and children in poor and near-poor families (especially working families living at the near-poverty level). Family income and ethnicity are the factors most associated with being uninsured. In 1990, Hispanic children were more than twice as likely to be uninsured as non-Hispanic white children. Similarly, children in poor and near-poor families were more than twice as likely to be uninsured as children in more advantaged families.

The percentage of children without health insurance grew sizably during the late 1970s and the 1980s. Between 1977 and 1987, the percentage of children without any form of health insurance rose by 40 percent. Since then, the overall percentage of uninsured children has remained relatively stable, though the distribution of children within various sources of insurance has dramatically shifted. Between 1987 and 1993, the proportion of children covered by private, employment-based insurance

declined 12 percent, from 60.7 percent to 53.6 percent. Meanwhile, the proportion of children covered by Medicaid increased from 15.6 percent to 23.9 percent, and the number of children covered by Medicaid climbed from 10.0 million in 1988 to 20 million in 1999, reflecting a fundamental shift in the type of insurance children hold.

A number of factors account for this dramatic shift in the distribution of children's insurance coverage. A nationwide recession, in addition to the rising cost of medical care, affected the ability of insurance companies to provide increasingly expensive health insurance benefits. A rapid shift of jobs away from industries such as manufacturing, which typically have generous benefits, to service jobs industries, which typically offer few, if any, benefits, also contributed to changes in children's insurance status.

The large increase in the number of children covered by Medicaid is the result of legislative changes enacted by the Congress and the states in the middle and late 1980s, as well as the recession that pushed more families into poverty during the early 1990s. Following more than a decade of retrenchment in Medicaid eligibility at the state and federal levels, Congress enacted a series of Medicaid expansions between 1984 and 1990. These laws were designed to gradually cover additional low-income children and pregnant women, and to increase uniformity in income-eligibility levels across states. Virtually all poor children (with incomes below the federal poverty level) are eligible for Medicaid (with the exception of those who are undocumented).

These Medicaid expansions have produced important results. Numerous studies demonstrate that the availability of Medicaid has resulted in improved access to care among low-income children. Poor children with Medicaid were far more likely than poor uninsured children to have access to care, based on multiple dimensions of access, including the presence of a usual source of care, frequency of unmet health needs, and the use of medical services. Among adolescents, the impact of Medicaid has been even more dramatic. Although poor adolescents were 35 percent more likely than nonpoor adolescents to have waited two or more years between physician contacts, poor adolescents with Medicaid coverage used physician services at rates similar to nonpoor adolescents. The availability of Medicaid has also led to improvements among children in terms of the use of preventive services. A full year of

Medicaid increases the chances that a child will have a well-child visit by 17 percent, and also increases compliance with national guidelines from the American Academy of Pediatrics by 13 percent.

The State Children's Insurance Program (SCHIP), established in 1997, provides additional assistance to low-income children. This program is designed for uninsured children who are not eligible for Medicaid because their families' incomes are too high, but for whom private insurance is unaffordable. Close to 90 percent of these uninsured children have at least one parent who works, but for many of these families affordable health coverage is not offered through their employer. As of 2000, nearly 2 million children were enrolled in the program nationwide.

Unfortunately, both Medicaid and SCHIP suffer from under-enrollment. Of the 10 million uninsured children in the United States, more than half are likely eligible for either program. Studies show a variety of reasons for under-enrollment, including negative views about public insurance programs, confusion about eligibility, and complex enrollment processes. In addition, studies show that potential enrollees associate Medicaid with burdensome eligibility requirements, difficult enrollment processes, demeaning attitudes of eligibility workers, and inadequate services by health care providers. Other research has found that some immigrants fail to enroll in public programs because of their fear of potential ramifications for their immigration status. There may also be problems associated with communicating clear information about the programs. Research indicates that many low-income parents have not heard of SCHIP or are confused about their children's eligibility. Whatever the reasons, improvements in access to health care cannot be reasonably expected as long as eligible children are not enrolled in available programs.

### **The Limitations of Insurance**

Extending health insurance to low-income children has a beneficial impact on access. However, simply providing insurance does not mean that children will necessarily have full access to health care, especially among low-income children. Indeed, insured low-income children use fewer services than more affluent, insured children. Moreover, poor children with insurance are less likely to go to a private physician's office and more likely to utilize community health centers, compared to nonpoor children with

insurance. There are a number of reasons for these differences. The families of poor children with insurance face nonfinancial barriers to health care that insurance cannot address, such as lack of transportation, lack of child care, inconvenient location of services, and service hours that conflict with work. Children of immigrant families may face additional barriers, such as an inability to communicate in their primary language, fear of deportation, and cultural conflicts with Western medicine. For these reasons, providing insurance without developing a delivery system to serve the needs of low-income children does not produce the desired outcome of improved access to quality health care.

### Conclusion

All children need health care, whether for regular check-ups, for episodic health problems such as ear infections, or for chronic conditions. Because health services are relatively expensive, children's access to care is largely dependent on whether or not they have health insurance. Unfortunately, far too many children are not covered and therefore, do not receive needed care. One solution is to assist eligible children to enroll in public programs like Medicaid and SCHIP. As indicated, approximately half of all uninsured children are eligible for these programs. To achieve this goal, the process by which children enroll must be simplified, eligibility rules clarified, and any negative stigma about public programs removed.

Other efforts will also be required for uninsured children who are not eligible for these programs. Many of these children are undocumented, which means that rules preventing them from participating in Medicaid and SCHIP would need to be revised, or special programs must be created for them.

## HEALTH EDUCATION, SCHOOL

School health programs are said to be one of the most efficient strategies that a nation might use to prevent major health and social problems. Next to the family, schools are the major institution for providing the instruction and experiences that prepare young people for their roles as healthy, productive adults. Schools can—and invariably do—play a powerful role in influencing students' health-related behaviors. Elementary, middle, and secondary schools are therefore prime settings for public health programming: in 1999, nearly 99 percent of young people ages seven through thirteen and 96 percent of those between fourteen and seventeen were enrolled in school in the United States. Appropriate school interventions can foster effective education, prevent destructive behavior, and promote enduring health practices. For many young people in their formative years, school may, in fact, be the only nurturing and supportive place where they learn health information and have positive behavior consistently reinforced.

In addition, health and success in school are inextricably intertwined. Good health facilitates chil-

dren's growth, development, and optimal learning, while education contributes to children's knowledge about being healthy. Studies of young people have found that health-risk behaviors negatively affect: (1) education outcomes, including graduation rates, class grades, and performance on standardized tests; (2) education behaviors, including attendance, dropout rates, behavioral problems, and degree of involvement in school activities such as homework and extracurricular pursuits; and (3) student attitudes, including aspirations for postsecondary education, feelings about safety at school, and positive personal attitudes.

Schools cannot achieve their primary mission of education if students and staff are not healthy and fit physically, mentally, and socially. Children who are sick, hungry, abused, using drugs, who feel that nobody cares, or who may be distracted by family problems are unlikely to learn well. One child's lack of progress can impede the learning of the other children in the classroom as well. Education reform efforts are bound to be of limited effectiveness unless health-related barriers to learning are directly addressed. As Harriet Tyson writes, "First among those barriers are poor physical and mental health conditions that prevent students from showing up for school, paying attention in class, restraining their anger, quieting their self-destructive impulses, and refraining from dropping out" (p. 2). When surveyed, most parents and members of the general public consistently rate health as an important topic that schools should address.

Although reliable data on the implementation of school health programs are lacking, there are indications that few schools operate comprehensive, coordinated programs designed to systematically address the nation's major health risks. For example, 71 percent of high school students surveyed in 1999 did not attend a daily physical education class, and 44 percent were not even enrolled in a physical education class. Only 72 percent of the nation's schools participated in the federal School Breakfast Program during the 1999-2000 school year, despite the well-documented health and educational benefits of doing so. In 1994 health education staff were involved in joint activities or projects with staff from other components of the school health program in only 65 percent of middle and high schools. Health services facilities were not available in 32 percent of all middle and high schools in 1994. During the 1998-1999 school year, 76 percent of public high

schools and 55 percent of public middle schools operated vending machines, most of which were located in or near the cafeteria. The most common types of food offered in school vending machines are soft drinks, chips, desserts, and candy. Few schools are known to sponsor health promotion activities for staff.

Educators should work to ensure that every elementary, middle, and high school establishes and maintains comprehensive, well-coordinated school health programs. The American Public Health Association (APHA) supports the definition offered by the Institute of Medicine: “A comprehensive school health program is an integrated set of planned, sequential, school-affiliated strategies, activities, and services designed to promote the optimal physical, emotional, social, and educational development of students. The program involves and is supportive of families and is determined by the local community, based on community needs, resources, standards, and requirements. It is coordinated by a multidisciplinary team and accountable to the community for program quality and effectiveness . . .” (p. 2). There is no single ‘best’ comprehensive school health program model that will work in every community. Programs must be designed locally, and collaboration among all stakeholders in the community is essential if programs are to be accepted and effective.

### Characteristics of Effective Programs

There are eight elements that characterize high-quality school health programs. These elements are described below.

**1. A focus on priority behaviors that affect health and learning.** School health programs were initiated early in the twentieth century, in large part to address the numerous infectious diseases afflicting children. At the beginning of the twenty-first century, the etiology of health risks facing young people—and the adults they will become—are most often social or behavioral. The Division of Adolescent and School Health (DASH) of the Centers for Disease Control and Prevention (CDC) documents that six health-risk behaviors account for nearly two-thirds of the morbidity and mortality in adolescents. These behaviors are tobacco use; unhealthful dietary behaviors; inadequate physical activity; alcohol and other drug use; sexual behaviors that may result in HIV infection, other sexually transmitted diseases, or unintended pregnancy; and behaviors that may result in intentional injuries (i.e., violence and sui-

cide) and unintentional injuries (e.g., motor vehicle crashes).

The leading causes of death among adults—including cardiovascular disease, cancer, and diabetes—are closely linked to these health-risk behaviors. In addition, these behaviors tend to co-occur, they tend to be established in youth, and they are preventable. Children and adolescents need to learn, and to practice, making health-enhancing choices before health-damaging behaviors are initiated or become ingrained.

CDC’s Youth Risk Behavior Surveillance System provides reliable national data on the prevalence of specified behaviors. Most states, and some large cities, also conduct the Youth Risk Behavior Survey. Results from these state and city surveys, and other available state and local data from education and health agencies, can be used to plan school health program activities.

**2. A foundation of support for every child and adolescent.** Whether a student engages in health-debilitating or health-enhancing behaviors depends on the interplay of assets and deficits in the influential support systems surrounding the student, including friends, peers, family, community, and schools. Three protective factors have been found to frequently help young people overcome stress and adversity to become healthy competent adults with a sense of purpose: (1) caring and supportive relationships, (2) high expectations for success, and (3) active participation in school and community activities. For example, the ongoing National Longitudinal Study of Adolescent Health has found that students who feel “connected” to schools are more likely to adopt health-enhancing behaviors (respectful and caring teachers are among the factors related to students feeling connected). Applying a “positive youth development” approach, schools should aim to develop a full range of “life competencies” among students—not only academic and vocational competencies but also healthful living skills, personal and social skills, ethics, and citizenship.

**3. A complete set of program components.** Many national organizations and membership associations, as well as CDC’s DASH, promote a school health program model consisting of eight mutually reinforcing components that communities can shape to fit their needs and circumstances. These eight basic components are health education; school health services; a healthy school environment; physi-

cal education; school nutrition services; counseling, psychological, and social services; health-promotion programs for staff; and family and community involvement.

*Health education* consists of a planned, sequential curriculum taught daily in every grade (pre-kindergarten through twelve) that addresses the physical, mental, emotional, social, and spiritual dimensions of health and is designed to motivate and help students maintain and improve their health, prevent disease, and avoid health-related risk behaviors. A quality curriculum allows students to develop and demonstrate increasingly sophisticated health-related knowledge, attitudes, skills, and practices while addressing a variety of topics, including personal health, family health, community health, consumer health, environmental health, sexuality education, mental and emotional health, injury prevention and safety, nutrition, prevention and control of disease, and substance use and abuse. The National Health Education Standards, jointly developed in 1995 by APHA, the American Cancer Society (ACS), the American School Health Association (ASHA), the American Association for Health Education (AAHE), and the Society of State Directors of Health, Physical Education and Recreation (SSDH-PER), provide useful guidance for curriculum development, instruction, and assessment of student performance. Well-implemented health education has been shown to improve the adoption of health enhancing behaviors and school achievement.

*School health services* are provided for students and are designed to appraise, protect, and promote health. These services are designed to ensure access and/or referral to primary health care services, foster appropriate use of primary health care services, prevent and control communicable diseases and other health problems, provide emergency care for illness or injury, promote and provide optimum sanitary conditions for safe school facilities and environments, and provide educational and counseling opportunities for the promotion and maintenance of individual, family, and community health. Services should be provided by qualified professionals such as physicians, nurses, dentists, and other allied health personnel. Health services via school-based clinics that are linked with enhanced academic services have been associated with reduced absenteeism, improved academic achievement, and improved health status.

Although only 53 percent of states required schools to offer school nurse services in 1994, nearly every school had provisions for administering first aid (99%), administering medications (97%), and conducting vision, hearing, and height/weight screenings (89%). However, fewer schools provided less traditional services, such as mental health counseling (56%) or conducting health-risk appraisals to help students determine their lifestyle practices (36%). School-based or school-linked health centers are becoming more common, however, and many of these centers offer a wide range of physical and mental health services. A national survey identified a total of 1,157 school-based health centers that provided in-school care to children during the 1997–1998 school year. Thirty-seven percent were housed in high schools, 16 percent in middle schools, 34 percent in elementary schools, and the remainder were off-site.

A *healthy school environment* attends to the physical and aesthetic surroundings and to the school's psychosocial climate and culture, thus protecting the health and safety of students and staff and promoting health-enhancing behaviors. Physical environmental concerns include indoor and outdoor safety hazards, biological or chemical agents that might be detrimental to health, air temperature and quality, water quality, sanitation, precautions for infection control, lighting, noise levels, and access for persons with disabling conditions. The psychological environment includes the interrelated physical, emotional, and social conditions that affect the well-being and productivity of students and staff, including physical and psychological safety, positive interpersonal relationships, recognition of needs and successes of the individual, and support for building self-esteem in students and staff. In considering the school environment, there are things that both large and small schools can implement. In fact, a large body of research in the affective and social realms overwhelmingly affirms the superiority of schools with small enrollments.

Bullying and harassment can have damaging effects on students' health and well-being. Those who manage school environments also need to actively encourage health-enhancing behaviors by assuring that nutritious foods are available as an affordable option whenever food is served or sold, providing convenient and appealing opportunities for physical activity, enforcing tobacco-free policies, and con-

ducting educational campaigns to promote positive health behaviors.

*Physical education* is a planned, sequential curriculum and program of physical activity taught daily in every grade. Cognitive content and learning experiences should be provided in a variety of activity areas, such as basic movement skills; physical fitness, rhythms and dance; games; team, dual, and individual sports; tumbling and gymnastics; and aquatics. Quality physical education should promote lifetime activities and sports that students can enjoy and pursue throughout their lives. The National Standards for Physical Education developed by the National Association for Sport and Physical Education (NASPE) provide useful guidance for curriculum development, instruction, and appropriate assessment of student performance.

Physical education needs to be taught by qualified teachers. Studies have found that well-prepared physical education specialists teach longer and higher-quality lessons than those not professionally prepared in physical education. Elementary schools also need to provide daily periods of supervised recess, and middle schools and high schools should provide multiple opportunities for all students to voluntarily participate in intramural programs, sports and recreation clubs, and interscholastic athletics. Links with community-based sports, recreation, and fitness programs should also be sought and fostered.

Studies among adolescents have demonstrated that physical activity is consistently related to higher self-esteem and to reduced levels of anxiety and stress. Conversely, low levels of physical activity are associated with high-risk behaviors such as cigarette smoking and marijuana use. Studies have found that students who participate in extracurricular programs tend to have higher grade point averages, better attendance records, lower dropout rates, and fewer discipline problems than students generally.

*School nutrition services* promote the health and education of students through access to a variety of nutritious and appealing meals, nutrition education, and a school environment that encourages students to make healthy food choices. The school food-service program can provide opportunities for students to practice healthful eating on a daily basis—more than half of the young people in the United States get one of their three major meals from school food programs, and 10 percent get two of their three main meals at school.

Sound school food-service programs reflect the current U.S. Dietary Guidelines for Americans (DGA) and other quality criteria necessary to achieve nutrition integrity. These programs provide pleasant eating areas for students and staff with adequate time for unhurried eating, offer opportunities for students to experience learning laboratories for classroom nutrition and health education, and serve as resources for linkages with nutrition-related community services.

Services should be provided by qualified child nutrition professionals. Studies have shown that chronically undernourished children attain lower scores on standardized achievement tests, especially tests of language ability. These children are also more likely than other children to become sick, to miss school, and to fall behind in class. Undernourished students are often irritable, have difficulty concentrating, and have low energy. School nutrition services have been associated with increases in learning, and studies of low-income elementary school students have shown that students who participate in the federal School Breakfast Program have greater improvements in standardized test scores and math grades, and reduced rates of absence, tardiness, and psychosocial problems, than children who qualify for the program but do not participate.

*Counseling, psychological, and social services* provide broad-based individual and group assessments, interventions, and referrals that attend to the mental, emotional, and social health of students in a range of school and community settings. Organizational assessment and consultation skills of counselors and psychologists contribute to the overall health of students, and to the health of the school environment. Services are provided by professionals, such as certified school counselors, psychologists, and social workers.

One in five visits to school-based health centers is related to mental health. In a 1999 report on mental health, the U.S. Surgeon General estimated that 21 percent of U.S. children ages nine through seventeen have a diagnosable mental or addictive disorder, yet studies indicate that approximately 70 percent of children and adolescents in need of treatment do not receive mental health services. Of those young people who do receive mental health services, about 70 percent receive services offered in school settings, compared to 40 percent using mental health specialists and 11 percent using the health sector (a young person might access more than one resource).

The report also acknowledges that private and public health insurance coverage for such services is often lacking. Schools can make efforts to enter into collaborative relationships with other service providers for help with the resource burden.

Some of the burdens students face include inadequate basic resources, such as food, clothing, housing; and a sense of security at home, at school, and in the neighborhood. Psychosocial problems include difficult relationships at home and at school; emotional upset; language problems; sexual, emotional, or physical abuse; substance abuse; delinquent or gang-related behavior; and psychopathology. Additional stressful situations, such as being unable to meet the demands made at school or at home, inadequate support systems, and hostile conditions at school or in the neighborhood, have also been identified. In addition, crises and emergencies such as the death of a classmate or relative, a shooting at school, or natural disasters such as earthquakes, floods, or tornadoes are becoming commonplace. Life transitions, such as the onset of puberty, entering a new school, and changes in life circumstances (moving, immigration, loss of a parent through divorce or death) also affect the health of the student.

*Health promotion programs for staff* are designed to promote the physical, emotional, and mental health of school employees through health assessments, health education, health-related fitness activities, and employee assistance programs. Evaluations have found that participation in staff health-promotion programs can increase morale, improve absenteeism rates, increase participation in vigorous activity, improve physical fitness, facilitate weight loss, lower blood pressure, and improve stress-management skills. Teachers who become interested in their own health have been found to take a greater interest in the health of their students and become more effective teachers of health.

Staff can influence student behaviors by being powerful role models for healthy lifestyles. Private industry has found that staff health-promotion programs can improve productivity, improve morale, reduce health insurance costs, and are usually well worth the cost: More than 81 percent of U.S. businesses with fifty or more employees have some form of health promotion program.

*Family and community involvement* promotes an integrated school, family, and community approach that establishes a dynamic partnership to enhance

the health and well-being of students. Involving family members and the community has been linked with improvements in students' health knowledge and behaviors. Numerous studies link parent/family involvement to their children's achievement, academic standing, and decreased school failure and grade repetition, and a number of studies have shown that involving families enhances the effects of school health-promotion efforts. School health programs should be designed to actively solicit family involvement and assist and support families to effectively reinforce children's healthful habits and behaviors. The National PTA has developed the National Standards for Parent/Family Involvement Programs, which provide PTAs, schools, and communities with voluntary guidelines and quality indicators for effective parent/family involvement programs.

Schools should be encouraged to engage community resources and services to respond more effectively to the health-related needs of students. State and local government agencies, private businesses, youth-serving organizations, and other organizations in the community can be valuable additions to school health programs by serving as resources for student learning, offering opportunities for student service, coordinating community health-promotion efforts with school programs, raising funds to support specific activities, and providing expert advice and assistance to school health program planners. The *full-service school* model involves locating a variety of family and youth services at school to improve families' access to the services. New Jersey and Kentucky have pioneered statewide programs of linking schools with community agencies. Providing these kinds of services does not necessarily require an increase in the school's budget: typically, many of these services already exist, but in a fragmented manner that some families find difficult to use.

**4. Multiple interventions.** As the Carnegie Corporation has stated, "Given the complex influences on adolescents, the essential requirements for ensuring healthy development must be met through the joint efforts of a set of pivotal institutions that powerfully shape adolescents' experiences. These pivotal institutions must begin with the family and include schools, health care institutions, a wide array of neighborhood and community organizations, and the mass media" (p. 23).

Because the health problems facing students have a multifactorial etiology, a single health message delivered by one teacher during the year, particularly when there are so many competing messages from friends, family, and the media, is rarely sufficient to promote the adoption or maintenance of health-enhancing behaviors. Consistent and repeated messages delivered by several teachers, school staff, peers, and families are more effective.

A health promotion model that uses a variety of interventions in addition to instruction to promote the adoption of health-enhancing behaviors among children and youth is needed. Interventions that have been successful include policy mandates, environmental changes, direct interventions (screening, referral, and treatment), social support/role modeling, and media. The number of interventions necessary to address any one problem is unknown. Larry Green and Marshall Kreuter suggest that a minimum of three interventions be employed for each behavior that is targeted, and John Elder states that “true progress will be realized by using multi-component packages which include multilevel and multiple-channel generalization efforts and appropriate evaluation criteria” (p. 31).

**5. Program coordination and oversight.** The value of a coordinated approach has been noted by numerous individuals. A variety of options have been proposed to implement and manage a coordinated school health program, including school health coordinators, school health advisory councils, interdisciplinary work committees and work teams, and interagency coordinating councils or networks. Health-program coordination can help reduce ambiguity about responsibilities and tasks, which often impedes program implementation, and can help ensure that the various program components are mutually reinforcing each other’s efforts. School health advisory councils can involve a variety of health and education professionals, parents, and other community members who can mobilize community resources, represent the diverse interests within the community, provide school personnel and families with a sense of program ownership, and provide guidance to the school board. A 1994 national survey found that 33 percent of school districts and 19 percent of secondary schools had such councils.

Others advise that a more formalized structure, such as a coordinating council, is inherently more effective than an advisory group, as committed leadership has been found to be critical to the success of

school-linked comprehensive services. In 2000 the American Cancer Society began conducting a national leadership program designed to train individuals to become school health coordinators, including the development of school health councils, and to replicate the training program in their respective regions of the nation. Responsibilities of a coordinating council can include assessing needs and resources, establishing program goals, developing a community plan, coordinating school programs with community programs and resources, providing leadership and assistance for local schools, and assuring continuous improvement through evaluation quality assurance mechanisms. The Institute of Medicine (IOM) recommends that a school health coordinator and a coordinating council are an integral part of the infrastructure needed to support a coordinated school health program.

**6. Systematic program planning.** Every organizational group that is part of the school health program (e.g., school work teams, school health committee, school-community coordinating council) needs to use a programming process to assure continuous improvements in programming. Included in the process is the need to involve all stakeholders, define the problem from a local perspective (a needs assessment), set realistic goals and objectives, identify priority strategies to be used in the action plan to attain goals and objectives, implement the plan, evaluate the results, and use the results to start the process over again. DASH has produced the *School Health Index for Physical Activity and Healthy Eating: A Self-Assessment and Planning Guide*, which schools can use to improve school health programs. Differences in health status among distinct regions and groups argue for the need to base policies on local data that might be available from public health departments. Planners should conduct needs assessments with community input; adapt activities to the interests and preferences of different ethnic, religious, and social groups; and foster effective school-community collaboration.

**7. Ongoing staff development.** To assure effective programming, there is a need for staff development programs. Many teachers received their training at a time when the problems and issues facing students were much different. Staff development increasingly is approached as the day-to-day fostering of continuous improvement in one’s professional practice, and not as a workshop that occurs in isolation. Phyl-

lis Gingiss has identified five concepts that those planning staff development need to consider:

- Teachers respond to innovations in developmental stages.
- A multiphase approach to staff development is necessary to assist teachers during each stage.
- Staff development requires opportunities for teacher collaboration.
- Approaches to staff development must fit the stage of teacher development.
- The organizational context for staff development is critical to its success.

Critical organizational and environmental factors that must be addressed before providing staff development programs include a positive school climate, administrative support, and supportive policies. Those schools that encourage teacher experimentation enhance the willingness of teachers to try new methods and programs. A meta-analysis of staff-development training revealed that the utilization of theory, demonstration, practice, and feedback produced meaningful differences in the faculty's acquisition attitudes, knowledge, and skills. However, for meaningful differences to occur in the transfer of training to the practitioners' practice in the classroom, peer coaching had to be added to the above mix of effective interventions. Without peer follow-up and peer coaching after training, transfer effects are negative to minimal.

The National Council for Accreditation of Teacher Education (NCATE) has developed various sets of standards for teacher preparation programs, in association with numerous professional organizations, including the American Association for Health Education (AAHE), the National Association for Sport and Physical Education (NASPE), and the National Association of School Psychologists (NASP). Many states and professional preparation programs have adopted or adapted the NCATE standards.

To ensure that students are taught by well-prepared and well-qualified teachers, health education and physical education professional associations suggest that state licensure agencies should: (1) establish separate teaching licenses for health education and physical education; (2) offer licenses for different levels (e.g., preschool and early elementary school, elementary school, middle school, high school); (3) require that all generalist teachers (preschool, elementary school, middle school) pass

courses or demonstrate their competence at applying the skills required to effectively teach health education; and (4) allow schools to assign teachers to courses they are not properly certified to teach only when a licensed teacher cannot be found and only on a temporary basis with the stipulation that such teachers receive the necessary training if they are to continue teaching the class.

**8. Active student involvement.** Peer instruction has proven effective in disseminating knowledge and changing behaviors. Students are more likely to turn to peers for advice, and change is more likely to occur, if someone similar to them recommends the change. In addition, peer instruction has been effective in improving decision-making and problem-solving skills, which may be prerequisites for implementing behavior change. Role modeling and peer support systems represent additional benefits of peer-education programs.

Peer involvement may occur in a variety of ways, such as peer counseling, peer instruction, peer theater, youth service, and cross-age mentoring. The elements of a successful peer program include positive interdependence, face-to-face interaction, individual accountability, training in social skills, time for group processing, heterogeneous composition, having each child be a helper, adequate duration, and involvement of participants in program implementation.

## Conclusion

Because the health of students is inextricably linked to educational achievement, it is critical that schools promote health. Schools can provide the nurture and support needed to facilitate the adoption of health-enhancing behaviors. This helps assure that the educational gains achieved by a student will be maximized by a long and healthy life as an adult. A comprehensive, well-coordinated school health program can promote the optimal physical, emotional, social, and educational development of students.

#### SCHOOL

Provision of public school health services in the United States has been sporadic, reflecting the tenor of the times, and influenced by pressure groups, vested interests, and resistance to change by those in administrative positions.

The initial justification for provision of school-based health services was primarily to control com-

municable diseases in order to cut down on school absenteeism. At the turn of the twentieth century, physicians were appointed as public school health officers. The first school nurse was employed by the New York City Board of Education in 1902, for the express purpose of controlling communicable diseases, particularly infectious skin diseases. Even though the number of physicians who were employed by schools outnumbered the number of nurses employed by schools by approximately three to one, school nurses were the main providers of school health services. Because of prevailing social mores, hygiene instruction in the late 1800s and early 1900s centered on a physiological and anatomical study of the negative effects of alcohol, tea, coffee, and tobacco.

Administrative responsibility for health services was often assigned to a specifically established department within the school, which was often under the direction of a local physician who was accountable to a school superintendent. In other instances, the responsibility for this service was assumed by a community health agency under the direction of a local health officer. These remained accepted practices even into the twenty-first century.

As new scientific knowledge emerged, new movements for improved personal and community health became popular. Addressing health problems of children and youth required a multidimensional approach. School health services only focused on medical related services, not environment or education. It became clear that the school needed to be concerned about not only school health services but also about the school environment and health education. Further, school health services, provision of a healthful school environment, and health education needed to function in a coordinated context in order to be effective. This set the foundation for the development of the school health program.

The original school health program model consisted of school health services, healthful school living, and health education. The goal of the school health program was to provide opportunities for every child to reach their full potential as a student as well as a contributing member of society. The major objective of the school health program was the promotion of physical, mental, social, and emotional well being. This model prevailed for years.

School health services as a part of the overall school health program provided health and medical

services to students. These services tended to be one of three types: basic, expanded, or comprehensive. Basic health services include such things as immunizations, hearing and vision screenings, scoliosis screening, sports physicals, health counseling, and nutritional screenings. Expanded health services included health promotion/disease prevention, mental health counseling, substance abuse counseling, family life/sex education, and care of special needs children. Finally, comprehensive health included reproductive health care, primary care, chronic illness management, and prenatal care.

### CDC Model

The services, environment, instruction focused model of the school health program worked well but still was not inclusive or comprehensive enough to meet the needs and interests of students. A more comprehensive model was needed. The concept of the Centers for Disease Control and Prevention (CDC) comprehensive school health programs model was first proposed in a landmark work published by Diane Allensworth and Lloyd Kolbe in 1987. The model employed the use of eight components. These include the following:

1. Health education: classroom instruction addressing physical, mental, and social dimensions of health; developing health knowledge, attitudes, and skills; and tailored to each age level. Designed to motivate and assist students in maintaining and improving their health, prevent disease, and reduce the number of health-related problem behaviors they exhibit.
2. Physical education: planned, sequential instruction that promotes lifelong physical activity. Designed to develop basic movement skills, sports skills, and physical fitness as well as to enhance mental, social, and emotional abilities.
3. School health services: preventive services, education, emergency care, referral, and management of acute and chronic health conditions. Designed to promote the health of students, identify and prevent health problems and injuries, and ensure care for students.
4. School nutrition services: integration of nutritious, affordable, and appealing meals; nutrition education; and an environment that

- promotes healthy eating behaviors for all children. Designed to maximize each child's education and health potential for a lifetime.
5. School counseling, psychological, and social services: activities that focus on cognitive, emotional, behavioral, and social needs of individuals, groups, and families. Designed to prevent and address problems, facilitate positive learning and healthy behavior, and enhance healthy development.
  6. Healthy school environment: the physical, social, and emotional climate of the school. Designed to provide a safe physical plant, as well as a healthy and supportive environment that fosters learning.
  7. School-site health promotion for staff: assessment, education, and fitness activities for school faculty and staff. Designed to maintain and improve the health and well-being of school staff, who serve as role models for students.
  8. Family and community involvement in school health: partnerships among schools, families, community groups, and individuals. Designed to share and maximize resources and expertise in addressing the healthy development of children, youth, and their families.

### Components to School Health Services

Every current comprehensive approach to school health includes at least the eight components of the CDC model. The School Health Services component is generally structured around preventive services, education, referral, emergency care, and management of acute and chronic conditions.

**Preventive services.** Activities typically included in preventive services are educating teachers on the signs and symptoms of health problems of students and health screenings. Teachers are in a unique position to observe health problems among students. They have an advantage in that they can compare students and notice differences that might indicate a potential health problem. Even parents do not have this strategic advantage. It requires that teachers be trained to identify health related issues that may be noticeable during their daily observations of students. This training is often included in a pre-professional course or through in-service instruction offered by the school or school district. The goal of teacher observation is not diagnosis but referral.

Preventive services also include health screenings of students. The most common health screenings conducted in schools include vision, hearing, growth and development, blood pressure, cholesterol, and dental health screenings. Often the school will establish a partnership with a local public health department. The health department's professional staff is responsible for conducting the screenings. The purpose of screening is not to diagnose but to identify a potential health problem and refer the student for a more complete evaluation.

Referral and follow-up represent the culmination of teacher observation and screening. The referral process is initiated in one of two ways: First, a teacher makes an observation that indicates a student might have a health problem, and refers the student to the school nurse or the person in the school responsible for health concerns. Second, if a student does not pass a particular health screening, the student is referred again to the school nurse or the person in the school responsible for health concerns. What follows is a series of conferences, such as teacher/nurse, nurse/parent, and student/nurse.

**Emergency care.** Unintentional injuries are the leading cause of death in children and youth ages one through twenty-one; for every childhood death caused by injury, there are approximately 34 hospitalizations, 1,000 emergency room visits, and many more visits to private physicians. Because of the magnitude of injuries to children and youth, and because many injuries occur in the school, it is important that schools as a part of health services address safety and emergency care.

Safety and emergency care is normally addressed in two ways: written policies including legal aspects and preparations for handling emergencies. All schools should have written policies, which reflect a sound philosophy of safety and emergency care and specific procedures for school personnel to follow in both prevention of accidents and the protocol in dealing with accidents and emergencies.

**Management of acute and chronic conditions.** School health services are concerned with both acute and chronic health conditions of students. Acute conditions are normally communicable diseases and chronic conditions are such things as diabetes, asthma, and juvenile arthritis.

It is extremely difficult if not impossible to prevent the spread of common communicable diseases in school settings. Such illnesses as colds and influ-

enza will run their epidemiologic course. School health services must include policies on how to handle communicable diseases; in other words, when to allow students back in school or sending students home who are sick. Further, schools health services must have documentation that students are up-to-date on immunizations. Schools will typically partner with local public health departments to receive guidance in how to handle communicable disease in the school setting.

Education and universal precautions are two important pieces in the management of acute conditions. Spread of communicable disease can be prevented through sound health practices, even as simple as washing hands. Schools must educate both personnel and students on the importance of sound health practices.

At times, a student will have an injury, perhaps resulting in their bleeding or vomiting. Both blood and vomit, as well as other body fluids, can contain pathogens and disease can be transmitted. Blood can contain HIV and the viruses responsible for viral hepatitis. Following universal precautions will limit the likelihood of transmission of disease through exposure to body fluids. Universal precautions are those activities designed to deal with body fluids and include use of gloves, masks, and proper receptacles for placing materials used to clean up body fluids. Schools are required to have an exposure control plan and have materials readily available for use when dealing with body fluids.

### Issues and Trends

Numerous health problems that were once largely family and community problems now impact the school. Violence, drug use, teen pregnancy, sexually transmitted diseases, and poverty all have tremendous implications for school health services, yet because of the political and economic environment, there is, in general, less funding for programs to deal with these issues. Further, the complexity of the health problems and issues makes citizens question what the exact role of the school is in trying to solve or manage problems that are a result of powerful cultural influences. There seem to be two major perspectives, both with political implications. One is that the role of the school is to teach basic skills, such as reading, writing, math, and history, and health-related issues are a family problem or at best a community problem. The opposite perspective is that the government and by extension the school should play

a major role with regard to student health problems and work closely with students in any way possible.

Perhaps the most controversial trend is the implementation of school-based health centers or clinics located in the school. School-based health centers were first established in the early 1970s. They were implemented as a response to health problems such as sexually transmitted diseases, unplanned teenage pregnancy, and substance abuse.

Funded by the federal government and private foundations, school-based health centers are located in forty-five states and the District of Columbia. As of 2000, approximately one-half of the health centers are located in high schools, one-quarter are located in elementary schools, and the remainder are located in other settings. The majority of the centers are located in poor urban and rural areas where coordinated medical and social services are lacking or where there are many uninsured children/parents, making access to services difficult.

Services provided by school-based health centers include but are not limited to primary care (diagnosis and treatment of simple illness), primary prevention (health education programs, vaccinations), and secondary prevention (early detection). These services range from diagnosing such maladies as colds, flu, and sexually transmitted diseases to substance abuse counseling. Services offered vary among communities and from community to community.

School-based health centers face an uncertain future primarily because they rely so heavily on external funding. As the nation grapples with the issue of providing access to health care for all Americans, school-based health centers need to be well positioned to meet the care and prevention needs of children and youth.

Given the political, cultural, and economic climate of the United States two future scenarios emerge. First, with the increasing emphasis on providing access to health care to all Americans it is possible that there will be a greater role for the school in providing health services to students, especially in medically underserved areas. Second, with the increasing shift to managed care it may prove more cost-effective for third-party payers to underwrite health services delivered in a school setting rather than in a community private sector setting.

## COLLEGES AND UNIVERSITIES

College health-service programs provide low-cost, primary medical care for students on college cam-

puses. Kevin Patrick estimated in 1988 that 80 percent of America's more than fourteen million college students received primary health care from campus health programs. Just as modern medicine has changed, so too has the scope of services college health centers provide. Medical developments allow for most injuries and illnesses to be treated by ambulatory clinics, and this same trend is seen in most college health centers. These centers often provide care for acute illnesses and injuries on an outpatient basis, while also meeting the needs of students with continued and chronic illnesses and providing wellness education to the campus community.

In addition to meeting the basic and most common needs of the students they serve, campus health-service programs also act as referral agents for students to connect with medical providers, as needed, in the local community. College health services are continually evolving and changing in order to best provide treatment and education for the campuses they serve.

### Staffing

College health-service staffs vary widely in the range and level of services they provide. Once directed mainly by full-time medical doctors, most college health centers are now lead by Licensed Nurse Practitioners (LPNs), Registered Nurses (RNs) or Physician Assistants (PAs). Some health centers continue to have full-time physicians on staff (particularly at larger universities and institutions with medical centers), while others maintain part-time relationships with local doctors to staff particular hours each week. Health centers with less comprehensive services (usually at smaller, private colleges) often act as a link to services in the immediate community.

### Services

College health-service programs tend to have three primary areas of responsibility: physical, mental, and educational. Medical services range from basic care in the form of treatment for colds, viruses, and minor injuries at less comprehensive centers to thorough lab tests, X rays, specialists, and pharmacies at the most comprehensive centers. Many college health programs also provide counseling services. Some counseling services are limited to basic intervention and referral for long-term care, while others provide extensive and long-term psychotherapy.

The most common, and a primary focus of college health-service programs, is that of intervention

and health, or wellness, education. Although all student health centers concern themselves with the immediate healing of ill students, most will also work to educate students about approaches to healthier lifestyles in order to prevent future illness or injury. Wellness themes exhibited on many college campuses are health and nutrition, stress management, eating disorder awareness, smoking cessation and prevention, time management, alcohol abuse prevention, strategies to avoid depression, and issues around sexually transmitted diseases and their prevention. Some colleges maintain twenty-four-hour care for students; however, most colleges maintain regular weekly hours during the academic year with a system for emergency assistance when needed.

### Payment

Many college health centers are funded through fees students pay to the college or university and subsidized with institutional resources. Sometimes these fees are included within the tuition charges of a college or university, while other institutions may charge a separate student health fee in addition to the college tuition. Prepayment for student health services ensures that students have access to the treatment and services needed while at school. At many colleges, basic and most common services are offered to full-time students at little or no charge. Many college health centers will provide, as needed, over the counter medications free of charge; however, they will charge for, or send students to a pharmacy for, prescription medications. Students will usually incur charges for lab work, other diagnostic tests, and services provided by referrals made to outside physicians and specialists. Most colleges and universities require students to have and maintain health insurance. Although many students may continue on their parent's health insurance plans, other students may need to purchase individual health insurance, and can usually do so through programs offered at their college or university.

### Requirements

Most, if not all, colleges and universities require that undergraduate students complete health history forms prior to their arrival on campus. This information assists health center staff to prepare for any special needs identified on the form and to have a recorded history in case information is needed to properly treat a student. In addition to the form, all students are required to have current immunizations

per state law and institution policy. Documentation of these immunizations must be provided in order to attend the institution.

### Confidentiality

Services provided by college health centers are deemed confidential. Health center staff work in partnership with students to get well, make good choices, and develop healthy living habits. The responsibility of informing parents falls to the student in most cases. Only when a condition warrants notification will health services staff break the confidence of the relationship, usually with the permission of the student unless there is concern about harm to self or others.

## HEARING IMPAIRMENT

---

### SCHOOL PROGRAMS

Susan Dalebout

### TEACHING METHODS

Elizabeth A. Martinez

Daniel P. Hallahan

### SCHOOL PROGRAMS

Hearing loss occurs along a broad continuum ranging in degree from slight to profound. Individuals with severe and profound hearing loss generally are characterized as *deaf*, whereas individuals with lesser degrees of impairment, including those with unilat-

eral hearing loss (i.e., involving only one ear), are characterized as *hard of hearing*. Childhood hearing loss of any type and degree, if unmanaged, is likely to have a negative impact on the development of spoken and receptive language, the ability to read and write, and academic achievement. For example, a 1998 study of 1,218 children with minimal hearing loss showed that 37 percent had failed a grade. Similarly, studies have shown that children with unilateral hearing loss are ten times more likely than normally hearing children to fail a grade. The vast majority (94–96%) of children with hearing loss are hard of hearing rather than deaf. For these children, speech may be *audible* (i.e., detectable) but not *intelligible* enough to allow them to hear one word as distinct from another.

There are approximately 50,000 school-age deaf children in the United States, a figure representing a dramatic decline since the early 1970s. An additional 5 million school-age children are permanently hard of hearing and at educational risk. An estimated 1.5 million more suffer from conductive, usually temporary, hearing loss. Inclusion of preschool children could put the total number of children with hearing loss close to 10 million.

### Historical Overview

Historically, approaches to educating children who are deaf have been based on emotion and personal philosophy rather than positive outcome; in contrast, the education of children who are hard of hearing has largely been ignored. Educational practices in the United States can be linked directly to the teachings of European educators active during the eighteenth and nineteenth centuries. Of note, in 1770 French cleric Charles-Michel de l'Épée founded a school in which he emphasized the use of sign language and finger spelling (i.e., a *manual* approach). Around the same time, schools were established in England by members of the Braidwood family, who emphasized the use of spoken language and speechreading without sign language (i.e., an *oral* approach).

In the United States, the father of Alice Cogswell, who lost her hearing at an early age, commissioned Thomas Hopkins Gallaudet to travel to Europe and learn methods for teaching deaf children. Refused help by the Braidwoods, Gallaudet learned de l'Épée's manual method. In 1817 Gallaudet opened a school in the United States based on the manual approach (now the American School for

the Deaf). Gallaudet's son became president of the first college for deaf students in the United States, now known as Gallaudet University.

Oralism took root years later when another young girl from a prominent family, Mabel Hubbard, lost her hearing. In 1867 her father helped establish an oral school. As an adult, Hubbard married Alexander Graham Bell, who became a passionate advocate for oralism. During the late nineteenth century, Bell and Gallaudet often engaged in debate about the merits of the oral and manual approaches. The debate would continue well into the twentieth century.

### Education of and Services for Hearing-Impaired Children

Children in the United States who are deaf or hard of hearing are legally entitled to a free and appropriate education. Federal law requires a continuum of educational options, ranging from placement in a self-contained classroom with other children who are deaf to full-time placement in a regular education classroom with normally hearing peers. Most often, the placement involves a variation or a combination of the two extremes. An alternative placement is attendance at a residential school, in which the child can participate fully in the deaf culture.

Perhaps the most important educational decision is the communication method that will be used. The choice lies with the parents, and the best decision is specific to each child and family. Most children who are deaf use one or some combination of three communication modes: American Sign Language, a manual language that is distinctly different from English (i.e., a person does not sign and speak at the same time); a system of manually coded English (i.e., a signed version of English); or hearing and spoken language. A relatively smaller number of children use Cued Speech, a system in which hand gestures enhance speechreading.

Children with hearing loss require support services in order to benefit maximally from a free and appropriate education. For example, it is essential that they receive services from an audiologist, including management of their hearing aids, classroom listening devices, and listening environments. Poor listening conditions can render a hard of hearing child functionally deaf.

## Trends and Research Findings

The education of children who are deaf will be revolutionized by two dramatic changes. First, legally mandated neonatal hearing-screening programs are changing the average age at identification from approximately three years to approximately three months. Research has shown that when appropriate hearing aids and early intervention are in place by six months of age, a child is likely to have age-normal language and learning milestones at kindergarten entry. In this light, the most important educational years are the child's very first years, when the family participates in parent-infant programming. Second, cochlear implants are being made available to increasingly younger children. These surgically implanted devices convert sound into electrical current, which then bypasses much of the hearing mechanism to stimulate surviving nerve elements directly. The coded electrical current creates sensations, which the brain, with considerable listening training, can learn to interpret as sound. Research suggests that children who use cochlear implants surpass children with similar degrees of hearing loss who use hearing aids in the areas of speech recognition, speech production, language content and form, and reading.

Children who benefit from early intervention and improved hearing technology, including cochlear implants, are likely to enter kindergarten ready for the educational mainstream. In the absence of additional disabilities, and with appropriate support services, it is possible that these children may never require special education placements and will choose to use sign language only if it is their cultural preference.

SUSAN DALEBOUT

## TEACHING METHODS

According to Lou Ann Walker, "the first real efforts to educate deaf people began around 1550 when Pedro Ponce de León, a monk from Spain, taught deaf children in a monastery in San Salvador" (p. 11). Seventy years later, Juan Pablo Bonet, a follower of Ponce de León, published the first book on the education of people who are deaf. In it he explained that he used a one-handed manual alphabet to build language. In 1700 Johann Ammons, a Swiss doctor,

devised a method to teach speech and lipreading (now more accurately referred to as speechreading) to people who are deaf. In the mid-1700s, schools for deaf children were established in Scotland, Germany, and France. Teaching methods, according to Walker, focused, for the most part, on a combination of *oralism*—teaching students speech and speechreading—and *manualism*—teaching students a manual alphabet. Schools for the deaf did not reach the United States until 1817, when Thomas Hopkins Gallaudet, a divinity student, and Laurent Clerc, a deaf student of the National Institute of France, opened the American School for the Deaf (originally named the Connecticut Asylum for the Education and Instruction of Deaf and Dumb Persons) in Hartford, Connecticut. Many teachers trained at the American School, which focused on American Sign Language.

The controversy surrounding how to teach children with hearing impairment, sometimes referred to as the oralism-manualism debate, began centuries ago and continues into the twenty-first century. Opponents of oralism contend that denying children sign language is tantamount to denying them a language to communicate. However, children who can learn language orally are better prepared for a hearing world. Most educational programs at the turn of the twenty-first century involve a *total communication* approach—a blend of oral and manual techniques; however, some members of the deaf community contend that it is inadequate, and they prefer a bicultural-bilingual approach, whereby students learn about the history of deaf culture after learning American Sign Language and English. A controversial piece of this approach is the focus on American Sign Language—a true language that has evolved over generations but one that does not follow the same word order as spoken English. Proponents of American Sign Language contend that it is natural, fluent, and efficient, whereas signing English systems, which correspond with spoken English, are cumbersome and awkward. To date, however, few public schools use American Sign Language.

Regardless of teaching method, students with hearing impairment experience difficulties acquiring the language of the hearing society. Educators pay very close attention to the age of onset of the hearing impairment and the degree of hearing loss because each is closely associated with the severity of language delay. The earlier the hearing loss occurs and

the more severe the hearing loss, the more severe the language delay. For many years, professionals believed that deficiencies in language among individuals with hearing impairment were related to deficiencies in intellectual ability; this is not the case. Unfortunately, results of research indicate that students with hearing impairment are behind their hearing peers in terms of academic achievement. Reading is the academic area most affected, wherein students with hearing impairment experience only one-third the reading growth of their hearing peers. They also lag behind their peers in mathematics. According to 1999 figures from the National Center for Health Statistics, “approximately 1.3 percent of all school-age students, ages six to twenty-one, who received special education services during the 1996–1997 school year were served under the disability category of hearing impairment” (Schirmer, p. 20). It is important to note, however, that estimates of the number of children with hearing impairment can differ markedly depending, for example, on definitions used, populations under investigation, and accuracy of testing.

Students with hearing impairment receive services in a variety of settings, from the general education classroom to residential schools. Parents and many professionals have not embraced the current controversial trend toward policies of inclusion (i.e., placing students with disabilities in general education classrooms for most or all of the school day). They caution that the general education classrooms are not necessarily the most appropriate placement for students with hearing impairment. However, some students with hearing impairment experience academic and social success in general education settings. This indicates that the preservation of the continuum of placements, whereby placement decisions can be made on individual bases, is in the best interest of students with hearing impairment.

## HERBART, JOHANN (1776–1841)

German philosopher Johann Friedrich Herbart is the founder of the pedagogical theory that bears his name, which eventually laid the groundwork for teacher education as a university enterprise in the United States and elsewhere. Herbart was born in Oldenburg, Germany, the only child of a gifted and strong-willed mother and a father whose attention was devoted to his legal practice. Herbart was tutored at home until he entered the gymnasium at the age of twelve, from which he went on as valedictorian to the University of Jena at a time when such stellar German intellectuals as Johann Gottfried Herder, Johann Gottlieb Fichte, Johann Wolfgang von Goethe, and Friedrich von Schiller were associated with that institution. It was apparently Schiller's *Briefe über die ästhetische Erziehung des Menschen* (Letters concerning the aesthetic education of man), then in progress in 1795, that influenced Herbart to devote himself to philosophy and education.

### Career

In 1797 and almost against his will Herbart was persuaded by his mother to accept a position as tutor to the sons of the regional governor of Interlaken in Switzerland. During his three years of work with these three very different boys, aged fourteen, ten, and eight when their relationship began, Herbart confronted in earnest the problems of teaching children, reporting monthly to their father on his methods and the results achieved. During his Swiss sojourn, he was also influenced by the thinking of Johann Heinrich Pestalozzi, whose school at Burgdorf he visited and whose ideas he systematized in 1802 in his *Pestalozzi's Idee eines ABC der Anschauung untersucht und wissenschaftlich ausgeführt* (Pestalozzi's idea of an ABC of sense impression investigated and laid out scientifically).

Returning to Germany in 1800, Herbart completed his remaining doctoral work at the University of Göttingen, receiving his degree in 1802. He remained there as a lecturer in both philosophy and pedagogy until he received an appointment as professor of philosophy in 1805. Chief works related to education from his Göttingen period are *Über die ästhetische Darstellung der Welt als das Hauptgeschäft der Erziehung* (On the aesthetic representation of the world as the main concern of education), published in 1804, and *Allgemeine Pädagogik aus dem Zweck der Erziehung abgeleitet* (General pedagogy deduced from the aim of education), published in 1806. He also published on metaphysics and psychology.

In 1809 Herbart accepted the chair of pedagogy and philosophy at the University of Königsberg, formerly occupied by Immanuel Kant, and began a period of great productivity, ranging across the full spectrum of philosophical investigations. In the midst of work in metaphysics and psychology he also organized a pedagogical seminar for advanced students, attached to a demonstration school in which he and his students attempted to implement his pedagogical ideas, which were then critiqued and revised through the seminar discussions. This seminar, widely imitated by his later disciplines in Germany and elsewhere, was a first step toward trying to approach educational work scientifically.

Herbart left Königsberg in 1833, apparently because of disagreements with the Prussian government over his educational views in relation to state and church power. He returned to the University of Göttingen, where he remained for the last eight years of his life, producing his *Umriss von pädagogischen Vorlesungen* (Outlines of pedagogical lectures) in 1835, in which he attempted to connect more directly his early pedagogical theory and his later psychological work. He gave his last lecture two days before he died of a stroke on August 14, 1841.

### Contribution

The legacy of Herbart to education was mediated through two major German disciples, Karl Volkmar Stoy and Tuiskon Ziller, who sought to implement his theories with varying degrees of alteration. Stoy was inspired by Herbart's early lectures in philosophy and pedagogy at the University of Göttingen and, upon qualifying as a lecturer at the University of Jena in 1842, took charge of a local private school that soon attracted students from all over Europe. In 1845 he was appointed professor at the university,

then he moved in 1865 to the University of Heidelberg, establishing at nearby Bielitz a normal school based upon Herbartian principles. He returned to Jena in 1874 and established there the pedagogical seminar that would be taken over upon his death in 1885 by Wilhelm Rein, and brought to international renown by the end of the nineteenth century both for its practices and for its incorporation of teacher education into the university. It was there that the majority of Herbartians from other countries, including the United States, developed their ideas.

Rein had studied with the second major disciple of Herbart, Ziller, who had pursued a career in law, being appointed a lecturer at the University of Leipzig in 1853. Like Herbart, a period of teaching during his doctoral work led Ziller to investigate educational questions, and his first works, published in 1856 and 1857, were direct extensions and applications of Herbart's ideas. He established at the University of Leipzig a pedagogical seminar and practice school modeled after that of Herbart at Königsberg. Ziller was instrumental in founding the *Verein für wissenschaftliche Pädagogik* (Society for Scientific Pedagogy) in 1868, which published a quarterly that disseminated Herbartian ideas, and spread all over Germany as local clubs for the study of Herbartian approaches to educational problems. Ziller wrote *Grundlegung zur Lehre vom erziehenden Unterricht* (Basis of the doctrine of instruction as a moral force), published in 1865, and his *Vorlesungen über allgemeine Pädagogik* (Lectures on general pedagogy), published in 1876, five years before his death. These works provided the Herbartian legacy that Wilhelm Rein as a student of Ziller at Leipzig brought to his work when Rein resuscitated the pedagogical seminar at the University of Jena in 1886, a year after Stoy's death.

The German tradition of Herbartianism distinguishes between the Stoy and Ziller schools, the former being considered truer to Herbart's own ideas and the latter an extension of them more or less justified. Scholarship on both schools continues, centered at the University of Jena since its international conference, *Der Herbartianismus: die vergessene Wissenschaftsgeschichte* (Herbartianism: the forgotten history of a science), in 1997. The investigation of, or even attention to, the fine points of Herbartian theory, was notably lacking in American Herbartianism, although the central ideas remained intact. First and foremost was the development of moral character as the central aim of education. Second was the

adoption of Herbart's notion of apperception as the dynamic of learning: the ideas already configured in the mind are stimulated into activity by new information and either integrate that new information through meaningful connections or let it pass if such connections are not made. The essential unity of the ideas present in the mind is reflected in the theory of concentration as a principle for organizing the curriculum, which in relating several subjects to one another in the course of instruction also nurtures the many-faceted interest that is essential to full intellectual and thus spiritual development. Ziller added to these basic ideas the notion of the cultural-historical epochs as a curriculum principle that responds to the recapitulation in the individual of the psychic and cultural development of his group.

Rein and others developed a full eight-year course of study built upon this principle, which was translated and adapted to American use by Charles A. McMurry, one of the major disseminators of Herbartianism in the United States and a student with Rein. Charles DeGarmo, on the other hand, brought back to the United States the more conservative Herbartianism of Stoy, whose ideas were mirrored in the secondary schools of the *Franckische Stiftungen* in Halle established for orphans by August Hermann Francke in 1695 and under the directorship of Otto Frick during DeGarmo's doctoral study at the University of Halle. DeGarmo also provided for American readers the most thorough survey of the German Herbartians and Herbartian concepts in his *Herbart and the Herbartians*, published in 1895. It joined a substantial number of translations of work by Herbart and various German Herbartians made available in the 1890s.

American Herbartianism enjoyed a brief burst of national attention in the 1890s because of attempts by U.S. Commissioner of Education William Torrey Harris to stop its spread and the formation of the National Herbart Society in 1895 in response to those efforts. Within seven years the National Herbart Society had become the National Society for the Study of Education and its yearbooks had lost any obvious association with Herbartianism. Within that period at least eight universities were offering heavily Herbartian programs, and the demand for American Herbartian texts, particularly those of Charles McMurry, lasted until nearly 1930. Integrated curriculum, elementary school history teaching, and constructivist learning theory are part of the contemporary legacy of Herbartianism.

## HIGHER EDUCATION CURRICULUM

*See:* CURRICULUM, HIGHER EDUCATION.

## HIGHER EDUCATION IN CONTEXT

---

Universities are not ivory towers and never have been. They are subject to pressures and influences from external social forces of many kinds. This is not surprising, in light of the importance of universities to society, as well as the fact that institutions of higher education obtain their funds from external sources such as the government, students and their families, and donors. In the twenty-first century, universities are subject to the pressures of society more than ever, largely because of their importance

to knowledge-based economies, and because more than half the college-age population attends postsecondary institutions.

Influences from external forces come from two basic directions. The first constitutes broad societal factors, such as economic trends and demographic factors, which affect the directions and realities of higher education. The second comes from the specific requirements of funding sources, government agencies, and others to account for, and sometimes control, the expenditure of funds, the nature and scope of research, and other university activities. This entry mainly discusses the broader external factors affecting higher education.

### Economic Factors

Academic institutions, with few exceptions, constantly face financial challenges. All, even the most wealthy, depend on external elements for financial survival, including tuition payments provided by students and their families, funds from the government for operating expenses, research and training grants and contracts from a range of external agencies, charitable donations from alumni and foundations, and income-generating projects (including, for a few, intercollegiate athletics).

In the United States, 80 percent of postsecondary students attend public colleges and universities. For almost all public institutions, financial support from state governments is critical. Indeed, most postsecondary institutions depend on a combination of student tuition and direct support from the state for their financing. Federally backed student loans are also a central financial underpinning for higher education. These grants and loans are provided to individual students, who may use them at any accredited academic institution. Private universities and colleges depend to a much lesser extent on public support. Most are eligible for the student loan programs, and some states provide direct financial support to private institutions. Private institutions can also receive government research funding.

During the last decades of the twentieth century, there was a significant change in government policy concerning funding for postsecondary education. Previously, higher education was seen by most as a *public good*—an investment in human capital that, in the long run, benefited society as well as the individual, and is therefore worthy of public support. However, academic study is increasingly seen as a

*private good*—something that mainly benefits the individual and should be paid for by the individual. Most states are less generous in their funding for higher education, and tuition charges have been raised. Nationally, students and their families are paying a higher proportion of the cost of higher education than was the case in the past. For many public universities, especially the nationally known public research institutions, less than one-third of income now comes from the states, with tuition, research grants, income generation, and donations constituting the majority of income.

Partly as a result of this change in philosophy, and partly because of competing state priorities and a general unwillingness to raise taxes, public higher education has faced financial problems, sometimes even during the boom years of the 1990s. External financial pressures also affect private colleges and universities. While the wealthiest institutions have endowments that provide a measure of financial stability, most private schools depend largely on tuition income. In the 1990s tuition increases were often higher than the level of inflation, and in the early twenty-first century there is resistance from students to high levels of tuition, and especially to rapid tuition increases. Private institutions have been forced to limit tuition increases, and this has had an impact on their financial viability in a competitive environment.

### **An Era of Competition**

Competition has always been an element of academic life—for prestige, for the best students, and for donations, among other things—and competition has become one of the central driving forces in higher education. Competition for the best faculty, for students, for research grants, and for the ever more important rankings by *U.S. News and World Report* and other publications are all central to the contemporary academic enterprise. The most prestigious academic institutions see themselves in a race to provide better dormitories and sports facilities, faster access to computer networks, and improved campus services as part of a competitive struggle with their peers.

A central element of the new competitive environment is that students increasingly see themselves as “buyers” of a higher-education product. They demand that the academic institutions serve their specific needs in terms of curriculum, degree offerings, and facilities. This is an age of student consumerism,

where even the most prestigious and selective institutions must respond to student interests and concerns. Academic institutions have moved to provide flexible degree structures, new majors to meet student demand, and to supply, in many other ways, the educational “product” demanded by an increasingly sophisticated market.

### **Demographic Realities**

This increased competition is partly a result of the changing demographic realities in American higher education. Dramatic changes have taken place that affect academic institutions. With the exception of a brief baby-boom *echo* for a few years at the beginning of the twenty-first century, the number of traditional college-age young people (18–21 year olds) has been modestly declining. Colleges and universities are thus competing for a declining number of potential students. Furthermore, the period of expansion in the proportion of college-age youth attending postsecondary education institutions has largely come to an end as well. The proportion of young people attending college increased from perhaps 20 percent in the period following World War II to more than 60 percent in the 1990s, but it did not increase between 1990 and 2000. Higher education in the United States has reached what sociologist Martin Trow has called “universal access.”

A significant part of the numerical expansion of enrollments in the late twentieth century consisted of nontraditional students—people who are older than the usual college age and who begin or return to study mainly for vocational reasons. Another new population group consists of students who do not possess all of the skills needed for postsecondary study. These students often require remedial courses that colleges and universities must provide. As American higher education has become a mass phenomenon, the academic system has had to adjust to a more diverse student body and a wider array of student interests.

There have been other important changes in the student population that have affected academe. With 14 million students attending the nation’s more than 3,000 colleges and universities, there is unprecedented diversity. Women constitute a majority of the student population, and racial and ethnic diversity has grown dramatically, with African Americans, Latinos, and especially Asian Americans present in large and growing numbers. Higher education is no longer a preserve of the white middle

classes, and many working-class students are able to gain access. Higher education is seen as a passport to economic success, and statistics show that those with a bachelor's degree earn much more over their lifetimes than those without academic qualifications. A majority of students study part-time and the traditional model of a full-time traditional-age student living on campus is no longer valid.

The pressures of demography on the higher-education system have been immense. The dramatic expansion of the student population, increased diversity, and more variation by age, ability, and interest have all transformed the academic landscape.

### **Political, Governmental, and Legal Challenges**

The higher-education system, as well as individual academic institutions, is affected by politics and government. The U. S. constitution stipulates that education is a responsibility of the states, and thus the fifty states have basic responsibility for higher education. As noted earlier, the states provide the bulk of funding for public higher education. They are also responsible for organizing and regulating public university systems, providing a legal structure for these systems, and in most cases providing charters and legal recognition for all higher-education institutions, both public and private. The state governments determine tuition charges, sponsor loan and grant programs, and in some cases determine admissions policy for the public colleges and universities. State authorities appoint governing boards (although in a few cases these boards are elected).

The policies of the fifty states are central to public higher education, though the states differ substantially in their approaches to higher education. Some states, especially in New England, where there is a strong tradition of private higher education, have provided limited support for public colleges and universities and tend to charge high tuition. In Massachusetts, for example, more than half the students attend private colleges—the highest proportion in the United States. In the Midwest and the West, however, states have been more supportive of large, and often excellent, public higher-education systems. California has the largest public higher-education system, and has been a model for shaping state higher education in an era of mass access. A combination of community colleges, four-year schools, and research universities has characterized the California system, and is common in other states. California has always had relatively low tu-

ition, while the New England states typically charge students more. The policies of the state governments concerning student tuition, financial support, access and accountability, and the size and shape of state systems of higher education are all crucial to public higher education. State policies also affect private universities and colleges. In some states, public funds are available for scholarships and other programs for private higher education, and in a few states, such as New York, the state has the power to approve degree programs and other initiatives in the private sector.

The federal government also has a significant impact on higher education. Indeed, the role of the federal government has increased dramatically in the period following World War II. The G.I. Bill, the major federally sponsored scholarship program following the war, enabled millions of returning veterans to attend college and resulted in a wave of expansion in higher education. Stimulated in part by the cold war, the federal government increased funding for research and became the major source of funding for scientific research. In the period of greatest expansion, during the 1960s, federal funds became available to build new facilities and expand libraries. Perhaps most important, the federal student loans programs and the Pell Grant system have become a major part of financing postsecondary education for millions of students.

The federal government regulates certain aspects of higher education, and these regulations reflect the external influences on American colleges and universities. Federal regulations affect such aspects of academic life as athletic programs, which are subject to regulations concerning gender equality and access, the use of human subjects in research, the treatment of animals in laboratories, and access to facilities through the Americans with Disabilities Act. Federal regulatory authority expanded during the 1980s and 1990s. Universities that receive federal funding, which means almost all American academic institutions, are subjects to regulations and reporting requirements. Statistics concerning the composition of the faculty and the student body, statistics on campus crime, and other aspects of academic life must all be submitted to the federal government to comply with regulatory requirements.

The legal system also affects higher education and constitutes an important external societal force for colleges and universities. Court decisions of all kinds directly affect higher education. Of consider-

able importance—and much controversy—have been court decisions concerning affirmative action for both students and faculty. The courts, for example, have limited, and in some cases even eliminated, considerations of race in university admissions and other programs, and they have ruled on faculty hiring and promotion. Courts occasionally intervene in university decisions concerning tenure and promotion if specific complaints are made, and academic decisions are sometimes overturned. Court decisions thus set precedents for academic policy.

Government, at all levels, is a central external force affecting colleges and universities. Because 80 percent of American postsecondary students attend public colleges and universities, governmental policy is especially important. The government provides the bulk of funding for public institutions, which are directly subject to government policy and direction. Although government funding supports a declining proportion of academic budgets, government influence and control remain strong. Higher education is subject to accountability at many levels, and the political, legal, and regulatory system of higher education has a strong influence on higher education at every level.

### Religious Factors

Historically, religion has been a central force in American higher education. Most of the early colleges, including Harvard and Yale, were established by religious organizations with specifically religious purposes in mind. For almost two centuries, religion was one of the major motivations for the expansion of higher education, and a large majority of academic institutions were controlled by religious bodies. The curriculum was a combination of religious and secular subjects, with the religious elements gradually decreasing in importance. Regulations imposed by church sponsors governed extracurricular life, and had an impact on the faculty as well. By the end of the nineteenth century, with the expansion of public higher education, church-related institutions became a smaller part of the higher-education system.

By the end of the twentieth century, religious influences became much less pervasive. Religion plays no significant role in the public colleges and universities in the early twenty-first century. This reduced role is strengthened by the constitutional separation of church and state. Many of the private colleges and universities once sponsored by religious bodies have become secularized. Church groups no longer spon-

sor institutions such as Harvard, the University of Chicago, and Duke. At the same time, there are hundreds of religiously sponsored institutions—there are more than 200 Roman Catholic colleges and universities, and a large number of Protestant institutions. But these schools educate only a small part of the student population, and even they are, in general, less influenced by religious factors than was once the case. It is fair to say that religion is no longer a major factor in American higher education, and that its influence is limited to a small number of private religiously sponsored colleges and universities.

### Societal Influences

Societal trends and developments uniquely influence American colleges and universities. Academe has always been attuned to demands for new curricula, new initiatives, and in general to the interests of external forces. This is in contrast to academe in many other parts of the world, which until recently were mostly elite institutions less influenced by society. Americans historically have established new institutions to meet perceived needs, from the desire of the Puritans to educate clergy, which led to the establishment of Harvard in 1636, to the growth of women's colleges in the nineteenth century to serve the needs of women seeking access to higher education, and to the inclusion of research in university curricula at the end of the nineteenth century to help meet the needs of a developing society.

Academic institutions have also moved quickly to expand and diversify the curriculum to meet new societal needs, whether it be the growth of medical education in the universities or the remarkable expansion of business schools in the post-World War II period. There is an inevitable tension between ideas of autonomy ingrained in academic institutions and pressures from society. In the twenty-first century, external pressures of all kinds—economic, political, and others—characterize the higher-education system.

## HIGHER EDUCATION, INTERNATIONAL ISSUES

---

Higher education has developed in numerous ways since the end of World War II. Throughout the world, issues such as autonomy and accountability, the impact of technology, the growing role of markets and the privatization of higher education, the role of research and teaching, various efforts toward curriculum reform, and the massive expansion that has characterized higher education systems in most countries have all played important roles in the development of higher education. Universities are international institutions, with common historical roots, and at the same time are embedded in national cultures and circumstances. It is worthwhile to examine the contemporary challenges to higher education in comparative perspective, as most issues affect academe everywhere.

### Expansion: Hallmark of the Postwar Era

Postsecondary education has expanded since World War II in virtually every country in the world. The growth of postsecondary education has, in proportional terms, been more dramatic than that of primary and secondary education. Writing in 1975, Martin Trow spoke of the transition from *elite* to *mass* and then to *universal* higher education in the industrialized nations. While the United States enrolled some 30 percent of the relevant age cohort (18–21 year olds) in higher education in the immediate postwar period, European nations generally maintained an elite higher education system, with fewer than 5 percent of the population attending postsecondary institutions. By the 1960s many European nations educated 15 percent or more of this age group—Sweden for example, enrolled 24 percent in 1970, with France at 17 percent. At the same time, the United States increased its proportion to around 50 percent, approaching universal access. By the mid-1990s many European countries, including France, Germany, and the United Kingdom, enrolled around 50 percent of the relevant age group, and the proportion in the United States increased to three-quarters. While Europe and North America are now relatively stable, middle-income countries and countries in the developing world have continued to expand at a rapid rate.

In the Third World, expansion has been similarly dramatic. Building on tiny and extraordinarily elitist universities, higher education expanded rapidly in the immediate post-independence period. In India, enrollments grew from approximately 100,000 at the time of independence in 1947 to over 6.5 million in the 1990s—although India enrolls just 7 percent of the relevant age group. China enrolls a similar number, though this represents only 5 percent of its young people. China, especially, is engaged in a dramatic expansion program. Expansion in Africa has also been rapid, with the postsecondary student population growing from 21,000 in 1960 to 437,000 in 1983, but with growth stagnating in the 1990s as a result of the economic and political difficulties experienced by many sub-Saharan African countries. Recent economic difficulties in much of sub-Saharan Africa have meant that per-student expenditure has dropped, contributing to a marked deterioration in academic standards. Enrollment growth has also slowed.

Expansion is also a hallmark elsewhere in the non-Western countries. The situation is complex. In

some countries, including the larger Latin American nations, the Philippines, and some others, enrollment rates have reached 30 percent or more. In most of the low-income nations, however, enrollments lag far behind. However, growth continues to be rapid in much of the Third World, with accompanying strains on budgets and facilities—and deterioration in standards. Expansion in the Third World has, in general, exceeded that in the industrialized nations, at least in proportional terms. It should be noted that there are significant variations among Third World nations—some countries maintain small and relatively elitist university systems, while others have expanded more rapidly. Among the highest rates of expansion, and now of participation, are in those newly industrialized countries such as South Korea and Taiwan.

There are many reasons for the expansion of higher education. A central cause has been the increasing complexity of modern societies and economies, which have demanded a more highly trained workforce. Almost without exception, postsecondary institutions have been called on to provide the required training. Indeed, training in many fields that had once been imparted on the job has become formalized in institutions of higher education. Whole new fields, such as computer science, have come into existence, and many of these rely on universities as a key source of research and training. Nations now developing scientific and industrial capacity, such as Korea and Taiwan, have depended on academic institutions to provide high-level training and research expertise to a greater extent than was the case during the first industrial revolution in Europe.

Not only do academic institutions provide training, they also test and provide certification for many roles and occupations in contemporary society. These roles have been central to universities from their origins in the medieval period, but have been vastly expanded in recent years. A university degree is a prerequisite for an increasing number of occupations in most societies. Indeed, it is fair to say that academic certification is necessary for most positions of power, authority, and prestige in modern societies. This places immense power in the hands of universities. Tests to gain admission to higher education are rites of passage in many societies and are important determinants of future success. Competition within academe varies from country to country, but in most cases an emphasis is also placed on high

academic performance and tests in the universities. There are often further examinations to permit entry into specific professions.

The role of the university as an examining body has grown for a number of reasons. As expansion has taken place, it has been necessary to provide ever more competitive sorting mechanisms to control access to high-prestige occupations. The universities are also seen as meritocratic institutions that can be trusted to provide fair and impartial tests to measure accomplishment honestly and, therefore, determine access. When such mechanisms break down—as they did in China during the Cultural Revolution—or where they are perceived to be subject to corrupt influences—as in India—the universities are significantly weakened. The older, more informal, and often more ascriptive means of controlling access to prestigious occupations are no longer able to provide the controls needed, nor are they perceived as fair. Entirely new fields have developed where no sorting mechanisms existed, and academic institutions have frequently been called upon to provide not only training but also examination and certification.

Expansion has also occurred because the growing segments of the population of modern societies demand it. The middle classes, seeing that academic qualifications are necessary for success, demand access to higher education. Governments generally respond by increasing enrollment. When governments do not move quickly enough, private initiatives frequently establish academic institutions in order to meet the demand. In countries like India, the Philippines, and Bangladesh, a majority of the students are educated in private colleges and universities. At present, there are powerful worldwide trends toward: (1) imposing user fees in the form of higher tuition charges, (2) increasingly stressing private higher education, and (3) defining education as a “private good” in economic terms. These changes are intended to reduce the cost of postsecondary education for governments, while maintaining access—although the long-term implications for the quality of, access to, and control over higher education remain unclear.

In most countries, higher education is heavily subsidized by the government, and most, if not all, academic institutions are in the public sector. While there is a growing trend toward private initiative and management sharing responsibility for education with public institutions, governments will likely con-

tinue to be central to funding postsecondary education, although the private sector is currently the major source of growth worldwide. The dramatic expansion of academic institutions in the postwar period has proved very expensive for governments and has led to a diversification of funding sources. Nonetheless, the demand for access has been an extraordinarily powerful one.

### Change and Reform: Trends since the 1960s

The demands placed on institutions of higher education to accommodate larger numbers of students and to serve expanding functions has resulted in reforms in higher education in many countries. Much debate has taken place concerning higher education reform in the 1960s—and a significant amount of change did take place. It is possible to identify several important factors that contributed both to the debate and to the changes that took place. Without question, the unprecedented student unrest of the period contributed to a sense of disarray in higher education. The unrest was in part precipitated by deteriorating academic conditions that were the result of the rapid expansion. In a few instances, students demanded far-reaching reforms, although they did not always propose specific changes. Students frequently demanded an end to the rigidly hierarchical organization of the traditional European university, and major reforms were made in this respect. The *chair* system, which gave total power to small groups of senior professors, was modified or eliminated, and the responsibility for academic decision making was expanded in some countries to include students. At the same time, the walls of the traditional academic disciplines were broken down by various plans for interdisciplinary teaching and research.

In the 1990s the major trend in restructuring European universities has been on improving the administrative efficiency and accountability of the universities, and many of the reforms of the 1960s were modified or even eliminated. Students, for example, have less power now. In the Netherlands, a national restructuring has increased the power of administrators, reformed the governance system by reducing the power of the senior professors, greatly increased accountability, and shifted more of the financial responsibilities to the academic institutions themselves. Students have little authority in the new arrangements. While the Dutch have implemented the most dramatic reforms, similar trends can be seen in Germany, Sweden, and other countries.

In many industrialized nations structural change has been modest. In the United States, for example, despite considerable debate during the 1960s, there was very limited change in the structure or governance of higher education. Japan, which saw unrest that disrupted higher education and spawned a large number of reports on university reform, experienced virtually no basic change in its higher education system, although several *new model* interdisciplinary institutions were established—such as the science-oriented Tsukuba University near Tokyo. Britain, less affected by student protest and with an established plan for expansion in operation, also experienced few reforms during the 1960s, and some of the changes implemented in the 1960s have since been criticized or abandoned. In Germany, reforms in governance that gave students and junior staff a dominant position in some university functions were ruled unconstitutional by the German courts.

Many of the structural reforms of the 1960s were abandoned after a decade of experimentation, or they were replaced by administrative arrangements that emphasized accountability and efficiency. Outside authorities—including government, but in some cases business, industry, or labor organizations—have come to play a more important role in academic governance. The curricular innovations of the 1960s, as well as later decades, have proved more durable. Interdisciplinary programs and initiatives and the introduction of new fields such as gender studies have characterized changes in many countries.

Vocationalization has been an important trend in higher education change. Throughout the world there is a conviction that the university curriculum must provide relevant training for a variety of increasingly complex jobs. The traditional notion that higher education should consist of liberal, nonvocational studies for elites, or should provide a broad but unfocused curriculum, has been widely criticized for lacking “relevance.” Students, worried about obtaining remunerative employment, have pressed the universities to be more focused. Employers have also demanded that the curriculum become more directly relevant to their needs. Enrollments in the social sciences and humanities, at least in the industrialized nations, have declined because these fields are not considered vocationally relevant.

Curricular vocationalism is linked to another key worldwide trend in higher education: the in-

creasingly close relationship between universities and industry. Industrial firms have sought to ensure that the skills they need are incorporated into the curriculum. This trend also has implications for academic research, since many university-industry relationships are focused largely on research. Industries have established formal linkages and research partnerships with universities in order to obtain help with research in which they are interested. In some countries, such as Sweden, representatives of industry have been added to the governing councils of higher education institutions.

University-industry relations have become crucial for higher education in many countries. Technical arrangements with regard to patents, confidentiality of research findings, and other fiscal matters have become important. Critics have pointed out that the nature of research in higher education may be altered by these new relationships, as industrial firms are not generally interested in basic research. University-based research, which has traditionally been oriented toward basic research, may be increasingly skewed to applied and profit-making topics. There has also been some discussion of the orientation of research, particularly in fields like biotechnology, where broader public policy matters may conflict with the needs of corporations. Specific funding arrangements have also been questioned. Pressure to serve the immediate needs of society, and particularly the training and research requirements of industry, is currently a key concern for universities, one that has implications for the organization of the curriculum, the nature and scope of research, and the traditional relationship between the university and society.

Universities have traditionally claimed significant autonomy for themselves. The traditional idea of academic governance stresses autonomy, and universities have tried to insulate themselves from direct control by external agencies. However, as universities have expanded and become more expensive, there has been immense pressure by those providing funds for higher education (mainly governments) to expect accountability from universities. The conflict between autonomy and accountability has been one of the flashpoints of controversy in recent years. Without exception, autonomy has been limited, and new administrative structures have been put into place in such countries as Britain and the Netherlands to ensure greater accountability. The issue takes on different implications in different parts of

the world. In the Third World, for example, traditions of autonomy have not been strong, and demands for accountability, which include both political and economic elements, are especially troublesome. In the industrialized nations accountability pressures are more fiscal in nature.

### The Twenty-First Century

The university in modern society is a durable institution. It has maintained key elements of the historical models from which it evolved over many centuries, while at the same time it has successfully evolved to serve the needs of societies during a period of tremendous social change. There has been a convergence of both ideas and institutional patterns and practices in higher education throughout the world. This has been due in part to the implantation of European-style universities in the developing areas during and after the colonial era, and in part to the fact universities have been crucial in the development and internationalization of science and scholarship.

Despite remarkable institutional stability over time, universities have changed and have been subjected to immense pressures in the post-World War II period. Many of the changes chronicled here are the result of great external pressure and were instituted despite opposition from within the institutions. Some have argued that the university has lost its soul. Others have claimed that the university is irresponsible because it uses public funds and does not always conform to the direct needs of industry and government. Pressure from governmental authorities, militant students, or external constituencies have all placed great strains on academic institutions.

The period since World War II has been one of unprecedented growth—the dominant trend worldwide has been toward mass higher education. The university is at the center of the postindustrial, knowledge-based society. The problems faced by higher education are, in part, related to growth and expansion. The following issues are among those that will be of concern in the coming decade and beyond.

**Access and adaption.** Although in a few countries access to postsecondary education has been provided to virtually all segments of the population, in most countries a continuing unmet demand exists for higher education. Progress toward broadening

the social class base of higher education has slowed (and in many industrialized countries stopped in the 1970s). With the arrival of democratic governments in eastern Europe, the reemergence of demand in western Europe, and continuing pressure for expansion in the Third World, demand for access continues, fueling an expansion of enrollments in many countries. Often, limited funds and a desire for efficient allocation of scarce postsecondary resources come into direct conflict with demands for access. In addition, demands for access by previously disenfranchised groups will continue to place great pressure on higher education. In many countries, racial, ethnic, or religious minorities play a role in shaping higher education policy.

#### **Administration, accountability, and governance.**

As academic institutions become larger and more complex, there is increasing pressure for a greater degree of professional administration. At the same time, the traditional forms of academic governance are increasingly criticized—not only because they are unwieldy, but also because in large and bureaucratic institutions they are inefficient. The administration of higher education will increasingly become a profession, much as it is in the United States. Academic institutions have become complex bureaucratic structures, requiring managerial expertise to administer. Demands for accountability are growing and will cause academic institutions considerable difficulty. As academic budgets expand, there are inevitable demands to monitor and control expenditures. The appropriate level of governmental supervision of higher education remains contested terrain. The challenge will be to ensure that the traditional—and valuable—patterns of faculty control over governance and the basic academic decisions in universities are maintained in a complex and bureaucratic environment.

**Research and knowledge dissemination.** Research is a central part of the mission of many universities, and of the academic system in general. Contemporary knowledge-based societies depend on research, both basic and applied, for their success, and universities have traditionally been key sources of research. Decisions concerning the control and funding of research, the relationship of research to the broader curriculum and teaching, the uses made of university-based research, and other related issues will all be in contention in future years. Current debates concerning the appropriate role of industry in sponsoring, and perhaps controlling, research, and about the

control of knowledge products, will help to shape the future of academic research.

The system of knowledge dissemination, including journals, books, and computer-based data systems, is rapidly changing, and many questions remain unanswered. Who should control the new data networks? How will traditional means of communication, such as journals, survive in this new climate? How will the scientific system avoid being overwhelmed by the proliferation of data? Who will pay for the costs of knowledge dissemination? In addition, the needs of peripheral scientific systems, including both the Third World and smaller academic systems in the industrialized world, have been largely ignored, but are nonetheless important.

While the technological means for rapid knowledge dissemination are available, issues of control and ownership, the appropriate use of databases, problems of maintaining quality standards in databases, and other related questions are very important. It is possible that the new technologies will lead to increased centralization rather than to wider access. It is also possible that libraries and other users of knowledge will be overwhelmed, both by the cost of obtaining new material and by the flow of knowledge. At present, academic institutions in the United States and other English-speaking nations, along with publishers and the owners of the communications networks, stand to gain. The major Western knowledge producers currently constitute a kind of cartel of information, dominating not only the creation of knowledge but also most of the major channels of distribution. Simply increasing the amount of research and creating new databases will not ensure a more equal and accessible knowledge system.

**The academic profession.** In most countries, the professoriate has found itself under great pressure at the turn of the twenty-first century. Demands for accountability, increased bureaucratization of institutions, fiscal constraints in many countries, and an increasingly diverse student body have all challenged the professoriate. In most industrialized nations, a combination of fiscal problems and demographic factors have led to a stagnating profession. At the beginning of the twenty-first century, demographic factors and a modest upturn in enrollments are beginning to turn surpluses into shortages. In the newly industrializing countries (NICs), the professoriate has significantly improved its status, remuneration, and working conditions. In the poorer nations, however, the situation has, if anything, become

more difficult with decreasing resources and ever-increasing enrollments. Overall, the professoriate will face severe problems as academic institutions change during the twenty-first century. Maintaining autonomy, academic freedom, and a commitment to the traditional goals of the university will be difficult.

In the West, it will be hard to lure the “best and brightest” into academe in a period when faculty positions are again relatively plentiful—in many fields, academic salaries have not kept pace with the private sector, and the traditional academic lifestyle has deteriorated. The pressure on the professoriate not only to teach and do research, but also to attract external grants, do consulting, and the like, is great. In Britain and Australia, for example, universities have become “cost centers,” and accountability has been pushed to its logical extreme. British academics entering the profession after 1989 will no longer have tenure, but will, in the future, be periodically evaluated. In the NICs, the challenge will be to create a fully autonomous academic profession in a context in which traditions of research and academic freedom are only now developing. The difficulties faced by the poorer Third World countries are perhaps the greatest, as they struggle to maintain a viable academic culture under deteriorating conditions.

**Private resources and public responsibility.** In almost every country there has been a growing emphasis on increasing the role of the private sector in higher education. One of the most direct manifestations of this trend is the role of the private sector in funding and directing university research. In many countries private academic institutions have expanded, or new ones have been established. In addition, students are paying an increasing share of the cost of their education as a result of tuition and fee increases, and through loan programs.

Governments try to limit their expenditures on postsecondary education, while at the same time recognizing that the functions of universities are important. Privatization has been the primary means of achieving this broad policy goal. Inevitably, decisions concerning academic developments will move increasingly to the private sector, with the possibility that broader public goals may be ignored. Whether private interests will support the traditional functions of universities, including academic freedom, basic research, and a pattern of governance that leaves the professoriate in control, is unclear. Some of the most interesting developments in private higher education can be found in such countries as

Vietnam, China, and Hungary, where private institutions have recently been established. The growth of a new for-profit private sector in the United States and elsewhere creates an entirely new sector of higher education, and private initiatives in higher education will bring a change in values and orientations. It is not clear, however, that these values will be in the long-term best interests of the university.

**Diversification and stratification.** While diversification—the establishing of new postsecondary institutions to meet diverse needs—is by no means an entirely unprecedented phenomenon, it is a trend that has been of primary importance, and it will continue to reshape the academic system. In recent years, the establishment of research institutions, community colleges, polytechnics, and other academic institutions designed to meet specialized needs and serve specific populations has been a primary characteristic of growth. At the same time, the academic system has become more stratified, and individuals within one sector of the system are finding it difficult to move to a different sector. There is often a high correlation between social class (and other variables) and selection to a particular sector of the system.

To some extent, the reluctance of traditional universities to change is responsible for some of the diversification. Perhaps more important, however, has been the belief that it is efficient and less expensive to establish new limited-function institutions.

One element of diversification is the inclusion of larger numbers of women and other previously disenfranchised segments of the population. Women now constitute 40 percent of the postsecondary student population worldwide—and they are now a majority in U.S. institutions. In many countries, students from lower socioeconomic groups, and racial and ethnic minorities, are entering postsecondary institutions in significant numbers. This diversification will also present challenges in the coming decades.

**Economic disparities.** There are substantial inequalities among the world’s universities—and these inequalities will likely grow. The major universities in the industrialized nations generally have the resources to play a leading role in scientific research—though it will be increasingly expensive to keep up with the expansion of knowledge. Universities in much of the Third World, however, simply cannot cope with the continuing pressure for increased en-

rollments, particularly when combined with budgetary constraints and, in some cases, fiscal disasters. For example, universities in much of sub-Saharan Africa have experienced dramatic budget cuts and find it difficult to function, not to mention to improve quality and compete in the international knowledge system. In the middle are academic institutions in the Asian NICs, where significant academic progress has taken place. Thus, the economic prospects for postsecondary education worldwide are mixed.

### Conclusion

Universities share a common culture and reality. In many basic ways there is an international convergence of institutional models and norms. At the same time, there are significant national differences that will continue to affect the development of academic systems and institutions. It is unlikely that the basic structures of academic institutions will change dramatically; the traditional university will survive, although it will be changed by the forces discussed here. Open universities and other distance education institutions have emerged, and may provide new institutional arrangements. Efforts to save money may yield further organizational changes as well. Unanticipated change is also possible.

The circumstances facing universities in the first part of twenty-first century are not, in general, favorable. The realities of higher education as a "mature industry," with stable, rather than growing, resources in the industrialized countries, will affect not only the funds available for postsecondary education, but also practices within academic institutions. Accountability, the impact of technologies, and the other forces discussed here will all affect colleges and universities. Patterns will, of course, vary worldwide. Some academic systems, especially those in the newly industrializing countries, will continue to grow. In parts of the world affected by significant political and economic change, the coming decades will be ones of reconstruction. The coming period, therefore, holds many challenges for higher education.

### HISTORICAL DEVELOPMENT

At the start of the twenty-first century, higher education in the United States stands as a formidable enterprise. As an established “knowledge industry” it represents about 3 percent of the gross national product. Virtually every governor and legislature across the nation evokes colleges and universities as critical to a state’s economic and cultural development. Its profile includes more than 4,000 accredited institutions that enroll over fifteen million students and confers in excess of two million degrees annually. Colleges and universities spend about \$26 billion per year on research and development, of which \$16 billion comes from federal agencies. The research universities’ ability to attract expertise is recognized internationally.

This success story of growth and expansion began more than 300 years ago before the United States existed. Beginning in the seventeenth century, the idea of an American higher education grew to fruition throughout the ensuing centuries. At the same time, differences developed with each new era of collegiate growth, but the story has remained one of expanding access.

#### The Colonial Period

Imperial governments usually invested little in colonial colleges. The typical mercantile approach emphasized the exportation of agricultural products

and raw materials from the provinces to the homeland. The British Empire, for instance, responded to Virginia’s request for a seminary to save their souls, with “Souls?!? Damn your souls! Make tobacco.” Despite such hostility, the American colonies generally enjoyed greater independence than the typical British territory. While a succession of kings and queens encouraged the cultivation and exportation of tobacco, rice, indigo, and cotton, colleges also flourished as an unlikely crop in America.

The colonists created institutions for higher education for several reasons. New England settlers included many alumni of the royally chartered British universities, Cambridge and Oxford, and therefore believed education was essential. In addition, the Puritans emphasized a learned clergy and an educated civil leadership. Their outlook generated Harvard College in 1636. Between Harvard’s founding and the start of the American Revolution, the colonists chartered nine colleges and seminaries although only one in the South.

Religion provided an impetus for the creation of colonial colleges. As the First Great Awakening of the 1730s to 1770s initiated growth in a wider variety of Protestant churches, each denomination often desired its own seminary. Furthermore, each colony tended to favor a particular denomination and so the new colleges took on an importance for regional development as well. Presbyterians in New Jersey founded the College of New Jersey (later renamed Princeton). The College of William and Mary in Virginia maintained a strong Anglican orientation, reflecting that colony’s settlement by landed gentry from England. The Baptists, who had been expelled from Massachusetts Bay Colony and settled in Rhode Island, established their own college but in an unusual move did not require religious tests for admission. Other dissenting religious groups, such as the Methodists and Quakers, became enthusiastic college builders after facing hostility in many colleges.

Small in size and limited in scope, colonial colleges rarely enrolled more than one hundred students and few completed their degrees. Yet the young men who attended these colonial colleges made historic and extraordinary contributions to both political thought and action. Also, colleges represented one of the few institutional ventures to receive royal and/or colonial government support and regulation during the eighteenth century. The college’s multipurpose buildings were typically among

the largest construction projects in the colony, matched only by a major church or a capitol.

Though colonial colleges were frontier institutions that expanded access to higher education, by contemporary standards the colonial period remained elite and exclusionary. Only white Christian males were allowed to matriculate. Women and African-Americans were denied participation by statute and custom, but colleges did serve Native Americans in a missionary capacity. The evangelism of the Protestant groups attracted donors, although in time the colonial colleges' devotion to such educational plans waned. In order to keep receiving financial support, however, the colleges argued that by educating young Christian men, missionaries would be available to preach Christianity to Native Americans.

Despite their limitations, the colonial colleges effectively educated a literate, articulate, and responsible American elite. Even though college education was not crucial for the professional and career advancement of sons of prosperous merchants and wealthy planters, the college alumni were disproportionately influential in politics and national affairs. Not only did they lead by action in revolutionary proclamations, but they followed through as military and political leaders. Due in part to a collegiate curriculum that drew from the advanced writings of Scottish and Enlightenment thinkers in political economy, the colonial college alumni designed a system of government destined to serve as a model for the world. The colonial colleges' legacy then was producing a generation of American leaders and thinkers whose combination of decisiveness and thoughtfulness literally turned the world "upside down."

### Higher Education in the New United States

With the founding of the United States of America, governmental policies towards English-chartered colleges became unclear. Wary of centralized power, Americans maintained educational control close to home. Therefore, governance of colonial colleges became almost exclusively the jurisdiction of local and state governments. In actuality the schools enjoyed independence as the Supreme Court's famous *Dartmouth* decision in 1819 demonstrated that the new federal government would protect colleges from state intervention.

With the reputation of colleges remaining high, most state legislatures, particularly in the newer

states west of the Allegheny and Appalachian mountain ranges, looked favorably on chartering colleges as long as the state did not have to provide financial support. Between 1800 and 1850, the United States experienced a "college building boom" in which more than two hundred degree-granting institutions were created. However, since most of these new colleges depended on student tuition payments and local donors, there was also a high closure rate and the schools that did survive typically struggled from year to year.

Although the classical languages and liberal studies of the bachelor of arts degree remained central to the character of American higher education in this era, several new fields gained a foothold in formal study. Engineering and science acquired a presence on the campus. Professional education for law and medicine usually also took place though in separate institutions. Nevertheless, few if any learned professions in the early nineteenth century required academic degrees or certification. Most states reserved the right to set requirements for professional practice, and these were for the most part meager.

Going to college early in the nineteenth century was not particularly expensive. The cost of potential lost opportunities presented a greater concern for students and parents. Employers seldom required college degrees, therefore college presidents faced the perpetual challenge of persuading young adults to delay pursuing their life's enterprises by spending four years on campus. Modest-income families decided whether or not a young man's potential contribution to family labor could be spared while he pursued higher education. The college experience and the college degree did confer prestige and often some professional advantages, but its perceived benefits did not always outweigh the costs.

The United States, for all its deserved acclaim of being a truly "new nation," remained faithful to many of the tenets of English common law. For example, in New England states, the small farms and principle of primogeniture forbade the division of a father's land among numerous sons, so families had to find useful work for those sons not inheriting land. Going to college provided an attractive alternative, especially in subsistence-farming regions. Affordable colleges in rural New England provided an important route to respect and employment in schools and churches. In fact, with the onset of the Second Great Awakening in the early nineteenth century, new denominations once again pushed for

clergy educated in institutions dedicated to their particulars of faith. Their “missionary zeal” led to the founding of new schools and an increase in college attendance. In short, college became useful not just for the elite, but also for sons who had fewer prospects in the new nation. This development resulted in a host of small liberal arts colleges in the Northeast and later in Ohio, Kentucky, and Tennessee that served as an important incubator for a growing middle class.

Educational opportunities for young women followed a comparable pattern. Families often wondered how a young single woman could be self-supporting or contribute to the family welfare. A growing national demand for trained teachers due to the “common-school movement” of the 1830s provided one answer. Women could achieve financial independence and respectability within a rather rigid social structure by attending a normal school or female seminary that provided them with an education for employment as teachers in the ever-expanding nation.

**The mid-nineteenth century.** Variety and growth characterized college building during the mid-nineteenth century. In addition to the conspicuous church-related liberal arts colleges, various groups founded a range of other special interest institutions for advanced study. These included agricultural colleges, proprietary medical schools, freestanding law schools, engineering schools, and scientific colleges. Private philanthropy indicated a growing American interest in founding new institutions concentrated on advanced scientific, technical, and engineering education. Illustrative of this realm was the generous support for such colleges as Rensselaer, Drexel, Cooper Union, and the Massachusetts Institute of Technology.

One of the biggest shifts was the federal government becoming directly involved in higher education, which developed during the Civil War when southern congressmen who opposed the legislation were absent. The Morrill Act of 1862 set in motion an elaborate program whereby states received profits from the sale of an allotted portion of western lands if used to establish programs of agricultural, mechanical, and military sciences, along with liberal arts. The so-called land-grant act thereby stimulated numerous creative proposals and projects. In some cases, states attached their new engineering or agricultural programs to historic colleges. In others, they opted to create new state colleges. Between 1887 and

1914, the land-grant colleges gained support and collective political strength and expanded the definition and scope of university curricula. Legislation such as the Hatch Act and the “Second Morrill Act” of 1890 continued the expansion of federal involvement in education by bringing federal funding and projects to the new land-grant campuses.

Amidst this flurry of federal legislation, African Americans also received attention though the treatment tended to have mixed results. On the one hand, the Morrill Act of 1890 provided funding for African-American education, which led to the creation of Negro colleges in seventeen southern states—a substantial gain in educational opportunities. On the other hand, the guidelines meant that the U.S. government accepted and endorsed state and local practices of racial segregation. By increasing their role in funding higher education, the federal government helped shift the focus of many American colleges.

**Higher education’s gilded age: 1870 to 1910.** Between 1870 and 1910 nearly all institutions of higher education enjoyed a surge in appeal both to prospective students and to benefactors. Some historians have called this period the “Age of the University.” Although accurate, the image remains incomplete. The university ideal certainly took root and blossomed during this period, but the historic undergraduate college also enjoyed growth, support, and popularity. Because of an unprecedented era of commercial and industrial expansion, a new period of philanthropy made possible the founding of well-endowed universities. One enduring sign of this growth came in 1900 when the presidents of fourteen institutions created the Association of American Universities. Its charter members included Johns Hopkins, Columbia, Harvard, Cornell, Yale, Clark, Catholic University, Princeton, Stanford, and the Universities of Chicago, Pennsylvania, California, Michigan, and Wisconsin. Gradually, over the next decades, relatively young state universities in the Midwest, along with private institutions such as Brown, Northwestern, Massachusetts Institute of Technology, and Vanderbilt, would also gain recognition and “university” status for their acceptance into the Association of American Universities.

The creation of the Association of American Universities reinvigorated an ongoing and intense debate over the proper definition and role of a modern American university. Nevertheless, without any official consensus, some general patterns of practice

and aspiration stood out. The new modern university emphasized graduate programs, including the study for and conferral of the doctor of philosophy degree or Ph.D. In fact, the proliferation of varied degree programs connected with professions illustrated a new era in higher education. Many undergraduate programs in agriculture, engineering, business, education, and home economics, along with military training, challenged the old definition of collegiate studies. Medicine, law, and theology, three traditional professions, developed varying relationships with universities and academic standards.

A lack of national academic standards, especially among secondary schools, colleges, and universities, gave rise to the entrance of private agencies into the higher education arena. Such organizations as the Carnegie Foundation for the Advancement of Teaching and the Rockefeller General Education Board adjudicated ratings among American universities. The foundation directors used a combination of coercion and incentives to prompt universities, including professional schools, to adhere to reasonable criteria of admissions, instruction, and certification. On balance, the foundations probably acknowledged and promoted those universities that were already reasonably strong and sound, and raised the floor for others.

Much to the chagrin of “serious scholars,” students shaped the undergraduate world according to their own preferences. It was in the elaborate extracurricular experiences of intercollegiate sports, campus newspapers, collegiate drama, literary societies, alumni groups, and fraternities that students reveled. Student (and public) enthusiasm for these activities grew as the popular media glamorized the social activities rather than scholarly pursuits.

Although the new structure and ethos of the “university” gained attention for its innovation, equally important was the support for and interest in smaller liberal arts colleges. This rising tide for colleges included an extended boom for the founding of women’s colleges. Mount Holyoke Seminary in western Massachusetts transformed itself into a bachelor’s degree-granting institution. Other prominent women’s colleges founded in this era were Smith, Wellesley, Radcliffe, Pembroke, Barnard, and Bryn Mawr. Women also gained access via new co-educational institutions such as the University of Chicago, Stanford University, and many state colleges and universities in the Midwest and the West.

**Higher education between the world wars.** Between 1914 and 1918 the American campus displayed some flexibility to accommodate special programs for the domestic effort during World War I. It included special training programs for military personnel and sporadic but important instances of faculty research leading to direct inventions and innovations in warfare. Projects such as future Harvard president James B. Conant’s efforts to develop mustard gas foreshadowed even greater cooperation between the universities and federal government during World War II.

College enrollments and public enthusiasm surged after World War I. One indicator of this popularity was the proliferation of huge football stadiums—most of which were named “Memorial Field.” Crowds exceeding 50,000 at campus games became standard at many universities. Although popular since the 1890s, intercollegiate athletics soared in commercial appeal during the 1920s. The absence of any substantive national voluntary self-regulation led the Carnegie Foundation for the Advancement of Teaching to publish a highly visible expose of college sports’ excesses in 1929. Some university officials denied the report’s findings, but the Carnegie Study was timely and accurate. The abuses in college sports underscored what Abraham Flexner of the Carnegie Foundation identified as the root source of problems in American higher education: a lack of consensus on clarity of mission and purpose. Unfortunately for Flexner and his colleagues, too many colleges and their constituencies were well served by the amorphous, unregulated nature of American higher education. What was intended as a marketplace of ideas became simply a marketplace, in which students were consumers and sports was the best-seller.

The onset of the Great Depression illustrated an interesting phenomenon: college enrollments increased during times of national financial hardship. While institutions reduced budgets, many worked to sustain American colleges in lean years. Some universities also demonstrated resourcefulness in seeking out business and industrial projects for their faculty in such fields as engineering and physics. These initiatives by such schools as Stanford, Massachusetts Institute of Technology, and California Institute of Technology laid the groundwork for external projects sponsored by both the private sector and the federal government that would come to fruition in the 1940s.

**Higher education's golden age: 1945 to 1970.** Between 1941 and 1945 American colleges and universities participated directly and effectively in a complex national war effort. This track record in times of duress brought long-term rewards and readjustments after the war. In 1947, the President's Commission on Higher Education in a Democracy concluded that federal funding of research should continue even in peacetime. In response to the "problem" of returning military personnel to the domestic economy and as a measure of gratitude, Congress passed the Servicemen's Readjustment Act (1944), popularly known as the "G.I. Bill." For at least a temporary period, this generous and flexible financial aid program enabled an unprecedented number of veterans to attend colleges, universities, and an array of "postsecondary" institutions. This legislation also gave energy to civil rights cases linked with educational access.

In addition to federal funding, growing states with enthusiastic governors and legislatures sought ways to work with their state's educational leaders to accommodate an impending enrollment boom. The rising birth rate and increased migration into selected states, along with a deliberate extension of college admissions, caused this dramatic growth. California led the way in statewide coordination with its Master Plan of 1960. This program aimed at accommodating mass access to affordable higher education by channeling students into tiered institutions.

Among the most conspicuous transformations was the emergence of a network of public junior colleges. Founded in the early 1900s, junior colleges experienced expansion in California during the 1930s. After World War II these institutions carried out two critical functions in mass postsecondary education. First, they developed a "transfer function" in which students could enter colleges or universities after two years of course work at the junior college. They also offered advanced, terminal degree instruction and certification in a range of professional and occupational fields. By the 1960s, the addition of a third function—readily accessible, low-priced continuing education for adults—led to a change in the name from *junior college* to *community college*.

The federal government participated in the expansion of sponsored research and development education during the 1950s and 1960s. Drawing from former MIT President Vannevar Bush's 1945 monograph, *Science: The Endless Frontier*, Congress and a succession of U.S. presidents endorsed federal spon-

sorship of high-level, peer-reviewed national research projects. Federal agencies that became most involved were those requiring applied technical research, specifically defense and agriculture. The behavioral sciences gradually adopted this model for large-scale psychological testing, and then various health care programs also sought funding. Agencies such as the National Institute of Health possessed a limited scope and a miniscule budget in the late 1940s, but acquired an increasing presence over the next four decades. In 1963, Clark Kerr's work *The Uses of the University* summarized this culmination of government patronage in research and development. According to Kerr, about fifty to one hundred institutions had positioned themselves to be "Federal Grant Universities": powerful incubators of advanced scholarship in the sciences possessing the ability to inspire confidence and funding in their research grant applications.

Both public and private universities benefited from governmental concerns about "cold war" defense and competition with the Soviet Union. Fears resulting from an extended definition of "national defense" led to funding for advanced studies in foreign languages, anthropology, and political science as well as the "hard" sciences of physics and chemistry. The transfer of these national programs to higher education institutions increased both the founding of new campuses and the construction of new buildings on older campuses. According to one study in 1986, about 75 percent of American campus buildings were constructed between 1960 and 1985, suggesting that the symbol for higher education during the cold war ought to be the building crane.

Enrollment also surged during the cold war era. Just prior to World War II the state universities with the largest enrollments—namely, the Ohio State University and the University of California at Berkeley—surged far ahead of other institutions with enrollments of around 19,000. Many major state universities prior to World War II had enrollments between 3,000 and 6,000. By 1970, however, the Ohio State University's main campus at Columbus enrolled more than 50,000—comparable to the University of Minnesota. The University of California had expanded its Berkeley campus enrollment to 26,000.

Some states responded to increasing enrollments with complex, multicampus systems. The University of California, for example, had ten campuses, with a total enrollment exceeding 150,000. At

the same time, the network of California state colleges formed its own system, eventually enrolling about two hundred thousand students as well. In addition, California's community colleges further expanded the accessibility to higher education by forming more than one hundred campuses. In New York, education officials and legislators created an expanded system of more than sixty campuses, the State University of New York (SUNY). While individual states pursued some variation of this theme, public community college systems enjoyed the greatest gains in student enrollments and campus expansion. Especially in such populous states as California, Texas, and Florida, the community college systems served a larger and expanding portion of the state's population. Although relative enrollment in private (independent) colleges decreased from approximately 50 percent of college students in 1950 to about 30 percent, this change did not preclude substantial numerical growth. Rather, the construction of new institutions in the public sector was exceptionally brisk.

Prior to the 1970s, the federal government did not venture much into substantial student financial aid programs. Rather, state and local policies produced low tuition rates at public institutions. However, with the passage of the Education Amendments of 1972, the federal government increasingly promoted college access, affordability, and choice. The showcase of this government interest was a commitment to need-based, portable student financial aid. The Pell Grant, officially known as the Basic Educational Opportunity Grant (BEOG), provided entitlements to enrolled college students who demonstrated financial need. These initiatives fueled dramatic enrollment growth. Though initially popular, by 1978 the emphasis on student grants shifted increasingly to providing low-interest student loans.

Expanded access and growing national investment in the higher education infrastructure increased the need for administration and planning both inside and outside the campus. Hence, higher education in the United States underwent a "managerial revolution" in its decision-making and attempts at coordination. On another level this led to the proliferation of an increasingly complex academic bureaucracy. On a second level, it gave rise to a reliance on a prodigious testing industry. Although the College Entrance Examination Board (CEEB) had been in existence since the turn of the century, it gained great influence after World War II with the

development and diffusion of the Educational Testing Service's Scholastic Aptitude Test (SAT). The capacity of the SAT to make determinations about college admissions and projections on college academic performance coexisted with doubts and controversies about the equity and validity of such high stakes tests. The SAT expanded the nationwide search for academic talent, and enabled the historic institutions of New England and the Atlantic Coast to draw a large percentage of students from public high schools (rather than primarily from nearby private prep schools), while attracting students from a wide geographic base. Despite the promise of standardized exams, by the 1960s there would be intense debates over the ability of the SAT and other such tests to identify genuine aptitude without bias toward socioeconomic class or educational experiences.

Questions of social justice and the clash of national laws with local practices came to the fore in the decade following *Brown v. the Board of Education of Topeka, Kansas* (1954) decision. In numerous states where public universities were segregated by race, policies were challenged. The southern campus came to be a real and symbolic focus of civil rights in American life.

**Tensions and transitions: 1970 to 1985.** Although American campuses expanded in the late 1950s and 1960s, many students did not feel they were well served. Crowding, lack of dormitories, and reliance on large lecture halls created the "impersonality of the multiversity." This malaise over the relative lack of attention to undergraduate education, combined with political activism over free speech, the antiwar protests, and issues of civil rights and social justice, spawned unrest on many American campuses between 1968 and 1972. Whether at such conspicuous universities as Berkeley, Columbia, or Michigan, or at quieter campuses, a generation of campus presidents and deans were unprepared to deal with widespread student dissatisfaction. Furthermore, the nation was unprepared for the tragedies that occurred at Kent State and Jackson State in 1970.

What governors and state legislators perceived as administrative failure to keep a campus house in order ultimately led to a loss of public and government confidence in colleges and universities. This change in attitude, combined with a stressed national economy, signaled for the first time in decades a tapering in public support for higher education. Double-digit inflation and an energy crisis, com-

bined with warnings of a decline in college matriculation, left most American colleges and universities in a troubled situation between 1975 and the early 1980s. Postsecondary institutions in the 1970s enrolled an increasingly diverse student body in areas of race, gender, and ethnicity. Less clear, however, was the question of whether the educational experiences within those institutional structures were effective and equitable, as American higher education faced criticisms for charges of tracking lower income students into particular subsets of institutions and courses of study.

**The end of the twentieth century.** A fifteen-year period beginning in 1985 was a financial roller coaster for higher education in the United States despite the underlying growth of the enterprise. By the mid-1980s virtually every gubernatorial candidate ran as an “education governor,” testimony to the hope that states placed in their colleges and universities to stimulate economic development. Ambitious presidents seized the opportunity to “buy the best,” whether it pertained to recruiting faculty, bright students, intense doctoral candidates, or, regrettably, even athletes. This period of opportunity, however, mortgaged institutions’ futures—a situation that became clear to accountants and boards soon after declines in the stock market and state revenues. Between 1990 and 1993 overextension and uncertainty loomed.

Illustrative of the partial gains in equity and meritocracy was the changing profile of females in higher education, especially in graduate and professional students. Whereas in 1970 relatively few women pursued doctorates or degrees in law or medicine, by 2000 women constituted close to half the students entering law school and about forty percent of first-year medical students. Women even constituted a majority of the Ph.D. recipients in biology, literature, and the humanities. At the same time, however, they were substantially underrepresented in such graduate fields as engineering and the physical sciences.

**Connecting past to present.** One theme that pervades higher education in the United States in the second half of the twentieth century is that of a “managerial revolution.” In response to the expanding definition of higher education, the ability to navigate institutions became a preoccupation. It extended to include the development of professional expertise in fund-raising, as colleges and universities acquired voracious appetites for resources while ex-

tending their mission into new fields and even into new roles. Higher education in the United States has succeeded in running its own operations while also considering new roles and constituencies. Its strength has ironically been its major source of weakness. In other words, the aspiration and ability of the American postsecondary institutions to accommodate some approximation of universal access has been its foremost characteristic. Institutions’ shortfalls in completely achieving that aspiration have been the major source of criticism and debate within American higher education. It is the perpetual American dilemma of how achieve both equality and excellence.

Grappling with the questions of educational equality and access has taken on increased urgency for two reasons. First, the widespread embrace of higher education as a means to legitimacy, literacy, and respectability strikes a deep chord in all sectors of American society. Secondly, since higher education has acquired the strength and stability of being a “mature industry,” it must then compete with numerous activities for a share of the public purse and private donations. Maintaining and bolstering widespread trust in postsecondary education will be the central determinant in present and future discussions about ways in which Americans support higher education.

## SYSTEM

The higher education system of the United States is not so much a formal system as it is an informal configuration of varied institutions. The development of the American system has been unique when compared with other national postsecondary educational systems around the world. Unlike most other countries, where higher education systems have largely developed outward from a central, government-supported university, the United States has never had such an institution. Instead, the evolution of the U.S. system has been shaped by many different influences, including state and local needs, demographics, religion, and changing social contexts. As a result, postsecondary institutions in the United States mirror the multifaceted complexities of the broader society in which they are embedded and the diversity of the people they serve. Moreover, American higher education is quite disorderly in structure and function in contrast to many national postsecondary systems and even in sharp contrast to the rationally organized American compulsory primary and secondary education system. Postsecondary institutions and the students they serve are diverse and not easily categorized. This disorder is characterized by a variety of individual institutional goals and missions, types of degrees offered, finance and gov-

ernance structures, and even curricula, course contents, and instructional methodologies.

In order to understand how this informal and loosely structured “system” of diverse institutions serves the wide-ranging needs of American society, it is necessary to identify some of the main features that define the major types of institutions found in American higher education. In 1983 Robert Birnbaum noted that institutional diversity can be defined across several categories of institutional features. The most useful of these categories include defining differences in terms of the following dimensions of institutional diversity: systemic, structural, constituent, and reputational.

### Systemic Diversity

Systemic diversity refers to differences in types of institutions with regard to their size and scope of mission. Starting in the 1970s, there have been many attempts to develop classification systems for categorizing postsecondary institutions in this manner. The best-known and most well-established classification system was developed by the Carnegie Foundation for the Advancement of Teaching and has come to be known as the “Carnegie Classification.” Originally developed by Clark Kerr in 1970, this classification system was designed to serve the research analysis needs of the Carnegie Commission on Higher Education. The commission “sought to identify categories of colleges and universities that would be relatively homogeneous with respect to the functions of the institutions as well as with respect to characteristics of students and faculty members” (Carnegie Commission on Higher Education, p. v). The Carnegie Classification was originally published in 1973 and has been updated several times, most recently in 2000. It is the framework most often used in describing institutional diversity in the United States and is relied upon by researchers and educational leaders to ensure appropriate comparisons between and among colleges and universities.

The current classification divides institutions into six main categories: doctoral/research institutions, master’s colleges and universities, baccalaureate colleges, associate’s colleges, specialized institutions, and tribal colleges. Within most categories are subcategories. Doctoral/research institutions can be either extensive or intensive and offer a wide range of undergraduate degrees as well as master’s and doctoral-level graduate degrees. Extensive doctoral/research institutions award more doctorates in

a wider range of fields than do intensive institutions. Master's colleges and universities fall into one of two categories (master's I or II) and typically offer a wide range of undergraduate programs as well as graduate education through the master's degree. Category I master's institutions award more master's degrees in a wider range of disciplines than do their category II peers. Baccalaureate colleges primarily focus on undergraduate education and are divided into three categories: baccalaureate colleges—liberal arts, baccalaureate colleges—general, and baccalaureate/associate's colleges. Liberal arts colleges award at least half of their degrees in liberal arts fields, whereas general colleges award less than half of their degrees in liberal arts fields. Baccalaureate/associate's colleges award both associate and baccalaureate degrees. Colleges and universities identified as specialized institutions in the Carnegie Classification may award degrees ranging from bachelor's to the doctorate, but they award the majority of those degrees in a single field. There are several subcategories of specialized institutions, including theological seminaries and other specialized faith-related institutions, medical schools and centers, other health profession schools, schools of engineering and technology, schools of business and management, fine arts schools, schools of law, teachers colleges, military institutes, and other types of specialized institutions. Tribal colleges are generally tribally controlled and located on reservations.

While the Carnegie classification system is often used in making qualitative distinctions among institutions, the commission denies that this is the classification's purpose. In his foreword to the 1987 edition of the classification, Ernest Boyer emphasized that the classification “is *not* intended to establish a hierarchy among learning institutions. Rather, the aim is to group institutions according to their shared characteristics, and we oppose the use of the classification as a way of making qualitative distinctions among the separate sectors” (Carnegie Foundation, p. 2). Nevertheless, the process of “institutional drift,” in which colleges strive to climb the hierarchy, is well documented in the literature. For example, junior colleges become baccalaureate-granting institutions by grafting another two years onto their programs, while doctoral/research-intensive universities increase funded research activities as they aspire to doctoral/research-extensive status. In the early twenty-first century, the Carnegie Foundation was in the process of reassessing the

classification system, rethinking how to characterize similarities and differences among institutions, and allowing multiple classifications of institutions. This work was expected to be concluded in 2005.

While the Carnegie Foundation's system is the most widely used typology in educational research, other classification schemes exist and are usually used for other purposes, such as providing information to prospective students and their families. For example, *U.S. News and World Report* classifies colleges and universities in several typologies. Institutions are divided into categories by whether they tend to serve a national or a regional population and then are rank-sorted into four “tiers.” Schools are also ranked according to best departments for a particular major and best financial value.

Although such categorization schemes are useful in a system that includes tremendous institutional variety, such simplification hides the true complexity of the higher education system of the United States. For example, an institution categorized as a “research university” may also have its roots in land-grant legislation, or may be single-sex or religiously affiliated. Other key hidden aspects of institutional identity include the institution's historical roots—whether it began as a land-grant college, historically black college or university, Hispanic-serving college, tribal college, or religiously affiliated institution. Additionally, there are less apparent dimensions of institutional difference, such as ratios between part-time and full-time students or residential versus commuter students. Athletic division membership is an important facet of institutional identity, as is location (region, urban, rural, suburban). Hence, it is important to pay attention to other aspects of institutional diversity in order to truly understand the nature of the diverse system of American higher education.

### **Structural Diversity**

Structural diversity focuses on the ways in which institutions are organized and controlled. Structural diversity is most often defined in terms of type of institutional control—public or private. Publicly controlled institutions are funded primarily by the government (usually by state governments) and are typically part of a larger state system. Private institutions are primarily funded by nongovernment sources and tend to be independent with their own private governing boards. There are many more private institutions in the United States than there are

public colleges and universities, although public higher education has grown significantly since the 1960s.

While there is no national system of higher education, all states have developed some type of public postsecondary educational system. There are a number of ways in which these systems are structured and organized. Public colleges and universities differ both in the ways in which they are governed and in the ways in which they are coordinated as part of a larger state system. All states assign responsibility for operating public colleges and universities to governing boards, and there are three main types of governing board structures: consolidated governance systems, segmental systems, and single-institution boards. Consolidated boards are responsible for all public postsecondary institutions in a particular state, although in some states this may apply only to the four-year institutions. Segmental systems have different governing boards for different types of campuses; in some states this may mean that public research universities are governed by one board, comprehensive state colleges by another board, and community colleges by yet another board. States that use single-institution boards grant governance autonomy to each public campus by allowing each to have its own board. Public boards vary in the degree to which they have formal governance authority and the extent to which they merely coordinate activities across the state's public postsecondary educational sector without any substantive decision-making powers.

Public institutions within these systems tend to fall into one of three major categories: universities, state colleges, and community colleges. Public universities typically grant a full range of graduate degrees (master's and doctoral), tend to have a strong research emphasis, and typically have large student enrollments. State colleges are typically smaller, may serve a particular region of a state, and usually offer both bachelor's and master's degrees. Community colleges are two-year colleges that provide associate degrees, preparation for transfer to four-year institutions, vocational and technical education and training, and large numbers of continuing education offerings. Some public institutions have been identified as land-grant institutions. Land-grant institutions were first established by the Morrill Act of 1862, which provided federal funds for establishing universities that (1) were open to all types of students (including women, minorities, and low-

income students), (2) offered degrees in practical and applied fields such as engineering and agriculture, and (3) shared knowledge with citizens throughout their state.

Private institutions are less easily characterized than are their public counterparts. Private institutions cover the full range of missions and structures found in American higher education. The most prestigious and highly selective institutions, whether they be Ivy League research universities or smaller liberal arts colleges, are private; but so too are the least well-known institutions. In fact, Alexander Astin and Calvin Lee noted in 1972 that there are literally hundreds of small colleges scattered across the United States that can be thought of as "the invisible colleges." These are small, private institutions with limited resources. Some are affiliated with a particular religion; others began life as private junior colleges. One of the key distinctions among private colleges is whether they are religiously affiliated or not. Religious affiliation occurs in many forms. A religious denomination or order directly controls some institutions, whereas others have only nominal relationships with religious bodies or sponsors. There are also increasing numbers of proprietary institutions that tend to award specialized degrees or that engage in alternative modes of educational delivery, such as distance learning.

### Constituent Diversity

Institutions also vary by the core constituencies they serve, particularly with regard to the particular types of students served. This type of constituent institutional diversity is manifested in many forms, but some of the most prominent institutions that serve particular types of students are those colleges and universities that provide education primarily for student groups that have been traditionally underserved by the majority of postsecondary institutions. These institutions include historically black colleges and universities (HBCUs), Hispanic-serving institutions (HSIs), tribal colleges, and women's institutions.

HBCUs primarily, although not exclusively, exist to provide postsecondary institutions that primarily serve African-American students. There are currently 109 HBCUs, almost half of which are public. They are concentrated in the southern region of the nation, with a few institutions located in the Northeast and Midwest. HBCUs enroll fewer than 20 percent of African-American undergraduates, yet

produce one-third of all African-American bachelor's degrees. HSIs are institutions in which at least one-quarter of the undergraduates are Hispanic. Rapidly growing as a group, there are well more than 100 such institutions in the early twenty-first century. Tribal colleges tend to be controlled by Native American tribes. There are currently twenty of these institutions in the United States. Women's colleges are primarily private and provide postsecondary educational environments that cater specifically to female students. Although there were hundreds of these institutions at one time, that number has dwindled to approximately seventy-five. There are also a handful of male-only institutions scattered across the country. All of these institutions reflect the diversity found in American society and provide the informal system of American higher education with a means of better serving the diverse groups of individuals that constitute a multicultural society. The existence of such diverse institutions has been noted as a particular strength of the American higher education system.

### Reputational Diversity

Another key feature of American higher education is reputational diversity. It has been noted that higher education institutions in the United States are extremely stratified. In 1956 David Riesman offered the classic characterization of the importance of hierarchy and stratification in American higher education when he described the system of higher education as a "snakelike" procession in which the tail (composed of institutions lower in the hierarchy) and the body (representing institutions in the middle of the hierarchy) of the snake continually try to move up and catch the head (those institutions at the top of the hierarchy that serve as a model for other institutions to follow). Reputation appears to depend on a complex set of factors, including undergraduate selectivity and peer evaluations of graduate programs.

### Advantages of the U.S. System

While the lack of systemwide structure creates a somewhat incoherent system of higher education in the United States where widespread coordination is virtually impossible, there are many advantages to this noncentralized approach to a national higher education system. The large degree of institutional diversity that has arisen from the decentralized nature of American higher education has generated

benefits on three levels: institutional, societal, and systemic. At the institutional level, arguments center on serving students' needs. Diversity in this sense would include variety of student body, institutional size, programs offered, and academic standards. Higher education does not exist in isolation, however. Birnbaum stated that "higher education is intimately connected to, and therefore interacts with, other societal systems" (p. 116). Aside from education and research, institutions of higher education have also long served various political, economic, and social functions. Societal arguments for diversity thus center on issues of social mobility and political interests. From a systems theory perspective, higher education is viewed as an "open system," characterized by diverse inputs and outputs. For example, if colleges and universities in the United States admit students with high levels of racial diversity (input), then the impact on society (output) will be very different from what it would be if the U.S. college student population were more homogeneous. Additionally, diversity in higher education is important because "differentiation of component units . . . leads to stability that protects the system itself" (Birnbaum, p. 121). Such systems are able to sense and respond to environmental pressures more quickly and effectively simply because they encompass such extensive variety. In sum, the diverse system of postsecondary institutions in America reflects the diverse composition and needs of the society it serves.

## HISPANIC-SERVING COLLEGES AND UNIVERSITIES

---

Hispanics constitute the fastest-growing minority population in the United States. According to the U.S. Census Bureau, Hispanics represented 12.5 percent of the national population of 281 million in 2000. This is also a fairly young population: 36 percent of Hispanics are under eighteen years of age, and only 5 percent are age sixty-five or older. Moreover, only slightly more than half of all Hispanics are high school graduates, and thus are employed more in service and unskilled occupations than are non-Hispanic whites. In light of these statistics, Hispanic-serving institutions (HSIs) have become important colleges and universities for increasing Hispanics' access to college and improving their economic opportunities.

HSIs are still largely unknown and little understood by most educators and policymakers in the

United States. Although HSIs represent almost 6 percent of all postsecondary institutions, they enroll approximately half of all Hispanic students in college, granting more associate and baccalaureate degrees to Hispanic students than all other American colleges or universities combined. Despite these impressive outcomes, a federal definition for HSIs exists only in the Higher Education Act of 1965, under Title V, as amended in 1992 and 1998. The 1998 legislation defines HSIs as accredited, degree-granting, public or private, nonprofit colleges and universities with 25 percent or more total undergraduate, full-time equivalent, Hispanic student enrollment. HSIs with this enrollment must also meet an additional criterion to qualify for Title V funds, which stipulates that no less than 50 percent of its Hispanic students must be low-income individuals.

The recruitment and retention of Hispanics to college has been the subject of long-standing concern among educators, policymakers, and practitioners. Although still largely unknown, HSIs attract and retain Hispanics in larger numbers than all other postsecondary institutions. Specifically, HSIs educate over 1.4 million students in the United States, of which 50 percent are Hispanic and another 20 percent are students from other ethnic backgrounds. In fact, HSIs might also be called minority-serving institutions, in light of the high percentage of diverse student populations they routinely educate.

### The History of HSIs

The vast majority of HSIs were not created to serve a specific population, as historically black colleges and universities (HBCUs) and tribal colleges were, but rather evolved, starting around 1970, due to their geographic proximity to Hispanic populations and to demographic shifts. With the exceptions of Hostos Community College and the four-year institutions of Boricua College and National Hispanic University, HSIs do not have charters or missions that address distinctive purposes and goals for Latinos. On the other hand, HBCUs, which were begun as early as the nineteenth century, and tribal colleges, which were founded after 1970, intentionally serve their target student populations in accordance with their declared mission statements. However, the incredibly rapid growth of Hispanic-serving colleges and universities since the 1970s has conferred on them an ad hoc mission to serve the Hispanic population, and they are recognized as such by Congress and the Higher Education Act.

The designation of HSIs, and the development of a national awareness of HSIs, is essentially due to the Hispanic Association of Colleges and Universities (HACU), which was founded in 1986. The concept of linking all colleges and universities serving high proportions of Hispanics into an association to gain national recognition and resources was the work of a group of prominent Hispanic educators. Working relationships with corporations, foundations, and federal government agencies were formed to increase funding and services to these institutions. These resources led to providing greater professional growth and development opportunities for Hispanic students, faculty, and administrators. In forming the HACU, a national office in San Antonio, Texas, and another in Washington, D.C., were established to parlay the organization into a national player in the educational, political, and policymaking arenas. As an advocate, HACU focuses on educating policymakers and national leaders about Hispanic educational needs and the resulting economic and political implications for a more democratic and just society.

The rise of HSIs has been rather rapid since these institutions were first recognized nationally. Their rapid growth stems primarily from three significant factors. First, the civil rights movement of the 1960s and college outreach efforts opened up educational opportunities to less traditional college-going populations, including Hispanics and others from diverse racial and ethnic backgrounds. This movement was accompanied by the development of federal and state financial aid that made it possible for more students to go to college. Second, Hispanic immigration to the United States has increased, especially in large urban areas and along the southwest border of the nation. Third, Hispanics are continuing to move into communities where other Hispanics already are established and that are geographically near higher education institutions. Migration patterns, however, also indicate that Hispanics are moving into regions of the country where they have not been before as they seek jobs and more affordable housing.

As a result of these factors, there were 195 HSIs in 2000 and 203 in 2001, according to the White House Initiative on Educational Excellence for Hispanic Americans. Of these, 156 are located in 12 states (Arizona, California, Colorado, Florida, Illinois, Kansas, Massachusetts, New Jersey, New Mexico, New York, Texas, and Washington) and 47 in Puerto Rico—geographic areas where large concen-

trations of Hispanics reside. California, with 57, has the most HSIs, followed by Puerto Rico with 47, and Texas with 32. In addition, Kansas, Massachusetts, and Washington each have one HSI. In terms of type and control, there are 96 four-year HSIs, of which 44 are public and 52 are private. Among the 107 two-year HSIs, 94 are public and 13 are private. Thus, the majority of HSIs are community colleges, and these institutions will most likely continue to increase their Hispanic student enrollments. It is not surprising that California has the highest number of HSIs in the nation. Nearly one out of every three residents of California is Hispanic and the state has a vast system of 108 community colleges, the largest in the United States. On the other hand, Florida's representation of only nine HSIs belies the fact that it is home to the largest community college in the nation: Miami-Dade Community College. This institution consists of five separate campuses, with a total combined enrollment of more than 50,000, and two-thirds of its students are Hispanic.

### **HSIs and Latino Educational Attainment**

Hispanic-serving institutions continue to demonstrate remarkable progress in assisting Hispanics to achieve academic and career success by stimulating higher college-attendance rates and higher degree-attainment rates. For example, the national college-attendance rate of Hispanics was 36 percent in 1997, up nearly 8 percent since 1990. However, this relatively low rate continues to be of national concern to educators and policymakers. Nonetheless, comparative U.S. data for college degrees awarded to Hispanics in HSIs and non-HSIs are remarkable. In 1997 Hispanics earned approximately 46 percent of all associate degrees awarded in HSIs, compared to 7.6 in non-HSIs. They received 23 percent of all bachelor's degrees awarded in HSIs, compared to 5.3 percent in non-HSIs; 19.5 percent of all master's degrees, compared to 3.7 percent in non-HSIs; 4.4 percent of all first professional degrees, compared to 4.6 in non-HSIs; and 6.1 percent of all doctorates, compared to 3.7 in non-HSIs. These data offer evidence that HSIs are directly responsible for increasing the educational attainment of Hispanics.

Data suggest that HSIs may also be credited as producers of the highest number of Hispanics who go on to pursue advanced degrees. Two-year HSIs lead the way in producing the highest number of Hispanic transfer students and associate degree recipients. Research studies further reveal that four-

year HSIs with high Hispanic baccalaureate graduation rates point directly back to community college HSIs as the source of a significant number of their transfer students. These studies also show that four-year HSIs are the highest producers of professional and graduate Hispanic students.

Although the term *Hispanic-serving institutions* was recognized by the Higher Education Act in 1992, HSIs are not listed as a distinct institutional type in the latest Carnegie Classification of Institutions of Higher Education, as are tribal colleges. Also, the federal definition of an HSI is the only one used formally, vis-à-vis Title V and by applicants for funds. The HACU promotes a less stringent definition. HACU members must only have a total of 25 percent Hispanic enrollment, and associate members need only a minimum of 1,000 students. Their publication, *The Voice*, their Internet site, and their annual conference all highlight members' activities and HACU's advocacy role in continuing to influence national policy and garnering corporate support. Yet as recently as March 2001, articles in *The Chronicle of Higher Education* still referred to HSIs as "so-called Hispanic-Serving Institutions" (Yachnin, p. A34), indicating that not everyone accepts this distinct designation thus far.

It is important, however, to consider not only what it is that these newcomers to the higher education lexicon are, but how they are successfully educating students in their institutions. Moreover, it is important to consider what lessons can be learned from them that may be applicable to diverse students in other collegiate environments. Public understanding about HSIs can undoubtedly affect their future in terms of educational policy decisions and funding allocations. Despite their large student enrollments and seemingly low resources, HSIs appear to buffer Hispanic students' socialization into college through culturally sensitive programs that facilitate student academic achievement and completion for these and other minority students. Outreach efforts into the local K-12 schools and surrounding communities where Hispanics reside also are part of the holistic approach many HSIs are taking to raising Hispanic educational attainment rates.

## Conclusion

It is clear that HSIs will continue to increase in number nationally from within the identified 3,856 American public and private, two- and four-year institutions of higher education. They will continue to

be important in the twenty-first century in educating Hispanics and other minorities, whose numbers will continue to rise (according to U.S. census projections). These institutions' unofficial, undeclared dual role will continue to be: to help increase Hispanic college participation and completion rates for this population; and to help narrow the educational and economic gaps for Hispanics. It may well be, as Lisa Wolf-Wendel notes in her 2000 study, that "differences in race, ethnicity, social class, and other experiences influence what students need from their campuses and how campuses should respond. While separate examinations of each institution's characteristics are illuminating, it is important to understand that their whole is greater than the sum of their parts . . . . Instead, it is the combination of characteristics—their ethos—that makes them unique, able to facilitate their students' success" (p. 342).

## HISTORICALLY BLACK COLLEGES AND UNIVERSITIES

Historically black colleges and universities (HBCUs) are institutions that were established prior to 1964 with the mission to educate black Americans. Perhaps one of the greatest struggles faced by blacks in the United States has been the struggle to be educated. This struggle has been guided by the philosophies of black scholars who believed that without struggle there was no progress; black revolutionists who believed that education was the passport to the future; and black clergy who sermonized that without vision the people would perish. Education is now, and always has been, a vital weapon in the black arsenal. Essentially, black Americans used education as their primary source of ammunition in the fight against a segregated society, racism, illiteracy, and poverty. The steadfast desire of the black population to be educated influenced the development of HBCUs, and HBCUs have likewise contributed much to the advancement of the black population.

### The Development of HBCUs

Since the establishment of the first HBCU, there has been a recurrent debate over the role of these institutions within the larger framework of higher education. During the years of strict and legal racial segregation in the United States, HBCUs served as "islands of hope" where blacks could learn to read and write without the fear of being retaliated against. The primary purpose of HBCUs was to educate black Americans, which they did almost exclusively from 1865 to the 1950s. The overwhelming majority

of HBCUs opened after 1865 in response to the need to have institutions to educate newly freed slaves and to avoid admitting those newly freed slaves into the existing white institutions.

The first HBCUs were established in the North and were products of independent religious institutions or philanthropic Christian missionaries. The first two were Cheyney University (Pennsylvania), founded in 1837, and Wilberforce University (Ohio), founded in 1856. However, historically black colleges and universities cannot be examined without revisiting major legislations and court decisions that led to the birth of many and the death of a few. The First Morrill Act (also known as the National Land-Grant Colleges Act of 1862) made postsecondary education accessible to a broader population of American citizens. Ten years after this act was legislated, the Freedman's Bureau was established to provide support to a small number of HBCUs. The Second Morrill Act of 1890 led to the establishment of nineteen HBCUs. Although these three legislative acts provided an atmosphere for change, it was the segregation movement in the South that provided the impetus for black higher education, particularly with the 1896 Supreme Court decision in *Plessy v. Ferguson*, which ultimately established by law the right to set up *separate but equal* schools for blacks. This decision led to the expansion and growth of historically black colleges and universities.

Historically black colleges and universities increased from one in 1837 to more than 100 in 1973. Most of these colleges were founded after the *Plessy v. Ferguson* decision. According to Jacqueline Fleming, "the majority of black public colleges, then, evolved out of state desires to avoid admitting blacks to existing white institutions" (p. 5). On May 17, 1954, the Supreme Court ruled in *Brown v. Board of Education of Topeka, Kansas* that separate education for blacks in public schools was unconstitutional because separate facilities are inherently unequal. This decision, which ended de jure racial segregation in public schools, also impacted higher education, as states were required to dismantle dual systems of higher education. This required predominantly white institutions (PWI) to open their doors to black students, who prior to this time could not attend these institutions.

Interestingly enough, the effects of a decision made in the mid-twentieth century still linger in higher education in the early twenty-first century,

for nowhere are the repercussions from the *Brown* decision more visible than in HBCUs. The dismantling of dual systems in higher education has resulted in mergers and closures of HBCUs because opponents of these institutions view them as segregated colleges and universities. This has led to a series of discussions, debates, and court rulings that underscore the fact that there not enough research has been done on this segment of higher education.

### Academic and Social Experiences at HBCUs

The literature on higher education is scant in the area of HBCUs. These institutions did not become the subject of research studies until the early 1970s. However, researchers have learned a considerable amount about the academic and social experiences of students who attend HBCUs. In 1992, Walter Allen reported that black students who attend HBCUs have better academic performance, greater social involvement, and higher occupational aspirations than black students who attend PWIs. On black campuses students emphasize feelings of engagement, extensive support, acceptance, encouragement, and connection. Allen also found that HBCUs communicate to black students that it is safe to take the risks associated with intellectual growth and development.

Proponents of HBCUs argue that they have served black students with considerable effectiveness. Researchers contend that HBCUs provide assets for black students that are unavailable and unattainable in white institutions. Socially, Donald Smith found that they provide an accepting environment with emotional support. He also found that they serve as repositories for the black heritage. The environment at HBCUs is one of acceptance of students for who they are, and students do not experience social isolation, but rather integration into campus life and extracurricular offerings. HBCUs also foster healthy social relationships, and students form positive relationships with faculty members as well as their peers. It is not uncommon to find formal and informal mentoring relationships developing in this environment. In addition, HBCUs foster ethnic pride and self-esteem.

Academically, HBCUs offer programs designed to meet the unique needs of black students and the black community, and they educate many students with learning deficiencies. Although the facilities are generally modest and resources are limited, numerous studies indicate that HBCUs have done an out-

standing job at educating their clientele. For an extensive period in American history, HBCUs were solely responsible for educating and preparing blacks to live as free people in the South. HBCUs accepted this responsibility and educated many black Americans with very little in the way of financial resources. The academic gains for black students attending HBCUs are high when compared to their counterparts at predominantly white schools. This is due in part to the nurturing campus environment and positive faculty relationships that motivate students to do well academically.

Historically black colleges and universities have been crucial in the development of black professionals. For more than 160 years, these institutions have educated a population that has lived under severe legal, education, economic, political, and social restrictions. Early HBCUs were established to train teachers, preachers, and other community members to remedy the despairs of slavery that scarred African Americans. First and foremost, HBCUs opened the door of educational opportunity for many blacks who were once legally denied an education. Secondly, they provided educational access to those who were educationally underprepared to enter predominantly white institutions. By 1950, HBCUs were responsible for serving 90 percent of black students in higher education. Moreover, HBCUs had produced 75 percent of all black Ph.D.'s, 75 percent of all black army officers, 80 percent of all black federal judges, and 85 percent of all black physicians. In 2001, HBCUs served 14 percent of all black students enrolled in college, but were annually responsible for 26 percent of black baccalaureate degrees.

### Conclusion

It has been stated that HBCUs have a unique chapter in the history of American postsecondary education. Despite the tremendous obstacles that these institutions faced, there are 104 HBCUs as of 2002—approximately 3 percent of U.S. higher education institutions. While there was a period where HBCUs had fallen from the research literature, current research scholars have developed a renewed interest in these institutions. This renewed interest partly stems from the fact that these institutions still play a vital role in American higher education. While black students in the early twenty-first century can choose to attend any type of institution, many are electing to attend an HBCU. While these colleges and universities achieve tremendous success, it is important to

further investigate the unique identity and the diversity they bring to higher education. In 2001, Coaxum called for a separate classification of HBCUs, on in which the diversity of these institutions could be understood within the context of their institutional peers.

### TEACHING OF

Bruce A. VanSledright

## LEARNING

The learning of history is a complex undertaking. Cognitive research done since 1980, much of it in Great Britain and North America, has indicated that it is more difficult to learn and understand history than previously thought. Before the 1980s it was generally assumed that a gradual process of committing historical narratives—constructed around key events, details, names, and dates (substantive knowledge)—to memory would eventually result in a sturdy understanding of the past. The body of research compiled since 1980, however, demonstrates that learning history, if it is to lead to deeper understanding, involves not only the repeated study of such narratives, but also the acquisition and use of a set of domain-specific cognitive strategies (strategic knowledge). Applying these strategies serves as the means by which the past is learned and understood. Researchers and educators frequently refer to the application of these domain-specific strategies to the process of exploring and interpreting the past as historical thinking. Before examining in more detail the implications of this research for learning history, it is important to understand the nature of the domain that learners are attempting to comprehend.

### History as a Subject Domain

History is a thoroughly interpretive discipline, closer in many ways to the humanities than to the social sciences. To understand the past, learners cannot conduct controlled experiments to recreate it and then study its effects. Nor can they travel back in time to witness events firsthand. And even if time travel were possible, learners would still be required to interpret the complex events that they were witnessing.

Access to the past is thus indirect, largely governed by artifacts and residue left behind by those who lived it. These include diaries, letters, journals, public records, newspapers, archeological artifacts, pictures, paintings, chroniclers' and historians' interpretations of past events, and the like. Those who make a living inquiring into the past divide the artifacts and historical residue into two types, primary

and secondary sources. Primary sources include, among other things, diaries and personal journals compiled by people who actually witnessed or participated in an incident about which they report. Secondary sources include history textbooks or historical narratives written by someone not present at an event but who has studied and interpreted the primary sources that remain. Historical sources form a type of evidence chain or trail that must be painstakingly pieced together into carefully argued interpretations of past events. This piecing-together that learners and inquirers do as they make sense of the past's artifacts and residues has been a central subject of cognitive research studies.

### **Substantive Historical Knowledge and Understanding**

Defining the nature of substantive historical knowledge is rife with debate. Largely, the debate turns on the matter of what constitutes historically significant events and occurrences. For roughly the first half the twentieth century, those who wrote American history, for example, seemed content to concentrate on political, military, and economic achievements in the United States. It was believed that those achievements were the most historically significant. During the 1960s, however, a new generation of historical scholars began to redefine significance in terms of what was often called "history from the bottom up." This generation (sometimes referred to as social historians) began inquiring into the influences on the American past of a variety of sociocultural groups that had often been rendered historically invisible by previous generations of scholars. These groups include antebellum slave communities, labor movements and their leaders, women, immigrants, and small, often marginalized, social organizations. The social historians maintained that these overlooked groups could be seen as powerful participants in, or resistors of, important changes and developments in American history, thus (at least in part) accounting for how change occurred as it did. To ignore such groups would be to misunderstand history. The work of social historians, with their proliferating foci and perspectives on events, has made constructing grand political-military-economic historical narratives less easy to accomplish.

This shifting terrain concerning issues of historical significance has raised difficult questions about what history students should learn. The late twentieth-century increase in the multiculturalization of

the United States, for example, has only added to this concern by also raising questions about *whose* history children should learn. Some participants in the debate, such as Arthur Schlesinger Jr., believe that all U.S. children should acquire the same "common cultural" core of substantive historical knowledge. Schlesinger defines this core largely in terms of those political, military, and economic events that made the United States the most powerful nation on earth. Knowledge of these events would be delivered by traditional, uplifting narratives of American success stories. Current social historians, and those who champion a more multiculturalist portrait of America, consider such definitions of core substantive historical knowledge misleading at best, and dangerous at worst, because they risk characterizing the contributions of those groups of people thought to be less significant as meaningless.

This debate has continued into the twenty-first century. What, and whose, history students have opportunities to learn about in school vary depending on how school officials define what is historically significant. To the extent that they define it in traditional narrative terms, children's opportunities to learn substantive historical knowledge are often determined by the content of school history textbooks, which, for publishers, in their efforts to find a palatable middle ground to bolster sales, means opting in the direction of more traditional narrative treatments. To the extent that a more multiculturalized view of substantive knowledge is in play, students are more apt to study history from multiple sources, such as trade books, historical fiction accounts, and primary sources, that explore the lives of those not frequently included in the more voluminous textbook treatments.

### **Strategic Historical Knowledge**

Much of the cognitive research done since 1980 has centered on the nature of expertise in historical thinking, and on how novices (e.g., grade school students, college undergraduates) differ from experts (e.g., historians). This research indicates that the process of thinking historically that enables deep historical understanding requires certain strategic-knowledge dispositions. These dispositions include the capacity to: (a) read, make sense, and judge the status of various of sources of evidence from the past; (b) corroborate that evidence by carefully comparing and contrasting it; (c) construct context-specific, evidenced-based interpretations; (d) assess

an author's perspective or position in an account being studied; and (e) make decisions about what is historically significant. These capacities are exercised while taking into conscious account the way the learner is, by necessity, also imposing his or her own view on the evidence being interpreted.

Learning to think using these cognitive strategies is no small task. First, as historian David Lowenthal has observed, the past is a foreign country, difficult to penetrate from the locus of the present. Reconstructing historical context is troublesome because it often remains virtually impossible for “moderns” to get inside and understand the experiences of those “ancients.” Second, evidence is often sparse, and thus so open to competing interpretations that understanding events by building context-sensitive, well-corroborated interpretations is tenuous at best. Third, any attempt to construct a history of events operates on a necessary connection between a past reality and present interpretations of that reality. This connection is, however, denied because there is no method for bringing that past reality back to life to establish the full accuracy of a contemporary interpretation. There are only chains of people's interpretations of the past, some more recent than others. Learning to use the strategies of thinking historically that enable an understanding of the past hinges on the cultivation of a number of such counterintuitive cognitive processes.

### **Development of Historical Thinking and Understanding**

Most of the more recent North American research on learning history has focused on either expert-novice studies, as noted, or on the relationship between how teachers teach history and how students learn to think historically. Views on how the historical thinking and understanding develop have largely been extrapolated from the expert-novice research cited above, and from studies that show how teaching can influence development among novices. Educational researchers in Great Britain—who were initially influenced in the 1970s by Piagetian developmental theories, but later abandoned them for the most part—have done considerably more work in this area. One of the more promising lines of research is called Project Chata. *Chata* is an acronym for Concepts of History and Teaching Approaches. The goal of Project Chata is to “map changes in students' ideas about history between the ages of seven and fourteen years. The project focused on second-

order procedural understandings like *evidence* or *cause*” (Lee and Ashby, p. 201).

Preliminary results of the research on the progression of students' ideas about historical evidence and its relationship to the past indicate that naive views of history begin with the understanding that the past is simply a given. As students grow more sophisticated in their understanding, this simplistic view is abandoned, though history remains relatively inaccessible. They follow this with the belief that the past is determined by stories people tell about it. As sophistication grows, students note that reports on the past are more or less biased. This idea gives way to noting that the viewpoint or perspective of a reporter or storyteller becomes important. Finally, students develop an understanding that it is in the nature of accounts to differ, because varying reporting criteria are used by storytellers and chroniclers.

Project Chata researchers have also studied students' development of ideas about causal structure and historical explanations. They observe that: (1) students' ideas about explanation vary widely, with some younger children having more sophisticated ideas than older children; (2) students' ideas about causation in history and their rational explanations of causal structures do not necessarily develop in parallel; (3) student's ideas about causal structures and explanations in history may develop at different intervals, with some ideas occurring in big gains in younger children and others occurring later; and (4) progression in students' ideas about causation and explanation occurred most markedly in schools where history was an identifiable subject matter.

### **Some Pedagogical Implications**

A tentative theory of how to teach learners to think and understand history can be fashioned from the current corpus of research studies. This results in certain propositions. First, learners construct deeper historical understandings when they have opportunities to consciously use their prior knowledge and assumptions about the past (regardless of how limited or naive) to investigate the past in depth. Second, as learners explore the past, attention must be paid not only to the products of historical investigation, but to the investigative process itself. Third, developing historical thinking and understanding necessitates opportunities for learners to work with various forms of evidence, deal with issues of interpretation, ask and address questions about the significance of events and the nature of evidence, wrestle with the

issues of historical agency, and cultivate and use thoughtful, context-sensitive imagination to fill in gaps in the evidence chain when they appear.

Applying this theory in the classroom would mean approaching history effectively from the inside out. Teachers would structure learning opportunities by posing compelling historical questions that have occupied the attention of historical inquirers (e.g., Why did so many colonists starve at Jamestown in the winter of 1609–1610? How did antebellum slave communities construct oral cultures and to what effect?). Students would adopt investigative roles, obtaining and scouring evidence (much of it obtained off the Internet from rich archival sources now online); reading, analyzing, and corroborating that evidence; addressing perspective in accounts; dealing with questions of agency and significance; and building their own interpretations of events as they addressed the questions posed.

## TEACHING OF

History has played a dominant role in the broader social studies curriculum in the United States and in other countries for at least the past 100 years. For example, in most school districts in the United States, state, national, or world history is taught in grades four through six, grade eight, and at several points in high school. In England, history forms the backbone of the social studies curriculum from primary through secondary schools. History is also a curriculum staple in continental European countries, among post-Soviet republics, in China, and in such places as post-apartheid South Africa.

History in the school curriculum has not been without a number of recurrent debates and controversies. Many of them stem from disputes over the goals and purposes school history should serve (e.g., political socialization and nationalist identity formation versus teaching historical habits of mind). Other issues arise in connection with questions about how, from the vastness of history itself, to define what constitutes historically significant events that should be taught. The proper role of integrating social science disciplines (e.g., geography, economics, political science) in the teaching of history is also a point of debate. Finally, various parties argue over maintaining a relative balance between transmitting historical knowledge derived from the work of historians and teaching students to learn to think and investigate the past the way historians do. Taking time to do both often creates time-use dilemmas within an already surfeited school curricula. Choosing between them repeatedly pits those who would use history for sociopolitical ends against those who see history's importance as a means of teaching critical reasoning and a fuller understanding of the past.

### Political Socialization of Historical Thinking and Understanding

The interest in securing a firm place for history in the curriculum frequently stems from its sociopoliti-

cal uses. This is especially true in the teaching of national histories. As George Orwell reminded readers in his book, *1984*, control of the present (and the future) depends in good measure on control over the past. In many countries, a principal goal of teaching the nation's history is deeply linked to socializing future citizens, as defined by whomever controls the sociopolitical agenda at the time, conservatives, liberals, revolutionaries, or others. Perhaps no other school subject serves this political socialization purpose more than the study of history.

As political parties change or revolutions occur, new regimes attempt to rewrite history in general, and school history in particular, in order to cast themselves and their new politics and policies in a favorable light. Those disempowered by political change often resist such efforts to recast the past. Various groups use history in an effort to shape (or reshape) the nationalist identities of youth around whatever the prevailing view privileged by those in power is at any given time. In post-Soviet eastern European countries, for example, a major educational agenda has been to rewrite history textbooks and reconfigure the history curriculum since 1990.

Prior to the mid-1970s, little systematic research had been done on how history was taught in schools and what students learned from studying it. Since then, there has been a surge of interest in studying school history teaching and its learning outcomes, particularly among researchers in England and in North America. As a result, a sizable body of scholarship has emerged. Much of it challenges the practice of using school history to advance sociopolitical ends. In general, the research indicates that the sociopolitical use of history in schools warps students' views of what history is as a discipline and a subject matter, tends to turn history into a lifeless parade of someone else's facts, and otherwise drives away students' motivation to learn the subject. History education researchers have attempted to divert the teaching of history away from an exercise in socializing students to particular partisan views; instead suggesting the aim of history as an investigation of the past and the social world.

If one of the principal goals for teaching history is to socialize grade-school students to accept certain views of a nation's accomplishments as defined by those in power, thus shaping their nationalist identities, teaching history should take on a transmission approach. In other words, it is likely that in history classrooms teachers would lecture or tell stories

about the past via lessons drawn from textbooks sanctioned by those in political control. Research bears out this image. For much of the past century, the teaching of history in schools in many places around the world has been dominated by textbook recitations and teacher lectures or storytelling. This has been especially true in the United States.

There have been moments of change in these traditional practices such as during the “New Social Studies” movement in the United States during the 1960s and early 1970s. During this period, historians and social scientists constructed curriculum units that were designed to assist students in learning more about how historical knowledge was constructed in the discipline. Teachers were to guide students in the process of investigating the past via study of primary sources, much the way historians do. However, such efforts to promote pedagogical and curricular change in history typically have not had lasting effects in the United States, and the traditional lecture-textbook-recitation-recall approach has remained dominant.

In England, the Schools Council History project had more lasting results. Educational and instructional changes there during the 1970s and 1980s in some ways mirrored the efforts of historians working under the auspices of the New Social Studies in the United States. The goal was for teachers to learn to teach students the reasoning process of historical investigators. Not only were students to study important ideas in English history, but also to learn how to read primary sources, judge their status relative to other sources, draw inferences about the past from them, and construct historical accounts of their own making. Research on the results of approaching history that way were generally favorable, indicating that students typically progressed in their capacity to learn to think historically as modeled by experts in the discipline itself. Data also indicated that students developed deeper understandings of English history. The project largely succeeded in changing the way teachers taught history because teacher educators and teachers along with education researchers were all involved in changing pedagogical and curricular practices.

In 1988 the Thatcher government attempted to reverse this trend. Alarmed that children in British schools, in their view, were not receiving adequate instruction in the stories of British national and international successes, the education establishment mandated significant changes in the British national

history curriculum. Those changes called for more emphasis on teaching stories drawn, for example, from the days of the British empire. Less stress was to be placed on teaching historical-reasoning processes. The changes brought on by the Schools Council project and by the work of teacher educators and researchers however, had been institutionalized in many places. Reverting back to teaching history in lecture-textbook-recitation fashion became difficult. Many of Great Britain’s history programs in schools therefore remain among the few in which history is taught more as a way of learning to think historically (as a way of knowing) than as a socialization exercise in memorization and recall of a nation’s grand accomplishments and celebrations.

This debate continues. Cognitive scientists interested in history education and researchers in general who study how history is taught and to what result stress the importance of teaching history more closely aligned with the way in which history operates as a distinctive discipline. Researchers such as Peter Lee and Rosalyn Ashby point to gains in students’ capacity to learn important thinking processes and habits of mind as they learn to understand the past more deeply. Those who are more interested in the power of using history to forge particular nationalist identities among youth remain skeptical of teaching history as an exercise in educating thinking processes and critical habits of mind. Generally, they prefer an approach that favors transmission of favored views of the past via lectures and textbook recitations, and a focus on stories that celebrate chosen accomplishments and historical successes.

### **Historical Significance**

The debates about the purposes, goals, and uses of school history are exacerbated by the problem of choosing what constitutes historically significant events worth teaching. The very breadth and vastness of the past from which school history lessons must be chosen coupled with the finiteness of the school day and the press for curricular room by other subjects makes this issue difficult. It would be convenient if those who devise the history curriculum in the schools could turn to the discipline and to historians for help in addressing which events and historical actors of significance to choose. The debate within the discipline over what constitutes historical significance is perhaps even more intense than in school history. This has been especially true since about 1970 and advent of postmodernism with

its deep skepticism about the veracity of Western knowledge-production projects rooted in the scientific method. The issue of historical significance has been further exacerbated by the multiculturalization of many Western societies, rendering questions about “whose” history to teach as important as “which” history.

The problem of defining historical significance leaves history teachers, curriculum designers, educational policymakers, and politicians without much firm ground upon which to anchor their decisions about which or whose history to teach. The inability to resolve this issue, however, gives history education researchers some support in their efforts to press the importance of teaching history primarily as an exercise in habits of mind.

### **Time in the Curriculum**

Teaching history as both knowledge about a nation’s history and its place in world history, and as an approach to learning a way of reasoning about the past requires more time than doing one or the other. Debates between advocates for the importance of subjects other than history can have the effect of reducing the time teaching history might otherwise have in the overall school curriculum. To the extent that politicians exercise greater control of textbooks and history curriculum and assessment approaches (e.g., in states, provinces, or countries where a centralized curriculum dominates), teaching history is often pressed into the service of socialization. History taught as historical reasoning and understanding tends to languish in the context of overabundant time pressures.

### **Interdisciplinarity**

In some countries, educational policymakers and curriculum developers see the teaching of history as an opportunity to integrate the social science disciplines into history syllabi. Issues arise over the right mix and relationships of such disciplines as geography and political science to the teaching of history. Some express concern that such interdisciplinary approaches effectively water down the actual teaching of history, reduce its value for students, and contribute to confusion about how to conduct appropriate assessments of student learning. Others argue that history already draws from the social science disciplines; therefore, calling attention to its interdisciplinarity makes good sense, opening up learning opportunities for students. Much like the controver-

sies over historical significance, this issue of interdisciplinarity has not been resolved. The time factor also plays a role in this debate.

### **Assessments**

The aforementioned issues and debates also intersect with questions about how to properly assess what students learn from being taught history. During the last quarter of the twentieth century, many Western countries moved closer to centralizing assessment practices in many school subjects including history. What consequences these tests hold vary from country to country. In the United States, a national test of history learning (the National Assessment of Educational Progress, or NAEP, which also tests other subject learning as well) was developed in the 1980s. It tests students’ capacity to both recall elements of American history as well as construct short answer responses to written prompts. As of 2001 this test was voluntary and was considered to hold low stakes for participants. However, the U.S. Congress is engaged in a debate to make the NAEP a required national test, thus making it a high-stakes test with sanctions and resource allocations related to outcomes.

Between the late 1980s and 2001 the history portion of the NAEP was given three times. During the administrations of George Bush and Bill Clinton, the data suggested that students in grades four, eight, and twelve recalled low to moderate levels of historical knowledge about the United States. Some critics, such as Diane Ravitch and Chester Finn Jr., argued that this level of recall meant that students effectively knew very little about their country and thus required even heavier doses of American history to overcome the deficits in their knowledge. Based on the growing number of in-depth studies of teaching and learning history, educational researchers such as Linda Levstik countered with the claim that more history, particularly if taught as lecture and textbook recitation, would do little to solve the problem. Reminiscent of the debates described above, the U.S. researchers called for immersing students in a pattern of historical study characterized by investigating history using strategic knowledge borrowed from expertise displayed by historians as a means of developing more powerful substantive understandings about the American past.

This debate over the most productive pedagogical approach to teaching history (e.g., more drill in the substantive knowledge of history versus instruc-

tion into and exercise of historical thinking practices to foster deeper knowledge about history) continues largely unabated.

#### HIV/AIDS

*See:* RISK BEHAVIORS, *subentry on* HIV/AIDS AND ITS IMPACT ON ADOLESCENTS.

## HOLT, JOHN (1923–1985)

John Caldwell Holt was a teacher, educational critic, and early spokesperson for the home-schooling movement. Born in Boston, Massachusetts, the son of well-to-do parents, he was formally educated in private schools in the United States and abroad. He described himself as a “good student in supposedly the best schools.” At Yale University, Holt studied to be an industrial engineer, but found no intrinsic connections between his studies and the world around him. He soon left to join the navy at age twenty, serving for three years aboard the submarine U.S.S. *Barbero* during World War II. Holt later identified his time on this submarine as yielding the first genuine, purposeful educational experiences of his life.

In 1946, immediately following his tour of duty, John Holt found work in New York with the American Movement for World Government, and later with the United World Federalists—an organization devoted to stopping the proliferation of atomic weapons. Between 1952 and 1953 he traveled throughout Europe before settling briefly with his sister in Taos, New Mexico. Holt joined the faculty at the Colorado Rocky Mountain School in Carbonade, despite his complete lack of preparation for or formal knowledge of teaching. Years later Holt characterized himself while at this school as a “perfectly conventional schoolmaster” who flunked numerous students.

After four years of teaching school, John Holt had surmised that students did poorly because they learned to believe that schooling expected them to do poorly. Given this working hypothesis, in 1957 he returned to Massachusetts to teach younger students, hoping to influence them before they learned to expect such failure; he would teach elementary and secondary students for the next ten years.

John Holt found himself struck by the natural learning instincts of children. His perceptions and beliefs rested comfortably with those of earlier “child-centered” educators and philosophers like Johann Heinrich Pestalozzi (1746–1827), Friedrich Wilhelm August Froebel (1782–1852), Johann Friedrich Herbart (1776–1841), Herbert Spencer (1820–1903), and at times, the Progressive educator and pragmatist John Dewey (1859–1952). In his first book, *How Children Fail* (1964), Holt argued that schools maximized compliance and “good work” at the expense of traits like curiosity and creativity.

This position remained solid in *How Children Learn* (1967), in which he made a point of criticizing large class sizes as he believed that children learned best alone or in small groups.

Holt left classroom teaching in 1967 to pursue writing and lecturing. He was among a small but widely read group of neo- or contemporary “romantic” critics of schools (a group that included Jonathan Kozol, George Dennison, James Herndon, Herb Kohl, and later, Ivan Illich). After two years lecturing at Harvard University, the University of California at Berkeley, and elsewhere around the world (while continuing to write and publish about educational reform), Holt’s perspective on both the purpose for and source of needed school reform began to shift. This shift is attributed, in no small part, to his decision to learn more about the thinking of Ivan Illich (who would soon publish his popular *Deschooling Society*) and his visit to Illich’s Intercultural Center of Documentation during the late 1960s. In 1969 Holt became the president of John Holt Associates, Incorporated.

Holt continued to criticize American public schooling, though with the publication of *Freedom and Beyond* in 1972 he had abandoned any hope that teachers, school personnel, or parents and community members could enable such change. Still searching for ways to promote deeply personal, transformative teaching/learning situations like those he experienced in the military, Holt had decided that such encounters would and could never occur within schools as formal, social institutions. Holt returned to his original focus on the learner, ceasing his passionate critique of the social contract inherent in public schooling and calling, instead, for individual families to “teach your own.” In 1977 Holt created a newsletter called “Growing Without Schooling” and published *Instead of Education*, in which he encouraged readers to forego efforts toward changing schools and to embrace his notion of “unschooling” (acknowledging, yet distinguishing himself from, Illich’s “deschooling” concept).

Holt had turned a crucial corner as an educational critic. Consequently, his educational works represent the best and worst elements of child-centered Progressive ideals of the late twentieth century. By the late 1970s he had become a conservative libertarian, dismissing any relationship between the responsibilities of the state and the family with respect to young people’s education. “Growing Without Schooling” became a support group by mail for

the nation's pioneer home schoolers, and Holt became their leader. His longstanding respect for natural learners resonated with increasing numbers of parents who, with Holt's personal encouragement, support and published tales of unschooling success, became the core of the early-twenty-first century burgeoning home-schooling movement in the United States.

Criticized by his former circle of Progressive colleagues, Holt had little interest in such philosophical discussions, spending his remaining days encouraging and helping families through his publication *Teach Your Own* (1981). In his final years, Holt promoted home schooling in numerous popular print forums, including *Harper's*, *Life*, *Look*, *Mother Earth News*, *Ms.*, *The Progressive*, *Psychology Today*, *Redbook*, *Saturday Evening Post*, *Time*, *USA Today*, and *The Wall Street Journal*. Begun before his death, Holt's final book, *Learning All the Time* (1989), was completed posthumously by members of its very audience—Holt's home-schooling colleagues.

## HOME SCHOOLING

The term *home schooling* refers to the practice of parents educating a child at home, rather than in a conventional public or private school setting. These children would otherwise be enrolled in elementary or secondary school. The parent responsible for home schooling generally does not work and is rarely a trained teaching professional. Primary concerns for most home schoolers are strengthening family bonds and developing religious values. Technological innovations in the late twentieth century made home schooling an increasingly manageable proposition, as the availability of personal computers and the Internet permitted families to access computer-driven instruction, multimedia resources, and far-flung support networks. Families provide home schooling in many different ways, with tremendous variation in curricula, teaching methods, and technology, and in the amount of peer interaction that children experience. Some home-schooling parents bring their children together for group outings and field trips to provide enhanced socialization, while others have formed cooperative schools or charter schools to support their efforts.

The estimated number of home-schooled children is unreliable, due largely to uneven record-keeping. However, in a 1999 report, the U.S. Department of Education estimated that more than 850,000 children were home schooled in the United States, and scholars purport that the population is increasing at an annual rate of between 7 to 15 percent. Researchers suggest that home educators are generally married couples with one nonworking spouse and more than two children and that their median income is generally comparable to that of all families with school-age children. In approximately one-quarter of home-schooling families, at least one parent is a licensed teacher; however, this is rarely the parent who is specifically responsible for the home schooling. The small amount of existent data suggests that very few minority students are educated through home schooling, and that three-quarters of home-schooling families are primarily motivated by religious concerns.

### History

From the colonial period through the mid-1800s, education was generally delivered through loosely-structured community schools. In the nineteenth century, in efforts that began in the northeast, re-

formers increasingly came to view public schools as a vital means of “Americanizing” the nation’s growing immigrant population and as an opportunity to foster a common American culture. This effort gained momentum after Massachusetts became the first state to adopt a compulsory education law in 1852. The law required parents to send their children to the state’s increasingly systematic public schools. In the early twentieth century, public schooling became an increasingly central component of American culture. Growing numbers of students attended public school and Progressive reformers promoted education as a means of social betterment. As formal public schooling expanded during the first half of the twentieth century, home education became virtually obsolete.

However, by the 1960s, some education critics had begun to voice concerns that public schools were preaching alien values, failing to adequately educate children, or were adopting unhealthy approaches to child development. As a result, a “de-schooling movement” took root in the 1960s and 1970s. Critics of public schooling primarily voiced two distinct ideologies, both emphasizing child-centered learning. Liberal critics of public schooling believed that schools did not adequately respect children as individuals, while conservative critics argued that public schools undermined traditional values.

Starting in the early 1980s, increasing numbers of parents chose to educate their children at home as a growing number of states relaxed their compulsory attendance laws to permit home schooling. Previously, parents who home schooled their children were in violation of compulsory attendance and truancy laws, and were therefore subject to legal action. While Nevada (1956) and Utah (1957) were the only states with home-schooling legislation prior to 1982, thirty-four states passed enabling legislation between 1982 and 1993. By 1998, under the pressure of an increasingly active home-schooling movement, all fifty states had passed home-school laws specifying attendance, subject, teacher, testing, and record-keeping requirements for home educators.

In 2002 state laws regulating home schooling vary widely regarding such matters as teacher licensure, testing, compulsory curriculum, and required paperwork. Some states impose exacting regulations on home schooling, while others legislate few requirements. Nine states place no restrictions on parents’ rights to home school, providing the legal option for any parent who is interested. Ten other

states simply require parents to notify the state when a child is being home schooled. On the other hand, twenty states demand that parents provide test scores or professional assessment to monitor the student’s progress. Finally, eleven states impose stringent requirements that mandate that parents provide the state with test scores or professional assessment to measure the student’s achievement, in addition to other requirements such as regular home visits or professional training.

### Legal Background

American courts have asserted that parents possess significant authority to direct the education of their children. *Meyer v. Nebraska* (1923) was the first case to protect parental educational authority against the incursion of state legislation, establishing a legal precedent when the U.S. Supreme Court found that states may not prohibit foreign language education if schools offer it and parents desire it. Parents’ fundamental right “to direct the upbringing and education of children under their control” was etched more firmly in *Pierce v. Society of Seven Sisters* (1925). The *Pierce* decision stated that parents should be allowed to choose the type of school their children attend, public or private, as Oregon law could not require that parents send their children to public schools. In a 1972 ruling crucial to the home-schooling cause, the Supreme Court held in *Wisconsin v. Yoder* that parents had the right to supersede compulsory education laws if the laws unduly impeded religious freedom. The Court ruled that it was permissible for Amish parents to remove their children from school at age twelve to maintain their way of life and exercise their religious freedom.

Although the courts have protected the rights of parents, they have also defended the right of states to require and extensively regulate educational instruction. Courts have ruled that if a state exempts home schoolers from compulsory attendance laws it is entitled to regulate their activities. States have the right to impose “reasonable” standards on home schoolers. These may include regulations as invasive as administering achievement tests to monitor students’ progress (*Murphy v. State of Arkansas*, 1988). While most state laws include such requirements, enforcement is often sporadic due to the decentralized nature of home schooling and the lack of established overseeing bodies.

Over the course of time, several states have refused to allow home instruction on the grounds that

it would stunt the social development of children and would prevent them from living normal, productive lives. The courts have determined that states are within their rights to make such determinations (*Knox v. O'Brien*, 1950). States may mandate that children must attend school because of the interaction it provides with their peers and the exposure it provides to different types of people (*State v. Edgington*, 1983).

### Legal Trends

In the late 1990s, the parents of home-schooled children began suing schools districts that denied requests for supplemental services, classes, extracurricular activities, and additional services such as lab science instruction that cannot be feasibly provided at home. However, the courts have not mandated that districts provide such additional services. In *Swanson v. Guthrie Independent School District* (1998), a U.S. Court of Appeals ruled that a school board may deny home-schooled children the right to attend public school part-time. Previously, the courts had held in *Bradstreet v. Sobol* (1996) that school districts could require students to be enrolled in public schools in order to be eligible to participate in interscholastic sports.

### Effects

Although no randomized field trials have been conducted, some preliminary research suggests that children who are home schooled may outperform their counterparts in public or private schools. However, given the variety of home-school settings and the uneven nature of preliminary research, it is not yet possible to reach any meaningful conclusions regarding the effectiveness of home schooling. Families who practice home schooling are often different in significant ways than families who do not. These differences, including higher levels of education, larger family size, and divergent child-rearing practices, make comparisons problematic. Moreover, it is advocates of home schooling who conduct of the research on the subject; this raises questions as to the validity and reliability of findings. The largest and most comprehensive as of 2001, conducted by the National Home Education Research Institute, examined over five thousand home-schooled students' scores on national standardized achievement tests for the 1994 through 1995 school year, and found that children who were home schooled outperformed their peers on standardized assessments.

### Future Implications

In the fall of 2000, Patrick Henry College in Purcellville, Virginia, became the first postsecondary institution intended primarily to serve students who had been schooled at home. Of the college's first class of ninety students, eighty had been home schooled. Patrick Henry College's curriculum has a moral focus comparable to many home schoolers' early education and values, and emphasizes traditional Christian values. The college is designed to address the typical challenges that many home schoolers face, as these students do not possess conventional educational records such as transcripts and may not be comfortable with their altered learning environment.

Home schooling poses a radical challenge to the centuries-long project of American public education. It raises important questions about how to balance the rights of family and community, of individual and state. There are no simple answers to these complex legal and ethical questions, and it is unclear the extent to which home schooling will transform educational practice in years to come.

## HOMEWORK

---

Homework is defined as tasks assigned to students by school teachers that are intended to be carried out during nonschool hours. This definition excludes in-school guided study (although homework is often worked on during school), home-study courses, and extracurricular activities such as sports teams and clubs.

### Purpose

The most common purpose of homework is to have students practice material already presented in class so as to reinforce learning and facilitate mastery of specific skills. Preparation assignments introduce the material that will be presented in future lessons. These assignments aim to help students obtain the maximum benefit when the new material is covered

in class. Extension homework involves the transfer of previously learned skills to new situations. For example, students might learn in class about factors that led to the French Revolution and then be asked as homework to apply them to the American Revolution. Finally, integration homework requires the student to apply separately learned skills to produce a single product, such as book reports, science projects, or creative writing.

Homework also can serve purposes that do not relate directly to instruction. Homework can be used to (1) establish communication between parents and children; (2) fulfill directives from school administrators; (3) punish students; and (4) inform parents about what is going on in school. Most homework assignments have elements of several different purposes.

### Public Attitudes toward Homework

Homework has been a part of student's lives since the beginning of formal schooling in the United States. However, the practice has been alternately accepted and rejected by educators and parents.

When the twentieth century began, the mind was viewed as a muscle that could be strengthened through mental exercise. Since this exercise could be done at home, homework was viewed favorably. During the 1940s, the emphasis in education shifted from drill to problem solving. Homework fell out of favor because it was closely associated with the repetition of material. The launch of the satellite *Sputnik* by the Soviet Union in the mid-1950s reversed this thinking. The American public worried that education lacked rigor and left children unprepared for complex technologies. Homework, it was believed, could accelerate knowledge acquisition.

The late 1960s witnessed yet another reversal. Educators and parents became concerned that homework was crowding out social experience, outdoor recreation, and creative activities. In the 1980s, homework once again leapt back into favor when *A Nation at Risk* (1983), the report by the National Commission on Excellence in Education, cited homework as a defense against the rising tide of mediocrity in American education. The push for more homework continued into the 1990s, fueled by increasingly rigorous state-mandated academic standards. As the century ended, a backlash against homework set in, led by parents concerned about too much stress on their children.

### **The Positive and Negative Effects of Homework**

The most direct positive effect of homework is that it can improve retention and understanding. More indirectly, homework can improve students' study skills and attitudes toward school, and teach students that learning can take place anywhere, not just in school buildings. The nonacademic benefits of homework include fostering independence and responsibility. Finally, homework can involve parents in the school process, enhancing their appreciation of education, and allowing them to express positive attitudes toward the value of school success.

Conversely, educators and parents worry that students will grow bored if they are required to spend too much time on academic material. Homework can deny access to leisure time and community activities that also teach important life skills. Parent involvement in homework can turn into parent interference. For example, parents can confuse children if the instructional techniques they use differ from those used by teachers. Homework can actually lead to the acquisition of undesirable character traits if it promotes cheating, either through the copying of assignments or help with homework that goes beyond tutoring. Finally, homework could accentuate existing social inequities. Children from disadvantaged homes may have more difficulty completing assignments than their middle-class counterparts.

### **Extensiveness of Homework**

In contrast to the shifts in public attitudes, surveys suggest that the amount of time students spend on homework has been relatively stable. Data from the National Assessment of Educational Progress suggests that in both 1984 and 1994, about one-third of nine-year-olds and one-quarter of thirteen- and seventeen-year-olds reported being assigned no homework at all, with an additional 5 percent to 10 percent admitting they did not do homework that was assigned. About one-half of nine-year-olds, one-third of thirteen-year-olds, and one-quarter of seventeen-year-olds said they did less than an hour of homework each night. In 1994 about 12 percent of nine-year-olds, 28 percent of thirteen-year-olds, and 26 percent of seventeen-year-olds said they did one to two hours of homework each night. These percentages were all within one point of the 1984 survey results.

A national survey of parents conducted by the polling agency Public Agenda, in October, 2000, re-

vealed that 64 percent of parents felt their child was getting "about the right amount" of homework, 25 percent felt their child was getting "too little" homework, and only 10 percent felt "too much homework" was being assigned.

International comparisons often suggest that U.S. students spend less time on homework than students in other industrialized nations. However, direct comparisons across countries are difficult to interpret because of different definitions of homework and differences in the length of the school day and year.

### **Appropriate Amounts of Homework**

Experts agree that the amount and type of homework should depend on the developmental level of the student. The National PTA and the National Education Association suggest that homework for children in grades K–2 is most effective when it does not exceed ten to twenty minutes each day. In grades three through six, children can benefit from thirty to sixty minutes daily. Junior high and high school students can benefit from more time on homework and the amount might vary from night to night. These recommendations are consistent with the conclusions reached by studies into the effectiveness of homework.

### **Research on Homework's Overall Effectiveness**

Three types of studies have been used to examine the relationship between homework and academic achievement. One type compares students who receive homework with students who receive none. Generally, these studies reveal homework to be a positive influence on achievement. However, they also reveal a relationship between homework and achievement for high school students that is about twice as strong as for junior high students. The relationship at the elementary school level is only one-quarter that of the high school level.

Another type of study compares homework to in-class supervised study. Overall, the positive relationship is about half as strong as in the first type of study. These studies again reveal a strong grade-level effect. When homework and in-class study were compared in elementary schools, in-class study proved superior.

The third type of study correlates the amount of homework students say they complete with their achievement test scores. Again, these surveys show

the relationship is influenced by the grade level of students. For students in primary grades, the correlation between time spent on homework and achievement is near zero. For students in middle and junior high school, the correlation suggests a positive but weak relationship. For high school students, the correlation suggests a moderate relationship between achievement and time spend on homework.

### Research on Effective Homework Assignments

The subject matter shows no consistent relationship to the value of homework. It appears that shorter and more frequent assignments may be more effective than longer but fewer assignments. Assignments that involve review and preparation are more effective than homework that focuses only on material covered in class on the day of the assignments. It can be beneficial to involve parents in homework when young children are experiencing problems in school. Older students and students doing well in school have more to gain from homework when it promotes independent learning.

Homework can be an effective instructional device. However, the relationship between homework and achievement is influenced greatly by the students' developmental level. Expectations for homework's effects, especially in the short term and in earlier grades, must be modest. Further, homework can have both positive and negative effects. Educators and parents should not be concerned with which list of homework effects is correct. Rather, homework policies and practices should give individual schools and teachers flexibility to take into account the unique needs and circumstances of their students so as to maximize positive effects and minimize negative ones.

### ALPHA CHI

A college honor scholarship society, Alpha Chi promotes academic excellence and exemplary character

among college and university students and honors those who achieve such distinction. As a general honor society, Alpha Chi admits students from all academic disciplines. A member institution, which must be a regionally accredited, baccalaureate-degree-granting college or university, may invite to membership no more than the top ten percent of the junior and senior classes. Membership recognizes previous accomplishments and provides opportunity for continued growth and service. As the society's constitution states, Alpha Chi seeks to find ways to assist students in "making scholarship effective for good."

Founded on February 22, 1922, by five Texas institutions of higher learning, Alpha Chi was first called the Scholarship Societies of Texas, then the Scholarship Societies of the South (1927), and finally Alpha Chi (1934) when the decision was made to become a national society. By 1955 there were only thirty-six active chapters, all in the south except for two chapters in Nebraska and Massachusetts, but in the 1960s expansion was rapid. By the end of 1971, Alpha Chi had installed chapter number 120 and restructured itself under a new constitution. Growth was strong through the next three decades, with more than 300 active chapters in almost every state by 2000 and an organizational structure of seven geographic regions.

Alpha Chi, legally chartered by the state of Texas, is a 501(c)(3) nonprofit entity with headquarters in Searcy, Arkansas, on the campus of Harding University, one of its member institutions. Its paid staff includes a half-time executive director who is an academic and two full-time professionals overseeing day-to-day operations. The executive director is appointed by the society's governing board, the National Council, made up of twenty-two faculty and students elected by the general membership at regional and national conventions; eight council members are faculty elected at large; the remaining members are seven faculty and seven students elected by their respective regions. The council meets annually, as does the executive committee consisting of the council's president, vice president, and secretary and the executive director. The regions also elect an executive committee consisting of a president, vice president, secretary-treasurer, and student representative. Campus chapters are served by an official faculty sponsor, who is appointed by the institution's president, and by student officers elected by the local membership.

In addition to undergraduate members, who are nominated by the faculty of member institutions, Alpha Chi elects a limited number of honorary members annually. These typically are faculty and administrators of institutions with Alpha Chi chapters or other individuals with acceptable academic credentials who have given special support to Alpha Chi chapters, to the organization as a whole, or to the cause of scholarship in general. After members receive their baccalaureate degrees, they also may choose to maintain an ongoing relationship with the society by paying an annual fee for "active alumni" status. Such members receive invitations to the annual conventions and the society's publications. These publications are the *Recorder*, issued twice yearly (one issue authored by undergraduates and the other, by alumni and others associated with the society); and the *Newsletter*, a bulletin issued three times yearly. Undergraduate members receive these publications through chapter sponsors. The society also publishes a handbook for chapter operations. In 1997 Alpha Chi published *Scholarship and Character: Seventy-Five Years of Alpha Chi*, written by Robert W. Sledge, a long-time leader.

In addition to recognizing students for their academic achievement, Alpha Chi also offers numerous opportunities for their further growth. The society sponsors a competition for scholarships and fellowships totaling more than \$50,000 yearly, mostly at the national level but also at the regional and local levels. Another program involves student scholarly and creative presentations at national and regional conventions. The 2001 national convention, which drew more than 500 students and faculty, featured the work of about 200 students from a wide range of fields. Many local chapters also sponsor programs on campus to promote scholarly activity, and engage in service projects benefiting the campus or the community, often with an academic focus, such as tutoring programs. Finally, students' involvement in leadership at all levels of the society's operation makes Alpha Chi distinctive among similar honor societies and provides excellent opportunities for members to develop their talents beyond the classroom.

DENNIS M. ORGAN

**ALPHA MU GAMMA**

A national honor society for students of community colleges, four-year colleges, and universities, Alpha Mu Gamma honors achievement in the study of foreign languages. The society strongly believes that such recognition stimulates a desire for linguistic achievement; nurtures and promotes interest in the study of foreign languages, literatures, and civilizations; and fosters a sympathetic understanding of other peoples through the medium of languages.

Alpha Mu Gamma was founded in 1931 by members of the foreign language faculty at Los Angeles City College in Los Angeles, California. A semi-annual publication, the *Scroll*, began production in 1933, and continues today as a newsletter. By 1938 there were chapters in five states: Arizona, California, Kansas, Missouri, and Minnesota. By 2001 there were 318 chapters in virtually every state.

The society annually awards scholarships for foreign language study and for study abroad to outstanding student members. Alpha Mu Gamma is registered in the state of California as a nonprofit educational organization. Its officers consist of a nationally elected president and vice president, regional vice presidents, a national executive secretary, a national treasurer, and an administrative assistant. The officers constitute the National Executive Council, which is responsible for the basic policies of the organization. The chapters must conform to the rules of the society concerning selection and initiation of members, and use of society regalia such as pins and cords; however, each chapter is completely autonomous in every other way.

Alpha Mu Gamma held its thirtieth biennial national convention at Fairfield University, Fairfield, Connecticut, in March 2001. The national convention of Alpha Mu Gamma is organized by member chapters to provide a forum where students and faculty can meet and make presentations related to foreign language teaching, study abroad, and the study of literature and culture. Often, scholars of national or international importance attend the conference as keynote speakers. The national convention also pro-

vides the society with an opportunity to honor its most distinguished student members and to install its nationally elected officers. The selection of a location for the convention is made by the National Executive Council based on proposals submitted by member chapters.

Alpha Mu Gamma derives its income primarily from student initiation fees and charter fees. It provides limited financial assistance to chapters involved in the organization of the national convention.

In January 1957, through the efforts of the eleventh national president, Sister Eloise-Therese of Sigma Chapter at Mount Saint Mary's College in Los Angeles, President Dwight D. Eisenhower proclaimed the third week of February as "National Foreign Language Week," now celebrated during the first full week of March. Every year since, the president of the United States and many of the nation's governors have continued to recognize this event. The National Executive Council annually commissions the design and publication of a poster, which is widely distributed among schools, colleges, and universities throughout the United States.

Alpha Mu Gamma not only provides a milieu for students to meet the high standards of achievement of a national honor society, but also offers students incentives to excel in foreign languages.

FRANKLIN I. TRIPLETT

**ALPHA OMEGA ALPHA**

The mission of Alpha Omega Alpha Honor Medical Society is to encourage high standards of scholarship among medical students, to enhance professionalism within medicine, and to encourage community and university service by all physicians and medical students.

Alpha Omega Alpha was founded in 1902 by a medical student, William Webster Root, and several of his classmates. (Root was also involved in the founding of the Association of College Honor Societies.) Steady growth of the society through the chartering of new chapters was facilitated by the encouragement of medical school faculties and deans. In 2000, Alpha Omega Alpha chapters in the United States, Canada, Puerto Rico, and at the American University of Beirut in Lebanon numbered 123.

Alpha Omega Alpha, a nonprofit society, is governed by a board of directors formed of twelve graduate members and three student members. Every chapter has a faculty councillor, secretary-treasurer, and a student president. The councillor is chosen by the dean. Chapters are organized into sixteen regions, each coordinated by a regional councillor.

Undergraduate medical students are elected by all members (residents, students, and faculty) at each institution. Students ranked academically in the top 25 percent of their graduating class are eligible for election, but only one-sixth of each class can be elected. The criteria, in addition to superior scholarship, include demonstration of collegiality, professionalism, service to the community, and promise for excellence as a practicing or academic physician. In addition to medical student members, each chapter may elect a limited number of faculty, alumni, and resident physicians at the institution. Honorary members may be nominated by any member of Alpha Omega Alpha; a number of those nominated are elected by the board. Honorary members are distinguished individuals not eligible for election by any other mechanism.

Upon payment of annual national dues, a member receives *The Pharos* (the Alpha Omega Alpha quarterly) and participates in supporting national programs. Lifetime membership is open to any member.

Each chapter is encouraged to sponsor service and educational projects within the medical school. The national office of Alpha Omega Alpha, located in Menlo Park, California, administers programs that include the following:

1. Alpha Omega Alpha Student Research Fellowships. These are awarded yearly for investigative and mentored activities for students in medical schools with active chapters.
2. The Alpha Omega Alpha Robert J. Glaser Distinguished Teacher Awards. As many as four outstanding teachers from American medical schools are chosen by committees representing Alpha Omega Alpha and the Association of American Medical Colleges (AAMC). The awards are presented each year at the annual meeting of the AAMC.
3. Alpha Omega Alpha Medical Student Service Project Awards. Any student or group of students at each medical school with an active

chapter may apply for financial support for service projects at the school or in the surrounding community.

4. *The Pharos*. First published by Alpha Omega Alpha in 1938, *The Pharos* is the quarterly publication of Alpha Omega Alpha. Nonfiction, nontechnical articles, poetry, and photography relevant to medicine are reviewed by members of *The Pharos* editorial board.
5. Alpha Omega Alpha Helen H. Glaser Student Essay Award. Any student at a medical school with an active chapter may submit a nonfiction essay on a nontechnical medical subject. Judged by members of *The Pharos* editorial board, winners receive a cash award and the essay is published in the quarterly.
6. Leaders in American Medicine videotape series. Available for loan or purchase are more than 100 interviews of outstanding physicians in American medicine.
7. Alpha Omega Alpha Visiting Professorships. This program is available to all active chapters. A respected physician is invited to spend up to two full days at the medical school, interacting with students and residents on rounds, giving specialty lectures, and often giving a special Alpha Omega Alpha lecture.

The only national honor society for medicine (with chapters at all but five U.S. medical schools), Alpha Omega Alpha continues to play a significant role in providing leadership in academia and the practice of medicine. Membership in Alpha Omega Alpha enhances a medical student's curriculum vitae, a vital part of the application for residency in all specialties.

EDWARD D. HARRIS JR.

## ASSOCIATION FOR WOMEN IN COMMUNICATIONS

In 1909 at the University of Washington in Seattle, seven female students who were enrolled in the country's second academically accredited journalism program decided to establish a women's journalism society. These students—Georgina MacDougall, Helen Ross, Blanche Brace, Rachel Marshall, Olive Mauermann, Helen Graves, and Irene Somerville—founded Theta Sigma Phi, which became the Association for Women in Communications in 1996, and

also began the publication of a special women's edition of the university newspaper, *The Pacific Daily Wave*.

In 1918 Theta Sigma Phi held its first national convention at the University of Kansas. After the convention, alumnae started professional chapters in Kansas City, Des Moines, and Indianapolis.

Despite the fact that women gained the right to vote in 1920, many editors relegated women to composing society pages, not allowing them to cover "hard news." In a 1931 issue of the *Matrix*, the society's quarterly journal, Ruby Black, the Theta Sigma Phi national president and the first manager of an employment bureau for members, noted that female journalists could not get reporting jobs at the same pay as similarly qualified males.

Inaugurating the Headliner Awards in 1939, the society honored Eleanor Roosevelt for her efforts to aid female communicators by closing her news conferences to male reporters. Mrs. Roosevelt also contributed several articles to the *Matrix*. During the 1950s and 1960s there were over forty-seven campus chapters and twenty-nine professional chapters, with the national headquarters in Austin, Texas.

### WICI and AWC

In 1973, during the national convention, Theta Sigma Phi delegates voted to change the name of the organization to Women in Communications, Inc. (WICI). Calling for institutions of higher learning to place more emphasis on affirmative action, to create more positions for female journalism professors, and to remove the discriminatory practices that impeded academic advancement, WICI members joined the national Equal Rights Amendment (ERA) coalition to fight the mounting opposition to the ERA. Accenting the need to promote professional excellence, WICI also created an awards program, which grew into the prestigious and highly competitive Clarion Awards.

In order to monitor legislation, national headquarters were moved closer to Washington, D.C. in 1988. Then, in the fall of 1996, the organization was again renamed—as the Association for Women in Communications (AWC). Increasing its influence on the professional growth of students in the communication fields, AWC moved into an alliance with the Accrediting Council on Education in Journalism and Mass Communications (ACEJMC). This resulted in AWC's participation in the development of

course offerings and requirements for institutions of higher learning.

### Mission and Organization

The AWC mission is to "champion the advancement of women across all communications disciplines by recognizing excellence, promoting leadership, and positioning its members at the forefront of the evolving communications era." By 2001 AWC had fully developed an electronic communication network through the Internet. The AWC website includes several online services, including a membership directory, job bank, listserves, the monthly newsletter *Intercom*, the *Matrix*, and an interactive membership response survey system.

Approaching its hundredth birthday, AWC had a membership of about 10,000 in 2001. Its professional awards include the Clarion Award, the International Matrix Award, the Headliner Award, the Rising Star Award, the Georgina MacDougall Davis Award, the AWC Champion Award, the Chair's First Women in Communications Award, the Chapter Recognition Program, the Lifetime Achievement Award, and the Ruth Wyand Awards. Furthermore, AWC has affirmed its long-standing commitment to education with the Matrix Foundation, which provides scholarships and supports educational research and publications.

AWC members range in age from eighteen through ninety-plus. The average age is forty-one, with most members living in urban or suburban settings in the United States and abroad. About 95 percent are college graduates, with about 47 percent holding advanced graduate degrees or involved in graduate study. Disciplines represented within the AWC membership include print and broadcast journalism, television and radio production, film, advertising, public relations, marketing, graphic design, multi-media design, photography, and related areas. A national conference is held annually, with featured guests and honorees representing a range of professions.

## ASSOCIATION OF COLLEGE HONOR SOCIETIES

The Association of College Honor Societies (ACHS) is a visibly cohesive community of national and international honor societies, individually and collaboratively exhibiting excellence in scholarship, service, programs, and governance. A coordinating agency for these societies in chartering chapters in accredited colleges and universities, the association sets a high priority on maintaining high standards, defining the honor society movement, and developing criteria for judging the credibility and legitimacy of honor societies.

### History

During the first quarter of the twentieth century, higher education witnessed a sporadic evolution of honor societies, resulting in proliferation, duplication, and low standards. In October 1925, six credible honor societies, seeing the urgent need to define and enhance the honor society movement, organized the Association of College Honor Societies. Other legitimate societies soon affiliated, beginning an expanding membership that as of 2001 included sixty-seven societies.

More than seventy-five years of dedication to excellence have produced a highly respected professional organization that gives continuous attention to developing high standards and a process of assuring that members are in compliance with the association's bylaws. The Association of College Honor Societies is the nation's only certifying agency for college and university honor societies.

### Membership

By certifying the quality of member societies, ACHS affirms that elections to honor society membership should represent superior academic achievement. Standards set by the association require membership participation in society governance in electing officers and board members, setting authority in organizational affairs, and keeping bylaws current. To provide guidelines for its diverse membership, the association has classified honor societies into distinctive groups and has set standards for societies in each group to follow in establishing their membership and induction requirements of scholarly achievement and leadership. For general honor societies, scholarship recognition represents the highest 20 percent of the college class no earlier than the

fifth semester, or seventh quarter. For honoring leadership, these societies choose from the highest 35 percent, while specialized societies, representing particular fields, induct students who rank in the highest 35 percent of the college class and have completed three semesters, or five quarters. All these societies may elect superior graduate students.

Association members are academic honor societies, as opposed to college professional and social fraternities. Honor societies recognize superior scholarship and/or leadership achievement either in broad academic disciplines or in departmental fields, including undergraduate and/or graduate levels. According to ACHS bylaws, character and specified eligibility are the sole criteria for membership in an honor society. Membership recruitment is by written invitation and conducted by campus chapters—without applying social pressures such as solicitation or “rushing” to enlist initiates. Likewise, association societies must function without preferences to gender, race, or religion.

### Programs

The association publishes the *ACHS Handbook*, which contains the association's bylaws, society profiles, a list of certified societies, and general information. Annual meetings offer opportunities to review standards, discuss issues of concern in higher education and the honors community, and provide guidance in society governance, operations, and campus activities. Information is available to all members through minutes, special studies, committee reports, or the ACHS website.

Recognition of the association at the national level is evident in the increasing collaboration with university administrators, faculty, educational associations, and other groups. Significant attention is seen in the use of the association's classification of honor societies in *Baird's Manual of American College Fraternities*, and in an action by the U.S. Civil Service Commission on April 13, 1973, stating that honor society membership meets one requirement for the civil service GS-7 level.

### Organization

Meeting annually, a council of sixty-seven affiliate societies governs the association with one vote per society to be cast by each society's official representative. Between meetings, the executive committee conducts all business of the association and administers the policies, programs, and activities formulated

by the council. The executive committee comprises the president, the vice president/president-elect, the secretary-treasurer, the immediate past president, and two members-at-large, elected from the council and representing general and specialized honor societies.

Annual dues from member societies provide the chief source of revenue, while other limited income may derive from vendor participation, annual meetings, and occasional grants.

JOHN W. WARREN

## BETA PHI MU

Beta Phi Mu is an international honor society that recognizes academic excellence and distinguished achievement in the field of library studies and information science. The society also sponsors and supports professional and scholarly projects, research, and publications related to librarianship, information science, and library studies.

### Program

Every year Beta Phi Mu awards several grants, scholarships, and fellowships to students of library and information science. The Sarah Rebecca Reed Scholarship of \$1,500 and the Blanche E. Woolls Scholarship of \$1,000 are awarded to students who are just beginning graduate studies in information science.

The \$1,000 Harold Lancour Scholarship for Foreign Study is awarded to a professional librarian or library student who wishes to study a foreign library or program, attend a foreign library school, or do research on library science in a foreign country. The \$750 Frank B. Sessa Scholarship for Continuing Professional Education is given to a member of Beta Phi Mu who wants to augment his or her professional skills through additional study. The \$1,500 Beta Phi Mu Doctoral Dissertation Scholarship and the \$3,000 Eugene Garfield Doctoral Dissertation Fellowship are awarded to doctoral students in library and information science who are working on their dissertations. The Society usually awards several dissertation fellowships each year. Individual Beta Phi Mu chapters may also award scholarship, grants, and awards to their own members.

In 1998, in recognition of the society's fiftieth anniversary, Beta Phi Mu inaugurated an annual Distinguished Lecture Series. Each year an outstanding professional member of Beta Phi Mu is invited to present a lecture on a topic of interest to members of the library and information science field. The lecture is usually given during the annual national conference of the American Library Association.

Beta Phi Mu publishes a semiannual national newsletter, which is sent to all members. Some chapters also publish their own newsletters. In 1990, the society began publishing a series of monographs about the history of libraries and library science in America. Profits from monograph sales fund the Beta Phi Mu Distinguished Lecture Series. From 1952 to 1989 the society also published a series of chapbooks intended to provide exemplary examples of graphic artistry, typography, and book binding.

### Organization

Beta Phi Mu is governed by an executive board consisting of a president, vice president, immediate past president, two directors-at-large, and six directors. Board officers are elected annually by mail ballot. Directors are selected by an assembly of representatives from each chapter. The executive board meets twice a year, usually in conjunction with the American Library Association's midwinter meeting and annual conference. An appointed executive director and treasurer carry out the administrative duties of the society. The president and board appoint members to both ad hoc and standing committees.

**Membership.** There are three categories of Beta Phi Mu membership: membership-at-large, member-

ship with chapter affiliation, and honorary membership. Membership requirements include a scholastic average no lower than 3.75 and completion of all requirements leading to a master's degree from a library and information sciences school accredited by the American Library Association. Candidates for membership must also be recommended by the faculty of the school attended. Graduates from schools outside the United States and Canada may be accepted for membership upon the approval of the society's executive board.

The membership initiation fee is the primary source of funding for Beta Phi Mu activities. Members do not pay annual dues to the national society, but individual chapters may levy dues. Revenue is also derived from private donations, from the sale of the society's monograph series, and from the sale of society pins and other products.

### History

Beta Phi Mu was founded in 1948 at an informal gathering of librarians and library school faculty at the University of Illinois. Twelve students from the University of Illinois Library School were invited to consider founding an honor society, with the faculty serving as sponsors. These students became the charter members of Beta Phi Mu, with Rolland Steven serving as the first Beta Phi Mu president and Harold Lancour as the first executive secretary. The founders chose the motto *Aliis inserviando consumer* (Latin for "consumed in the service of others") as the Beta Phi Mu motto to express the professional librarian's ethic of dedicated service. The following year, thirty-four members of the graduating class of the University of Illinois Library School were initiated into the society. In 1969 Beta Phi Mu became a member of American Association of College Honor Societies. Beta Phi Mu became an affiliate of the American Library Association in 1997. By 2001 Beta Phi Mu had forty-three active chapters in the United States and Canada.

JUDITH J. CULLIGAN

## DELTA KAPPA GAMMA SOCIETY

The Delta Kappa Gamma Society is an international professional organization for women in education and closely allied fields. The largest organized group of women educators in the world, the society's purpose is to improve opportunities, to develop leadership qualities, and to advance the status of women educators employed at every level of education.

### Program

The society annually awards more than twenty scholarships for advanced graduate study, numerous grants-in-aid to undergraduate women students interested in entering the teaching profession, and fellowships to women educators from other countries to pursue graduate study at universities in the United States or Canada. Each year the society sponsors several educational tours abroad. Delta Kappa Gamma also makes a biennial monetary award to the woman author whose educational publication is selected by a committee as the most significant contribution to education during the two-year period. Through conventions, conferences, committee meetings, and seminars, the society provides an outlet for the creativity of women educators and for the exchange of ideas of leaders in all fields of education.

Other Delta Kappa Gamma programs include the Golden Gift Fund, which provides travel grants and special stipends for education research and helps fund seminars and workshops; the Eunah Temple Holden Leadership Fund, which promotes leadership development projects; and the International Speakers Fund, which helps pay travel expenses for speakers invited to give addresses at Delta Kappa Gamma meetings and conferences.

One of the society's most important programs is the Educational Foundation, which encourages standards of excellence in education. It assists and cooperates with schools, colleges, universities, organizations, trusts, funds, or foundations to support, encourage, and improve education. The foundation has made grants to researchers and authors in the field of education, has supplemented the society's scholarship and world fellowship program, and has sponsored numerous study seminars. Delta Kappa Gamma has had continuing interest in fostering international understanding and providing educational services to underdeveloped areas or countries. Educational Foundation ambassadors have visited numerous countries, including Nicaragua, Costa

Rica, Ecuador, Peru, Chile, and Uruguay. Foundation ambassadors recommend and help implement teacher education programs in these countries, recruiting staff and planning courses and facilities.

The society publishes and distributes *The Delta Kappa Gamma Bulletin*, a quarterly professional journal containing articles of general educational interest, and *The Delta Kappa Gamma News*, published eight times a year. Numerous other intrasociety publications facilitate the work of committees and aid the implementation of special projects. Pamphlets and reports of general interest are available to non-members.

### Organization

The Delta Kappa Gamma Society is made up of approximately 3,100 chapters in seventy-five state organizations in fourteen countries. The activities of the society are carried on by twenty standing committees and additional special committees working for teacher welfare, school support, graduate-study scholarships for women, educational research, development of leadership skills, service to children and youth, fellowship with women educators throughout the world, and recognition of women who have given distinctive service. Individuals hold membership in a chapter. Each state has a state organization of chapters within the state. The four regional units are composed of state organizations. The international society comprises the individual chapters and the state and regional units. Chapters meet six to eight times each year. State units usually meet annually, regions meet biennially, and the international society meets biennially.

### Membership

Individuals make up the membership of the chapters and include rural and urban teachers who work at the kindergarten, elementary, high school, and college level. School librarians, administrators, and supervisors are also accepted as members. The requirements for membership include a minimum of five years of successful experience in educational work. Membership is by invitation; individuals are recommended by colleagues and are voted on by the chapters. Honorary membership on the chapter, state, and international levels is extended to women who are not professional educators but who have made significant contributions to education. In 2001 the society had more than 150,000 members.

### History

The Delta Kappa Gamma Society was founded in May 1929 by Professor Annie Webb Blanton and eleven other women educators at the Faculty Women's Club of the University of Texas in Austin. Within its first year, the society was granted a charter and seventeen more chapters were formed. The international Delta Kappa Gamma office is located in Austin, Texas.

## DELTA SIGMA RHO-TAU KAPPA ALPHA

Delta Sigma Rho-Tau Kappa Alpha is a collegiate honor society devoted to the promotion of public speaking (forensics). It is a member of the Association of College Honor Societies (ACHS), and it seeks to reward excellence and to foster respect for freedom of speech.

### Program

The society maintains high standards for membership and for the establishment and conduct of its campus chapters. Faculty affiliated with the society are expected to supervise extracurricular debates and other public speaking activities in addition to teaching speech-related courses. In addition the society sponsors a variety of regional and national competitions in debate, prepared speech, and extemporaneous speech, and student members are expected to participate. The society publishes a journal, *Speaker and Gavel*, and has produced a textbook for use in public speaking courses: *Argumentation and Debate: Principles and Practices*. Written by David Potter under the auspices of Tau Kappa Alpha in 1954, it was revised and reissued in 1963.

The society seeks to attract promising candidates for membership well before they enter college. To this end the society provides a trophy to the winner of the annual National Forensics League tournament for high-school public speakers. It also awards

a Student Speaker of the Year trophy to a college chapter member who is chosen for the honor by the vote of the entire national membership. Another Speaker of the Year trophy is awarded to a nonmember who, in the view of the society, epitomizes effective, intelligent, and responsible public speaking. Past honorees include LeRoy Collins, Reverend Billy Graham, J. William Fulbright, and Edward W. Brooks.

### Organization and Funding

In 2002 the society had 195 active chapters serving 58,150 members. Campus chapters are organized into ten regions. Each region is administered by a governor chosen by active members of the regional chapters. A national council sets overall society policy, but local chapters enjoy a degree of autonomy in planning activities. The council officers are recruited from active or retired college speech faculty members. Society expenses are offset by an initiation fee charged to each new member and by subscriptions to the society journal. In addition fund-raising activities are held by campus chapters.

### Membership

Eligibility for membership is based on active participation in college-level forensics or original speaking. A prospective member must demonstrate skill in these areas but must also show that he or she has the capability of achieving general academic excellence. Thus the student must have completed three semesters or five quarter terms of college-level study and must have attained a high level of scholastic achievement, demonstrated by a combination of high grade point average and class rank. Membership is for life, contingent on payment of annual dues. New members must pay an initiation fee, which entitles them to a two-year subscription to *Speaker and Gavel* along with the insignia of the society.

### History

Delta Sigma Rho was founded in Chicago, Illinois, on April 13, 1906, by speech faculty from eight Midwestern colleges. Two years later, on May 13, 1908, Tau Kappa Alpha was founded by a similarly interested faculty at Butler University in Indianapolis, Indiana. Tau Kappa Alpha became a recognized member of the ACHS in 1937, and steadily gained chapters over the next two decades, achieving a total of ninety chapters by the fiftieth anniversary of its founding. Delta Sigma Rho, which had extremely

rigid standards for prospective chapters, grew less quickly and was admitted to the ACHS in 1955. A year later it had eighty active campus chapters.

The two separate societies merged in Denver, Colorado, in 1963. The archives of both are maintained at Butler University, along with a research library for the use of scholars of American forensics. The society's official contact is through the Communications Department of the University of Alabama, Tuscaloosa.

NANCY E. GRATTON

## KAPPA DELTA PI

Kappa Delta Pi, an international honor society in education, was founded on March 8, 1911, at the University of Illinois. Selection as a member of Kappa Delta Pi is based on high academic achievement, a commitment to education as a career, and a professional attitude that assures steady growth in the profession. Kappa Delta Pi is an honor society of, about, and for educators. The society has 60,000 active members (as of 2001) that include outstanding leaders in the KDP Laureate Chapter, National and State Teacher of the Year winners, American Teacher Award winners, National Teacher Hall of Fame members, and Chicago Golden Apple Teachers. Membership in Kappa Delta Pi signifies more than a well-deserved line on a résumé: Members have the responsibility as a recognized honor student and honored educator to maintain the high ideals of the society and to extend the society's influence. Attending chapter meetings, performing service projects, serving as an officer, and modeling the behaviors and attitudes appropriate to the honor bestowed upon members are ways to contribute to the profession. Kappa Delta Pi supports member development through a multitude of member services. Because teaching is a lifelong process and a worthy profession and career, members are urged to renew their membership annually. The society's goal is to provide resources and services at each phase of members' careers.

The society as a whole prospers, and its influence is felt, to the degree that individuals in the chapters develop both personally and professionally. Membership in Kappa Delta Pi involves both privileges and responsibilities. Persons elected to mem-

bership remain members for life; however, active membership is maintained through the payment of annual dues. An active member is invited to attend the meetings of the chapter into which he or she was initiated and the meeting of any other chapter of Kappa Delta Pi. Attendance at conferences and the biennial Convocation is also open to active members. Each member's name is recorded permanently at society headquarters, located in Indianapolis, Indiana, with the name of the initiating chapter. However, any member may become affiliated with any other chapter of the Society and, upon payment of local dues, enjoy all the rights and privileges of membership in that chapter.

### Mission

Kappa Delta Pi is dedicated to scholarship and excellence in education. The Society is a community of scholars dedicated to the following ideals:

- Scholarship and excellence in education
- Development and dissemination of worthy educational ideals and practices
- Continuous professional growth and leadership of its diverse membership
- Inquiry and reflection on significant educational issues
- A high degree of professional fellowship

### Membership Opportunities

The Kappa Delta Pi Educational Foundation and local chapters award more than \$80,000 in scholarship monies to members each year. Kappa Delta Pi sponsors—with the Association of Teacher Educators—the National Student Teacher/Intern of the Year Award Program. It also sponsors—with the American Education Research Association—the Outstanding Young Researcher Award. In addition, the society presents awards to counselors and chapters for outstanding achievements.

**Publications.** The *Kappa Delta Pi Record* is a quarterly journal for all members. It features articles with practical strategies for learning and teaching. The *New Teacher Advocate* is a quarterly newsletter, judged best among U.S. association newsletters by the American Educational Press Association. It features topics and practical strategies important to preservice and beginning teachers. *The Educational Forum* is an award-winning quarterly scholarly journal containing critical analyses of issues and practices that are of great importance to the improvement of education and educators.

**Conferences.** The Kappa Delta Pi Convocation is a biennial conference at which Society business is conducted and professional development workshops are presented. Regional Leadership Forums are daylong training conferences for members to learn leadership and chapter-management skills.

In addition, worldwide study tours and teacher exchanges are offered each summer. Members may access up-to-date information on society activities, job postings, and information on current issues in education at the society's website.

MICHAEL P. WOLFE

## KAPPA OMICRON NU

The Kappa Omicron Nu Honor Society is dedicated to empowering leaders through scholarship, research, and leadership development and to preparing scholars and researchers to be leaders in society. Kappa Omicron Nu aims to bring leadership to a sizable scholarly community in the human sciences and to emphasize the responsibility of scholars to the family and consumer sciences/human sciences professions and society. By enriching the intellectual environment through its local and national initiatives, Kappa Omicron Nu has provided leadership for collaboration among various organizations within the human sciences in leadership development, in strategic thinking about the future of the field in higher education, and in undergraduate research.

### History

Kappa Omicron Nu was established on February 21, 1990, by the consolidation of Kappa Omicron Phi and Omicron Nu. Following a successful three-year collaboration as an Administrative Merger, Kappa Omicron Nu was structured to realize the synergistic benefits of the two organizations. Kappa Omicron Nu is headquartered in East Lansing, Michigan, close to the Michigan State University campus, which was the founding institution of Omicron Nu.

Omicron Nu was founded in 1912 at Michigan Agricultural College (now Michigan State University). Faculty members were familiar with other honor societies, so Dean Maude Gilchrist and the faculty decided to recognize home economics scholarship.

Promoting scholarship, research, and leadership motivated the expansion of Omicron Nu to campuses across the country.

Kappa Omicron Phi was formed in 1922 at Northwest Missouri State Teacher College, Maryville (now Northwest Missouri State University), with an emphasis on intellectual and scholastic excellence as well as personal development, including intellectual, spiritual, ethical, and aesthetic qualities.

### Governance

Kappa Omicron Nu has adopted a governance model, by which the board of directors achieves its directives and avoids unacceptable circumstances and actions by stating what it will not accept. Policy categories include: (1) ends, (2) executive limitations, (3) board process, and (4) board-staff linkage. The effects of the model are clarity of values, a focus on results rather than administrative process, empowerment of executive authority, and an enhanced board-member relationship.

The Kappa Omicron Nu board includes the chair, chair-elect, vice chair for programs, vice chair for finance, secretary, and three student board members. The executive director is a nonvoting member of the board. The board is elected by active members, and the Biennial Conclave Assembly of Delegates sets authority for organizational affairs.

### Membership

To be considered for membership, undergraduate students must have completed forty-five semester hours (or the equivalent), have a minimum grade point average of 3.0, and rank in the top 25 percent of their class. Graduate students shall have completed twelve semester hours of graduate work (or the equivalent) and have a minimum grade point average of 3.5. Professionals not previously initiated into the honor society and those with degrees outside the profession are also eligible.

### Major Activities

Kappa Omicron Nu awards scholar program grants of between \$150 and \$500 to each chapter once each biennium. In total, fellowships and grants in excess of \$30,000 are awarded each biennium. Chapter programming focuses on a national program theme and scholarly priorities, including undergraduate writing, ethics, mentoring, cultural diversity, leadership, and undergraduate research. The society's website is

designed to support the development of a learning community. The Leadership Academy sponsors innovative programs and leadership development, including online courses. In collaboration with the Undergraduate Research Community for the Human Sciences, Kappa Omicron Nu sponsors an annual undergraduate research conference.

The society publishes *Kappa Omicron Nu FORUM*, a refereed, thematic scholarly journal, and *Kappa Omicron Nu Dialogue*, a substantive newsletter containing issue discussion, program themes, announcements, and awards. *FORUM* has featured a series titled "Legacies for the Future," which tells the stories of leaders who helped to develop the field of human sciences. Other stories have focused on the concepts of community, collaboration, empowerment, and leadership. *FORUM* is also available online, and an online newsletter, *Kappa Omicron Nu Spotlight*, serves as the annual report of Kappa Omicron Nu activities.

## LAMBDA IOTA TAU

An international honor society, Lambda Iota Tau recognizes and promotes excellence in the study of literature in all languages.

Lambda Iota Tau was founded at Michigan State University on December 3, 1953, and was incorporated in 1954 by representatives of chapters at Aquinas College, Baldwin-Wallace College, Eastern Michigan University, Marygrove College, Mercy College of Detroit, Purdue University, Sioux Falls College, and the University of Detroit. In 2001 the society had forty-seven active chapters with a total membership of approximately 40,000. The international office is located at Ball State University in Muncie, Indiana.

The society is a nonprofit organization. Elected officers of Lambda Iota Tau are the international executive secretary, the international assistant executive secretary, the treasurer, and the international board of chapter advisers. The international executive secretary conducts the affairs of the society, arranges for and presides over all international meetings, and consults with the international board

in all actions affecting the society as a whole. The treasurer receives all dues and pays all financial obligations of the society. The international board of chapter advisers consists of five chapter advisers from five geographical areas. The board elects its own president, determines and initiates new policies within the constitutional limitations of the society, ratifies the appointments of the secretaries and treasurer, nominates candidates for all elective offices, corresponds with the chapters in their geographical areas, and determines the international dues.

Members are students majoring or minoring in literature, including literature written in foreign languages, who are in the upper 35 percent of their class in cumulative grade point average, have attained at least a full B average in at least twelve semester credit hours or eighteen term hours of literature and all prerequisites thereto, are enrolled in at least their fifth college semester or seventh college term, and have presented an initiation paper. The initiation paper is presented in such a manner as the local chapter requires, is of a quality certified by the chapter adviser, and is on a literary topic (research or critical) or of a creative nature (short story, essay, poem, drama). Graduate students must have completed one semester term with an A- average.

Members are initiated into local chapters established and maintained only at colleges or universities that grant the baccalaureate or higher degrees and that are accredited by the appropriate regional agency and certain appropriate professional accrediting agencies. The local chapters are approved by the administrations of their institutions. Lambda Iota Tau is a member of the Association of College Honor Societies and meets all of the high standards for member organizations.

Lambda Iota Tau publishes its annual journal *LIT*, which includes noteworthy poems, short stories, essays, and critical analyses written by its members. The best piece in each category of *LIT* is awarded a publication prize. The society also publishes a semiannual *Newsletter*. In addition, several scholarships are awarded to the membership each year.

Chapters are encouraged to hold regular meetings and to sponsor events and activities that will bring the study of literature to the attention of the campus at large. Chapters sponsor such projects as the appearance of outstanding speakers on their campuses, motion pictures based on works of litera-

ture, publications of student creative and critical writing, and library exhibits. They also hold book sales to foster more reading of literature. Some chapters volunteer for local Habitat for Humanity projects and various local literacy projects.

The international office has in the past sponsored lectures by famous individuals such as John Crowe Ransom, Robert Lowell, and Richard Eberhart. The society currently confers honorary memberships on individuals who have made worthy contributions to some area of literature, language, or linguistics, or who have demonstrated proficiency in teaching, scholarship, criticism, or creative writing. The society also bestows an honorary presidency on a literary figure who has achieved distinction in both critical and creative writing. Honorary presidents have included W. H. Auden, Archibald MacLeish, Daniel Hoffman, Robert Penn Warren, Richard Eberhart, Richard Marius, and Robert Pinsky.

BRUCE W. HOZESKI

## PHI BETA KAPPA

Founded at the College of William and Mary in Williamsburg, Virginia, in 1776, Phi Beta Kappa is a college and university honor society established to recognize and promote intellectual scholarship and liberal arts education. Phi Beta Kappa is the oldest Greek-letter organization and national academic honor society. In addition to awarding membership to distinguished undergraduates, the Phi Beta Kappa Society also offers scholarships, awards, funding for visiting scholars, and high-school development programs.

### Goals

For more than 200 years the Phi Beta Kappa Society has engaged its mission of promoting and recognizing excellence in the liberal arts and sciences. Phi Beta Kappa's purpose is to emphasize the importance of the literary and humane tradition by recognizing outstanding scholarship in those fields. At its inception, Phi Beta Kappa was distinguished by such characteristics as an oath of secrecy, a badge, mottoes in Latin and Greek, a code of laws, elaborate initiation rituals, a seal, and a special handshake. The society's distinctive emblem, a golden key, is widely recognized as a symbol of academic achievement. Though the original standards have been modified over time by such changes as omitting the secrecy

clause and through the inclusion of women for membership, the focus on excellence in the liberal arts and scholarly achievement remain central tenets of Phi Beta Kappa's mission.

### Programs and Activities

Programs are offered through the chapters and their community counterparts, the associations, both of which work in conjunction with the national office. The goal of the programs is to honor and champion liberal arts scholarship. Through its various programs and activities, Phi Beta Kappa provides support via scholarships and lectureships, book and essay awards, and funds for visiting scholars. More than one million dollars is raised and distributed each year to support these efforts and the students whom they benefit.

Scholarships are available from the national office, individual chapters, and associations. Individuals must apply for these scholarships and demonstrate merit for receipt of a scholarship. There is an application process, outlined by each respective organization, and committees that evaluate the applicants and confer the awards.

Sponsored by the Phi Beta Kappa Society, the Phi Beta Kappa book awards are granted annually to authors of exceptional scholarly books published in the United States in the fields of the humanities, the social sciences, the natural sciences, and mathematics. There are three book awards that each bestow a prize of \$2,500 to recipients. The awards include the Christian Gauss Award in the field of literary scholarship or criticism; the Phi Beta Kappa Award in Science for contributions to the literature of science; and the Ralph Waldo Emerson Award for scholarship regarding the intellectual and cultural condition of humanity. In addition, the Phi Beta Kappa Poetry Award is presented annually for the best book of poems published in the United States within a given year. It carries a \$10,000 one-time award.

The Visiting Scholar program affords chapters the opportunity to bring renowned scholars to their campuses to participate in lectures and seminars, meet with faculty and students, and address each institution's academic community over a two-day period. The objective of the program is to enhance the intellectual life of campuses by allowing an exchange among visiting scholars, faculty, and students. Twelve or more scholars participate each year.

To foster academic excellence and promote liberal learning at the secondary level, Phi Beta Kappa

has built a partnership with the National Honor Society and the National Junior Honor Society. The partnership was initiated in 1994 and has as its central feature the participation of Phi Beta Kappa in the National Honor Society's annual meeting wherein the society provides the central academic program.

The society also circulates two main publications. *The American Scholar*, which has been in quarterly circulation since 1932, is a scholarly journal that provides articles and essays on various literary, artistic, and scientific subjects. *The Key Reporter* is distributed to all Phi Beta Kappa members and provides organizational information and news.

### The Development of College and University Chapters

When Phi Beta Kappa was initially established, chapters were founded when a chartered Phi Beta Kappa organization on one campus granted a charter to another institution. This process details how the founding chapter at William and Mary awarded chapters to Yale, Harvard, and Dartmouth between 1776 and 1781. Then, in 1881, a national organization was created—the United Chapters of Phi Beta Kappa—to coordinate Phi Beta Kappa programs, activities, and membership. The United Chapters of Phi Beta Kappa evolved into what is known today as the Phi Beta Kappa Society.

The society's governing body, the Council, convenes every three years and brings together national representatives from every chapter and alumni association. This council sets general policies, elects officers and members to the twenty-four-member senate governing board, and decides on applications for new chapters. A Committee on Qualifications—a twelve-member elected body—receives all chapter applications, reviews them, and recommends to the Senate their opinions regarding applicants.

When a campus decides it would like to apply for membership, an informal group of faculty must organize to begin the process of applying for a charter. Since charters are granted to the Phi Beta Kappa members on the faculty rather than to an institution, adequate faculty representation is essential to the vitality and stability of organizing a new Phi Beta Kappa chapter. The appropriate faculty representatives communicate with Phi Beta Kappa headquarters to obtain an application and begin the

documentation process. Because the Council only convenes every three years, timing is also critical. After submission of the application and the appropriate fee, the Committee on Qualifications considers applications and seeks reliable evidence that an applicant institution can meet the Phi Beta Kappa selection criteria.

Phi Beta Kappa sets very high standards not only for the students selected for membership but also for institutions desiring a campus Phi Beta Kappa chapter. Due to the vast differences among colleges and universities, no uniform, abstract standards exist for institutional membership and the awarding of Phi Beta Kappa chapters. Rather, institutions must provide valid evidence and submit to a rigorous assessment process based on individual campus distinctions. It is critical that institutions demonstrate their ability and willingness to uphold the Phi Beta Kappa ideals and standards in cultivating liberal learning. For example, the selection process gives careful consideration to the degree to which institutions possess standards that encourage excellence, a governance structure that fosters academic freedom and vitality, a scholarly faculty, a promising student body, sufficient resources (i.e., libraries and educational facilities), and adequate institutional income.

If institutions meet these standards and are deemed worthy candidates, a site visit is arranged. Phi Beta Kappa representatives conduct the site visits and reconvene to discuss their recommendations. These recommendations are forwarded to the Senate for discussion at the triennial Council meeting. A two-thirds vote by attending chapter and association delegations is required for approval of a new chapter. Upon approval, the charter for a new chapter is promptly granted and formal initiation procedures are arranged. In 2001 there were more than 250 chapters of Phi Beta Kappa in the United States.

## PHI DELTA KAPPA INTERNATIONAL

Phi Delta Kappa International is a not-for-profit professional association of women and men in education. The purpose of the organization is to promote quality education—with particular emphasis on publicly supported and universally available education—as essential to the development and maintenance of a democratic way of life. This purpose is achieved through the genuine acceptance, continuing interpretation, and appropriate implementation of the ideals of leadership, service, and research.

### History

Phi Delta Kappa was established in 1910 by representatives of three educational fraternities: Pi Kappa Mu at Indiana University (1906), Phi Delta Kappa of Columbia University (1908), and Nu Rho Beta at the University of Missouri (1909). Chapters were categorized as either *campus chapters* or *field chapters*, a practice that was abolished in 1973. The racial barrier for membership was stricken from the constitution of Phi Delta Kappa in 1938, but it was not until 1974 that the gender barrier was eliminated. The first international chapter was approved in 1955 at the University of Toronto, and in 1999 the constitution of Phi Delta Kappa was changed by chapter referendum to eliminate the use of the term *fraternity* and replace it with *association*.

### Membership

Membership is open to professionals at all levels of education and to individuals in educationally related fields who have a baccalaureate degree and have academic standing sufficient for admission to graduate school. Student teachers are also eligible for membership. Membership is by election through the chapter structure; candidates for membership may be nominated by current members or through self-nomination. Membership is also available without affiliation with a Phi Delta Kappa chapter. Additionally, Phi Delta Kappa provides undergraduate student membership at half the amount of regular dues. Life, senior, and emeritus membership categories are also available.

### Programs

Phi Delta Kappa International offers a variety of programs focused on members, local chapters of the association, the broader education profession, and local communities. Professional development activi-

ties are emphasized by the Center for Professional Development and Services (CPD&S), which offers seminars to school districts. CPD&S also houses the International Curriculum Management Audit Center. The Center for Evaluation, Development, and Research (CEDR) disseminates research information through publications and supports research activities through programs and services. The *Phi Delta Kappan*, the association's journal, is published ten times each year and confronts the most current issues facing K–12 schools and institutions of higher education.

Phi Delta Kappa International underwrites a number of scholarship programs for pre-service and in-service educators, as well as offering support to the Future Educators of America, which promotes teaching as a viable career option for young people. Through the International Travel Scholarship Program, Phi Delta Kappa also makes annual awards to members who wish to participate in educational travel tours sponsored by the association.

The association contributes to the national dialogue in the United States between the education community and U.S. citizens through its sponsorship of the Phi Delta Kappa/Gallup Poll of the Public's Attitudes Toward the Public Schools. The results of the poll are reported each September in the *Phi Delta Kappan*.

### Organization and Governance

As of 2001, there were more than 600 Phi Delta Kappa chapters located in North America and approximately twenty others outside the United States and Canada. Chapters are grouped into areas, each under the direct administration of an elected area coordinator. Coordinators visit chapters, provide leadership training, and disseminate information about the international association. Areas are grouped into nine districts, each under the administration of an elected district representative who also serves on the international board of directors. The legislative council, meeting in odd-numbered years, sets association policy, elects international officers, and adopts the biennial budget. The international board of directors serves as the policymaking agent between meetings of the legislative council and employs the executive director who oversees a staff of approximately sixty persons. Financial support is derived through dues, the sale of publications, services, and grants.

GEORGE KERSEY JR.

## PI KAPPA LAMBDA

Pi Kappa Lambda is a collegiate honor society dedicated "to the furtherance of music in education and education in music." Its goal is to honor outstanding academic and artistic achievement on the part of music majors working at the college or graduate-school level and to encourage students to continue to strive for excellence throughout their careers.

### Program

The primary purpose of Pi Kappa Lambda is to recognize and encourage talented individuals working in the field of music by offering membership to qualified candidates. This honor is conferred by the election to membership itself, along with which the honoree is awarded an insignia of the organization (a symbolic key) and, on paying a nominal membership fee, is entitled to receive a copy of the society newsletter. In addition, the founding (Alpha) chapter at Northwestern University has underwritten several publications, most notably a series of monographs on American music. These monographs and similar studies have been published by Northwestern University Press.

### Organization

Pi Kappa Lambda has enjoyed steady growth since its inception in 1916 and by 2002 enrolled 203 chapters, with 58,000 members, at colleges and universities throughout the United States and in Canada. A board of regents, elected from the official membership, oversees the business of the society during annual meetings. Every other year the society holds a national convention, to which local chapters may send delegates to express their concerns and interests. Every two years the regents commission a new composition.

### Membership

Every year local chapters review the recommendations of their college's or university's school of music and choose from these candidates the students whose work, both artistic and academic, is judged to be outstanding. Students are eligible for consideration only if they meet certain stringent criteria:

They must be at an advanced stage in their studies—junior or senior undergraduates or graduate students. They must have elected music as their major course of study. In addition, they must have the support of their faculty, whose recommendations are carefully considered. Finally, they must meet or exceed certain academic standards. All candidates for membership must maintain a grade point average equivalent to the top 20 percent of the current graduating class, and juniors must be in the top 10 percent of their own class as well.

New members are required to pay a small fee, a portion of which covers the cost of their insignia and subscription to the society newsletter. The remainder of the fee goes to support the work of the national office. The society also earns revenues from its periodic publishing projects.

### History

In 1916 several members of the alumni association of the School of Music at Northwestern University met to discuss ways in which they could help to encourage future students to strive for excellence in both their artistic and their academic lives. Of particular concern was the marriage of music and education, which these founding members felt was too often underappreciated. The group agreed to organize an honor society devoted to these issues. Among this group was Peter Christian Lutkin, whose enthusiasm for the project earned him the distinction of being the very first member of the newly organized honor society. Professor Lutkin contributed more than his enthusiasm, however. When deciding on the name for the new society, the founding group chose Professor Lutkin's initials (in their Greek form), thus, Pi Kappa Lambda.

The society, though still only local, grew quickly, and in 1918 it was officially granted a charter by the state of Illinois. Soon chapters were formed at other universities, and by the early 1970s it had grown to more than 13,000 members at seventy institutions of higher learning. The 1980s and 1990s were a time of dramatic growth, and during this period the society went international, with the first chapters forming in Canada.

The national office remains at Northwestern University where the first chapter was formed. Also at Northwestern are the society's archives, where the very first Pi Kappa Lambda key, issued to Professor Lutkin, is kept.

NANCY E. GRATTON

### PI SIGMA ALPHA

Pi Sigma Alpha is the national honor society in political science. Its purpose is to encourage, recognize, and reward academic and professional achievement in the study of politics and government. It pursues its objectives through awards, grants, scholarships, subsidies, meetings, and publications.

The honor society operates through a system of local chapters based in political science departments on the campuses of colleges and universities across the United States. Each chapter establishes and administers its own programs and activities to stimulate interest in politics and reward academic excellence. New chapters of the honor society are chartered by the national office. To qualify for a chapter, a political science department must meet a set of strict academic standards established by the rules of the honor society. These standards include official accreditation, autonomy over curriculum and faculty hiring, academic qualifications of faculty, number of majors, and size of the student body.

As a national honor society, Pi Sigma Alpha's primary responsibility is to oversee the annual induction into membership of students who have excelled both in their general academic course work and more specifically in their political science classes. Students are inducted into membership by local chapters based exclusively on academic performance. The national constitution establishes minimum academic standards for admission. These qualifications include a minimum grade point average, minimum number of semester hours completed in political science, and minimum class rank. Individual chapters may raise the eligibility standards, but they may not lower them. The honor society inducts approximately 6,000 new undergraduate and graduate student members each year. Since 1920 the society has inducted more than 160,000 members, and includes among its membership some of the nation's most distinguished and prominent politicians, civil servants, political consultants, journalists, and political scientists.

Pi Sigma Alpha promotes its objectives through a variety of programs. Some programs are directed toward student members and local chapters directly; others are directed more generally toward the broader community of political science scholars. Programs targeted directly at chapters and members include grants to local chapters to support noteworthy and worthwhile campus activities and programs, awards for best undergraduate student papers and theses and best graduate student papers, scholarships for first- and second-year graduate study in political science, awards for best chapters and chapter advisers, a biannual newsletter, and subsidies for student memberships in professional political science associations.

For the political science profession, the national society awards prizes for the best papers written and submitted by political scientists at national and regional political science association conventions; hosts lectures by prominent national politicians, policymakers, and journalists at national, regional, and state political science association conventions; and supports teaching awards for political scientists who distinguish themselves in the classroom.

Pi Sigma Alpha is governed by its biennial national convention. Each chapter may send one faculty delegate and one student to the convention. Representatives at the convention elect the officers and discuss and determine the policies of the society. Each chapter is entitled to one vote at the convention. Between conventions, the affairs of the society are directed by an executive council consisting of the president, president-elect, executive director, newsletter editor, the three most recent past presidents, and twelve council members elected by the membership. Council members serve four-year terms, with half of the council elected every two years.

The national office and the society's programs are funded by a national initiation fee paid by each new member inducted into the society. Individual chapters and their programs are supported by such additional local fees or dues as each chapter may determine.

Pi Sigma Alpha was founded in 1920 at the University of Texas. In 2001 there were more than 560 chapters of Pi Sigma Alpha throughout the United States. Pi Sigma Alpha has been a member of the Association of College Honor Societies since 1949.

#### INTERNET RESOURCE

THE NATIONAL POLITICAL SCIENCE HONOR SOCIETY. 2002. <[www.pisigmaalpha.org](http://www.pisigmaalpha.org)>.

JAMES I. LENGLE

#### RHO CHI

Rho Chi is a collegiate and professional honor society devoted to the promotion of the pharmaceutical sciences. Induction into the society is a mark of recognized excellence in scholarship and professionalism. Goals of the society are to encourage teaching, scholastic achievement, and research and to encourage promising students to pursue graduate-level study in pharmaceutical studies.

#### Program

Like many other national honor societies, Rho Chi's primary mission is to recognize academic and professional excellence through induction into the society. Although membership brings the newcomer into association with others of professional caliber in the field of pharmacy, it is primarily the honor of recognition that membership endows on an initiate. However, the society is strongly committed to its mission of encouraging graduate-level study and to that end it cosponsors, with the American Association for Pharmaceutical Education, an annual first-year graduate fellowship to the most promising candidate embarking on a master's or doctoral program at an accredited institution.

In addition the society circulates an annual publication, *The Report*, which provides a forum for articles of professional, ethical, or educational importance written by its members. Each year the society honors the contributions of a distinguished member of the profession by presenting the Rho Chi Award, and it invites the recipient to deliver an address to the assembled members at a meeting held during the American Pharmaceutical Association's annual conference.

At the local chapter level, the most important event is the induction of new members into the society. The ritual for induction is prescribed by the national committee and is designed to be an occasion of dignified recognition of the inductees' proven excellence. Each initiate receives a copy of *The Rho Chi Society*, the official history of the organization; a copy of the *Constitution and Bylaws* of the society; and a key bearing the official insignia of the group.

At their graduation ceremony, following completion of their degree programs, they are entitled to wear the purple and white insignia of the society over their graduation gowns.

### Membership

Undergraduate candidates for induction into the society must be enrolled in a program of pharmaceutical studies at an institution accredited by the American Council on Pharmaceutical Education (ACPE) and must have completed at least two years of the course work necessary for earning the degree. They must have demonstrated their commitment to scholastic excellence by earning a 3.0 grade point average (on a four-point scale) and ranking in the top twentieth percentile of their class. Finally, they must be certified as eligible by the dean of their degree program and must have no record of disciplinary problems.

Graduate students must meet similar standards of demonstrated excellence, but the grade point average is higher, at 3.5 on a four-point scale. Membership is also open to alumni of undergraduate or graduate programs, after they have entered the profession, and to faculty teaching pharmaceutical studies, if in the course of their professional work they have earned recognition by the society. Honorary memberships are also occasionally conferred.

New members pay an initiation fee that covers the cost of their key and insignia and entitles them to receive a copy of the annual publication. Annual dues are paid to the national board to support the society's activities.

### Organization

Individual chapters must have a minimum of five members under the supervision of a faculty member appointed by the dean of the school of pharmacy at the institution. Local chapters are autonomous in planning activities and in electing their officers. The national organization is governed by an executive council, the members of which are elected for two-year terms. At the annual meeting each chapter is entitled to send one delegate and one alternate to represent the local organization.

### History

The impetus for the formation of a national honor society in the field of pharmaceutical studies began at the University of Michigan, where the School of

Pharmacy had established a local society in 1908. This group, known then as the Aristolochite Society, decided in 1917 to extend its message to other colleges and universities in the country and had succeeded in gaining the interest of pharmaceutical faculties at Oregon Agricultural College, which established a chapter in 1918. Also in 1917, the president of the national professional organization, the American Council of Pharmaceutical Faculties (ACPF, now the American Association of Colleges of Pharmacy) devoted a portion of his annual address to the membership to a call for the establishment of a national honor society, which would promote the council's principles and goals.

The ACPF found that the University of Michigan local organization shared its general philosophy and goals, and ACPE joined forces with them. By 1922 the Michigan organization had succeeded in founding a chapter at the University of Oklahoma and had changed its name to Rho Chi. In that same year it received a charter from the state of Michigan recognizing it as an official honor society.

The Rho Chi society grew slowly during the early years, with only ten chapters by 1932. By 1942, however, it had grown enough to earn recognition by and membership in the Association of College Honor Societies (ACHS), and as of 2002 it had seventy-seven chapters across the nation, serving 73,000 members.

NANCY E. GRATTON

## SIGMA XI

Sigma Xi, The Scientific Research Society was founded in 1886 at Cornell University in Ithaca, New York, as an honor society for science and engineering. It is an international, nonprofit membership society of more than 70,000 scientists and engineers elected because of their research achievements or potential.

### Goals

Originally established to recognize the scholarly potential and accomplishments of young scientists and

engineers, Sigma Xi also had the objective of bringing together scholars from a number of scientific disciplines so that they might communicate and collaborate. With these guiding principles, the main purpose of the Sigma Xi today is to honor scientific achievement and encourage research in science and technology through awareness, advocacy, and scholarly activities. Sigma Xi strives to promote an appreciation of the roles of science and research in society, and to foster worldwide interactions among science, technology, and society.

### Programs and Activities

Sigma Xi sponsors numerous programs to support ethics and values in research; to improve science and education—and the public's understanding of science; and to promote the health of scientific research worldwide. Key programs include Distinguished Lectureships, the Forum Series of national and international conferences, and Grants-in-Aid of Research. The society also produces numerous publications.

The Distinguished Lectureship program provides an opportunity for society chapters to host visits from outstanding individuals who are at the leading edge of science. The lecturers are brought to campus to communicate their insights and excitement about science and technology to scholars, students, and to the community at large.

The Forum Series was initiated to provide national and international conferences on topics that concern the intersection of science and society. The conference and forum initiative was conceived at the society's centennial celebration in 1986 as part of its New Agenda for Science.

The Grants-in-Aid program awards stipends of \$100 to \$1,000 to support scientific investigation in any field. To be considered for a grant-in-aid, an individual must be an undergraduate or graduate student in a degree program. While membership in Sigma Xi is not a requirement for the program, the majority of the funds are designated for use by individuals whose primary advisers are Sigma Xi members or who are Sigma Xi student members themselves. Individuals are eligible to receive a total of two Grants-in-Aid from Sigma Xi headquarters in their lifetime. No citizenship restrictions apply, and international students and non-U.S. citizens are encouraged to apply. Upon the committee's receipt of an application for aid, notification occurs within twelve weeks of the application deadline.

*American Scientist*, a bimonthly magazine of science and technology, is the publication of Sigma Xi. Containing reviews of current research written by prominent scientists and engineers, it has been produced since 1913 and has received many awards for its exceptional quality.

Additionally, a number of new, smaller programs have also been developed to extend Sigma Xi's mission: The International Chapter Sponsorship Program promotes and assists the formation of new chapters worldwide; the Partnership Programs support joint initiatives sponsored by Sigma Xi and other organizations; and the Science, Math and Engineering Education Program that offers one-time grants of up to \$1,000 to support science education projects. The basic policy is to provide seed money to initiate innovative programs, with special consideration given to those projects that are designed to stimulate young people's interest in science and mathematics.

### The Development of College and University Chapters

Sigma Xi has more than 500 chapters at universities and colleges, government laboratories, and industry research centers worldwide. Having a chapter affords institutions the opportunity to honor individuals involved in science-related activities, supplies a vehicle for providing services (i.e. seminar series, awards, grants), and allows fellowship and interaction with colleagues across science, math, and engineering disciplines.

To receive approval for a chapter charter, Sigma Xi headquarters (in Research Triangle Park, North Carolina) must receive a letter of intent to petition for a charter that includes the signatures of at least eighteen active members in the area. With the letter and appropriate signatures, a description of the sponsoring institution is required, along with supporting recommendations from administrators, a proposed three-year schedule of activities, and member recruitment plans.

The review process is overseen by the Committee on Qualifications and Membership, and, upon their recommendation of approval of an application, the Sigma Xi Board of Directors gives final approval. For chapters to remain in good standing, regular communication with Sigma Xi headquarters is required, minimally providing officer names and an annual report each year. Representation at least once

every three years at the Society's annual meeting is also mandatory. Activity within the chapter evidenced by new membership and programs is also critical to a chapter's good standing.

MEAGHAN E. MUNDY

### TAU BETA PI

Founded at Lehigh University in 1885 to recognize engineering students of distinguished scholarship and exemplary character, Tau Beta Pi is the only engineering honor society representing the entire engineering profession. The primary goals of Tau Beta Pi are to honor students and engineers who have demonstrated their abilities and shown an appreciation of high standards of character and ethics and to provide opportunities to students and engineers to further their scholarly activities and development in the field of engineering.

#### Programs and Activities

Tau Beta Pi offers a number of programs that assist the organization in carrying out its goals. These activities are implemented at both the local and national levels to generate interest and increase awareness among engineers, to recognize outstanding scholarship, and to emphasize civic responsibility. Key programs offered by Tau Beta Pi include the Engineering Futures program, the Fellowship Program, undergraduate scholarships, and chapter community service projects.

The Engineering Futures program teaches interpersonal skills to engineering students. This is accomplished by utilizing alumni who conduct on-campus training in people skills, team chartering, analytical problem solving, and group process. The Fellowship Program is Tau Beta Pi's single most important project for the advancement of engineering education and the profession. The purpose of the Fellowship Program is to finance a select group of

members chosen for merit and need, providing each of them a year of graduate studies at the college of his or her choice. Unlike many fellowships, a distinguishing feature of the Tau Beta Pi fellowship is that it is free of excessively binding restrictions. Tau Beta Pi fellows are free to do graduate work in any field that will enable them to contribute to the engineering profession. The only specific responsibility fellows must fulfill is to write a summary report at the completion of their fellowship year.

The Tau Beta Pi Association Scholarship Program was established in 1998 for undergraduates in their senior year of full-time engineering study. The amount of the scholarship awards is \$2,000. Other gifts and endowments such as the Dodson Scholarship/Fellowship Fund, the Stabile Scholarship, and the Soderberg Awards, as well as gifts from such companies as Alabama Power Foundation and Merck and Co., also afford financial aid to undergraduate students. At the national level, Tau Beta Pi participates in the Society of Automotive Engineers scholarship program and the National Society of Professional Engineers educational program for first-year engineering students.

Another valuable service the Tau Beta Pi headquarters provides is employment resources for college students and alumni. Various jobs and internships in the engineering field are posted for Tau Beta Pi members through a contracted Internet server. Tau Beta Pi also offers a Recruiting Center at its Knoxville, Tennessee, headquarters, and many companies place recruitment advertisements in *The Bent*, the society's magazine. *The Bent* has been published since 1906 and is available quarterly with more than 94,000 copies circulated per issue. *The Bulletin of Tau Beta Pi*, published three times per year, disseminates news and information on the organization to collegiate chapters.

#### The Development of College and University Chapters

With approximately 429,000 total initiated members in Tau Beta Pi nationally, college chapters exist at more than 220 United States colleges and universities, and active alumnus chapters are available in sixteen regions across the nation. To establish a chapter at an institution of higher education, the recommended requirements are outlined in the Tau Beta Pi bylaws. These standards require that institutions have a specified number of engineering programs accredited by the Accreditation Board for

Engineering and Technology, at least forty engineering graduates per year, and a minimum of three faculty members who are also members of Tau Beta Pi.

To obtain a Tau Beta Pi chapter, an institution must first organize a local engineering honor society with members selected from the top fifth of the senior class or top eighth of the junior class. The chapter is open to all engineering students who fit these distinctions; technology students are ineligible. With the initial membership intact, this organization is expected to govern itself and elect members for two years in the exact ways a formal Tau Beta Pi chapter operates. After this two-year probationary period, a formal petition made to Tau Beta Pi headquarters can be accepted for consideration.

The formal petition and college catalogues are examined by the executive council of Tau Beta Pi, who, upon approval, direct a campus inspection visit. If the recommendations from the inspection group prove favorable, then the petitioners must prepare a formal request and send two representatives—a student and an adviser—to the next Tau Beta Pi National Convention. Based on convention approval, the new chapter would be formally instated and its first members initiated shortly thereafter. To ensure quality and commitment of new chapters, the lengthy process of developing a chapter typically takes about four years. Holding in high regard integrity and excellence in the field of engineering, Tau Beta Pi requires members, chapters, and alumni groups to meet the highest of standards of excellence in their roles as broadly based engineers in society.

## HONORS PROGRAMS IN HIGHER EDUCATION

---

Honors programs are housed in many different types of institutions of higher education. In general, honors education consists of “the total means by which a college or university seeks to meet the educational needs of its ablest and most highly motivated students” (Austin, p. 5). The goals of honors

programs usually include identifying and selecting highly able students; challenging those students academically and allowing them to exercise their potential; and, as the National Collegiate Honors Council website states, serving as a means by which to “raise the level of education . . . for all the students” by acting as an intellectual “laboratory.” Institutional objectives for creating honors programs often include attracting and retaining students and faculty by displaying a “commitment to quality education,” attracting funds, and “enhancing the public image of the institution as a place of superior scholarship” (Austin, p. 7). Not surprisingly, there are many different types of honors programs, often tailored to their specific types of institutions.

While Wesleyan University has had honors at graduation since 1873, and the University of Michigan (1873–1900), the University of Vermont (1888), Princeton (1905), Columbia (1920), and Harvard (1914) had some type of tutorial, exam, or thesis honors, fully developed honors education in America began in 1922 with the implementation of Frank Aydelotte’s program at Swarthmore, which was modeled after the Oxford program of “pass/honors”—a system in which the only grades are pass, fail, or honors. In expectation of a student boom after World War II, Aydelotte felt that America’s future depended on allowing gifted students to break out of the “academic lock step” through challenging courses of study that encouraged them to accept more freedom and responsibility and to develop their intellectual independence and initiative (Aydelotte, p. 15). Aydelotte’s program allowed for greater student independence and specialization by replacing the traditional curriculum of the junior and senior years with unique “free-discussion” seminars with no attendance or hour requirements, culminating in a series of “less frequent, but more comprehensive” written and oral exams (Aydelotte, p. 37).

Subsequent to the success of the Swarthmore program, most universities developed honors programs—following either Swarthmore’s plan of replacing the curriculum in its entirety, or using one of two other models: (1) honors work that replaced a specific number of courses, or (2) honors work as an extra activity beyond ordinary requirements for graduation. In 1928 Joseph W. Cohen, who developed an honors program for the University of Colorado, founded the Interuniversity Committee on Superior Students (ICSS). In 1966 the ICSS became the National Collegiate Honors Council (NCHC),

which in the early twenty-first century has its own scholarly journal, numerous conventions, and publications, and also maintains a list of national and international honors programs, all available through their website.

At the beginning of the twenty-first century, there are almost as many different types of honors programs as there are institutions that create them. Still, as Clifford Adelman found in his 1985 study of postsecondary honors programs, there are “dominant models: the honors community, ‘supply-side’ honors, the ‘exponential major’ and general honors” (Adelman, p. 57). The *honors community* is a program that focuses on developing a “small select group of learners within an institution . . . tending to emphasize organization and support services over curriculum” (Adelman, p. 57). In *supply-side honors*, students are selected at different stages of their college careers and the emphasis lies on the programs—with variety viewed as the key to student demand and achievement. The *exponential major* is an honors version of a traditional major, and is usually open to students after their first year of college. It focuses on a coherent thematic or disciplinary program. The *general honors* model is an “interdisciplinary General Education program, confined to the first two years of college, and with a heavy emphasis on the traditional Liberal Arts” (Adelman, p. 57). In addition to these models, there are programs of independent study and mentor research participation, which involve close relationships with individual faculty members and often culminate in a senior honors thesis or creative project. Regardless of type, honors programs tend to emphasize selectivity and active student participation as customary characteristics, with many programs embracing the goal of producing “a knowledgeable and effective person” (Austin, p. 8).

While honors education has been plagued by accusations of elitism since its inception, this question became even more pressing with the spread of honors programs to community colleges in the early 1980s, particularly since community colleges have often been seen as serving diverse, and usually less-prepared, populations. Recent studies have found, however, that approximately 20 percent of community college students are “high-ability” students who are likely to benefit significantly from honors programs. In light of this, there has been growing recognition that honors programs play an important role in serving the diverse population of community col-

leges, which includes gifted students who are attending community college because of lower tuition, convenience, or for a variety of other reasons.

The goals of community college honors programs are very similar to those of four-year institutions. One role that honors programs serve in community colleges is facilitating students’ transfer to first-rate baccalaureate programs, which helps to bolster the reputation of both community colleges and community college students. This is especially important in education systems such as the City University of New York (CUNY) that link community colleges and senior colleges.

Regardless of their design, most honors programs have at their core the goal of encouraging high levels of excellence in talented and motivated students. To support this goal, the NCHC urges all honors programs to have an articulated mission statement, to employ a director that reports to the chief academic officer of the institution, to occupy suitable quarters, to promote student liaisons with other committees, to offer special academic counseling, and to maintain continuous and critical program review.

## HOPKINS, L. THOMAS (1889–1982)

---

Noted Progressive education theorist, consultant, and curriculum leader, L. Thomas Hopkins completed his major writings while a professor and laboratory school director at Teachers College, Columbia University.

Born in Truro, Massachusetts, Hopkins received his bachelor's and master's degrees from Tufts University in 1910 and 1911, respectively. Hopkins claimed that the central ideas of his philosophy of education derived principally from the influence of his mother, careful observation of nature, and interaction with students he taught.

In 1922 he completed the Ed.D. degree at Harvard University under the mentorship of professors Alexander Inglis and Walter Dearborn. Following his work at Harvard, Hopkins accepted an offer to become a tenured faculty member at the University of Colorado at Boulder. Through that post he began an extensive consulting career. One of his first major consultations was with the Denver Curriculum Revision Project, 1923 through 1925; its notoriety launched consultations with many other school districts across the country. His consulting and curriculum ideas are explicated in his *Curriculum Principles and Practices* (1929), which was built heuristically around a wide array of questions to guide curriculum leaders, school administrators, and teachers.

In 1929 Hopkins was invited to join the faculty of Teachers College, Columbia University, as professor of education; he remained there for twenty-five years. At Teachers College he also held the position of director of Lincoln School.

Following his retirement from Teachers College in 1954, Hopkins was a Fulbright scholar in Egypt (1956–1957). He surveyed Italian schools in 1957 and taught at Wheelock College in Boston and at the

University of Maine in the 1960s. In 1960 he chaired the Committee on Schools and Moral Values for the White House Conference on Education. In 1971 he retired for a second time with his wife, Hester Hopkins, to Truro on Cape Cod. There, he continued to write, speak, complete his memoirs, and organize his papers until shortly before his death in 1982. His papers are located at the University of Colorado Library in Boulder, Colorado.

Hopkins's major ideas are outlined in three of his numerous books. In *Integration, Its Meaning and Application* (1937), he argued, contrary to many current interpretations of integrated curriculum, that integration is much more than merely combining subject matter areas around a common theme (i.e., the thematic unit). For Hopkins, integrating the curriculum meant integrating the person; thus, the organizing center for the integrated curriculum was not principally subject matter, but the individual. Drawing analogies from the study of physiology and embryology, Hopkins saw educative growth as moving through three phases: expansion, differentiation, and finally integration. He labeled these phases the normal learning process. In his view of integrated curriculum, subject matter and informal personal knowledge are to be acquired through inquiry that is expressly directed to build the self into a more diverse and integrated human being. An integrated person was, for Hopkins, one whose personal development incorporated the physical, social, mental, emotional, and spiritual aspects of the human organism into a functioning whole.

In *Interaction: The Democratic Process* (1941), Hopkins incorporated a social dynamic to expand the idea of the development of the individual or personal organism. Again, the process of the interacting forces of the normal learning process (expansion, differentiation, and integration) come into play in a social or political realm that argues for a democratic society as well as for the individual. Like John Dewey, Hopkins saw curriculum, writ large, as a dynamic interaction of school and society, experience and nature, and democracy and education. In the *Emerging Self in School and Home* (1954), Hopkins showed that education is not a function of schooling alone. In this book, he developed the image of an organic group, contrasting it with a mere aggregate group, to depict the integration of school, home, and community. Therein he argued that the needs and interests of the individual and those of the community and society are reciprocal. In fact, he argues for

the home as a major site for education to take place, leading to speculation about the need to study other societal venues in which education takes place, which could include homes and families, nonschool organizations, mass media, peer groups, vocations and avocations, and more.

In the early twenty-first century, consistent interpretation of Hopkins's work can be seen in the writings of James A. Beane and in curriculum leadership. Hopkins condemned much that is fashionable in education (memorized knowledge, standardization, external control, extensive testing), calling it the "was curriculum" and characterizing it as useless. In contrast, he advocated the "is curriculum," which "celebrates the experiential . . . deals with the whole pupil who develops through internal control of the learnings that he or she self-selects . . . for personal growth." The is curriculum "is what each pupil can take from the teacher-pupil relationship to help him or her better understand and develop the self, for growth toward the highest possible maturity is the direction of all living organisms" (1970, p. 213).

### HORTON, MYLES (1905–1990)

Activist and founder of the Highlander Folk School, Myles Falls Horton was born in a log cabin near Savannah, Tennessee, on July 9, 1905. His parents, Elsie Falls Horton and Perry Horton, had both been school teachers before Horton's birth, but had lost their jobs when the requirements for teachers were increased to include one year of high school, which neither had. After that, his parents supported their family (Horton was firstborn, followed by brothers Delmas and Daniel, and sister Elsie Pearl) by working in factories, as sharecroppers, and taking other jobs when they could find them. In his autobiography, Horton wrote, "We didn't think of ourselves as working-class, or poor, we just thought of ourselves as being conventional people who didn't have any money" (1990a, p. 1).

The Horton family was socially active; his mother shared scarce family resources with and organized classes for less well-off and often illiterate neighbors, and his father was a member of the Worker's Alliance, the union of the Worker's Progress Administration (WPA). "From my mother and father," Horton wrote, "I learned the idea of service and the value of education. They taught me by their actions that you are supposed to serve your fellow men, you're supposed to do something worthwhile with your life, and education is meant to help you do something for others" (1990a, p. 2).

Horton left home at fifteen to attend high school—his hometown had no secondary school—and he supported himself there by working first in a saw mill and then a box factory, where he said he learned about organizing and the strength of collective action. "When I heard people insulted by the factory owners, it hurt me personally," he wrote in his autobiography. "I guess I got as much help from the opposition in firming up my beliefs as I did from

more positive sources” (1990a, p. 8). Later, with co-workers at a crate-building job, he formed a union that held a successful work slowdown for a wage increase.

Horton read widely, and was deeply influenced by the writings of social critics and Marxists. He felt he could learn from many sources, but that in the end he was responsible to himself and his own ideals. “I have to be the final arbiter of my beliefs and my actions,” he said, “and I can’t fall back and justify it by saying, I’m a Marxist, I’m a Christian, I’m a technological expert, I’m an educator” (1990a, p. 45). He worked with a wide range of people who shared a broad vision of a better world, but he remained a stubborn individualist who never joined a party. “I understood the need for organizations, but I was always afraid of what they did to people” (1990a, p. 49).

He attended Cumberland University, the University of Chicago, and the Union Theological Seminary, and sought out teachers who in many cases became lifelong supporters and friends; among these were Reinhold Neibuhr, John Dewey, Jane Addams, and George Counts. As a student in Chicago he heard about the Danish Folk School movement, a populist education experiment that had developed in opposition to the lifelessness of traditional schools and the detachment of academic schooling in Denmark. Danish Folk Schools encouraged students to broaden their experience by analyzing important questions and problems, and then actively participating in practical solutions. Horton resolved to go and see these schools himself.

In Denmark, Horton focused on a specific project: creating a school for life—a place where students and teachers could live together to pose and solve problems; an informal setting where experience could be the main teacher; a site for activists, organizers, and teachers for social justice. In his diary, Horton wrote, “The school will be for young men and women of the mountains and workers from the factories. Negroes would be among the students who will live in close personal contact with teachers. Out of their experiential learning through living, working, and studying together could come an understanding of how to take their place intelligently in the changing world” (1990a, p. 54). He worried that preparation to build his school might take forever, and although he felt inadequate to the task; he decided that the only way he could learn to embody his vision was to simply begin his project.

Horton opened the school, the Southern Mountains School, in 1932. A short time later, he and codirector Don West changed the name to the Highlander Folk School. At Highlander the purpose of education was to make people more powerful, and more capable in their work and their lives. Horton had what he called a “two-eye” approach to teaching: with one eye he tried to look at people as they were, while with the other he looked at what they might become. “My job as a gardener or educator is to know that the potential is there and that it will unfold. People have a potential for growth; it’s inside, it’s in the seed” (1990a, p. 33).

The school was a free space in an oppressive atmosphere—a place where labor organizers, civil rights activists, antipoverty workers, and others assembled to develop solutions. Through the 1930s Highlander was the education arm of the Congress of Industrial Organizations (CIO) in the South. Horton realized that labor would never be emancipated as long as racial segregation—turning workers against each other based on race privilege—remained intact, and he began organizing workshops designed to destroy racist social structures.

For many years Highlander was the only place in the South where white and African-American citizens lived and worked together, something that was illegal in that strictly segregated society. Highlander, Horton once claimed, held the record for sustained civil disobedience, breaking the Tennessee Jim Crow laws every day for over forty years, until the segregation laws were finally repealed.

The list of students at Highlander is a roll call of social activists: Rosa Parks, Eleanor Roosevelt, Pete Seeger, Woody Guthrie, Martin Luther King Jr., Andrew Young, Fanny Lou Hamer. People from the surrounding community used the school as well; all gathered there to give voice to the obstacles to their hopes and dreams, gather the conceptual, human, and material resources needed to continue, and to return home with a plan for forward progress. The school was under constant attack from white supremacists, antilabor groups, and the government.

Myles Horton died on January 19, 1990; his school, now known as the Highlander Research and Education Center, continues to be a catalyst for social change in the early twenty-first century.

## HUMAN SUBJECTS, PROTECTION OF

---

In 1974, after a long history of harmful research studies conducted on unwilling human subjects (such as the Tuskegee Syphilis Study initiated in the 1930s and a series of studies conducted in the 1960s at the Willowbrook State School, a New York institution for “mentally defective” children), the U.S. Congress established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. Four years later, this commission issued the *Belmont Report*, which is the cornerstone of the ethical principals guiding federal regulations for the protection of human subjects.

There are three fundamental ethical principles, as outlined in the *Belmont Report*, that guide research involving human subjects: (1) respect for persons, (2) beneficence, and (3) justice. By 1991, seventeen federal departments and agencies had adopted the federal regulations known as the *Common Rule* (Title 45 Code of Federal Regulations Part 46 [43CFR46]).

*Research* is defined as a systematic investigation (including development, testing, and evaluation of programs and methods) designed to discover or

contribute to a body of generalizable knowledge. Not all scientific or scholarly activities qualify as research, nor does all research involve human participants. A *human subject* is a living individual about whom an investigator obtains either (1) data through interaction or intervention with the person, or (2) identifiable private information. Each investigator must decide if their study is to include human participants. If human participants are to be involved, the researcher is ethically obligated to become familiar with and adhere to the regulations governing the rights and safety of the human research participants.

### Vulnerable Populations

Certain groups of human research participants—such as children, prisoners, individuals with questionable capacity to consent, students, or employees of the institution conducting the research—are considered to be either relatively or absolutely incapable of protecting their own interests. Because children have not legally attained an age where they can consent on their own to research or treatment, a parent or legal guardian may provide consent for a child to participate in a study. Above the age of seven, the child must also show willingness to participate by assenting to the study. Although many college students are below the age of twenty-one, they are generally treated as “emancipated adults” for the purpose of consenting to participate in research studies.

### Institutional Review Boards

The National Research Act passed by Congress in 1974 that resulted in the Belmont Report also required the establishment of Institutional Review Boards (IRBs) to review all research involving human subjects funded by the Department of Health and Human Services. The regulations governing IRBs were revised in 1981.

Every institution in the United States receiving federal support for research with human subjects has to have its own IRB or access to an IRB. An IRB protects the rights, safety, and welfare of human research participants by: (1) reviewing research plans to ensure that, in its judgement, the research meets the criteria found in 45CFR46.111; (2) confirming that the research plans do not expose participants to unreasonable risks; (3) conducting continuing review of approved research at intervals commensurate with the degree of risk of the trial—but not less than once a year—to assure that human participant

protections remain in force; and (4) assessing suspected or alleged protocol violations, complaints raised by research participants, or violations of institutional policies.

The IRB has the authority to approve, disapprove, or terminate all research activities that fall within its jurisdiction; require modifications in protocols, including previously approved research; require that information, in addition to that specifically mentioned in 45CFR46.116, be given to participants when the IRB deems that this information would add to the protection of their rights and welfare; and require documentation of informed consent or allow waiver of documentation, in accordance with 45CFR46.117.

IRBs must have at least five members with varied backgrounds who have no vested interest in the conduct or outcomes of the proposed research. At least one member of the IRB must not be affiliated with the institution, and the membership should be as diverse as possible. Most IRBs have many more than five members, and most are divided into subcommittees for the purpose of handling different types of studies, such as biomedical or behavioral studies.

In order to approve a research study, the IRB must assure that risks to participants are reasonable and minimized; that the selection of participants is equitable; that informed consent from each participant is sought and documented; and, when appropriate, that there are adequate provisions to protect the safety and privacy of the participants and the confidentiality of the data. Depending on the level of risk and the type of subject population, review may be done by the full IRB, or it may be expedited. Certain types of studies are exempted from IRB review and approval. Even in these exempt cases (many of which involve educational practices or tests), however, it is not the researcher but the IRB that makes this determination.

### **Informed Consent**

Informed consent, as a legal, regulatory, and ethical concept, has become widely accepted as an integral part of research involving human subjects. A written consent document is a key part of the proposal submitted to an IRB. This is a document written to the proposed subject in a language understandable by the subject. All of the elements required by 45CFR46.116 must be included, plus any other in-

formation necessary for the prospective participant to make an informed decision. The required elements include a statement that the study involves research; an explanation of the purpose of the research, including why the individual was selected and the expected duration of the individual's participation; a description of all procedures to be followed; a description of any foreseeable risks, discomforts, and inconveniences (and what will be done to minimize or deal with them); a description of any anticipated benefits, both to the individual subject and to society; information about who to contact if there are additional questions; a statement that participation in the research is voluntary, that withdrawal may occur at any time, and that there is no penalty for withdrawal or refusal to participate; and, finally, an invitation for the participant to ask any questions about the proposed study before agreeing to participate.

In 2001 the National Cancer Institute of the National Institutes of Health introduced an online training program to educate research teams about human participant protections. This free access program available via the Internet elaborates greatly on all of the information contained in this article.

## HUNTER, MADELINE CHEEK (1916–1994)

---

Madeline Cheek Hunter, professor of educational administration and teacher education, was the creator of the Instructional Theory Into Practice (ITIP) teaching model, an inservice/staff development program widely used during the 1970s and 1980s.

Hunter entered the University of California, Los Angeles (UCLA), at the age of sixteen and, over the course of her career, earned four degrees in psychology and education. In the early 1960s Hunter became principal of the University Elementary School, the laboratory school at UCLA, where she worked under John Goodlad. She left the school in 1982 amidst controversy over her methods, but continued at UCLA as a professor in administration and teacher education. She also continued to lecture and write, and by the time of her death at the age of seventy-eight, Hunter had written twelve books and over three hundred articles, and produced seventeen videotape collections.

Hunter's influence on American education came at a time when public schools were criticized widely for falling test scores, increasing dropout rates, and discipline problems. Hunter claimed that her teaching methods would transform classrooms into learning environments, allow the dissemination of more knowledge at a faster rate, and use positive reinforcement and discipline with dignity to greatly reduce disruptive behavior. Her seven-step model and related educational theories, outlined in her extensive writings, lectures, and videotape series, gave teachers strategies for controlling their classrooms and planning their lessons. Administrators used the model as a way to assess the effectiveness of their teachers.

Hunter defined teaching as a series of decisions that take place in three realms: content, learning behaviors of students, and teacher behaviors. Content refers to the specific information, skill, or process that is appropriate for students at a particular time.

Content decisions are based upon students' prior knowledge and how it relates to future instruction; simple understandings must precede more complex understandings. Decisions regarding learning behaviors indicate how a student will learn and show evidence of that learning. Because there is no best way for all students to learn, a variety of learning behaviors is usually more effective than one. Evidence of learning must be perceivable by the teacher to ensure that learning has occurred. The third area of decision-making, teacher behavior, refers to the use of principles of learning—validated by research—that enhance student achievement.

In order to successfully implement Hunter's methods, teachers undergo extensive professional development that conveys the types of decisions they must make. Training includes viewing videotapes that demonstrate effective decision-making in the classroom, and the Teaching Appraisal for Instructional Improvement Instrument (TAIII), administered by a trained observer or coach, which diagnoses and prescribes teacher behaviors to increase the likelihood of student learning.

Hunter's method of direct instruction, generally referred to as the *Madeline Hunter Method*, includes seven elements: objectives; standards; anticipatory set; teaching; guided practice; closure; and independent practice. Behavioral objectives are formulated before the lesson and clearly indicate what the student should be able to do when the lesson is accomplished. Standards of performance inform the student about the forthcoming instruction, what the student is expected to do, what procedures will be followed, and what knowledge or skills will be demonstrated. The anticipatory set is the hook that captures the student's attention. Teaching includes the acts of input, modeling, and checking for understanding. Input involves providing basic information in an organized way and in a variety of formats, including lecture, videos, or pictures. Modeling is used to exemplify critical attributes of the topic of study, and various techniques are used to determine if students understand the material before proceeding. The teacher then assists students through each step of the material with guided practice and gives appropriate feedback. Closure reviews and organizes the critical aspects of the lesson to help students incorporate information into their knowledge base. Independent practice, accomplished at various intervals, helps students retain information after initial instruction.

Although the Hunter Method was widely used during the last quarter of the twentieth century, it has not been without its critics. Based on behavioral psychological theory, some educators concluded that it is mechanistic and simplistic and is only useful—if at all—to teach the acquisition of information or basic skill mastery at the cost of stifling teacher and student creativity and independent thinking. Others deplore the use of the Hunter Method as a lockstep approach to instructional design. The *Hunterization* of teaching has even led some districts to require teachers to utilize the Hunter approach and base their teacher evaluation instruments on it. Hunter herself lamented this misuse of her methods and claimed that there was no such thing as a “Madeline Hunter-type” lesson. A significant body of criticism questions her claims that her method could enable students to learn more at a faster rate and improve student achievement. Several studies, most notably the Napa County, California, study, indicate little, if any, evidence to justify her claims.

Proponents point to Hunter’s clear and systematic approach to mastery teaching. They argue that, rather than being prescriptive, Hunter provides a framework within which teachers can make decisions that are applicable to their own classrooms. Rather than being simplistic or superficial, Hunter’s method is straightforward and uses a common language that classroom teachers can easily understand. Although Hunter’s method may be easy to implement, it may also be complex in its application, depending upon the specific objectives of the teacher.

During the height of her popularity, Hunter’s ITIP Model for mastery teaching was formally adopted in sixteen states and widely used by many others. Hunter is regarded by many as a “teacher’s teacher” for her ability to translate educational and psychological theory into practical, easy-to-understand pedagogy, and her influence on classroom teaching techniques is still evident in the twenty-first century.

MARILYN HEATH

### HUTCHINS, ROBERT (1899–1977)

A major voice for general education in American higher education, Robert Maynard Hutchins wrote, spoke about, and influenced public policy during his almost fifty years as teacher, educator, and administrator. Known in the educational world for his enthusiasm and dedication to liberal education with an emphasis on the Great Books and great ideas, he was also, during various times in his career, an ardent defender of academic freedom in the university and of democratic freedoms and principles in American society. He was known, too, for his style, wit, and sense of humor as he argued for what were often both iconoclastic and unpopular points of view.

Hutchins, born in Brooklyn, New York, moved at age eight to Oberlin, Ohio, where his father, a minister, taught at Oberlin College, an institution Hutchins attended from 1915 to 1917. He served in the ambulance service during World War I prior to attending and graduating from Yale University (1921) and the Yale Law School (1925). He was named dean of the Yale Law School in 1927 where he presided until 1930, when he became the youngest president ever of a major university, the University of Chicago. Upon leaving the University of Chicago in 1951, he spent four years with the Ford Foundation (1951–1954) and then the remainder of his career with the Ford Foundation-sponsored Fund for the Republic (1954–1977) and the Center for the Study of Democratic Institutions (1959–1973, 1975–1977).

While president of the University of Chicago (1930–1951), Hutchins was an eloquent spokesper-

son for a particular view of higher education. A liberal education was a moral endeavor to discover what was good and how to act on it. He believed that the university should nurture the life of the mind and be a community of scholars rather than an organization without a core, with specialization in the disciplines, and with increased vocationalism framing the curriculum. An expression of his approach was the Hutchins College of the University of Chicago, where young students who had not yet finished high school were admitted to study and acquired a liberal education and where, for example, successful completion of a degree was based on passing comprehensive examinations rather than accumulating course credits. The pedagogical model of choice was small discussion classes and the Socratic method, and the content for discussions included interacting with the Great Books.

Hutchins was a controversial administrator and no area of the university escaped his scrutiny. He continually engaged members of the University of Chicago faculty in attempts to make the university, from his point of view, more just and equitable. In the extracurricular arena, despite the fact that the University of Chicago dominated football in the Western Conference (later to become the Big Ten) and one of its players was the first Heisman trophy winner, Hutchins in 1939 convinced the university that it should drop intercollegiate football. He purportedly claimed, as the reason for dropping it, that it was possible to win 12 letters before learning to write one.

During his presidency at Chicago, Hutchins defended the university and its faculty in academic freedom issues. A staunch defender of free speech in both the academy and in a democratic society, his principled defenses prevailed. When the case of one faculty member accused of teaching communism was to be discussed by the board of trustees, a faculty colleague confronted Hutchins and said: "If the trustees fire [the faculty member], you will receive the resignations of 20 full professors tomorrow morning. Hutchins replied, "Oh, no, I won't. My successor will" (Mayer, p. xii).

During his tenure at the university Hutchins was involved in the publication of the *Great Books of the Western World* and the *Encyclopaedia Britannica*. These two enterprises both enhanced Chicago's reputation and brought additional monetary resources for use in the university. Despite his opposition to the pragmatists in the philosophy depart-

ment, Hutchins was a consummately successful fundraiser who had no difficulty spending money (he always exceeded the yearly university budget).

During World War II Hutchins committed the university to complete support of the war effort. The university was the site, or more precisely and perhaps ironically, a squash court under the football stands in Stagg Field was the site, of the first self-sustaining nuclear chain reaction. This theoretical advance, a part of the Manhattan project, led, of course, to the first atomic bomb and the beginning of the nuclear age. After the war Hutchins tried but failed to get nuclear physicists to not disseminate their knowledge and techniques and to discontinue such work.

Hutchins' strong beliefs in democratic values and his defense of fundamental freedoms continued during his tenure with Fund for the Republic, a Ford Foundation-sponsored organization. He led a number of projects that directly opposed the political machinations of the now infamous Joseph McCarthy, the House Un-American Activities Committee (HUAC) and other groups that perceived communist threats to the United States. Among the most devastating projects of the Fund for the Republic was one that produced a two-volume report of blacklisting in industry with an emphasis on television and the movies. Hutchins, however, did not emerge unscathed from this work and was attacked by the press and popular media for his views.

During its first few years the Fund for the Republic concentrated on projects that produced information and knowledge that could be widely disseminated. The major activity of the fund from the late 1950s until the mid-1970s, however, was support for the Center for the Study of Democratic Institutions. His last attempt to create a community of scholars, the Center in Santa Barbara, California, was a place for resident scholars and invited guests to discuss serious issues. Under Hutchins the Center hosted and supported numerous international conferences and a publishing enterprise that created an international presence for its deliberations.

### UNITED STATES

The United States is often called a “nation of immigrants”; more accurately the nation always comprised both newcomers and those who worry about the impact of the newcomers on the existing society. The relationship between newcomers and established families has always been in some sense filled with tensions, uncertainties, and even bitter conflicts. It has also been characterized by varied efforts at accommodation and adaptation, often but not always on the part of the newcomers alone.

#### Immigration to the United States

Between 1820 and 1996, 63 million immigrants arrived in the United States. Germans were cumulatively the largest group, with 7.1 million, followed by Mexicans, with 5.5 million (60 percent of the Mexican immigrants over the 176-year period had arrived in the last 15 years). Other groups of immigrants, in order, were from Italy (5.4 million), the United Kingdom (5.2 million), Ireland (4.8 million), Canada (4.4 million, however, many Irish immigrants

came via Canada), and Russia (which used to include much of Poland and the Baltic states—3.8 million).

Immigrants who arrived before the 1840s were for the most part similar to the native population, if not superior in education and ambition; they were rarely considered a problem by the native-born population. With the arrival of large numbers of Irish and German Catholics in the two decades before the Civil War, however, immigrants began to be seen as a threat to American society. The number of immigrants tripled between the 1830s and the 1840s, and the country received as many immigrants in the 1850s as in the two previous decades combined. Between 1845 and 1854 immigration increased the American population by 17.6 percent, a much higher rate than in the latter half of the twentieth century.

After many decades of essentially unrestricted admission, the United States imposed restrictions in 1882 excluding criminals, prostitutes, and the physically and mentally ill. “Nine years later the category of excluded undesirables was extended to take in as well believers in anarchism and in polygamy. These minimal controls reflected no disposition to check the total volume of immigration” (Handlin, p. 287).

Late in the nineteenth century and early in the twentieth century immigrants from southern and eastern Europe, widely considered to come from “inferior stock,” were restricted, though much needed by an expanding economy. In the wave of xenophobia that swept over the United States during World War I, a literacy requirement was imposed in 1917. The phase of qualitative restrictions ended with the National Origins Act of 1924, which placed strict quantitative restrictions on the number of im-

migrants allowed from various nations, explicitly designed to limit immigration from countries that were considered less desirable sources of future citizens.

Puerto Ricans, as United States citizens, enjoyed an unrestricted right to migrate in search of better economic conditions. With the introduction of air service between San Juan and New York City after World War II, the United States experienced what was surely the world's first mass migration by air, with almost 136,250 Puerto Ricans coming to the U.S. mainland in 1947 alone.

The Immigration and Naturalization Act Amendments of 1965 repealed the quotas favoring northwestern Europe (such as those established by the National Origins Act of 1924) but set a limit of 20,000 immigrants per year from each nation of the Eastern Hemisphere and for the first time placed restrictions on immigration from the Western Hemisphere. The Immigration Reform and Control Act of 1986 and subsequent laws have continued to tinker with the terms for the admission of immigrants and refugees.

### Reactions to Immigrants

The American colonists' own adaptation to the new circumstances of their life, especially in the mid-Atlantic colonies, involved a largely unproblematic mixing of people who had had much less contact in their home countries of early modern Europe. By the time of the American Revolution, the French immigrant turned American farmer St. John de Crèvecoeur would write that the nations of Europe had been combined to create: "the American, this new man . . . leaving behind all his ancient prejudices and manners . . . he must therefore entertain new ideas and form new opinions" (pp. 49–50).

The prominent physician and signer of the Declaration of Independence Benjamin Rush published an essay in 1786 that called for the establishment of public schools in Pennsylvania. A remarkable feature of his proposal was its recommendation that children "be taught to read and write the English and German languages," and attendance districts be so arranged that "children of the same religious sect and nation may be educated as much as possible together" (pp. 5, 7).

In fact, until the 1830s most schooling in Pennsylvania (and in the states to its south) was provided by church initiatives, usually on a denominational

and thus ethnic basis. Quaker, Anglican, and Presbyterian schools, schools of German Lutheran and Reformed congregations, and a whole range of other variations provided what schooling was available. State authorities sought to meet their obligation to provide for the schooling of those whose parents could not afford to pay tuition by providing what would now be called *vouchers*, enabling them to go to existing nonpublic schools and academies, including church schools.

In Pennsylvania, what would become a widespread anxiety about the effects on American society of immigration was anticipated (like so much else) by Benjamin Franklin. In 1752 he asked "Why should Pennsylvania, founded by the English, become a colony of Aliens, who will shortly be so numerous as to Germanize us rather than our Anglifying them, and will never adopt our language or customs?" On the eve of the American Revolution, Franklin returned to this theme, noting "the vast unpeopled [sic] Territories of North America," and warning that "Germans are now pouring into it, to take possession of it, and fill it with their Posterity" (pp. 374, 709–710).

Similarly, Thomas Jefferson warned in 1787 that immigrants would "bring with them the principles of the governments they leave, imbibed in their early youth; or, if able to throw them off, it will be in exchange for an unbridled licentiousness . . . These principles, with their language, they will transmit to their children" (p. 211).

It was only in the 1830s, though, that concern about the cultural and religious differences of immigrants began to be a basis for educational policy. In 1836 Calvin Stowe of Ohio warned that "unless we educate our immigrants, they will be our ruin . . . The intellectual and religious training of our foreign population has become essential to our own safety" (p. 993). This was a primary motivation for the extension of the "common school" system of publicly controlled education, and for opposition to public funding for Catholic schools.

When Catholic immigrants (first Germans, then other groups) began to organize their own schools, as did some Protestant and Jewish immigrants, it was perceived by many as an expression of refusal to accept the requirements of life in American society. Their children "will be shut up," warned a prominent Protestant minister in 1853, "in schools that do not teach them what, as Americans, they most of all

need to know . . . They will be instructed mainly into the foreign prejudices and superstitions of their fathers." If, instead, the children of immigrants could be gathered into the common public school, "we may be gradually melted into one homogeneous people" (Bushnell, pp. 209–303).

In fact, religious schools do not seem to have retarded what came to be called *Americanization*; to the contrary, they have provided a safe setting for millions of immigrant children to learn American ways without turning their backs on their families. In a study of Mexican-American children in San Antonio, Philip Lampe found that those who attended Catholic schools "were more likely to have non-Hispanic friends, were more willing to date and marry outside their own ethnic group, were more willing to identify with the WASP value system, showed significantly less prejudice against other ethnic groups, and were more willing to perform their civic duties" than their public school counterparts (Walch, p. 202).

As anxiety about Catholicism began to fade, other cultural differences came to be the primary concern. The immigrants arriving from southern and eastern Europe in the late nineteenth and early twentieth centuries seemed to many commentators to be of an inferior stock. As John R. Commons, a leading social scientist of the Progressive era wrote in 1907, "If in America our boasted freedom from the evils of social classes fails to be vindicated in the future, the reasons will be found in the immigration of races and classes incompetent to share in our democratic opportunities." After all, he pointed out, "race differences are established in the very blood and physical constitution. They are most difficult to eradicate, and they yield only to the slow processes of the centuries. Races may change their religions, their forms of government, their modes of industry, and their languages, but underneath all these changes they may continue the physical, mental, and moral capacities and incapacities which determine the real character of their religion, government, industry, and literature" (pp. 12, 7).

More optimistic observers insisted upon the capacity of the public school to transform the children of immigrants into "real Americans," and it was this impulse which led to several decades of emphasis upon Americanization through schools and other agencies of popular education like settlement houses and civic associations. Ellwood Cubberley, the enormously influential Stanford University professor, ar-

gued in 1909 that the highest mission of public education was "to assimilate and amalgamate those people as part of our American race, and to implant in their children, so far as can be done, the Anglo-Saxon conception of righteousness, law and order, and popular government, and to awaken in them a reverence for our democratic institutions and for those things in our national life which we as a people hold to be of abiding worth" (Cremin, p. 68).

Although the "intelligence tests" conducted by the U.S. Army during World War I seemed to confirm the intellectual inferiority of Slavic, Jewish, and southern European immigrants, the findings reflected a generational phenomenon. Although immigrants in the early decades of the twentieth century had low levels of education compared to their native-born contemporaries, there was a "massive educational jump among the new Europeans in the cohort born between 1925 and 1935 in the concentration in professional jobs . . . The analogous change for native whites of native parentage was much smaller" (Sollors, pp. 206, 329).

### **Immigrants and Language**

The desire to preserve German language and culture had been one of the motivations behind the organization of Catholic and Lutheran parochial schools in the nineteenth century, and Polish, Bohemian, and other immigrant groups made efforts in the same direction. Public schools in some cities responded to this competition by offering classes designed to maintain and develop the languages that pupils spoke at home. In 1877 the superintendent of schools in San Francisco argued that public schools should begin offering French and German. Public schools in Chicago began offering German in confidence that "the number of private schools now to be found in every nook and cranny of the city will decrease, and the children of all nationalities will be assembled in the public schools, and thereby be radically Americanized" (Peterson, pp. 54–55). By the late 1880s, eight states had statutes authorizing bilingual instruction in public schools.

Such measures on the part of public authorities should not be construed as reflecting acceptance of bilingualism as a long-term educational goal; the mounting concern about how immigrants seemed to be building separate communities led by 1911 seventeen states to require that English be the sole language of instruction at the elementary level in public schools. The anti-German sentiment of World War

I led twenty-one states to add such a requirement for private schools as well—a requirement that the U.S. Supreme Court struck down in *Meyer v. State of Nebraska* in 1923.

The supposed failure of immigrants and their children to learn English is the basis for much concern about immigration and about bilingual education in the early twenty-first century. In fact, there is no reason to believe that current immigrants, any more than those in the past, will seek or be able to persuade their children to remain linguistically separate. Two leading supporters of bilingual education concede that “the United States is, at the societal level, staunchly monolingual. Legislating monolingualism as a requirement for citizenship could hardly have been more successful in creating a monolingual society than have been the unofficial economic and social forces at work.” Among immigrant minority groups, “only the old folks, the very young, and the recent arrivals, in general, speak these other languages; the school children and young adults have often switched to ‘dominance’ in English” (Snow and Hakuta, p. 385). The continuing use of Spanish in California has not slowed the rate of shift to English as the primary language for individuals of Hispanic descent; while “in most areas of the United States approximately 70 percent of the native born currently are adopting English as their usual language,” the rate is 85 percent in California (Veltman, p. 66).

It is sometimes suggested that the heavy concentrations of Hispanics constitutes an exception to the usual pattern of language shift, but this seems to reflect mostly the language use of newcomers. A 1973 study by Alejandro Portes and Ruben G. Rumbaut in Los Angeles found that, among third-generation Mexican-American women, 4 percent spoke only Spanish at home, and 84 percent only English. The transition to English among men was even more rapid.

Because of this pattern of language loss, some argue that the public schools have an obligation to help maintain minority languages and cultures. It would be more accurate to say that, while this policy option certainly could be justified on educational grounds, it is not a legal requirement. In no case have the courts found a legal right to public support in maintaining a group’s identity or language as a remedy of past discrimination.

Even if language maintenance were to be accepted as an educational goal, there is little reason to be-

lieve that even full-time bilingual classes would have the effect of maintaining the active use of minority languages, unless these languages were strongly supported outside the school.

Immigrant parents are especially likely to question language-maintenance efforts in schools if they believe there is any chance this will limit their children’s acquisition of the majority language that they themselves cannot teach their children well. Mexican-American parents surveyed by the Educational Testing Service in 1987 supported bilingual education and said it was important that their children speak Spanish well, but rejected instruction in Spanish nearly four to one if it would take away from learning English. In a 1998 survey, the foundation Public Agenda posed the question: “With students who are new immigrants, which is more important for the public schools to do? Teach them English as quickly as possible, even if this means they fall behind in other subjects, or teach them other subjects in their native language, even if this means it takes them longer to learn English?” Foreign-born parents favored “English as quickly as possible” by 75 percent to 21 percent, while Hispanic parents supported that option by 66 percent to 30 percent.

### **Educating the Children of Immigrants**

No special arrangements were made for immigrant pupils through most of the nineteenth century, apart from being in a public school classroom, with what was then a strong emphasis upon basic skills and upon patriotism and civic morality. In some cases, indeed, they were not allowed to attend school with native children. Children of Chinese immigrants were segregated by law in a number of states. The California legislature enacted a requirement during its 1859–1860 session that “Negroes, Mongolians, and Indians, shall not be admitted into the public schools.” The legislature, however, did allow local school boards to establish separate schools for such children; this segregation was reaffirmed in the school code adopted ten years later.

Such discrimination was not confined to California. The U.S. Supreme Court ruled in *Gong Lum v. Rice* (1927) that school officials in Mississippi could exclude a Chinese-American child from the local “white” school. Martha Lum had “the right to attend and enjoy the privileges of a common school education in a colored school” or her father could send her to a private school at his own expense.

Although persons of Mexican descent were considered “white” under state laws requiring school segregation of blacks, they were often segregated by local practices. Local practices included drawing school attendance lines to correspond with residential segregation—and the segregation already existing within schools—and assigning all Mexican-American children automatically to the lowest instructional track, according to Guadalupe Salinas’s 1971 study. As a result of such practices, “in 1931, 85 per cent of California schools surveyed by the state government reported segregating Mexican students either in separate classrooms or in separate schools . . . . By 1930, 90 per cent of the schools in Texas were racially segregated” (Donato, Menchaca, and Valencia, p. 35).

Separation was not always permanent, or motivated by distaste for the immigrant. Special reception classes to teach essential language skills in an otherwise unmodified school program were considered an especially progressive measure in the period of heaviest immigration to the United States in the early twentieth century. So-called steamer classes were provided in many cities for children newly arrived “off the boat” from Europe. In Massachusetts alone, twenty-six cities and towns reported providing such classes in 1914. The Boston school superintendent asserted that “there is general agreement in the practice of progressive communities in grouping older immigrant children in special classes for intensive work in English, in order that they may acquire the common tongue as a tool for work through which they can be advanced rapidly to classes of children of their own age” (Thompson, p. 118).

Special language support did not become a right until the Supreme Court’s 1974 decision in *Lau v. Nichols*. This decision stated that San Francisco was violating the Civil Rights Act of 1964 by failing to provide programs that met the needs of several thousand pupils of Chinese ancestry who did not speak English. The implication of the decision was that no violation would have been found if all of the pupils in question had participated in supplemental English instruction (ESL), as did about a thousand others. The court left the method of meeting this obligation to the discretion of school districts. “Teaching English to the students of Chinese ancestry who do not speak the [English] language is one choice. Giving instructions to this group in Chinese is another. There may be others.” The court took care to point out that it would not be appropriate to sepa-

rate minority children more than was required by their educational needs, citing an earlier federal government regulation specifying that any ability grouping or tracking system employed by the school system to deal with the special language skill needs of national origin, minority children must be designed to meet such language skill needs as soon as possible and must not operate as an educational dead-end or permanent track.

In retrospect, however, it seems almost inevitable that such a targeted program would develop a momentum of its own and that those educators who made it their specialty would discover an ever-increasing need for what only they could provide, and ever new reasons not to integrate language minority children into the mainstream. The “Lau remedies” issued in draft form subsequently by the federal government, influenced by bilingual education advocates, leaned heavily toward requiring use of the home language for instruction in a separate program, so-called transitional bilingual education. School administrators had every reason to believe that they were not only permitted but required to educate language minority pupils separately, at least for whatever period of time was required to bring them up to speed in English. The argument, by some linguists and minority language advocates, that the best way to learn English was through a number of years (five to seven years is the figure most commonly used) of a bilingual program provided a strong rationale for extending this period of separation.

Much conflicting research exists on the issue of whether children should first be instructed through their home language if that is not the language of their continuing education. Fortunately, a very complete review of more than thirty years of studies was carried out on behalf of the National Research Council. “It is clear,” the experts note,

that many children first learn to read in a second language without serious negative consequences. These include children in early-immersion, two-way, and English as a second language (ESL)-based programs in North America, as well as those in formerly colonial countries that have maintained the official language [of the colonizer] as the medium of instruction, immigrant children in Israel, children whose parents opt for elite international schools, and many others . . . . The high literacy achievement of Spanish-speaking children in English-

medium Success for All schools . . . that feature carefully-designed direct literacy instruction suggests that even children from low-literacy homes can learn to read in a second language if the risk associated with poor instruction is eliminated. (August and Hakuta, p. 60)

Later in the report, indeed, Diane August and Kenji Hukuta conclude candidly that “we do not yet know whether there will be long-term advantages or disadvantages to initial literacy instruction in the primary language versus English, given a very high-quality program of known effectiveness in both cases” (p. 177). This would seem to argue for allowing the individual school to adopt whatever method produces satisfactory results.

Bilingual education was developed initially not as a remedial program but as an enrichment of the education of middle-class children, responding to demands of a relatively high-status refugee group that included many teachers, the Cubans who fled to Miami from the Castro regime in the early 1960s. According to James Crawford, this group, expecting to return to Cuba, was strongly motivated to maintain Spanish. The Dade County school system launched the first experiment in bilingual education at the Coral Way School. This was an unabashed Spanish-maintenance program for Cuban children and at the same time a Spanish immersion program for Anglo children. The goal was fluency in both languages for both groups.

Transitional bilingual education (TBE) programs have a different goal: they provide support in the home language while the pupil becomes proficient in English. TBE has been provided by hundreds of local school systems as a result of the requirements of state laws (the first was enacted in Massachusetts in 1971) or as a means of complying with the requirements of the 1974 *Lau v. Nichols* case. While federal law leaves it up to local education officials to determine how to overcome language barriers, a strong encouragement has been given to bilingual programs by federal funding that supports “educational programs using bilingual education practices, techniques and methods.”

Pupils are assigned to TBE programs on the basis of an assessment that they are unable to perform ordinary classwork in English and speak another language at home. Pupils stay in these separate classes typically for three years, though many remain

longer and advocates argue that five to seven years would be preferable. “Late-exit” bilingual programs, with an explicit intention of maintaining and developing the home language while English is learned, are less common.

A 1980 survey found that local school districts in thirty-eight of the fifty states provided TBE for Spanish-speaking youngsters, in twenty states they did so for Vietnamese children, in twelve for Korean youngsters, in ten for French-speaking children, and in nine for speakers of Greek. Half the states had laws that mandated or permitted bilingual instruction as needed—or were in the process of enacting such legislation—and the other half did not seem to have significant enrollments of affected students. The 1980s were probably the high-water mark of this approach to educating the children of immigrants.

California adopted a mandate of bilingual and “bicultural” education in 1976, requiring school districts with more than fifty pupils of limited proficiency in English to develop and implement district master plans. This law was not reenacted in 1987, but most large school systems continued to implement bilingual programs until the referendum (Proposition 227) organized by Ron Unz. In June 1998 California voters decisively mandated that the children of immigrants be given one year of “structured immersion” in English before mainstreaming into regular classes, unless a sufficient number of parents petitioned for a bilingual class.

Voters in Arizona followed the California example and, as of 2001, similar efforts are under way in Colorado and Massachusetts. Even liberal newspapers like the *New York Times* have begun to criticize bilingual programs, which face new demands for accountability and results. The alternative offered is no longer “sink-or-swim,” but carefully designed programs that focus (like those in other countries with large numbers of immigrants) on developing an initial proficiency in English so that the pupil can as soon as possible be placed with classmates for whom that is the first language and with whom he will communicate naturally and so become more and more proficient.

It should be noted that proficiency in a language other than that of the school is by no means of itself a barrier to success in school, and may indeed be associated (whether as cause or effect) with academic achievement, provided that the pupil is also proficient in the school language. A study conducted by

the Educational Testing Service in conjunction with the National Assessment of Educational Progress concluded that “whether or not one comes from a home where a second language [that is, other than English] is frequently spoken is not the critical issue, but rather the central question is whether or not one is competent in English” (Baratz-Snowden et al., p. iii).

In the early twenty-first century American education seems to be entering a period in which a variety of approaches to the education of immigrant children will be employed, based upon local judgments about what will work best and what parents want; a new emphasis on accountability for results will prevent schools from sliding back into the old complacency about whether immigrant students learn or not.

## INTERNATIONAL

The social and cultural effects of immigration have been in the forefront of policy debate a number of times in U.S. history (and in that of Canada and of Australia) but it is a largely unfamiliar and thus all the more difficult question in Europe. As the late Willem Fase noted, "Western Europe quickly moves in the direction of immigration countries such as the United States, Canada and Australia" but there is "crossnational variation in social and educational provisions for ethnic minority groups" (p. 7). The focus here will be upon the members of the European Union and Canada, Australia, and New Zealand.

Ethnicity and its consequences are among the most difficult and potentially destabilizing political issues in most of the Western democracies, as well as in the former Soviet Union and Yugoslavia and the developing nations. In recent years, commentators in Germany, France, Australia, and elsewhere have ranked immigration as the leading "hot button" topic in political discourse. The education of the children of immigrants is a challenge that professionals in the United States have faced for many years, but it is a relatively recent concern in Europe.

Certain countries, such as Australia, Canada, the United States, and South Africa, have long welcomed immigrants, though often with restrictions based upon origin, race, or skills. Migrant workers have been moving, and often settling, within Europe for centuries. Since World War II, Western Europe has absorbed millions of "guest workers," immigrants from former colonies who became permanent

residents and brought their families; and more recently, millions of migrants from Eastern Europe. Even countries like Italy, Spain, Portugal, and Greece that were long exporters of their citizens to other countries now find themselves seeking to integrate hundreds of thousands of immigrants from North Africa, Eastern Europe, and elsewhere. Most European cities now have areas inhabited mostly by immigrant families.

Exceptional groups aside, the educational outcomes of immigrant children are generally inferior to those of native children. This has led to high rates of grade-retention and to frequent failure of students to obtain qualifications for technical or university education. Immigrant children are also often concentrated in schools that, in some cases, enroll no native pupils at all. Policy responses have included "reception classes" for pupils who are not proficient in the language of the school, supplemental programs to support home language and culture, and the designation of special zones or schools that receive additional funding to permit a more favorable pupil-teacher ratio and other supports. In a few cases that have not been widely copied, authorities have provided bilingual education or made efforts to desegregate schools.

### Reception Classes

Typically, children of immigrant parents who are older than primary school age when they arrive are placed in reception classes for a year, where they are given an intensive program in the language of the school as well as orientation to life in the host society. In France, for example, it is assumed that young immigrant children should be treated like and integrated with French children of the same age; should learn numbers, colors, and reading in French; and should receive supplemental help only as individually needed, just as a child from a French-speaking home would. Special reception programs are regarded as an essential transitional measure only for pupils who start French schools at ages when their classmates would already be well advanced in their studies.

Some classes have a teacher who speaks the language of most of the children, as well as a native teacher. The role of the former is to assist with explanations and not to instruct in academic subjects through the home language; the goal is to prepare pupils as quickly as possible for participation in a regular class.

### Supplemental Home Language and Culture Programs

In the countries under consideration some arrangement has been made to enable immigrant children to continue to develop their home language and to gain some knowledge of the culture of the country from which their parents came. Some of these programs are funded by the governments of the sending countries or by ethnic organizations, but many are supported by the educational system of the host society. Typically, pupils attend these classes on a voluntary basis for several hours per week, so arranged as not to conflict with regular academic instruction.

Supplemental language programs should not be confused with "bilingual education" (BE) as it is practiced in the United States. The intent is not, as in BE, to develop initial literacy in the home language or to teach the academic subjects through that language, but rather to enable immigrant children to retain some link with the homeland and the culture of their families.

### Extra Resources for Immigrant Pupils

A number of efforts have been made to increase the effectiveness of the schooling provided to children from immigrant families by devoting additional resources to their schools. France has a system of "priority educational zones" (ZEPs) that receive additional support and attention.

### Bilingual Education

Although instruction provided in two languages is common in some areas with linguistically mixed native populations, such as Catalonia in Spain, Friesland in the Netherlands, Schleswig-Holstein in Germany, and Wales, bilingual education has seldom been provided for the children of immigrants. The exceptions include some programs for Finnish immigrants in Sweden and experimental classes in other countries. The results have not been sufficiently positive to encourage widescale adoption of this approach.

### School Desegregation

Only a few scattered attempts have been made in Western Europe to ensure that ethnic minority children are not concentrated in certain schools. It has frequently been pointed out that the growing tendency toward segregation of the children of immigrants has a negative effect upon their opportunities

to learn the language of the school and reduces the motivation of foreign pupils and their parents to take seriously schooling in which no native pupils participate.

One German community that made a determined and comprehensive effort to promote ethnic integration is Krefeld in North Rhine/Westphalia. While the "Krefeld Model" was most notable for its stress upon pedagogical integration, it also included an element of deliberate assignment of pupils to create the preconditions for successful integration. Similar efforts have been made in Gouda and Amsterdam in the Netherlands, and in a number of cities of Flanders in Belgium.

## IMMUNIZATION AND CHILDREN'S PHYSICAL HEALTH

With the exception of safe water, no other public health intervention has had a greater impact in reducing deaths related to infectious disease than vaccinations. Smallpox was eradicated in 1977; wild-type poliomyelitis was eliminated from the Western hemisphere in 1991. Among children under five, measles and invasive *Haemophilus influenzae* type b (Hib) have both been reduced to record low numbers. Deaths associated with smallpox, diphtheria, pertussis, tetanus, paralytic poliomyelitis, measles, mumps, rubella, congenital rubella syndrome, and Hib decreased an average of nearly 100 percent during the twentieth century.

Though the United States is reaching record low levels of vaccine-preventable disease, continued immunization is important. Pathogenic viruses and bacteria still circulate in the United States, and with continuing globalization, the threat of disease spread increases. Immunization protects the general population from disease; individuals who are immunized have inherent protection from disease while those who are not immunized are protected by the limited likelihood that they will be exposed to another unimmunized and infected individual. Furthermore, immunization protects a population from disease;

vaccinated individuals acquire immunologic protection from pathogens for themselves. As a consequence, immunized individuals are protected secondary to a decreased incidence of disease. This phenomenon of *herd immunity*, however, will not be achieved unless 80 percent to 95 percent of the population is immunized.

### Childhood Immunizations

A detailed childhood immunization schedule is released yearly by the National Immunization Program (NIP), the American Academy of Pediatrics (AAP), and the American Academy of Family Physicians (AAFP). This schedule informs parents and health care providers which vaccines children need to receive and when they should receive them. An updated schedule can be found at the website of the Centers for Disease Control and Prevention.

State governments are responsible for passing and enforcing school immunization laws. Currently all fifty states have immunization requirements for children entering school. The vaccinations required may be different for different states. Additionally, states may also differ in the number and types of philosophical or religious exemptions they allow for children entering school. Vaccination decreases the risk of infection and outbreaks in schools by reducing the number of unprotected people who may be infected that are capable of transmitting the disease within their schools and communities.

Immunizations are available either free of charge or for a reduced cost at local health departments for children whose parents cannot afford to take their children to private physicians for immunization. Furthermore, on August 10, 1993, the Omnibus Budget Reconciliation Act (OBRA) created the Vaccines for Children Program (VFC) program as Section 1928 of the Social Security Act in order to increase access to immunizations. The program began on October 1, 1994; it provides vaccinations at no cost to VFC-eligible children seeing either public or private providers.

### Vaccine-Preventable Diseases

The following eleven vaccine-preventable diseases are addressed through standard vaccination programs. A number of these diseases are covered by mandatory school immunization laws.

*Diphtheria* is a respiratory disease caused by a virus that is spread by coughing and sneezing. Symp-

toms include sore throat and low-grade fever. Left untreated, diphtheria can lead to airway obstruction, coma, and death. Vaccines that contain the diphtheria toxoid include the DTP, DtaP, DT, and Td vaccines.

*Tetanus* (lockjaw) is a disease of the nervous system that is caused by bacteria that enters the body through a break in the skin. Early symptoms include lockjaw, stiffness in the neck and abdomen, and difficulty in swallowing. Later onset symptoms include fever, elevated blood pressure, and severe muscle spasms. Death occurs in one third of all cases, especially among the elderly. Tetanus toxoid is also contained in the DTP, DT, DtaP, and Td vaccines.

*Pertussis* (whooping cough) is a highly contagious bacterial respiratory disease spread through coughing and sneezing. Symptoms include severe fits of coughing that may interfere with eating, drinking, and breathing. Pertussis may cause pneumonia, encephalitis, and infant death. The pertussis vaccine is contained within the DTP and DtaP vaccines.

*Haemophilus influenzae* type b is a bacterial infection that predominantly affects infants. It is spread by coughing and sneezing. Symptoms include skin and throat infections, meningitis, pneumonia, sepsis, and arthritis and may be severe for children under the age of one. Risk of disease is reduced after the age of five. A Hib vaccine can prevent the disease.

*Hepatitis A* is caused by the Hepatitis A virus and is spread most commonly through the fecal-oral route when the stool of an infected person is put into another person's mouth. It can also be transmitted by ingesting food or water that contain the virus. The disease affects the liver. Symptoms are unlikely, but if present they may include yellow skin or eyes, fatigue, stomach ache, loss of appetite, and nausea. This disease is prevented using the Hepatitis A vaccine.

*Hepatitis B* is caused by the Hepatitis B virus and is spread through sexual contact or through contact with the blood of an infected person. As with the initial clinical presentation of Hepatitis A, infection with Hepatitis B may follow an indolent course and manifest no symptoms. The likelihood of developing Hepatitis B increases with age. If present, symptoms are similar to Hepatitis A. The Hepatitis B vaccine prevents the disease.

*Mumps* is caused by a virus and is spread through coughing and sneezing. It is a disease that affects the lymph nodes. Symptoms include fever,

headache, muscle ache and swelling of the lymph nodes close to the jaw. Infection with the mumps virus may also lead to meningitis, inflammation of the testicles or ovaries, inflammation of the pancreas and permanent deafness.

*Measles* is a highly contagious respiratory disease caused by a virus that is transmitted through coughing or sneezing. Symptoms include rash; high fever; cough; runny nose; and red, watery eyes lasting about a week. The measles may cause diarrhea, ear infections, pneumonia, encephalitis, seizures, and death. The measles vaccine is contained within the MMR, MR and measles vaccines.

*Rubella* (German measles) is a viral respiratory disease spread through coughing and sneezing. Symptoms may include a mild rash and fever for two to three days in children and young adults. Complications are severe for pregnant women, whose children frequently have congenital birth defects. The rubella vaccine is contained within the MMR, MR, and rubella vaccines.

*Polio* is a viral disease of the lymphatic and nervous systems. Transmission occurs through contact with an infected person. Symptoms include fever, sore throat, nausea, headaches, stomach aches, and stiffness in the neck, back and legs. OPV and IPV are the vaccines in current use.

*Varicella* (chickenpox) is a highly contagious disease caused by bacteria and is spread by coughing or sneezing. Symptoms are a skin rash of blister-like lesions on the face, scalp, or trunk. The varicella vaccine prevents this disease.

### Immunization Safety

Before vaccines are approved by the Food and Drug Administration, they undergo rigorous scientific testing to ensure that they are safe and effective. However, differences in each individual's response to an antigenic vaccine challenge account for the rare occurrences ranging from vaccine failure to anaphylaxis. The National Childhood Vaccine Injury Act (NCVIA) of 1986 created the National Vaccine Program Office within the Department of Health and Human Services. It requires that all providers who administer vaccines provide a Vaccine Information Statement that explains the disease and the risks and benefits of vaccination to the vaccine recipient, parent, or legal guardian. The NCVIA also created the Vaccine Adverse Event Reporting System, a mandatory reporting system for health care provid-

ers. The National Vaccine Injury Compensation Program was also created under the NCVIA as a no-fault system for compensating people injured by vaccination.

## IMPACT AID, PUBLIC LAWS 815 AND 874

Public Laws 81-815 and 81-874 were approved by the U.S. Congress in 1950 to assist local school districts with the construction and cost of public educational activities impacted by federal defense efforts. The so-called impact laws were an extension of a 1941 federal emergency measure, the Lanham Act. The precedence of the Lanham Act, the rising educational burden placed on local school districts near military bases, and the advent of the Korean War (1950–1953) contributed to the subsequent passage of the impact laws. A House Committee on Education and Labor studied the strain on local districts and concluded that unless federal assistance were provided, "more than 1.8 million children in these federally impacted areas would not receive normal school services" (National Association of Federally Impacted Schools, p. 9).

To ameliorate the loss of local taxes from personnel residing on federal lands, the authorizing

committees of both the House and the Senate passed legislation (H.R. 7940 and S. 2317) to provide federal aid for the construction and maintenance of new schools in defense areas. On July 13, 1950, Public Law 81-874 was initially authorized for four years. Public Law 81-815 was passed on August 22, 1950 for an initial two-year authorization. The passage of the impact laws in 1950 and subsequent reauthorization during the 1950s represented a significant exception to the contentious federal school politics of the 1940s and early 1950s. Numerous federal aid-to-education bills had failed because of racial and religious dissent. Until the passage of the Elementary and Secondary Education Act in 1965, impact laws were the only form of federal general aid for K–12 education. Furthermore, school districts receiving impact aid funds were generally free from federal governmental interference. For example, until the 1964 Civil Rights Bill enabled the U.S. Office of Education to withhold federal money from districts maintaining racial segregation, impact aid schools were not pressured to desegregate.

Children attending schools in impacted areas or federally connected children were (1) children who lived on federal property and whose parents worked on federal property; (2) children who either lived on federal property or whose parents worked on federal property; and (3) children whose parents came into the district as a result of federal contracts with private firms. A minimum of 3 percent or 400 federally connected children had to be in average daily attendance in a given district to qualify for impact aid.

The Elementary and Secondary Education Act (ESEA) of 1965 and subsequent amendments altered the original criteria for impact laws to assist not only areas affected by military personnel but also those with high poverty rates and other hardships such as rapid growth. Under Title I, Public Law 81-874 created a new three-year program of basic federal grants to the states. Funds would be allotted to districts where at least 100 school-age children, or 3 percent of the total number of school-age children were from families with low annual incomes. Under Title VI of the 1966 ESEA amendments the stipulation that three percent of children in a district must be federally connected to receive impact aid was altered to substitute a minimum of 400 children even if three percent were not federally connected. Public Law 81-815 also was broadened under the 1966 ESEA amendments to allow districts with rapid enrollment to qualify for aid.

Native American children living on federally owned lands also were eligible for funds under Public Law 81-874 and Public Law 81-815. However, it was not until passage of Title IV of the 1972 Amendments, the Indian Education Act, that Native Americans were explicitly included. In that year Public Law 81-874 was amended to financially assist local educational agencies for the education of Indian children.

Impact Aid funds flow primarily through basic support payments on behalf of federally connected children. Additional payments are made for federally connected children with disabilities, for heavily impacted districts, for federal property removed from local tax rolls after 1938, and for construction and renovation of school facilities. The bulk of the appropriation goes directly to student compensation. For fiscal year 1999, the Department of Education found that close to 97 percent of the \$864 million allocation was for federally connected children, whereas little more than 3 percent was targeted for school districts that lost significant local assessed value due to the acquisition of property by the federal government since 1938.

### Program Analysis

Researchers from RAND's National Defense Research Institute analyzed the Impact Aid Program, with an emphasis on its effect on the children of military personnel. Their findings are documented in a 2001 publication by Richard Buddin, Brian P. Gill, and Ron Zimmer. The authors drew the following conclusions.

- The complex Impact Aid formula results in large payment disparities for the same type of students.
- Differences in how school districts are defined makes the link between them and reimbursements inherently flawed.
- Educational opportunities of military and civilian children appear roughly comparable.
- Concern over the extra cost of military children may be misplaced.
- Military children have a much higher migration rate than do civilian children.

### Future Directions

The U.S. Department of Education continually proposes changes for funding via appropriations lan-

guage and annual budget requests to best serve the needs of all federally connected children, and to improve the targeting of districts experiencing the greatest impact from federal activities. To improve the timely processing of Impact Aid payments, the department is increasing its use of technology and endeavoring to establish improved review procedures. According to the department's biennial report for the fiscal year 1995–1996, however, the program objectives have remained substantially the same: to support local school districts impacted by children who reside on military bases, Indian lands, federal properties, or in federally subsidized housing; or to a lesser extent, for children who have parents in the uniformed services or who are employed on eligible federal properties, but do not also reside there.

## INCLUSION

*See:* SPECIAL EDUCATION.

## INDEPENDENT SCHOOLS

*See:* PRIVATE SCHOOLING.

### INDEPENDENT STUDY

Independent study programs are found at nearly every level of education in the United States, from elementary school through graduate school. Although the concept of independent study was not new, a spectacular increase in interest in the subject occurred in elementary and secondary schools in the 1960s. In the early twenty-first century, many courses delivered within a traditional format are expected to have some component of independent study and to build independent learning skills. The major elements of independent study are the following:

- Individualized teaching and learning takes place through the student's activity.
- A tutorial relationship exists.
- Learning is made convenient for the student.
- The learner takes responsibility for progress.

Independent study programs are sometimes criticized because they release students from group-learning situations. Students themselves, while they may select or volunteer for independent study experiences, are frequently unprepared because they lack experience with any other way to learn except in a classroom. However, some research has shown that computer-based learning is as effective as traditional instruction. Students were able to organize their own learning effectively, were generally positive about using this form of instruction, and scored similarly on examinations.

#### Purposes and Goals of Independent Study

Successful independent study programs provide preparation for students and guidance along the way:

- Students are taught knowledge and skills that cannot easily be communicated in classrooms.
- As evaluated by exams, independent students learn at least as well as students in classes.
- Independent study provides useful practice in the process of learning.

- Independent study is viable when an educational institution is inaccessible to the learner.
- Independent study meets the convenience needs of many learners.
- Independent study develops self-motivation, concentration, and discipline.
- The learner is taught to identify a problem, gather data, and take responsibility for conclusions.
- The learner does all the work and cannot slide by on the anonymity of group activity.

#### Independent Study and Extensiveness in Grades K–12

The amount of time that students devote to independent study could be much greater than is the case in most schools. Although often identified as a tool for meeting the needs of gifted students, independent study should be available for all. Each year, teachers demand more group attention on the part of students, leaving less time for independent study even though the students' capacity for independent study grows. Of course, students differ in their degree of self-direction, creativity, and performance, but all can profit from a greater amount of independence. In the past independent study has too often been viewed as being synonymous with learning by doing or with special term projects. Independent study needs to be viewed as an integral part of the total process of learning in all fields. Each curricular area needs sequenced materials that enable students to learn independently effectively. The materials first should describe the required outcomes in terms that each student can understand. Concepts and skills should be defined in behavioral terms. For example, if students are asked to research an issue through independent study, the exact parameters of their project, depth and breadth, the types and numbers of sources, the form conclusions should take, and the formats that may be used to present the results should be clearly spelled out, so that each student will know precisely what the school expects. Each segment in the learning sequence should provide a variety of learning activities that may be used to arrive at specified outcomes. Pretests and self-tests that enable monitoring of learning and suggestions of some ways to study in greater depth should be included. Motivation is enhanced by self-selection of learning strategies that work well for individual students and by the immediate reinforcement of self-

testing. Provocative questions or activities to stimulate the learner's creativity such as those described by Phil Schlemmer (1999) for students in grade six and above can be used in concert with a traditional curriculum. Students no longer fail; they simply make less progress in the learning sequence. Each student's special projects should be recorded as part of an educational portfolio (now required by some states for graduation).

The University of Missouri-Columbia High School (MU High School), part of the University of Missouri Center for Distance and Independent Study, has an accredited diploma program for students of varying ages interested in alternatives to traditional high school. These include students who are home schooled, rural students wishing for additional college preparation, gifted students who need coursework above their current grade level, and students who need to make up courses. More than 150 different courses can be applied toward credit to a high school transcript. John Marlowe (2000) recommends that educators offering independent study to high school students analyze individual needs, match needs to options, use a paper trail to manage each program, enlist teacher support, guarantee academic rigor, and include some component that allows for students to socialize. Programs to teach independent and strategic learning skills to this age student also exist. In summary, students at the high school level use independent study to do the following:

- Earn university credit before they begin college.
- Earn extra credits to finish high school early.
- Supplement schedules with courses not offered at their schools.
- Enrich their high school experiences.
- Make up credits to graduate on time.
- Earn a high school diploma.

Similar programs also exist at the elementary and middle school level. The University of Missouri's Distance and Independent Study Center also offers a program for elementary and middle school students in grades three through eight that covers curriculum in language arts, mathematics, science, and social studies. All the courses were written by licensed teachers and are equivalent to a semester of work. Coursework can be completed through the mail, online, or by fax.

### Trends, Issues, and Controversies

The movement toward independent study at the elementary and middle school level has been fueled by an increase in the number of students who are home schooled. Although developed primarily for this consumer group, such courses are being offered to schools as supplements to the regular curriculum and as a way to meet the needs of diverse learners. Schools may opt for these programs for use in enrichment programs, especially for students in accelerated programs or those identified as gifted, for remediation, for use with students with identified learning problems, or in place of summer school programs. Programs to teach independent and strategic learning skills also exist for grades K–12.

There are several reasons for this trend. First, independent study programs have been successful in meeting the needs of students who lack other educational opportunities. Second, increasing pressure on adults to continue learning to upgrade skills for their current job or to prepare themselves for new careers has created a concomitant expectation that students will learn how to do this in grades K–12. Third, educational technology has gained increasing acceptance as an ally of the teacher and student in accomplishing tasks that would be more difficult and expensive in conventional formats. Fourth, improved understanding of the nature of the individual process of learning has yielded greater emphasis on teaching the student to learn and solve problems independently and with less emphasis on information transfer.

At the beginning of the twenty-first century, the infusion of technology (particularly the Internet and video-conferencing) has made independent learning and distance education a focus for all schools. Carefully conducted research and a rigorous evaluation of the effectiveness of independent study programs, especially those that rely heavily on technology over a long period of time, are needed. Such evaluation should analyze not only differences in achievement, as measured by existing standardized tests, but also changes in student attitudes and the quality of their experience. The changes that independent study and distance education bring in the learning and teaching environment must also be a focus of study.

## ABILITIES AND APTITUDES

Abilities are cognitive or mental characteristics that affect one's potential to learn or to perform. Aptitudes are sometimes treated as interchangeable with abilities, particularly when they focus on prediction of performance in other settings or on other occasions. Cognitive abilities have been conceived very broadly (e.g., intelligence) and also in terms of specialized abilities such as verbal, spatial, memory, reasoning, problem solving, and psychomotor ability. Some authors have defined aptitudes more broadly than abilities, to include any number of individual-differences factors— affective, cognitive, and personality characteristics—that influence one's readiness or likelihood of learning or performing successfully.

During the twentieth century, there have been significant changes in conceptions of ability, moving from atheoretical models that have their basis in measurement and psychophysics to ones that are based largely on cognitive theories of human performance. Social issues continue to influence conceptions of ability and practices of ability testing. The scientific measurement of abilities has been viewed as either enabling or stifling social progress, and such controversy continues in the twenty-first century.

### History

Ability testing in education began in 1905 in Paris when Alfred Binet along with his assistant Théodore Simon developed the Binet-Simon scale to solve the practical problem of reliably differentiating between educable, educable with special help, and uneducable children. Prior to the development of the scale, such classifications were made subjectively and inconsistently; thus the scale was considered a signifi-

cant practical achievement. The scale consisted of thirty tests, such as “naming objects in pictures,” “defining common words by function,” and “retaining a memory of a picture.” In historical treatments, Binet and Simon’s approach is sometimes referred to as a task-sampling approach, in that the tests are essentially samples of typical educational events.

The task-sampling approach may be contrasted with another tradition in ability testing, a basic elements approach. This tradition began with Francis Galton’s development of a battery of basic sensory-motor, reaction time, and memory tests. Galton believed that a general mental ability with biological underpinnings underlay performance on these tests, but to his disappointment, he found no relationship with educational or occupational levels. Charles Spearman developed a statistical method known as factor analysis, which demonstrated that Galton’s hypothesis of a general ability was supported after all. Later, researchers such as Louis Thurstone and J.P. Guilford refined Spearman’s notion, by adding various kinds of tests to the more basic batteries, and identifying “group factors” such as spatial and verbal ability in addition to general ability (Spearman’s “g”) to account for patterns of performance.

Developing conceptions of ability and aptitude have proceeded in tandem with practical applications, particularly in military, educational, and employment settings. In the military, the development of the “Army Alpha and Beta” intelligence tests during World War I, which helped efficiently sort 1.7 million World War I conscripts into job classifications (training, frontline, officer, and so forth) has been cited by Frederick McGuire as one of psychology’s most influential contributions to American society. The Army Alpha, used essentially as a measure of general cognitive ability, consisted of eight subtests (oral directions, arithmetic problems, practical judgment, antonyms, disarranged sentences, number series, analogies, and information), most of which are still being used in test batteries today. During World War II and through the 1950s the number of abilities measured was expanded to include such constructs as verbal and quantitative ability, technical knowledge, and psychomotor abilities, the latter being particularly important for pilot and navigator selection. In the early twenty-first century the U.S. military services use a multidimensional test battery, the Armed Services Vocational Aptitude Battery (ASVAB), for both selecting applicants and

assigning them to training and occupational specialties.

Following the success of the Army Alpha, there was general optimism about the role ability assessment could play in “social engineering,” such as providing opportunities for higher education to students based on merit rather than on birthright. An example was the Scholastic Aptitude Test (now known as the SAT) during the period between World War I and World War II. The SAT was designed, in the words of the American educator James Bryant Conant, to “reorder the ‘haves and have-nots’ in every generation to give flux to our social order.” The composition of the SAT has fluctuated minimally over the years, consistently yielding “verbal” and “mathematical” scores, relying on tasks that are arguably work samples of academic tasks (e.g., reading comprehension) to those that are more abstract from such tasks (e.g., verbal analogies).

A third major application of abilities and aptitudes is in employment testing. The General Aptitude Test Battery (GATB) was developed around the time of World War II, by a commission of industrial psychologists and measurement experts for the U.S. Department of Labor. The test measures general ability, verbal aptitude, numerical aptitude, psychomotor ability (motor coordination, finger dexterity, and manual dexterity), and general perceptual ability (spatial aptitude, form perception, and clerical perception). The GATB was designed to predict job performance. More than seven hundred validity studies have demonstrated that it does so, and consequently the test is widely used as an employment screen. A meta-analysis of these studies conducted by John Hunter and Ronda Hunter has shown that general cognitive ability is the primary determinant of job success, but that psychomotor ability is important for relatively low complexity jobs.

### Modern Views

The major aptitude batteries—the ASVAB, GATB, and SAT, in the military, industrial, and educational sectors, respectively—were developed in the post-World War I period, and although still in use in the early twenty-first century, have not fundamentally changed over the years in what they measure or how they measure it. But advances in the knowledge of how people think, learn, and solve problems, since the 1970s, has triggered a reevaluation of what abilities are and how they ought to be measured.

**Information processing.** The information-processing view likens the individual to an information-processing system, suggesting that the parameters governing the performance of an information-processing system, such as speed and memory capacity, might be the abilities that govern human learning and performance. Since the 1960s, numerous studies have examined the relationship between mental speed and learning and performance. The conclusion has been that increased sophistication in the procedures for measurement are responsible for a slightly more favorable view than Galton had of the importance of mental speed in everyday life. Still, the work has primarily been of theoretical interest, and there have been few suggestions that mental speed is an important ability to begin routinely including it in large-scale aptitude batteries. In fact, to the contrary, the military services are in the process of removing their “speed” composite from the ASVAB because it has proven not to be a valid predictor of training success or job performance. Similarly, ETS routinely considers speed to be an irrelevant factor for most of its measures.

There has been considerable support, though, for the notion that another aspect of information processing, working-memory capacity, is central to human performance. Several studies have shown that working-memory capacity (as measured by tasks such as mental arithmetic) is indistinguishable from Spearman’s “g” and therefore is the primary ability governing learning and performance. Ian Deary has suggested that Spearman’s “g” is simply being relabeled to have a more contemporary-sounding title. But information-processing explanations of abilities have several advantages. One is that they allow for the construction of ability measures based not simply on previous measures, but on the understanding of how people learn, think, and solve problems. A second is that an information-processing scheme has potential use in task analysis. For example, as Susan Embretson has demonstrated, the requirements of a task can be characterized in information-processing terms, enabling the a priori prediction of item difficulty. A third advantage is that information-processing based concepts connect with wider areas of inquiry such as cognitive and brain sciences, and therefore allow for the uniting of what Lee Cronbach referred to as the two disciplines of scientific psychology, the correlational and the experimental.

**Knowledge and expertise.** A second perspective based on new conceptions in cognitive science might be called the knowledge and expertise view. In this view, characteristics such as working-memory capacity and information-processing speed are not viewed as fixed characteristics of an individual, but as dependent upon knowledge and skill that is developed over long periods of time. So, for example, expert chess players have the ability to recall actual chess positions with impressive accuracy and to a much greater extent than novice players. However, when chess pieces are arranged in random fashion, the two groups have equal recall. Similarly, many studies have demonstrated that processing speed is a direct function of repeated practice. These studies have demonstrated that efficient information processes are, in large part, the residue of well-organized knowledge structures that are developed over years of active engagement and practice within a domain. Further, well-developed knowledge structures in a domain make one a much more effective learner of other concepts in that domain, since there is an established knowledge organization within which to embed and connect new information.

This emphasis on domain specific expertise has profound implications for considering ability testing and ability development. The implication of the expertise approach is to assess and then facilitate the development of knowledge structures and processing skills that will support performance and learning within a domain, without significant attention paid to broad, domain-independent skills. Clearly, the debate over how much of ability is specific to or independent of particular domains continues, and has profound implications for the selection, education, and training of individuals.

**Hierarchical model.** A third new development might be called the hierarchical model of ability differences. This work continues the factor analytic tradition began by Spearman, and further refined by Thurstone and Guilford. The key idea behind the hierarchical model is that what had been thought to be rival hypotheses concerning the number and organization of human abilities can be now seen as compatible. Even into the 1980s one had to take a position on whether the evidence was more favorable towards the Spearman view of one general ability (along with number test-specific abilities); with Thurstone’s view of eight to eleven primary mental abilities; or Guilford’s 120 or 160 ability models. The hierarchical model, as developed by Jan-Eric Gustaf-

sson and John Carroll, shows the fruitfulness of considering abilities as varying in their generality from fairly specific abilities (e.g., memory span, associative memory, and free recall memory), to broader ones (e.g., general memory and learning), to the most broad (general intelligence). In fact, this example is taken from Carroll's "Three-stratum structure of cognitive abilities," which posits sixty-seven or so "Stratum I" abilities, eight "Stratum II" abilities, and one "Stratum III" ability. Gustafsson's scheme is similar in spirit, but he did not consider nearly as many datasets as Carroll did, and so consequently his proposal may be seen as a subset of Carroll's.

**Multiple intelligences.** A final new development might be called the "multiple intelligences" view. There are actually two quite distinct notions that might be considered in this category, the "triarchic theory" of Robert Sternberg and the "multiple intelligences" theory of Howard Gardner. Sternberg's idea is that the field, the testing industry, and the application sectors themselves (education, industry, and the military) are preoccupied with one notion of abilities, which he playfully refers to as the "g-centric view." He also calls this analytic intelligence, and suggests that while important, success in school and in life is perhaps equally if not more importantly determined by other intelligences, namely creativity and practical intelligence. Although this work has not yet resulted in any widescale applications, preliminary work, particularly in the area of practical intelligence appears promising.

Gardner has proposed a different scheme, called "multiple intelligence theory," which identifies eight abilities—linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, interpersonal, intrapersonal, and naturalist intelligences. This scheme is quite popular in educational circles, perhaps attributable to its elevation of abilities other than the usual linguistic and logical-mathematical abilities, encouraging the recognition of some students for talents normally overlooked. However, the scheme is often dismissed in scientific circles because by eschewing measurement, it fails to allow for its validity to be tested. As Nathan Brody has pointed out, multiple-intelligence theory is at odds with the rest of the field in its rejection of a general cognitive ability, and with its choice of the particular eight abilities—neither empirical nor theoretical justifications for these features of the theory have been produced.

## Controversies

Discussions and investigations of aptitudes, abilities, and individual differences have been fraught with controversy throughout their history. Certainly one of the most contentious issues is that of the heritability of abilities. Comparisons of monozygotic and dizygotic twins, twins reared apart versus together, adoption studies, and various other behavioral genetics studies, suggest that abilities are somewhat heritable, although the issue of by what amount remains unsettled. There is ample evidence for notably high consistency in test scores over time. A study reported by Ian Deary showed that Scottish eleven-year-olds performed remarkably similarly on an identical test of mental ability administered sixty-six years later, when they were seventy-seven years old.

Some of the reason for the intense interest in heritability seems to be inappropriately due to a misconception that to the degree that abilities are inherited, there is not much one can do to improve one's abilities. Heritability, however, is not synonymous with immutability, as can be proven with a simple thought experiment. Height is highly heritable, but has steadily increased over the twentieth century due to improvements in environmental factors such as nutrition. Similarly, as documented by James Flynn, intelligence scores have been shown to have risen quite dramatically in the second half of the twentieth century in numerous parts of the world. Early childhood intervention programs, such as Head Start, have met with mixed success, but others, such as the Carolina Abecedarian project, have shown strong and persistent gains in cognitive skills, academic test scores, and language use in follow-up studies through the age of fifteen.

Another area of some controversy in the abilities and aptitudes literature concerns the role of other factors such as metacognition, attitudes, motivation, and concepts such as emotional intelligence, in performance in school and the workplace. Concepts such as test anxiety have for a long time been cited as a threat to the validity of an estimate of a student's ability. Claude Steele has suggested that additional attitudinal factors, "disidentification" and "stereotype threat," may impair the performance of minority students in certain contexts. Motivation has long been considered an important factor in governing learning and performance success and related concepts such as goal setting, self-efficacy, and optimism are being investigated for their role in learning. Emotional intelligence refers to a wide variety of fac-

tors that may mediate the relationship between abilities and performance, or may serve as abilities and aptitudes in their own right.

A third controversy centers on the extent to which ability can even be considered as an individual phenomenon. In the situated cognition view, abilities can only be considered as they are manifest and develop within social situations. The interaction of the person with the social environment is what defines ability—it is not a construct that can be defined independent of such interaction. Much of the support for this work comes from examining very sophisticated cognitive strategies that develop without the benefit of any formal academic training or ability to demonstrate the strategies in traditional academic ways.

### Further Directions

The predominant use of individual differences in abilities and aptitudes in education has been in assigning students to special remedial programs, selecting them for admission into schools (e.g., colleges), or identifying them for receiving awards such as scholarships or fellowships. Although this use will undoubtedly continue, it is likely that an increasing emphasis will be put on new uses, opening the door to additional opportunities, in the form of diagnosis, tailored educational programs, and self-assessments to facilitate more efficacious career choices. It is likely that the noncognitive ability and aptitude variables, including interests, personality, motivation, and the like, will prove particularly important for the new uses role.

Another trend in ability and aptitude testing in education is an increased emphasis on the assessment of achievements rather than the more basic abilities. Some of this is due to what some have characterized as the pernicious effects of test coaching, and is certainly consistent with cognitive conceptions of expertise. The idea is that as long as there are high-stakes ability tests, there will be a coaching industry designed to help students improve their chances of succeeding on those tests. To the extent that the tests directly reflect the achievements that are supposed to be learned in school, coaching then becomes a positive force, a productive adjunct to the school curriculum, reinforcing lessons learned in school. Another reason for this trend is that test users and the public in general have increasingly demanded tests that look more like the learning or performance activities that the tests are designed to

predict. There seems to be less patience with arguments based exclusively on predictive validity statistics. One sees this in military and industry testing as well as educational testing.

A third trend in abilities and aptitude assessment is what is sometimes called “embedded assessment” or the insertion of abilities tests within the context of instruction itself. This trend fits with the general trend toward the increased use of achievement testing, but for the specific purpose of tailoring instruction to a particular individual, based on that individual’s changing knowledge and understanding of a particular topic area. Richard Snow and Valerie Shute have suggested both “macroadaptive” and “microadaptive” responding on the part of a computerized (“intelligent”) tutoring system. Microadaptive instruction refers to the specific reactions a tutor makes in response to its continually updated understanding of what a student knows and is learning; macroadaptive instruction refers to more global approaches to delivering coaching and feedback the tutor makes based on more general assessments of a student’s abilities.

Finally, a possible future trend is increasing attention paid to what might be called “mediators” for their role in affecting abilities and aptitudes. These include factors such as nutrition, psychopharmacology, fatigue, and circadian rhythms. Nutritional explanations have begun to appear more frequently in discussions of changes in abilities, and the role of nutrition, vitamins, and glucose has been investigated but as of yet, little is known. Similarly, there have been some investigations of “smart drugs,” such as caffeine, ginseng, and ginko biloba, as well as other psychopharmacological agents, particularly cholinergic enhancers. Finally, much has been learned over the past decade about the role of circadian rhythms in affecting hormonal production and concomitant behavioral effects such as fatigue and alertness over the course of the day. There has been some work suggesting that “morningness” and “eveningness” may be characteristic dispositions that mediate both cognitive abilities and personality factors.

DREW H. GITOMER

## AFFECTIVE AND CONATIVE PROCESSES

People react emotionally to their own and others’ performances, often in characteristic ways. Getting

a grade of “B” in a course can produce devastation in an anxious student who expected an “A.” Psychologists believe that the student’s temperament interacts with expectations for the course grade to produce a negative emotional response.

Characteristic emotional reactions and certain qualities of temperament are examples of psychological processes that are affective. Affective processes include all feelings and responses, positive or negative, related to emotion-laden behavior, knowledge, or beliefs. Affect can alter perceptions of situations as well as outcomes of cognitive effort; it can also fuel, block, or terminate cognition and behavior.

Affective processes intertwine with aspects of motivation and volition. In educational situations, students’ motivational beliefs and judgments of their own capabilities influence their intentions and plans. Thus students who see themselves as “not good at math” will prefer other subjects and struggle in math class. Conation, an ancient psychological concept whose dictionary definition refers to purposive striving, covers the range of motivational and volitional processes that human beings display. Motivational processes underlie the decision to pursue a goal; they are the wishes and desires that lead to intentions, in turn dictated by interest and experience. Volitional processes come into play after goals and intentions are formed; these processes reflect steps to implement goals, and ways of managing resources. Modern psychology has come to see motivation and volition as category labels for distinct conative processes.

In 1980 Ernest Hilgard wrote that the main agenda for modern scientific psychology ought to be to understand the processes underlying three central human functions—cognition (perception, memory, and the processing of information), affection, and conation. Indeed, since the beginning of the twentieth century, psychology in education has been peppered with programs of research on the qualities and characteristics of people that fit into one of these three functional categories. Intelligence, for example, is cognitive, impulsivity is affective, and self-concept is conative. Within conation, some well-studied processes influence commitments and are therefore considered motivational. One example is self-efficacy, a kind of personal capability belief. Other research examines processes that people use to protect commitments already formed—for example, self-monitoring and self-rewards. When these

processes occur once a commitment is made, they are volitional.

As early as the mid-twentieth century, theories began to identify the range of variables within and between categories that could be measured validly and reliably in persons. But despite much progress up to and past Hilgard's writing in 1980, more effort is needed to explain how the triad of human functions works together at the process level. Moreover, this research agenda is virtually unknown to those outside psychology, and laypeople are frequently unaware of how psychologists use these terms.

For some purposes, affective and conative processes have proven to be so interconnected that it makes little sense even to psychologists to separate them. One group of researchers, the Stanford Aptitude Seminar, invented the hybrid term, *affcon*, to reflect this viewpoint. Given the complicated sociocultural context in which schooling takes place today, it is hard to dismiss the importance for educators, parents, and counselors of understanding how changes in affect can influence conation and vice versa: Both play central roles in the willingness to work and quality of effort invested by students in academics.

Three examples serve to illustrate how the interplay between academic-intellectual processes and affcon processes affects objectives of educational practitioners, decision makers, and students. The examples reflect current issues as well as persistent problems.

### **Cognitive Engagement**

A school classroom is a social context offering many opportunities for students to be distracted from their work. At the same time, the organization of a classroom demands behavioral self-control. This paradoxical combination of opportunities and demands suggests the need for creative curricular experiences that engage students fully in classroom work, making them want to succeed. The concept of cognitive engagement is a prominent goal of classroom teaching, at virtually all levels of education.

Part of what new paradigms for instruction are about is providing teachers with a repertoire of strategies for promoting cognitive engagement. Modern education reform emphasizes success as its own reward, but encourages teachers to use other incentives to move students along. Activities and experiences grounded in students' own interests,

and assignments that require meaningful discussion of topics and material, help to promote cognitive engagement. Also supported by empirical research are inquiry teaching methods that make thinking explicit, and uncover hidden assumptions in content ranging from narratives to persuasive arguments. Research on teaching conducted between 1970 and the early twenty-first century makes it clear that students tune out in tired models of conventional teaching, where students listen and teachers talk.

Knowledge about which reforms and strategies work in different situations has been informed by evaluations of educational programs. Frequently, these demonstrate the insufficiency of seeking direct impact on learning outcomes such as achievement scores. Rather, achievement improves as a result of tapping into the affcon responses of students as they engage in and with schoolwork.

### **Student Responsibility**

A student who takes responsibility for learning is self-regulated and self-motivated, intentionally directing energy toward learning tasks. Self-starters have long reaped academic rewards. Research conducted between 1980 and the early twenty-first century has uncovered the attitudes, skills, and behavior that characterize self-regulated learners, and emphasized the important role played by self-regulation skills in schooling outcomes. Researchers have also designed programs to help weaker students acquire self-regulation knowledge and skills. Counselors and teachers can use such programs to teach students responsibility. Likewise, parents can model self-regulation and strategies for doing homework.

Self-regulation and personal responsibility involve affcon processes. Careful self-management is necessary when follow-through is in jeopardy; for example, when a student experiences boredom or perceives that a task will be difficult to perform. The effortful processes that mark volition come forward then, with the sense to "buckle down." Not all academic situations demand volitional control, however. In some activities in the curriculum, learning can seem to occur with no effort, almost automatically. When a person is in the affective state that Mihalyi Csikszentmihalyi called "flow," there is no need to drain volitional reserves.

Astute teachers and parents will listen and watch closely for evidence of emotional stress in school children, and encourage the highly motivated to

enjoy their time between work and play. Negative physiological as well as emotional changes can result from too much pressure on children in school. Although the ability to monitor and control emotions increases developmentally, some variation remains even among adults.

### Adaptive Teaching

An increasingly diverse population of students leads teachers to differentiate curriculum and instruction. Some common differentiation strategies have proven ineffective from an academic standpoint; for example, teaching to the bottom third of the class. There are also well-documented negative social consequences to other differentiation strategies, most notably the common practices of tracking and retention in grades. To accommodate individual differences in students, a teacher must do only good.

Some types of cooperative work groups, formed to reflect the heterogeneity of students within classes, produce positive affect outcomes: Students give and receive help from peers; they learn how to organize and manage due dates; the whole group incurs rewards when individuals contribute best efforts. But even effective grouping arrangements work best in short bursts of time; motivation and affect are buoyed by flexibility. In forming cooperative groups teachers should take into account students' affect and self-regulatory styles as well as their status characteristics and levels of achievement. The importance of considering the affect profile of students has historically been left out of adaptive teaching discussions and decisions.

Another important point to make about adaptive teaching is that good teachers have always addressed students according to attitudinal and work styles. For any given task, what a student presents in the way of interest and attitude, as well as prior knowledge, often dictates a particular explanation, example, or suggestion for improvement. Different explanations, examples, and suggestions will reach students with other interests or markedly opposite styles of behavior. Moreover, teaching adaptively means shifting with the student's own development. Hence, the teacher's dictum of "If you can't reach them one way, then try another" comes into play. Adaptive teaching not only requires a teacher to circumvent observed student weaknesses, but also to capitalize on strengths. When a student is removed from conventional instruction for compensatory purposes, there ought to be simultaneous efforts to

develop an aptitude for conventional instruction directly. It is, after all, to the regular classroom that many special program students eventually will return.

Despite the growing body of research on affective and conative processes in education, many programs remain disjointed, even when constructs overlap considerably. There are important theoretical issues still contested, including the need for distinctions between concepts as interrelated as motivation and volition, and the precise nature of the connections in Hilgard's trilogy of mental functions. Some highly regarded theorists, such as Richard Snow and Julius Kuhl, offer sophisticated and situated (context-dependent) models, models that suggest the need for new language as well as new methods of practical assessment and clinical treatment. As the twenty-first century continues, work will advance in these directions, ultimately producing entirely different ways of thinking about affect and conation in education.

## ETHNICITY

As the student population in the United States continues to become more ethnically diverse, the central challenge facing education is how to provide schooling experiences that maximize the participation and academic success of all students. The representation of ethnic minority students rose from 22 percent in 1972 to 38 percent in 2000, and is expected to increase dramatically through the year 2020, when more than two-thirds of the total public-school stu-

dent population will be African American, Asian American, Hispanic, or Native American. Meanwhile, comparison studies continue to show a consistent gap in school achievement for various ethnic school populations.

Derived from the Greek term *ethnos*, meaning *people*, ethnicity refers to a sense of membership in and identification with a distinct group in which members perceive themselves, and are perceived by outside observers, to be bound together by a common origin, history, and culture. Cultural features that define an ethnic group include shared expectations for behavior, such as family roles, health practices, and work and recreational activities; shared values, such as religion, politics, and concepts of achievement, beauty, time and space; and shared symbols, such as language, art, music, and modes of dress. Although broad ethnic categories such as African American, Asian American, Hispanic, Native American, and white are used conventionally in the United States, there are, in fact, important national, linguistic, religious, tribal, regional, and generational differences within each of these broad categories.

### Empirical Approaches: Cross-Cultural and Cultural Process

In the social sciences, two main approaches, distinct in their assumptions, foci, and methodologies, are used to investigate the role of ethnicity and culture in education: a *cross-cultural* approach and a *cultural-process* approach. In a cross-cultural approach, ethnicity and culture are viewed as separate from human behaviors. Cross-cultural researchers focus on the influence that ethnicity and culture have on human behavior. Alternatively, the cultural-process approach treats ethnicity and culture as interdependent with social processes; in other words, ethnicity and culture influence human interactions, and, at the same time, are constructed within those interactions.

Cross-cultural researchers tend to view ethnicity as relatively stable and fixed, while cultural-process researchers tend to view ethnicity as more dynamic with its content and boundaries continually under revision and redefinition. Cross-cultural researchers usually employ quantitative methodologies, such as survey questionnaires and experiments, with a focus on the attributes of individuals. Cultural-process researchers almost exclusively utilize qualitative methodologies, such as observations and interviews, with a focus on actions and interactions in context. For

example, in studying parent involvement, a researcher using a cross-cultural approach might conduct a survey on a large sample of families from different ethnic groups to assess group differences in the amount of time parents spend on a variety of activities related to their child's schooling. A researcher using a cultural-process approach might interview parents from several ethnic groups on what it means to be involved with their child's school, while also engaging in an observational study of the interactions between students and parents, in order to detail the processes through which the parents engage with their children in their schoolwork. Ultimately, the combination of both a cross-cultural approach and a cultural-process approach is beneficial for a more in-depth understanding of the role of ethnicity and culture in education.

### The Achievement Gap

The results of numerous cross-cultural studies indicate that many ethnic minority students are not faring well in U.S. schools. Ethnic group differences are found in school grades, standardized achievement tests, course enrollment, grade retention rates, high school graduation, and level of educational attainment. The achievement gap appears in the early school years, increases during the elementary school years, and persists through the secondary school years. While achievement gaps narrowed between 1971 and 1999, the average scores of African-American and Hispanic students have remained significantly below those of non-Hispanic white students.

Rates of grade retention tend to be higher for African-American and Hispanic students (particularly males), when compared to other groups. High school dropout rates tend to be highest for Hispanic students, followed by African-American students. African-American males tend to be disproportionately represented in special education classes. With the exception of Asian Americans, ethnic minority students are not adequately represented within programs for gifted and talented education (GATE).

In general, Asian-American students fare well academically, displaying high levels of performance on standard achievement indicators. With respect to the educational attainment level of students, high school graduation rates since 1971 have greatly increased overall for ethnic minority youth, however the rates in 2000 were lower for Hispanic and African-American students than for Asian-American

and white students. Asian-American students, in general, show higher college graduation rates, as well as higher graduate degree attainment, than white students. It may be noted that for some of the cross-cultural studies, comparisons were not made across all of the major ethnic groups due to the relatively small sample sizes of Native American students and, in some cases, Asian-American students.

A number of issues require consideration in light of these general findings of ethnic group differences in school achievement. First, many studies do not account for socioeconomic differences, such as family income, parental employment and education, when examining ethnic groups. Given that the average socioeconomic status (SES) differs substantially among ethnic groups, the failure to disentangle ethnicity and SES can lead to erroneous interpretations. SES is a significant predictor of academic success, and ethnic minority families are disproportionately represented in the lower SES bracket. Moreover, schools with the highest proportion of low-income students are more likely to have fewer qualified teachers, have substantially fewer resources (computers, enrichment materials), and be located in a neighborhood with fewer informal educational resources (such as museums and libraries). Economic pressures at home, compounded by poor neighborhoods and poor schools, makes the separation of socioeconomic factors from ethnic cultural factors even more difficult. Thus, it is imperative for future studies to examine comparability as well as account for the disparities among ethnic groups with respect to SES levels.

Many educators and policymakers often perceive technology as a promising tool for leveling inequities in educational achievement. However, studies show that children who come from lower-income families (which are disproportionately ethnic minority families) have fewer computers in the home. The provision of updated educational technology within schools is uneven at best, and this, combined with unequal access within the home, limits such computer-based activities as homework completion, research, word processing of reports, and presentations.

Second, while many comparative studies typically focus on the major ethnic groups as broad groups, it is important to acknowledge that individual differences within each ethnic group are substantial. Such categorization may give the illusion of overall cultural similarity and obscure substantial

national, tribal, or other subgroup differences. For example, the broad category of Asian Americans is comprised of diverse national backgrounds, including Cambodian, Chinese, Filipino, Korean, Japanese, Vietnamese, Thai, Khmer, and Asian Indian. Additionally, much variation within an ethnic group is likely to exist with respect to variables such as gender, social class, generation/immigrant status, and level of assimilation.

Studies that examine differences within an ethnic group are useful for a variety of reasons. First, within-group studies may serve to weaken the uniform, and often stereotyped, views associated with particular ethnic groups. Second, studies of within-group differences in which the subgroups differ on various demographic variables would be helpful in understanding the role that variables such as generation/immigration status, level of assimilation, language, and socioeconomic status may play. Third, within-group studies may provide a further understanding of the cultural processes underlying achievement-related outcomes.

### **Theoretical Models Explaining the Achievement Gap**

Researchers have attempted to explain the consistent achievement gap among ethnic groups from a number of different perspectives. The explanations offered may be grouped into three theoretical models. The first, a *cultural deprivation*, or *deficit*, model, explains the poor performance of ethnic minority students as the result of an impoverished and restricted home life. The underlying theory is that “culturally deprived” or “socially disadvantaged” students do not achieve because they lack a cognitively stimulating environment. Research may identify, for example, a lack of parental support, a low value placed on education, a language-poor environment, or even low intellectual capacity. The use of whites as the norm against which other ethnic minority groups are compared may perpetuate a deficit model in which ethnic minority groups are perceived as second-rate to the majority group.

The second theoretical model, the *cultural difference* model, points to differences in values, expectations, languages, and communication patterns between teachers and students—or between schools and families—as a source of difficulty for ethnic minority students. The underlying theory is that the social organization, learning formats and expectations, communication patterns, and sociolinguistic envi-

ronment of schools are incongruent with the cultural patterns of different ethnic groups, and therefore limit the opportunities for student success. For some researchers in this area, the important differences exist at the level of interpersonal communication, where teachers and students are unable to fully understand each other. Important communicative differences may be identified at many levels, including formal language (e.g., English versus Spanish), conventions for interacting (e.g. distance between speakers, acceptable physical contact, and turn-taking rules), preferences for rhetorical style (e.g., the use of emotion in persuasion), and storytelling patterns.

A number of studies have also suggested that differences between social worlds, such as home and school, can be difficult for ethnic minority students to negotiate. For example, where U. S. public schooling tends to encourage independence, with competition and rewards for individual achievement, some ethnic groups may tend to encourage interdependence among members, with rewards for collaborative effort. Socialization practices also vary across ethnic groups, so that, for example, the parenting styles acceptable within one ethnic group may vary significantly from the parenting styles valued by schools and educators. Likewise, expectations for the role of parents in education may differ across ethnic groups, so that while some teachers expect active parent involvement at school, parents’ conceptions of involvement may be altogether different. Additionally, some parenting practices may focus on social and observational learning and apprenticeship examples, and thus favor visual rather than auditory information processing. Insofar as early learning experiences may vary systematically by ethnic group, ethnicity can have important consequences for learning in (and out) of school.

Some researchers argue that the cultural difference model presumes ethnic differences to be inherently problematic when, in fact, it is the perception of differences and how people act on such perceived differences that is an important source of difficulty for minority students. These researchers typically utilize a cultural-process approach and focus on social interactions. Barriers to school success are identified by examining how students, teachers, and parents understand patterns of language use and socialization. In any case, the cultural difference model has made important contributions to understanding the relationship between ethnicity and school

achievement by pointing out that children from different ethnic groups may vary in culturally patterned ways, some of which are relevant for educators.

A third theoretical model, which can be termed *sociosystemic*, moves outside the classroom in an effort to identify the social, economic, and political forces that contribute to the achievement gap. Researchers have come to recognize how differences in perceived economic opportunity affect the level of school engagement for ethnic minority students. For example, when students' families, peers, and community members hold beliefs that economic and social opportunities are limited, regardless of school achievement, students are far less likely to engage in meaningful ways with formal educational activities. Such beliefs may lead to a youth's active resistance to school or a "disidentification" with schooling overall (i.e., when students are apathetic or disaffected toward schooling). Some studies have identified patterns of differences within ethnic minority groups, where school achievement varies according to the conditions of one's minority status. Specifically, members of *voluntary* minority groups, including those who immigrated for improved economic opportunity, often do better in school than members of *involuntary* minority groups, such as those who were colonized or whose residency was forced (e.g., through slavery). Research utilizing a sociosystemic model has also identified schools as the places where societal pressure to assimilate is most keenly perceived—and often resisted. Many researchers and practitioners, for example, have noted that student peer groups link school achievement to the acceptance or rejection of various identities.

Each of the theoretical models on the achievement gap—cultural deficit, cultural difference, and sociosystemic—corresponds with specific policies (federal, state, regional, district, school), curricula, and teaching practices seeking to narrow the gap. Within the cultural deficit model, educators are encouraged to intervene as early as possible in children's development. Many federal and state programs, such as Head Start, focus on the compensation of deficits. From the cultural difference model, schools and teachers are encouraged to make better use of the knowledge and practices of diverse cultures and to form home-school connections. The various forms of multicultural education also derive from a basic cultural difference model, as do some bilingual education programs. Also included in this model are recent efforts to develop theories and

practices of *culturally-relevant pedagogy*, an approach to teaching that modifies both curriculum and communication to reflect the diverse cultural practices of students. The cultural difference model appears to decrease the pressure on children to conform to mainstream culture standards, yet increase the pressure on teachers and schools to transform their practices to better reflect the diversity that is present around them.

For those with a sociosystemic perspective, repairing the achievement gap demands a commitment to an ongoing examination of the social and political systems, along with direct action to counter systemic bias. Few formal policies or programs with this model exist, although *critical theory* and *critical pedagogy* are actively promoted within this perspective. Critical theory seeks to make systemic injustice visible and critical pedagogy encourages teachers and students to understand and contend with stereotyping, racism, sexism, and other forms of prejudice.

Because of the tremendous variation within any ethnic group, it would be inappropriate to make generalizations about the needs and abilities of any individual student based solely on his or her membership in a given ethnic group. That said, there is no doubt that variation does exist along several lines, and educators should be aware of this. Perhaps most important of all, members of the teaching and learning community should be reflective of their own perceptions and actions with respect to all learners. It must be recognized that just as schools themselves vary, so do the students within them. Schools are the spaces where a great deal of a youth's development occurs, and on multiple levels, including academic achievement, identity, and social competence. In the end, ethnicity and culture must become part of the face of education in order to reflect and better serve our youth as they encounter an increasingly diverse world.

## GENDER EQUITY AND SCHOOLING

The 1992 publication of the landmark report *How Schools Shortchange Girls*, by the American Association of University Women (AAUW) Educational Foundation, brought gender equity to the forefront of educational reform. Since then, the focus of discussions about quality education for all students has shifted from *equality* to *equity*. In the context of gender, equitable education appropriately addresses the needs of both girls and boys rather than assuming that those needs are identical. Thus, equity in education provides equal opportunities for reaching a shared standard of excellence. Simply defined, gender equity in education is the absence of gender differences in educational outcomes.

Researchers struggling to identify the origins of gender differences have examined a range of theories, including biological, psychoanalytic, social learning, and cognitive developmental approaches to gender differences. While there has been ongoing debate about the role of biology as a source of cognitive differences, educators agree that changes in educational outcomes must focus on the psychosocial aspects of behavior. Regardless of the specific causes of gender gaps, schools have a mission to ensure that all students can fully participate in and experience educational success. While acknowledging that individual differences within each gender are substantial, this analysis will focus on girls and boys as aggregate groups in an examination of similarities and differences in schooling experiences and outcomes. These differences will be reviewed in relation to mathematics, science, humanities, technology, and extracur-

ricular activities, including differences in both attitudes and outcomes. Except where noted, the information presented here is based on data from public schools in the United States, for kindergarten through twelfth grade. Statistical findings reported are based primarily upon results from a number of large-scaled studies and reports, such as those of the American Association of University Women, the U.S. Department of Education, and the National Center for Education Statistics.

### Gender Equity Pertains to Boys and Girls

Because much of the literature regarding gender in education has focused on areas where girls are underserved, some have argued that gender equity appeared to pertain to girls only. Near the turn of the new millennium, however, a few authors brought attention to the education gender gap for boys, showing that the national phenomenon of male underachievement has been nearly invisible in the gender-equity literature. Gender equity is not “for girls only,” and improvement for one gender should not imply a disadvantage for the other.

### Early Behavioral Outcomes

Girls and boys appear to have similar types and amounts of opportunities to help them prepare for elementary school. For example, equal numbers of girls and boys are enrolled in center-based preschool programs and receive equivalent amounts of literacy activities at home. Preschool girls perform higher on tests of small motor skills than boys, and they show fewer signs of developmental difficulties in areas such as physical activity, attention, and speech. Boys in the early grades are more likely to be identified as learning disabled, to be tracked into remedial and special education classes, to be diagnosed with attention-deficit disorder, to be involved with crimes and violence on school property, to repeat a grade, and to be suspended from school. Subsequently, boys are more likely to drop out of school altogether. Girls, on average, receive higher grades than boys in all subjects beginning in the early grades—a trend that continues throughout middle and secondary school.

### Classroom Environment

Aspects of the classroom environment have been found to foster and/or reinforce gender biases. Often unintentionally, many teachers exhibit gender biases when interacting with students. For example, teachers generally give more attention to boys than to

girls. Ironically, this is partly caused by the fact that girls tend to be better behaved in the classroom and more attentive to assigned tasks. Teachers’ attention is often consumed by boisterous or aggressive behaviors more typical of boys. Teachers also tend to give less feedback (positive or negative) to female students. Without such feedback, girls may be deprived of valuable opportunities to evaluate their own behaviors and ideas and to learn to cope with constructive criticism. Boys, on the other hand, when reinforced for their boisterous behaviors, may fail to learn self-control, listening skills, and respect for others.

Classroom materials may also serve to reinforce gender biases in the schools. Although editors of textbooks and other instructional materials have made greater efforts to include women since 1992, female characters continue to play a smaller role than male characters in classroom materials. Moreover, when female characters are represented, they are often shown in stereotypical roles that reinforce gender biases.

### Attitudes

Among the core academic subjects, some are considered typically “male,” and others “female.” In spite of increased female enrollment in mathematics and science courses, ideas persist that these subjects are for boys, while the humanities and social sciences are for girls. Students often act on these stereotypes in class activities by self-selecting into groups and roles according to gender norms. In science classes, for example, boys often dominate laboratory equipment, controlling hands-on experiments while girls observe and take notes. Similarly, when boys and girls work together on computers, boys tend to sit where they can more easily view the monitor and take control of the mouse. Also, computer usage is typically dominated by boys during after-school activities.

Differences remain in boys’ and girls’ attitudes toward academic subjects. On average, girls report liking mathematics and science less than boys, and having less confidence in their ability to succeed at these subjects. Girls also rate themselves lower in computer abilities than boys, and are far more likely to suffer from *math anxiety* or *tech anxiety*. They tend to perceive these subjects as being less useful in their lives, which may diminish their achievement motivation in these areas. Hence, fewer girls plan to choose careers in mathematics, science, or technology. Additionally, whereas boys tend to believe their

success in academics is the result of ability, girls tend to attribute academic successes and failures to luck and other external factors. This attribution of success to factors other than effort may lead some girls to feel “helpless,” particularly in subjects they perceive as male domains.

### **Mathematics and Science**

Encouragingly, the gender gap in mathematics and science course enrollment is closing. At least as many girls as boys are now enrolling in algebra, geometry, precalculus, calculus, trigonometry, and statistics/probability courses. Moreover, girls receive higher grades than boys, on average, in math classes (as in all academic subjects). Nevertheless, girls consistently lag behind boys in scores on standardized mathematics assessments, including the mathematics sections of the Preliminary SAT (PSAT), the SAT, the National Assessment of Educational Progress (NAEP), and mathematics Advanced Placement (AP) exams. Such “high-stakes” exams are critical factors in determining college admission and scholarship awards, and lower scores can therefore limit career opportunities.

Gender differences found in science are similar to those in mathematics. In high school, girls are more likely than boys to take biology and chemistry, while about equal numbers of girls and boys enroll in engineering and geology. Physics, however, continues to be a male-dominated subject. Girls also take fewer AP science exams than boys, and they receive proportionately fewer top grades.

### **Humanities**

Humanities, an area in which female students typically excel, receives little attention in the research about gender in education. With the shrinking of gender gaps in math and science, however, the humanities are quickly becoming an area in which the most substantial gender differences can be found. More girls than boys enroll in English, sociology, psychology, foreign languages, and fine arts. Particularly notable because of its role in standardized testing is the subject of English. Girls consistently outnumber boys in English classes, and significantly outperform them in most reading and writing assessments, with the notable exception of the AP English exam.

### **Technology**

Many educators, administrators, and policymakers advocate technology as a tool for empowering other-

wise disadvantaged groups, thus leveling inequities in educational achievement. Nevertheless, a number of disturbing gender inequities have already been observed in educational technology use. For example, female enrollment in computer science courses lags significantly behind that of males. Moreover, only a small percentage of the students taking the AP exam in computer science (17% in 1995 and 1996) is female. Many more men than women are computer educators, and women remain greatly underrepresented in computer technology careers. Such disparities are of particular concern because technology skills are increasingly crucial for high-skill, well-paying jobs.

Several hypotheses have been suggested to explain the gender gaps in technology. Social and parental expectations, along with teacher biases, are commonly suggested reasons. Differential access to computers is also thought to play a significant role in creating gender disparities. It is often reported that parents are more likely to buy computers for boys than girls. Moreover, even when given equal access, boys use computers at home more frequently than girls. Additionally, computer software may appeal more to boys than to girls. Computer-related toys and games, designed mostly by males, are marketed primarily to boys and are typically found in the “boys’ aisles” in toy stores. Games, which play a significant role in computer use, are dominated by images of competition, sports, and violence, which typically appeal more to males. These games, along with other technology-based materials, may help to perpetuate gender stereotypes.

### **Extracurricular School Activities**

Girls and boys tend to participate in different types of extracurricular activities, representing traditional areas of gender dominance. Females, for example, are more likely than males to participate in performing arts, belong to academic clubs, work on the school newspaper or yearbook, or participate in the student council or government. Females are also more active than males in community service. Males, on the other hand, are more likely than females to play on athletic teams. While girls’ rates of participation in team sports have increased since 1972, equity has not been achieved.

The differences in boys’ and girls’ choices of extracurricular activities may have important consequences. For example, sports participation has been linked to higher academic achievement as well as

greater leadership capacity, better overall health, higher self-esteem, and more positive attitudes toward school. On the other hand, participation in non-sports-based extracurricular activities has also been found to build self-esteem, leadership, and social skills; to improve general health; and is associated with higher mathematics and reading test scores.

### Individual Differences

It is important to acknowledge that the gender differences described above are based on average group scores. Girls (and boys) are not a uniform group and their needs are certainly not singular. In fact, large differences exist within each gender across different racial, ethnic, and socioeconomic groups. For example, African-American girls, despite the existence of both racial and gender discrimination, have a higher self-esteem, healthier body image, and greater social assertiveness than their white female counterparts. These girls also perform better on many academic indicators than their black male counterparts. Similarly, Latino girls score higher than Latino boys in mathematics by the eighth grade, and in science by the twelfth grade—contradicting patterns for girls on the whole. However, Latino females also have the highest dropout rate of all groups of girls, with one in five leaving school by the age of seventeen.

Race, ethnicity, and socioeconomic status (SES) appear to play a larger role than gender in determining enrollment in remedial and special education classes; and participation rates are lower in all extracurricular activities for low-SES students. Furthermore, students in ethnically diverse and low socioeconomic schools have less access to technology. Finally, regional differences may also contribute to gaps in educational outcomes. Girls in rural southern regions of the country consistently perform below girls from rural and nonrural areas in other regions. Greater understanding of gender, racial, ethnic, regional, and socioeconomic class differences and needs can only improve U.S. schooling. Building on all students' cultures, interests, and ways of knowing can make schooling experiences meaningful to their lives and useful for addressing social problems. At its core, educational equity seeks to enrich classrooms, expand choices, and widen opportunities for reaching a shared standard of excellence for all students.

## INDIVIDUALIZED INSTRUCTION

The improvement of instruction has been a goal of educators as far back as the teachings of the Greek philosopher Socrates. Although there are a wide variety of approaches, in most cases instruction can be characterized by the following tasks: setting objectives, teaching content based on these objectives, and evaluating performance. This formula is indeed the most common; however, there have been many advocates of alternative approaches. Among the alternative approaches there is a focus on a more individualized approach to instruction, where the traits of the individual learner are given more consideration. Each approach to individualizing instruction is different, but they all seek to manipulate the three following fundamental variables:

- **Pace:** the amount of time given to a student to learn the content
- **Method:** the way that the instruction is structured and managed
- **Content:** the material to be learned

### **Pace**

There are two basic extremes when the pace of instruction is considered. The first is when someone other than student, usually a teacher or instructor, controls the amount of time spent learning the material. In this case specific due dates are defined before instruction begins. This is currently the predominant model in most educational systems. The opposite extreme would be if the learner had exclusive control over the pace of instruction, without a time limit. Between these two extremes are situations where control of the pace of instruction is shared or negotiated, not necessarily equally, by the teacher and learner.

### **Method**

As theories of learning and instruction develop and mature, more and more consideration is given to the way in which learning occurs. In an attempt to account for the way that students learn, instructors may apply a combination of theories and principles in preparing instruction. This can influence whether instruction is designed for one homogenous group, or is flexible, in anticipation of individual differences among learners. In the majority of cases, instruction is designed for the average learner, and is customized ad-hoc by the teacher or instructor as needed once instruction begins. This type of instruction, although it does give some consideration to individual differences among learners during instruction, does not fall into the typically accepted definition of individualized instruction. For instruction to be considered individualized, the instruction is usually designed to account for specific learner characteristics. This could include alternative instructional methods for students with different backgrounds and learning styles.

To help clarify this point, the instructional method used can be considered in terms of extremes. In the first extreme, one instructional method is used for everyone. Terms like *inclusion* and *mainstreaming* have been used to describe this first case. In the second extreme, a specific instructional method is used for each individual. Between these extremes lie situations where students are arranged into groups according to their characteristics. These groups can vary in size, and the instructional method is tailored to each group.

### **Content**

Perhaps the least frequently modified component is the actual learning content. However, it is possible to vary the content taught to different learners or groups of learners. Both "tracking" and "enrichment" are examples of customizing instructional content. A renewed movement toward learner-centered principles in education has given this component more consideration in the 1990s. It has become possible to find examples of instructional settings in which students define their own content, and pursue learning based on their own interests. In most cases, however, this opportunity is limited to high-achieving students. In terms of extremes, content can be uniform for everyone, or unique to each individual. Between these extremes lie cases where the content can be varied, but only within a prede-

finer range. The range of activities available to the learner is an indicator of how individualized the content is in an instructional setting.

### Examples of Individualized Instruction

There are many examples of instructional approaches that have modified some or all of these three components. In all of these examples, the goal was to improve the instructional experience for the individual learner. Some of the most historically notable approaches are discussed below. Within each example both the benefits and criticisms of each approach are discussed.

**Personalized System of Instruction.** Introduced in 1964 by Fred Keller, the Personalized System of Instruction, or the Keller Plan, is perhaps one of the first comprehensive systems of individualized instruction. Keller based his system on ten accepted educational principles (McGaw, p. 4):

1. Active responding
2. Positive conditions and consequences
3. Specification of objectives
4. Organization of material
5. Mastery before advancement
6. Evaluation/objectives congruence
7. Frequent evaluation
8. Immediate feedback
9. Self-pacing
10. Personalization

None of these ten principles should be considered unique, as they all can be easily found in other more traditional educational settings. Rather, it is the components of the Keller plan—based on these ten principles—that makes the Keller Plan somewhat different: self-pacing; unit mastery; student tutors; optional motivational lectures; and learning from written material. It is the first component, self-pacing, that is the most obvious attempt at individualizing the instruction. From the second component, unit mastery, it can be seen that the content does not vary, as the unit content is fixed. To illustrate the static nature of the content, Mike Naumes describes the basic design of a course using Keller's personalized system of instruction:

breaking the material of the course into several units. . . . dividing the material into units one to two weeks long. . . . [and] as each unit of material is covered, specific

learning objectives are given to the students. These state exactly what a student must know to pass a unit quiz. (p. 2)

The last three components indicate that the method of instruction does vary slightly from individual to individual. Although all students learn from written material and student tutors, the motivational lectures are optional. Making these lectures optional does constitute some flexibility in terms of instructional method, albeit extremely limited. Fundamentally, it is the self-pacing that more or less stands alone as the individualized component of this instructional system.

Proponents of the Keller Plan cite many benefits, including better retention and increased motivation for further learning. At the same time, there are others with criticisms of the Keller Plan such as the following: limited instructional methods, high dropout rates, and decreased human interaction. The debate over the effectiveness of Keller's Personalized System of Instruction, with its advantages and disadvantages, raises fundamental questions about the nature of self-contained, self-paced learning. There are indeed opportunities for designing instruction that lend themselves to the Personalized System of Instruction approach. This would apply especially to cases where enrollment is high, course material is standardized and stable, and faculty resources are scarce. On the other hand, when there is not a shortage of faculty, or the class size is not large, the course would be better taught with more conventional methods, yet still based on sound educational principles. Where the line is drawn on the continuum between these two extremes is a matter of opinion, and should be based on the context in which the instruction is to take place. It would be inappropriate to claim that one of the extremes is completely right, and the other wrong, given the vast number of studies and evaluations that support either side.

**Audio-Tutorial.** Audio-Tutorial is a method of individualized instruction developed by Samuel N. Postlethwait in 1961 at Purdue University. His goal was to find an improved method of teaching botany to a larger number of college students and to effectively assist the students who possessed only limited backgrounds in the subject. The development of an Audio-Tutorial program requires a significant amount of planning and time by the instructor. Although there is some room for modification for each specific program, the general principles remain the same. Students have access to a taped presentation

of a specifically designed program that directs their activities one at a time. The basic principles of Audio-Tutorial are “(1) repetition; (2) concentration; (3) association; (4) unit steps; (5) use of the communication vehicle appropriate to the objective; (6) use of multiplicity of approaches; and (7) use of an integrated experience approach” (Couch, p. 6).

The major benefits of Audio-Tutorial are that “students can adopt the study pace to their ability to assimilate the information. Exposure to difficult subjects is repeated as often as necessary for any particular student” (Postlethwait, Novak, and Murray, p. 5). In addition to taking more time if they wish, students can also accelerate the pace of their learning. Other benefits are that students feel more responsible for their learning, and more students can be accommodated in less laboratory space and with less staff.

Some of the major criticisms that are common to Audio-Tutorial courses were illustrated by Robert K. Snortland upon evaluating a course in graphics design. The primary criticism concerns the claim of responsibility. It seems that some students respond to the responsibility placed upon them, while others do not. There was a problem with the initial dropout rate, which seemed to be explained by the lack of willingness of some students to take on the amount of responsibility that was required in order to complete the course. Snortland advised that “since many freshmen students are not ready for additional self-discipline required of them in the A-T format, the choice of either a structured approach or an individualized approach should always remain open” (p. 8). Many other criticisms of Audio-Tutorial courses are concerned with teacher control. The instructor dictates all of the material including the learning and feedback procedures. The criticism is that this is a severe form of teacher control over the student.

Like the Keller Plan, Audio-Tutorial allows the individual student to determine his or her own pace, and the content is fixed. Unlike the Keller Plan, however, there are more instructional delivery methods available when designing the course. Yet the locus of control remains with the instructor in the Audio-Tutorial as well.

**Computer-Assisted Instruction (CAI).** Most proponents of individualized instruction saw the computer as a way to further improve the design and delivery of individualized instruction—now in an electronic environment. With the advent of the

computer came the potential to deliver individualized instruction in a more powerful way. This potential was anticipated long before the proliferation of the home computer. John E. Coulson wrote in 1970: “A modern computer has characteristics that closely parallel those needed in any educational system that wishes to provide highly individualized instruction” (p. 4). He also noted the specific benefits that the computer could offer (p. 5):

1. “It has a very large memory capacity that can be used to store instructional content material or . . . to generate such material.”
2. “The computer can perform complex analyses of student responses.”
3. “The computer can make decisions based on the assessments of student performance, matching resources to individual student needs.”

Although there were many anticipated benefits to using the computer to deliver instruction, in practice, CAI has been heavily criticized for its hidden side-effects. These are nicely articulated by Henry F. Olds:

Learning is in control of some unknown source that determines almost all aspects of the interactive process. To learn one must suspend all normal forms of interaction and engage only in those called for by the program. Learning is an isolated activity to be carried on primarily in a one-to-one interaction with the computer. Normal inter-human dialogue is to be suspended while learning with the computer. Learning involves understanding (psyching out) how the program expects one to behave and adapting one’s behavior accordingly. One must suspend idiosyncratic behavior. Learning (even in highly sophisticated, branching programs) is a linear, step-by-step process. In learning from the computer, one must suspend creative insights, intuitions, cognitive leaps, and other nonlinear mental phenomena. (p. 9)

Olds even offered some solutions to these problems, indicating that “time on-line needs to be mixed with plenty of opportunities for human interaction” and that computer should allow people to “jump around within the program structure” (p. 9).

CAI became the forerunner in individualized instruction during the 1980s and early 1990s, as the

home computer became more powerful and less expensive. The changes that the computer environment helped to make were predominantly a change in the delivery mechanism of individualized instruction, rather than a fundamental change in purpose or method. In a sense, the computer, especially the home computer, offered a convenience that other delivery mechanisms lacked. This convenience was accelerated with the proliferation of the Internet in late 1990s. Starting as an extension of computer-based instruction, online education became increasingly popular and eventually began to supplant CAI as the predominant form of individualized instruction.

**Distance education.** A surge in the number of non-traditional students attending college in the 1990s, combined with the technological potential of the Internet, has caused a renewed effort to deliver instruction in a nontraditional fashion. Accessibility and convenience—not research—are the primary driving forces in this movement toward instruction in the form of online education. When reviewing more than 200 articles on online instruction over the 1990s, James DiPerna and Robert Volpe found that only one article directly addressed the impact of the technology on learning. Partnerships between businesses and institutions of higher learning have arisen to address the increased need for continuing education.

Whether it is more effective or less effective than traditional education seems less a concern. In many cases, the audience addressed is nontraditional, and they have limited access to traditional education. Additionally, many students who could otherwise attend brick-and-mortar institutions are choosing online education for the convenience. In other words, what was established initially due to necessity has now expanded as students choose this route because of its convenience. The rate of expansion of online education has accelerated to a point where the general feeling among institutions of higher learning is of willing participation. In terms of pace, method, and content, there is a large variety of competing approaches to distance education, and no dominant model has emerged. Like previous iterations of individualized instruction, it is usually the pace of instruction that most often varies. The content is still fixed in most cases, as is the method (predominantly via the Internet).

## Final Issues

Individualized instruction comes in many forms, all of which seek to improve instruction in some way. As can be seen in the examples above, alternative instructional approaches most often vary the pace and method of instruction, but not the content itself. The content is usually consistent with traditional instruction, although it may be segmented differently.

Other benefits are also significant, but not as consistent among approaches. Each approach has its own set of prescriptions, and each has been heavily criticized—yet that is to be expected. Even now, individualized instruction in its various forms is still a relatively recent innovation, and will remain under scrutiny until several criticisms are accounted for.

Perhaps the most profound criticism comes in the article “Individualization: The Hidden Agenda,” by Ronald T. Hyman. He was concerned with the latent functions of individualization generally. In the push for individualization, the most common approach is to divide the subject matter up into segments and teach it at a self-taught level, but Hyman warns that “Segmented Junk Is Still Junk” (p. 414). There is no concern for what really is the problem, and that is the subject matter itself. He claims that individualized instruction typically does not alter the subject matter based on the needs of the student. Without doing this, there is a compromise of individualized instruction.

In summary, individualized instruction has the potential to improve instruction by varying the pace of instruction, the instructional method, and the content. Most approaches allow for self-pacing, yet variation in method and content is rare, and when it does occur, is usually very limited. As of the early twenty-first century, there are no indications that this trend will change in the immediate future, although as the research base in this area increases, major improvements are certain to come.

## INFANT SCHOOLS IN ENGLAND

Infant schools in England provide publicly funded education for children age five to seven and repre-

sent the first level of compulsory education in England. Infant schools and junior schools are often housed together in primary schools. Together, they furnish education to children until they reach eleven years of age. As of 1998 there were 18,230 primary schools in England providing full-time education for almost 4 million children. Twelve percent of these schools were infant schools, providing children with two years of education only. All infant schools educate children age five to seven, but the traditional infant school approach to education has influenced educational programs for younger and older children.

Children enter infant schools shortly after their fifth birthday, and it is here that they learn to manipulate numbers, read, and write. Traditional infant schools offer an informal education using child-centered techniques. They encourage hands-on manipulation, group and individual learning, and learning through play. Infant schools have been characterized as progressive, child-centered, open and exploratory; they educate children in a way that recognizes their development from a holistic perspective.

Classes are typically vertically grouped to accommodate children age five through seven. Class size may be as large as forty children. Infant schools use an open classroom approach where children move freely from indoor to outdoor environments. The teachers' role is one of facilitation; he or she (usually she) works individually with students or with small groups of students and provides students the opportunity to choose from a range of options appropriate to their developmental level. Infant schools utilize an integrated day, where children pursue various interests or themes without rigid time periods.

Infant schools have a rich conceptual heritage. Their approach draws on the ideas of Friedrich Froebel, who emphasized the importance of play and object in learning; Maria Montessori, who emphasized self-correcting play and an individualized pace in learning; John Dewey, who characterized the community of the school and emphasized integration among subject areas; and Jean Piaget, who supported a developmentally-sensitive approach to learning and advocated hands-on exploration of materials.

Most infant schools encourage children's choice. For example, children typically choose where

to sit and whether they would like to work individually or with peers. Infant schools permit freedom of movement and conversation, encouraging children's natural curiosity and exploratory tendencies.

Infant school teachers are trained to understand the interrelation between social, emotional, and intellectual development, and accommodate children's individual variability within these developmental domains. Infant school teachers are expected to acknowledge the immaturity, innocence, and lack of self-control of young children, employing oblique, indirect strategies toward discipline. Teachers are expected to demonstrate pleasantness, affection, and level-headedness toward misbehaving children. For example, when a child misbehaves, it is more typical for a teacher to chide, "Someone's being silly" rather than scold, "Don't do that!"

### A History of Infant Schools

Robert Owen established the first infant school in 1816 in Scotland. His goal was to shield children from the effects of poverty. This school was designed to provide children with a pleasant school environment where they could think about practical problems and experience little punishment. Teachers encouraged children to help each other, dance, sing, and play outside.

In nineteenth-century England, many mothers worked outside of the home. Forty-five percent of children under the age of five were enrolled in school. Consistent with Owen's objectives, infant schools aimed to protect children and promote a better society. In 1870 the official age for school entrance was set at five, but infant schools accepted poor children of two to seven years, space permitting. During this period, the government imposed standards for children to attain so that children would be prepared to enter school (first standard) at age six. When these standards were relaxed at the end of the nineteenth century, infant schools began a new period of development that strengthened their child-centered ideology.

An early step in this direction was an 1893 government circular encouraging educators to consider all facets of children's development in creating educational programs. By the 1920s and 1930s the infant schools adopted a child-centered approach. The *Report of the Hadow Committee* in 1933, written by the Consultative Committee of the Board of Education on the Primary School, stated explicitly that primary

schools should provide discovery learning and child-centered practice.

The Education Act of 1944 required that primary education be available to all children age five through eleven. The act was vague on what this entailed, mandating "[education] suitable to the requirements of junior pupils." Because this definition was imprecise, curriculum decisions were ceded to the schools. Infant schools offered a wide variety of curricula, structures, and functions. This same act created a selective system of secondary education. As a result, one of the implicit goals for primary education was to begin the process of streaming or tracking, a goal that was discredited gradually over subsequent decades.

In 1967 the Central Advisory Council for Education issued "Children and Their Primary Schools," known as the Plowden Report. This report was based on observations in infant schools. It described the state of primary education in Britain, and endorsed those schools subscribing to "informal, child-centered education." As a result of this report, teachers were given increased freedom to teach children as they saw fit, with less emphasis on strict schedules and specific curricula.

The Plowden Report also assessed the effectiveness of the child-centered infant schools. It asserted that children in traditional, formal classes performed slightly better on conventional tests than children in child-centered, open classrooms. These differences were greatest for arithmetic, smallest for reading, and disappeared in later school years. Some proponents of the child-centered infant schools dismissed these findings on the basis that traditional, formal schools spend time teaching children how to take conventional tests. Despite these results, the Plowden Report advocated the child-centered approach.

The Education Reform Act of 1988 produced a radical restructuring of British education. This included infant schools. England was experiencing uncertainty about its status in the world, and these new laws represented an attempt by the government to control the content and the balance of the curriculum. The Education Reform Act of 1988 required that children be offered "a balanced and broadly based curriculum which promotes the spiritual, moral, cultural, mental and physical development of pupils at the school and of society; and prepares such pupils for the opportunities, responsibilities, and experiences of adult life."

The Education Reform Act ushered in a new national curriculum and a matching set of assessment procedures. Primary schools, including infant schools, were required to teach a core curriculum of mathematics, English, science, history, geography, technology, music, art, and physical education, requiring approximately 70 percent of the instructional time. Specific provisions were created for children with special educational needs.

The act also mandated testing. Children's achievement was to be measured based on a combination of teachers' assessment and Standardized Assessment Tasks (SAT). The SATs were integrated into the normal classroom routines; children were to experience them as normal classroom tasks that they might do individually or with other children, but would reflect their academic progress. Children had to attain specific English, mathematics, and science competencies by age seven.

The Education Reform Act supported parents' rights to choose their children's schools and encouraged competition among schools. By imposing free market models on educators, the government hoped to provide more cost-effective and efficient schools.

Several studies have examined the implications of the Education Reform Act on educational practice and effectiveness. The PACE (Primary Assessment Curriculum and Experience) study found less use of an integrated day, more use of whole class teaching, and a new emphasis on assessment compared to the traditional infant school model. According to the PRINDEP (Primary Needs Independent Evaluation Project) study, teachers found the national curriculum burdensome, but reported few changes in their balance between individual, group, and whole class pedagogy. Teachers in the PRINDEP study reported increased professionalism in the climate at their school following the act. Finally, the new ORACLE (Observational Research and Classroom Learning Evaluation) study compared basic skills in 1976 with basic skills in 1996, cross-sectionally, and showed declines in mathematics, language, and reading skills between these time periods.

### **Influences of the Infant Schools on Education in Other Countries**

France, Switzerland, Belgium, the Netherlands, and other European countries adopted infant schools in the early to mid-1800s. Their goal was to buffer children from poverty-related stressors. Infant schools

on the Continent were similar to those in England, providing children with a child-centered educational environment.

Infant schools of England were again influential throughout Europe during the 1960s and 1970s. Existing programs adopted aspects of the English child-centered approach. For example, the Netherlands fully subsidized infant schools and included them as part of their public school system in 1965. In the 1970s the German Federal Republic's Council on Education opened *Eingangsstufe*, a transitional class in primary schools for five-year-old children that resembled infant schools in England.

Several infant schools were established in the United States in the 1820s in response to Owen's writings, but these disappeared within ten years. The infant school movement had a larger influence on preschool and primary education in the United States during the 1960s and 1970s. At this time, U.S. preschool programs were viewed as "preparatory programs for rigid kindergarten classrooms" (Featherstone 1967, p. 19). To U.S. observers, the infant schools in England offered a demonstration that a child-centered, informal education for young children could exist within in the public schools. As Lillian Weber wrote in 1971, "By observing somewhat analogous situations in the industrial cities of England, I sought relevant answers to the problems of present preschool expansion in the United States and to the needs of children in our deteriorated areas of our cities" (p. 7).

Thus, as Head Start and Follow-Through programs developed, they incorporated practices from the English infant schools. British heads and teachers ran workshops on "informal education." They trained American teachers to recognize individual and uneven patterns of development, reorganize classrooms to enable teachers to interact with small groups and individuals, and establish opportunities for children to manipulate and discover materials independently. There was a proliferation of books designed specifically for early childhood teachers wanting to provide an informal education to their students. These books were rooted in the infant school philosophy, and explained the role of the school, teachers, and families; appropriate curricula; approaches to discipline; the physical organization of schools; and the construction of materials, such as easels and aquariums, to promote children's curiosity.

Also during the 1970s, infant schools influenced practice in U.S. elementary schools. Open schools, which grew from infant school principles, emphasized the holistic development of the child and children's interests as the basis for school learning. Schools implementing this approach offered decentralized learning, freedom of movement from one space to another, unstructured periods of study, and individualized and group-oriented student activities. This approach faced implementation problems in the U.S., which included improper training of teachers and unsupportive administrators and families.

### Summary

Infant schools offer a child-centered, informal approach to education that has been recognized as being sensitive to the development of young children. Educational reforms late in the twentieth century have demanded higher levels of competency from young children and have affected the direction and practices of infant schools in England. English infant schools have had a lasting impact on educational policy and practice in many countries.

## INSTITUTE OF INTERNATIONAL EDUCATION

---

The Institute of International Education (IIE) is a world leader in the international exchange of people and ideas. Its mission is to foster international understanding by opening minds to the world. It does this by assisting college and university students to study abroad; advising institutions of higher education on ways to internationalize their student body, faculty, and curriculum; fostering sustainable development through training programs in energy, the environment, enterprise management, and leadership development; and partnering with corporations, foundations, and governments in developing people's ability to think and work on a global basis.

### Program

Sponsors of IIE's more than 250 programs include government departments and agencies in industrialized and developing countries, the World Bank, major philanthropic foundations, public corporations, and individuals. Nearly 4,000 men and women from the United States and 14,000 people from 175 countries study, conduct research, receive practical training, or provide technical assistance through these programs each year. IIE has administered the Fulbright Program on behalf of the U.S. Department of State since its inception in 1946, and, since 1948, has also conducted the annual *Open Doors* census on international student mobility to and from the United States.

IIE's programs are managed by professional staff with expertise in fields such as higher education

and scholarship administration, energy and the environment, business and public administration, human rights, economic development, and the arts. The institute's program staff serve in four departments:

- **Exchange Programs and Regional Services.** This department manages the U.S. and Foreign Fulbright Student Programs and the International Visitor Program, both funded by the U.S. Department of State, as well as other privately funded academic and professional exchange programs. With 140 staff in New York, Washington D.C., Chicago, Denver, Houston, and San Francisco, this department conducts extensive outreach to local communities throughout the United States.
- **Center for Global Development (CGD).** The CGD administers capacity-building programs serving participants from developing countries. CGD professional exchange programs have allowed participants to gain industry expertise and learn leadership and technical skills in national energy and environmental program implementation, health care, and civil society development. With a staff of more than 100 people in sixteen countries, CGD is IIE's primary mechanism for initiating multisector development assistance contracts worldwide.
- **Educational and Corporate Services.** This department administers scholarship programs and leadership development and skills training programs for midcareer professionals. Educational Services staff also conduct policy and statistical research on international academic mobility and provide educational advising and testing services in the institute's international offices. The department has 100 staff members in nine offices around the world.
- **Council for the International Exchange of Scholars (CIES).** CIES was founded in 1947 to administer the Fulbright Scholar Program and has grown to house other international scholarly exchange initiatives. In 1997 CIES became a department of IIE, based in Washington D.C. More than 1,600 U.S. academics and international scholars are served by CIES programs annually. The day-to-day work of the department is carried out by more than forty-five program officers and staff.

## Organizational Structure

IIE has a staff of more than 475 professionals and relies on the services of more than 6,000 volunteers who serve on regional advisory boards, scholarship screening and selection panels, and program committees. In addition to its headquarters in New York City, IIE has offices in Chicago, Denver, Houston, San Francisco, and Washington, D.C. International offices are located in Bangladesh, Brazil, China, Egypt, Hong Kong, Hungary, India, Indonesia, Kazakhstan, Mexico, Philippines, Russia, South Africa, Thailand, Ukraine, and Vietnam.

Staff members in U.S. offices administer IIE-related programs, mobilize community support for international exchange, provide information and counseling to individuals and institutions, and maintain contact with grantees and the institutions they attend.

Personnel in the international offices assist students and scholars wishing to study or conduct research in the United States; administer U.S. admissions tests for international applicants; report on educational systems, institutions, and developments; cooperate with other private and government agencies abroad to facilitate international exchange; and provide technical assistance and training in selected development fields. The institute is governed by an international board of trustees composed of corporate executives, diplomats, college and university presidents, and artistic and civic leaders.

IIE disburses more than \$150 million annually on programs and services. Most funds provide direct support to sponsored students and professionals. These funds also materially assist the universities and research and training institutions at which IIE grantees study and work.

## History and Development

Until the twentieth century there were no programs for study abroad in American higher education. The U.S. Bureau of Education began collecting data on foreign students in 1904, and published a guidebook in 1915. The YMCA formed a Committee on Friendly Relations Among Foreign Students in 1911, and three bilateral exchange programs came into existence during this time: the Rhodes Trust, the American-Scandinavian Foundation, and the China Foundation for the Promotion of Education and Culture. IIE was established in 1919 as the first independent, nonprofit organization dedicated to pro-

moting all aspects of educational exchange on a global basis. The founders were Elihu Root, the Nobel Prize-winning secretary of state; Nicholas Murray Butler, then president of Columbia University and subsequently a recipient of the Nobel Peace Prize; and Dr. Stephen Duggan, a professor at the City College of New York. These men were deeply committed internationalists in an age when this was not popular. They believed that academic travel abroad would promote mutual understanding and closer cultural relations between Americans and leaders of other countries. Dr. Duggan became the first director, and the institute's first programs were supported by grants from the Carnegie Endowment for International Peace.

The institute lobbied for the creation of non-immigrant student visas in 1921 and designed a new application to assist American consular officials to process visa requests. Its first student exchange was negotiated in 1922 with five American and five Czechoslovakian students. In 1925 the institute created a junior year abroad program for American undergraduates. In 1933 it established the Emergency Committee in Aid of Displaced German Scholars, under the institute's then assistant director, Edward R. Murrow. Its activities saved more than 300 European scholars from the Holocaust. In 1941, the U.S. State Department called upon IIE to administer the country's first nationally sponsored educational exchange scholarships with Latin America under the Buenos Aires Cultural Convention Program. Additional work for the U.S. government necessitated the institute's opening an office in Washington, D.C., in 1943. In 1948, the State Department appointed the institute to screen, place, and supervise student exchange under the Fulbright program.

As African nations emerged from colonial rule in the 1950s, IIE created new U.S. scholarship opportunities for African students. In 1952 the Educational Associates program was established by the institute, providing services for U.S. colleges and universities. In the late 1970s IIE designed and implemented the U.S. government's Hubert H. Humphrey Fellowship program for midcareer professionals from developing nations, as well as creating the South African Education Program to help prepare black South Africans for leadership in a post-apartheid future. The institute also assumed responsibility for a portion of the U.S. government's International Visitor Program and began to run the ITT Corporation's International Fellowship Pro-

gram, which for seventeen years was an exemplary model of corporate involvement in international educational exchange. In the 1980's, the institute began managing short-term, hands-on professional development projects and internships for sponsors such as USAID, expanding its service for scientific and technical development, and establishing a division to undertake energy training programs. IIE has created innovative programs in journalism and human rights, and opened new offices in Jakarta, Zimbabwe, Sri Lanka, and Cairo.

Taking advantage of improving relations with Communist governments, IIE developed the U.S.-USSR Student Exchange Program in cooperation with the Soviet State Committee for Public Education and extended its educational advising services in the People's Republic of China.

In the 1990s IIE initiated programs for leaders, managers, professors, and students in formerly Communist countries to enable them to learn about market economics and democratic institutions. It also developed collaborative programs with Japan and Southeast Asian nations to deepen mutual understanding and address issues of common concern. In response to the Balkan conflicts and the Asian currency crisis, IIE designed and implemented Balkan-Help and Asia-Help emergency assistance funds to enable students from these regions to stay in the United States to complete their degrees.

In 2000 the Ford Foundation turned to the institute to help administer the single largest program in the foundation's history—The International Fellowships Program. This program recruits candidates that lack systematic access to higher education from social groups and communities around the world. These individuals are provided with full scholarships for graduate education in the hope that they will become leaders in their respective fields, furthering social justice and economic development in their own countries.

The institute also helped to develop, and now administers, the Benjamin A. Gilman International Scholarship Program on behalf of the State Department. This program provides awards for undergraduate study abroad for U.S. students who are receiving federal need-based financial aid under Pell Grants, Federal Work-Study, Stafford Loans, Perkins Loans, and Supplemental Educational Opportunity Grants.

## **INSTITUTIONAL ADVANCEMENT IN HIGHER EDUCATION**

---

With the rapid increase in the costs associated with higher education, there has been an ever-increasing pressure placed upon colleges and universities to raise funds for institutional support. Fund-raising drives in excess of \$1 billion are commonplace among top tier institutions in the early twenty-first century. The responsibility for identifying individuals capable of making gifts to the institution falls under the umbrella of institutional advancement.

Offices of institutional advancement are typically responsible for all of the institution's relationships with individuals external to the institution. This discussion of institutional advancement in higher education includes two sections. First, it presents a brief history of institutional advancement. In the second section, the four functional areas of institutional advancement are discussed (public relations, publications, alumni relations, and development).

**Historical Background**

The philanthropic support of educational institutions is not a new concept. Some of the earliest examples of educational philanthropy include Greek philanthropist Cimon's support of the Academy of Socrates and Plato and Alexander the Great's assistance in opening Aristotle's Lyceum through his financial support.

The history of educational philanthropy in the United States can be traced back to medieval universities in twelfth-century Europe. In these institutions, founders were forced to approach potential donors for money and resources for college operations. Wealthy individuals established endowments to support the universities of Paris, Oxford, and Cambridge. The idea of the chief faculty member raising funds for the institution was transferred to the early colonial American colleges.

The first president of Harvard College, Henry Dunster, counted generating resources as part of his duties. While the first solicitation for Harvard College in 1641 is cited as the beginning of fund-raising in this country, Kathleen Kelly commented in 1998 that the extent of the solicitation efforts tends to be overstated and presents a misleading portrayal of early educational institutions as heavily dependent on financial donations. Others also dismiss the notion that fund-raising began in the 1600s given that most early colleges were supported by government funds and taxes. Systematic fund-raising traces its roots to the twentieth century; early efforts were limited and involved only a few wealthy benefactors.

In 1821 Williams College established the first alumni association and in 1823 Brown University established the first alumni fund. Not until 1897 did the first public university, the University of Michigan, establish an alumni association. This difference in organizational behavior between public and private institutions is repeated throughout fund-raising history, although only minor differences exist today.

One of the first great institutional fundraisers was William Lawrence, an Episcopal bishop, who raised more than \$2 million for Harvard in 1904–1905 as president of the alumni association and who led a drive at Wellesley College that brought in nearly \$2 million. From 1905 to 1915 Charles Sumner Ward and Lyman L. Pierce conducted the first “capital campaign” for the YMCA that raised about \$60 million in capital funds.

However, in 1936 fewer than fifty percent of colleges and universities had alumni funds in place and. According to Kelly “apart from a few exceptions related to annual giving. . . the first full-time staff fundraisers did not appear on the scene until the late 1940’s” (p. 149). Private, rather than public institutions employed the first fundraisers, “with only 25 percent of all institutions reporting a centralized development function as recently as 1970” (Brittingham and Pezzulo, p. 82). The majority of those were private institutions. In 1912, twenty-three men who were responsible for organizing former students of their universities founded the Association of Alumni Secretaries (AAS). While some of those involved had responsibilities for raising funds, the majority were engaged in the organization of alumni to support their universities in ways other than financial. By 1938 only one fifth of those surveyed by the American Alumni Council (the new name adopted by the AAS) were engaged in fund-raising activities.

In the spring of 1958 the American Public Relations Association (ACPRA) and the American Alumni Council (AAC) met at the Greenbrier Hotel in White Springs, Virginia. The purpose of the meeting was to discuss the need for administrative coordination of the functions of public relations, alumni relations, and fund-raising. In 1974 the AAC and ACPRA merged to form the Council for the Advancement and Support of Education (CASE). This organization brought together the organizational functions of public relations, publications, fund-raising, and alumni relations under the umbrella of institutional advancement.

### Areas of Institutional Advancement

**Public relations.** The first functional area within institutional advancement is public relations. Through this department, an institution crafts messages for its various publics. Frequently the director of public relations serves as the institution’s chief spokesperson. The public relations arm of institutional advancement also cultivates and manages the university’s re-

lationships with members of the media, which may consist of being available to members of the media when they have questions about the institution or its activities or contacting the media to get placement of stories. Many public relations offices facilitate media relationships by maintaining a list of faculty members who are experts on specific subject areas and having them available for media interviews when comments are needed for news stories.

In some public relations offices, there is an individual or a team that is responsible for planning special events for the institution. These may include commencement events or other large-scale special occasions that will increase the public visibility of the institution.

**Publications.** The second functional area within institutional advancement is publications. Publications offices are responsible for all print materials used by the institution. Within publications offices are graphic designers, proofreaders, and photographers.

Typically, an institution’s publications office is responsible for the design and production of the alumni magazine. This is frequently the largest and most visible of the publications produced by an institution. Depending upon the size of a college or university, individual colleges, schools, or departments may have their own magazines or newsletters. The design and maintenance of the college or university web pages also falls to members of the publications staff.

Publications departments are also responsible for the consistency of an institution’s print image and the proper use of university symbols. This is frequently accomplished by requiring internal production of all print pieces or by subjecting anything that has been designed outside of the publications office to scrutiny by a member of the publications staff. This review, coupled with the office having the ability to stop the printing of a publication that does not conform to university standards, allows for a tight maintenance of the institution’s graphic identity.

**Alumni relations.** The alumni relations office is primarily responsible for maintaining ties between graduates of a higher education institution and their alma maters. This is typically accomplished through events held for alumni either at the university or college or by scheduling programs away from campus. For example, a college or university alumni office may be responsible for organizing homecoming festivities for alumni at the institution.

The activities of the alumni office are frequently directed by an alumni board. At some colleges and universities, the board has hiring and firing authority over the director of alumni relations. The board helps to direct the activities of the association and to shape the programming for alumni. Two different types of alumni associations exist in higher education. The first is a dues-based organization that requires graduates to join the association by paying yearly dues (or perhaps by making a certain level of gift to the annual fund). The other type is an alumni association to which all alumni become members automatically without any required contribution or dues payment.

The office of alumni relations is also responsible for maintaining a chapter or club system for the institution. These clubs or chapters are separate organizations located in cities in which there are large concentrations of alumni. Frequently these organizations have their own officers and may have responsibility for their own finances.

Alumni offices also design programs targeted to specific alumni affinity groups, for example, a program designed for graduates of an institution who were members of a fraternity or sorority. These programs help maintain the bond created by the extracurricular activities alumni participated in while they were students on campus.

**Development.** The development office frequently contains the largest number of positions within an institutional advancement division. The office's organization may be centralized, decentralized, or a hybrid of these two. Organization is often dependent upon the size of the institution. In a centralized environment, all individuals responsible for fund-raising are housed in one physical location and report either directly or indirectly to the same person. This type of organization is better suited to smaller colleges and universities. In a decentralized environment, development officers are spread out among the various academic units of the institution. The fund-raisers in these schools and colleges report to the deans of their respective areas. This organization is often found in larger institutions. The hybrid model mixes the centralized and decentralized, with development officers physically located in a college or school, yet reporting to both a dean and a chief development officer.

Within a development office, there are a number of distinct areas of operation, each of which are discussed in detail.

**Annual fund.** The primary responsibility of the annual fund of a college or university is to ask graduates of the institution for small gifts that are given yearly. Annual fund gifts can range from one dollar to ten thousand dollars or more. These gifts are solicited primarily through the mail or by telephone. Occasionally, high-end annual fund gifts are solicited in person. Annual fund gifts can be either restricted (to be used only for a specific purpose) or unrestricted (to be used however the institution deems appropriate).

The annual fund is one of the most important components of a mature development program. Not only does it provide annual operating dollars for the institution's budget, it also helps to identify individuals who are interested in making gifts to the institution and who may want to make larger gifts in the future.

The annual fund office may also help to organize a senior class gift program through which graduating seniors make a pledge (either for a single year or over a number of years) to donate for a specific project identified by the graduating class. Many annual funds are also responsible for a parents fund, through which parents of current and former students are asked for gifts.

Annual fund offices are also the coordinators of matching gift solicitations. Some companies have standing agreements with their employees that the company will match any gifts made to a charitable organization. Annual fund officers craft specific solicitations to their graduates who are employees of those companies, asking them for gifts and reminding them that their donation comes with additional funds for the institution.

**Major gifts.** Major gifts are larger than annual gifts. They frequently are composed of a pledge, on which payments are spread over a number of years. Because of the large amounts of money involved in major gift solicitations, individuals who have long-standing relationships with the potential donors usually solicit them.

Major gift prospects are identified in many ways. They may be annual fund donors who have a history of providing support to the institution. Other individuals are identified because they have a level of wealth that would allow them to make a major gift to the institution and they have an interest in an area which the institution is seeking support.

Once major gift prospects have been identified, they are assigned either to a development officer or

to an individual who is engaged in major gifts fundraising. At most institutions the president has a list of individuals with whom close relationships must be developed or already exist. Other individuals who are involved in the major gift process include deans, some department chairs, and select faculty members and administrators.

These individuals bring their prospects closer to the institution by involving them in programs, inviting them to serve on advisory committees or on boards of trustees. Throughout this process, the prospect's interests emerge. Once the development officer has an idea of what sort of gift the prospect might make, a team is assembled of individuals who are closest to the prospect and who are best suited to ask the prospect to consider the donation. The actual solicitation is usually done face-to-face. Actually getting a definitive "yes" to a major gift solicitation may take a considerable amount of negotiation. The prospective donor may want to change how the gift would be used, the amount of the gift, or other specifics related to the request.

**Capital campaigns.** Capital campaigns are intensive efforts to raise a significant amount of money for an institution over a limited period of time in order to increase the institution's capital assets, either physical (through the erection of buildings, etc.) or financial (by increasing the institution's endowment). Many institutions also conduct comprehensive campaigns that raise operating funds in addition to capital funds.

Campaigns generally progress in four phases: the planning phase, the silent phase, the public phase, and the accounting phase. In the planning phase, the institution determines what dollar amount could realistically be raised over the period of the campaign. Additionally, the organization ascertains what volunteers will be recruited to help with the campaign, how many staff members will be needed to meet the goal, and how many individuals will be identified as campaign prospects. Colleges and universities may employ outside counsel to assist with this phase of the campaign.

In the silent phase, individuals who have been cultivated are solicited for campaign gifts. The institution's prospects who have been cultivated the most and have the capacity to make the largest gifts are usually solicited first. While active requests are being made during this phase, only individuals who are very close to the institution would be aware that a

campaign is in progress. Most institutions attempt to raise between one-half to two-thirds of the dollar total in this phase of the campaign. Doing so reduces the risk that the institution will not make the campaign goal in the next phase.

In the public phase of a campaign, the institution lets all of its constituencies know that a campaign is in progress, what the dollar goal for the campaign is, the total amount of money raised to date, and the date selected for the end of the campaign. This is usually done in conjunction with a special event for those who have been involved in the campaign and those who will be asked to be major contributors. Additionally, press conferences may be held for the media and if building projects are involved, official groundbreaking ceremonies may be conducted. During the public phase, individuals who have been cultivated through the silent phase are solicited. Finally, in the closing months of the campaign, a large-scale mailing is frequently conducted so that individuals who cannot contribute at a major gift level have the opportunity to participate and feel included.

The final phase of a campaign is the accounting phase. During this phase staff members who were brought on board specifically for the campaign may be let go, the institution tries to collect unfulfilled pledges, and the plans are made for either restarting the campaign cycle or returning to noncampaign operations.

**Planned giving.** Planned giving is the term given to any gift which involves a transfer of assets other than cash. These gifts are planned because they frequently have tax consequences or involve other structuring. The most familiar of all planned gifts is the bequest, where an individual leaves either a portion or all of their estates to a higher education institution after their death. Also quite common is the transfer of stock or real estate to the institution. However, many other vehicles exist for potential donors to make planned gifts, including those that create a lifetime income for the donor or a beneficiary.

Planned giving officers are often attorneys familiar with tax and estate law. While other development officers may have the ability to discuss planned giving options with prospects, many institutions have planned giving officers on staff to deal with the details of a structured gift.

**Prospect research.** Within the development department, identification of individuals who have the

ability to make major gifts to the institution falls to the prospect research department. Once these prospects have been identified, prospect research, through the use of print and electronic resources, develops dossiers on each individual. These profiles include information on the prospect's family background, interests, previous giving history for the institution and other institutions, a rating indicating for how much the prospect should be solicited, and a cultivation and solicitation strategy based upon the office's research.

**Advancement records.** The advancement records area is responsible for all gifts and pledges that come into the university. Specifically, advancement records documents donations and pledges electronically for each donor in the university's alumni and donor record system. Address information is kept on each alumnus or alumna, parent, and friend of the institution. Additionally, information that is frequently attached to each address record can include previous gifts and pledges, interests, names of family members, year of graduation and degree type (if a graduate), and other biographical information.

Donor records also generates receipts for those making gifts and may also generate acknowledgment letters letting donors know that their gifts were received and that the college or university appreciates the gift.

Advancement records also sees that daily receipts are deposited into the university accounts and that restricted gifts are posted to the correct funds. At the end of each month this office also generates income statements breaking down gift totals in many categories, and may provide year-to-date totals along with comparisons to previous years.

**Corporate and foundation relations.** Depending upon the size of the development operation, there may be a department of corporate and foundation relations or an individual who has the same responsibility. Because of the intense writing required for submitting a foundation proposal, individuals in corporate and foundation relations spend much of their time writing grant proposals. In smaller offices, the responsibility for developing relationships with foundations and corporations falls to individual development officers.

**Stewardship.** Once an individual, foundation, or corporation makes a gift to an institution, the responsibility of maintaining the relationship falls to the stewardship office (in addition to those involved

in the solicitation). Being good stewards of a gift includes providing donors with annual reports detailing how their gifts were used and which individuals benefited from the generosity. Additionally, the stewardship office maintains the record of the things to which pledges are designated and to whom the end of the year reports should be sent. The institution also has a responsibility to the donor that it will be a good steward of the donated funds and that they will be used according to the donor's wishes. Finally, the process of thanking a donor is critical to the development process because individuals who have made gifts in the past are the best prospects for the future.

TIMOTHY C. CABONI

## INSTITUTIONAL RESEARCH IN HIGHER EDUCATION

---

Institutional research is research activity carried out in colleges and universities to collect and analyze data concerning students, faculty, staff, and other educational facilities. The primary purpose of institutional research is to promote institutional effectiveness. It does this by providing information for institutional planning, policy formation, and decision-making within the college or university.

Largely as a result of the significant role institutional research plays in keeping track of the performance of the institution, higher educational institutions have created a special office, called the Office of Institutional Research. This office usually is placed in the higher hierarchy of the administrative units of the institution.

The size of the Office of Institutional Research depends upon the educational programs and services of the institution. The Office of Institutional Research for a larger higher educational institution usually reports to the provost. In a smaller institution, the Office of Institutional Research reports to the vice-president for academic affairs. No matter

the size or the organizational structure, all institutional research offices exist to provide information for institutional planning, policy formation and implementation, and decision-making.

### Tasks Performed

The primary role of the Office of Institutional Research in the institutional setup is to collect, analyze, and interpret institutional data on students, faculty, educational programs, and administrative and support services so as to provide accurate information to support planning and decision making activities within the educational institution.

It is the responsibility of the Office of Institutional Research to compile data on course enrollments every semester or quarter. The course enrollment data shows the distribution and major of students enrolled in each department and course. With this knowledge, the institution is in a better position to discontinue a program that is not attracting students. It also allows the administration to allocate more funds to programs that are attractive to students. This helps the institution to utilize its resources for efficient organization and management.

The Office of Institutional Research gathers and maintains data on student retention in terms of gender, race, age, geographic location, and test scores, and shares this information with the student admission office. Student retention is the ability of an educational institution to recruit and retain a student until the student graduates from that institution. A higher retention rate is a reflection of the effectiveness of the programs the institution offers students. Any higher educational institution with a higher retention rate takes delight in displaying this information in a brochure to showcase the effectiveness of their educational programs to prospective students and the general public. Therefore, at the end of every term, the Office of Institutional Research looks into the student population and provides the admissions office data that it needs for its recruitment and retention efforts.

Apart from recruitment and retention records, the Office of Institutional Research keeps track of degrees granted by every department of the institution. In particular, it identifies students who graduate with certificate, associate, bachelor, master, or doctoral degrees. This information is often compiled in terms of discipline or area of study, gender, race, age, or number of years the student studied to com-

plete the program. Information on graduation records is essential because it reflects the number of students who are able to successfully complete their studies in the institution. It also makes the administration aware of educational programs or fields of study that are or are not attracting and maintaining students through graduation.

Of primary importance to the work of the Office of Institutional Research is enrollment management. Often the Office of Institutional Research collaborates with the Student Affairs Office to engage in enrollment and retention management activities to find out how best to retain students in their programs. As a result of such collaborative activities, many colleges and universities have established special programs such as scholarships or grants to attract students who are under-represented in their institutions.

The Office of Institutional Research maintains a plethora of data relating to the financial status of the institution. It shares this information with the Finance Office, which in turn uses this data to conveniently determine and allocate funds for such institutional programs as faculty development, instructional materials, research, work-study students, and faculty and staff salary.

The Office of Institutional Research at the end of every term or year also examines and evaluates the performance of its program faculty. It examines such variables as faculty publications, research, and general contributions to the academic community. Through student evaluations of faculty at the end of every semester or quarter, the Office of Institutional Research is able to document the performance of its program faculty. Students evaluate faculty on such items as grading procedures, knowledge of content, pace of instruction, and respect for student views in the learning process. Assessment of program faculty is done essentially for the purposes of faculty development, retention, recruitment, and promotion.

Institutional research offices produce what is called a "fact book" about the institution. The fact book presents, at a glance, general information and data concerning academic programs, students, degrees conferred, faculty and staff, finances, institutional facilities such as library holdings, and research activities by the institution. The fact book serves as a window to the institution. It provides a summary of the achievements, programs, progress, and facilities of the institution. The Office of Institutional Re-

search takes great pains to prepare it because it gives the public a taste of what awaits students who decide to enroll in that institution.

By the nature of its work, the Office of Institutional Research provides vital data for internal and external surveys and reports. It compiles data for institutional self-study and accreditation by external agencies. Institutional self-study is an attempt that every institution makes to evaluate the effectiveness of its programs and activities. It reveals strengths and weaknesses in the institution. It is done with the aim of making sure the institution is working to accomplish its educational mission. Accreditation is also of significant importance to all colleges and universities because it is an indication that the academic programs of the institution conform to federal or state established standards. Accreditation acts as a benchmark for institutional effectiveness and gives the institution a higher academic ranking.

Institutional research offices also serve as contact points for reports and surveys requested from governmental and nongovernmental agencies such as the United States Department of Education. These agencies may require this data to compile reports on issues such as affirmative action and college guidebooks.

The smooth functioning of educational institutions, like any other organization, depends upon the ability of the institution to identify problems and find appropriate solutions for them. Without this ability, no organization can function effectively. The Office of Institutional Research conducts research into specific problems facing the institution. The research may be focused on such areas as student attrition or retention rate, faculty turnover, or student diversity. It shares the research findings with other departments in the institution. Many of the research activities may be carried out annually or otherwise as needed. The Office of Institutional Research carries out such research with the sole purpose of finding solutions to challenges the institution might encounter in the future. At other times, the research may be conducted with the aim of finding a solution to an existing problem or adding a new program to the curriculum of the institution.

Facilities in educational institutions have the potential effect of attracting students to that institution. Therefore, the Office of Institutional Research compiles data on educational facilities in the institution for organizational purposes. The data on facili-

ties indicates the number of classrooms, teaching laboratories, meeting or conference rooms, offices, libraries, media and technology, space utilization, housing, and vehicles. In addition to compiling the data, the Office of Institutional Research presents an annual report on facility utilization in the institution.

As in all organizations, educational institutions need common guidelines and procedures for implementing policies. The Office of Institutional Research defines common data sets used by the college or university to establish policies for administrative procedures. It is the responsibility of this office to define a part-time student or a part-time faculty member, as well as the concepts of doctoral degree, bachelor's degree, master's degree, a commuter, credit hour, contact hour, credit, or grade point average. The common data set is essential to the smooth administration of the institution because it helps the institution to develop rules, regulations, and policies to guide staff, student, and faculty conduct in the service of the institution.

## OVERVIEW

Instructional-design theory provides guidance on how to help people learn (or develop) in different situations and under different conditions. This guidance includes what to teach and how to teach it. To do this, instructional-design theory must take into account both methods and situations. Just as a carpenter uses different tools for different situations, so do instructional design theories offer instructional designers and teachers different tools for facilitating learning in different situations.

### Elements of Instructional-Design Theory

Elements of instructional-design theory include instructional outcomes, conditions, methods, and values. Instructional values are an individual's or group's philosophy or beliefs about instruction. Instructional design theories ought to inform possible users (teachers and instructional designers) of the values about learning and instruction with which the theory was constructed, for they are the values that users and students must hold in order for the theory to work well.

Instructional outcomes include both results that are intentional and those that are incidental. Outcomes include the instruction's effectiveness, efficiency, and appeal. Instructional outcomes should not be confused with learning outcomes. Instructional outcomes focus on the degree of success in attaining the desired learning outcomes (the effectiveness of instruction) but also include the efficiency and appeal of the instruction.

Instructional conditions are factors beyond the influence of the instructional designer that impact upon the effects of the methods of instruction. Conditions may include the nature of what is being learned (the content), the learner, the learning environment, and the instructional development constraints (e.g., time and money). Instructional-design theory, in attempting to provide guidance for people to help others learn, ought to state explicitly the conditions under which different methods should and should not be used.

Instructional methods are the “how to” for facilitating human learning. They are the elements of guidelines that inform designers and teachers what to do to help students learn. They can be very general, such as “provide opportunities for practice,” or they can be broken down into much more detailed specifications, such as (for learning concept classifi-

cation) presenting previously unencountered examples and nonexamples of the concept in random order and asking the learner to identify those that are examples of the concept.

Instructional methods are situational rather than universal. This means that there are values, desired instructional outcomes, and instructional conditions (collectively referred to as instructional situations) in any context that influence whether or not a given instructional method should be used. Hence, instructional-design theory should specify the values, outcomes, and conditions for which each method should be used. Also, instructional methods are probabilistic rather than deterministic. That is, their use can only increase the probability that the desired outcomes will be attained.

### Differences

Instructional design theories differ most importantly by the methods they offer. But the methods differ because of differences in the outcomes, values, and conditions for which they are intended.

For example, regarding instructional outcomes, some theories may focus more on effectiveness of the instruction, while others may focus more on appeal or efficiency. Also, regarding learning outcomes, different instructional theories can promote very different kinds of learning: from memorization to deep understandings or higher-order thinking and self-regulatory skills; from cognitive goals to such affective goals as emotional and social development.

Instructional values may differ, and they lead one to select different goals and different methods to attain those goals. Traditional instruction systems design (ISD), “a systematic approach to the planning and development of a means to meet instructional needs and goals” (Briggs, p. xxi), specifies that goals should be selected based on an assessment of learners' needs. However, in 1999 Charles Reigeluth proposed that users also consider teachers' and learners' values about goals. Furthermore, designers have tried to rely on experimental research to determine which methods are best for any given situation. Reigeluth countered that users also consider teachers' and learners' values about methods. If a teacher does not value learner-centered methods, then forcing the teacher to use them is not likely to ensure success.

Instructional conditions may also differ across instructional design theories. First, the nature of

what is to be learned (the content) may differ. For example, some theories, such as those of David Perkins and Chris Unger, focus on deep understandings, which are taught differently than skills. Second, the nature of the learner may differ, including prior knowledge, skills, understandings, motivation to learn, and learning strategies. Third, the nature of the learning environment may differ. And finally, different instructional design theories may be intended for different constraints on instructional development (time and money). In essence, different instructional theories use different methods to attain different outcomes under different conditions and based on different values.

### Major Trends

Two major trends in the field of instructional-design theory are apparent: the increasing predominance of an information-age paradigm of theories and the broadening of the kinds of learning and human development addressed by instructional theorists.

**Information-age paradigm.** Scholars, such as Bernie Trilling and Paul Hood, are increasingly drawing attention to the need for an attainment-based, “learning-focused paradigm” of instruction to meet learners’ new educational needs in the information age, compared to the time-based, “sorting-focused paradigm” of the industrial age. Reigeluth (1999) distinguishes between the industrial and information ages with certain “key markers” (see Table 1).

In the early twenty-first century there is a growing recognition that the current system of education is beginning to fail society, not in its ability to attain traditional goals, but in its ability to provide what is increasingly needed in the emerging information society. There has begun a societal transition in which the complexity of human activity systems is growing dramatically, and learning has become the “indispensable investment” according to the National Commission on Excellence in Education 1983 report, *A Nation at Risk*. This has important implications for both what should be taught and how it should be taught.

### Broadening the scope of instructional theory.

Much of the work that has been done in relation to and with instructional-design theory has been focused on teaching and learning procedural tasks, which are performed by following sets of defined mental or physical steps that were predominant in the industrial age. However, educational and corpo-

rate settings increasingly require people to solve problems in ill-structured and complex domains—problems for which there is not a clear solution or just one way of doing things. These “heuristic” tasks entail the use of causal models and “rules of thumb,” along with other kinds of typically tacit knowledge that require different methods of instruction. This heuristic knowledge because of its nature often takes years for experts to develop through trial and error, if at all. Therefore, it would be valuable for schools and corporations to be able to teach it well.

Several new methods and tools are designed to assist learners with real-world problem solving, including just-in-time instruction and electronic performance support systems (EPSSs). However, they do not provide the appropriate amount or types of support for learning this usually tacit heuristic knowledge. Only toward the close of the twentieth century have instructional design theorists seriously attempted to address this complex type of learning. Promising work has been done in the area of problem-based learning by such theorists as John D. Bransford and colleagues, David Jonassen, Laurie Nelson, and Roger Schank.

Other current areas of promising instructional-design theory include collaborative learning, self-regulated learning, and such affective areas as emotional development and social development.

Peter Senge highlighted the importance of the “learning organization,” which he defined as “an organization that is continually expanding its capacity to create its future” (p.14) through the use of five disciplines: systems thinking, personal mastery, mental models, building shared vision, and team learning. A challenge for instructional design theorists is to develop comprehensive theories that foster such organizational learning.

The preceding offers only a sampling of areas in which instructional-design theory is currently being developed. Due to the nature of human learning, there exist many more domains of instructional guidance that require greater study.

### Controversial Issues

Three controversial or problematic issues are discussed below: (1) Should instructional design theories be “theoretically pure” or eclectic? (2) Are traditional research methods appropriate for advancing instructional design theories, or is a different paradigm of research needed? (3) Should

instructional-design theories be strictly “local” in scope, or should they generalize across settings?

**Eclecticism versus purism.** Some scholars, such as Anne K. Bednar and colleagues, argue that an instructional-design theory should be “theoretically pure” in that it should follow a set of assumptions from a single theoretical perspective, such as constructivism or behaviorism. Others, such as Peggy Ertmer and Timothy Newby, believe that such is true for descriptive theories, but that design theories, with their goal orientation, should draw on all useful methods for accomplishing the stated goals. For example, a behaviorist perspective would offer the method of drill and practice to help learners remember important information, whereas a cognitive perspective would offer the use of mnemonics to relate the new information to meaningful information. Perhaps there are some situations where good mnemonics cannot be developed, in which case drill and practice would be suggested by a design theory. Is it unwise for a teacher to draw on both kinds of methods because they hail from different theoretical perspectives? This issue is particularly important because it greatly influences the nature of an instructional theory.

**Traditional versus new research methods.** Many scholars advocate experimental and/or descriptive case studies or other kinds of descriptive research to advance our knowledge about design theories. Other theorists, such as James Greeno and colleagues, advocate new forms of research, such as “design experiments” and “formative research” (Reigeluth and Frick). “Design experiments” is the term Greeno, Allan Collins, and Lauren Resnick have come to use to refer to educators collaborating to analyze and design changes in institutional practice. “Formative research” is a form of research developed by Charles Reigeluth and Theodore Frick that is meant to help improve instructional-design theory. In an analysis of this issue, Glenn Snelbecker argued in 1974 that descriptive theories in the field are evaluated by how truthfully they describe why learning occurs, whereas instructional theories are evaluated by how useful their methods are for attaining their stated goals. Given this very different orientation toward usefulness rather than truthfulness, Reigeluth (1999) has proposed that the major concern in research on design theory should be “preferability” (whether or not a given method is more useful than the alternatives), rather than “validity” (whether or not the description is truthful). He has also suggested that the

SOURCE: Reigeluth, Charles M. 1999. “What Is Instructional-Design Theory and How Is It Changing?” In *Instructional-Design Theories and Models, Vol. II: A New Paradigm of Instructional Theory*, ed. Charles M. Reigeluth. Mahwah, NJ: Erlbaum. Page 17. Reprinted with permission.

focus for research on a design theory should be to improve it rather than to prove it, because most of our methods of instruction are not nearly as successful as we need them to be. There is also clearly a role for descriptive research on instructional design theories, however. It is occasionally helpful to compare one method with another for a given situation, and descriptions of what a highly effective teacher or computer program does can be helpful for improving an instructional theory.

Although most researchers recognize that different research methods are useful for different purposes, perhaps there has not been enough emphasis on research to improve the preferability of instructional-design theories.

**Generalizable versus local knowledge.** Some scholars argue that instructional design theories should be “local” in scope because every situation is unique and methods that work well in one situation may not work well in another. Others believe that the purpose of an instructional-design theory is to generalize across situations—that if it loses this quality, it has little usefulness. Given that the standard for a design theory is usefulness rather than truthfulness, the issue may boil down to whether a highly local theory is more useful than a highly generalizable theory, or even whether a design theory that is intermediate between local and general may be the most useful.

There is another consideration that may enlighten this issue. Design theories are made up of not only methods, but also situations (values, desired outcomes, and conditions) that serve as a basis for deciding when to use each method. If a design theory offers different methods for different situations, the theory is at once both local and generalizable. It recognizes the unique needs of each situation but also offers methods for a wide range of situations. In this manner perhaps the profession can transcend “either-or” thinking and be both local and global.

### Further Directions

Instructional-design theory bridges the gap between descriptive theory and practice and offers powerful guidance for practitioners. It has the potential to spur tremendous improvements in practice, but it currently constitutes a minor percentage of scholarly efforts devoted to education. Partnering of researchers and practitioners to develop and improve more powerful instructional-design theories can provide valuable insights and improvements for more useful design theory to facilitate human learning and development.

## ANCHORED INSTRUCTION

*Anchored instruction* (AI) is an example of an approach to curriculum and instruction that provides opportunities for students to learn important content while attempting to understand and solve authentic problems that arise within particular disciplines. Other related approaches are case-based learning, which is used in law and business education, and problem-based learning, sometimes used in medical education. Another way of organizing instruction around problem solving is through project-based learning.

### The Problem of Inert Knowledge

In 1929 the English philosopher Alfred Whitehead identified a major problem in schools, namely the problem of *inert knowledge*. Inert knowledge is knowledge that can be recalled when people are explicitly prompted to remember it, but is not spontaneously used to solve problems even though it is relevant. A major goal of AI is to create learning environments that overcome the inert knowledge problem.

Research suggests that the degree to which knowledge remains inert is strongly affected by the way the information was learned initially. One factor contributing to the problem of inert knowledge is that traditional instruction too often consists of learning isolated facts and procedures. As a consequence, students do not learn when or how to use what they have learned. The knowledge is not organized in memory with information on the conditions under which to apply it. In AI students are provided with opportunities to solve realistic problems—called anchors—that help them learn when and how to apply knowledge.

### The Role of Prior Knowledge in Learning

Research indicates that learning is affected by the knowledge that people bring to the learning situation. Sometimes people’s prior knowledge of a situation enables them to understand with little effort the meaning and significance of new information. More typically, especially in the case of young learners, prior knowledge of the situation is limited and the learner is unable to make sense of new information and has difficulty discriminating important from less important aspects of the information. When learners lack sufficient prior knowledge, information is treated as facts to be memorized. Anchored instruction was developed to compensate for learners’ lack of experience and knowledge. Anchors consist of multimedia (e.g., video or audio with pictures) scenarios that are designed to improve learners’ understanding of the problems to be solved.

### Experience Being an Expert

Another major goal of AI is to help people learn the kinds of problems that experts in various areas encounter and to experience how experts identify, represent, and solve problems. The problems that experts encounter are more complex and open ended than the problems that students are asked to solve in school. Experts also assume greater autonomy than students in solving problems, including learning new skills and knowledge on an as-needed basis to solve problems. Anchors are designed to afford these kinds of experiences.

### An Example of AI: *The Adventures of Jasper Woodbury*

Some of the original work on AI was conducted in the domain of middle school mathematics by the Cognition and Technology Group at Vanderbilt. These efforts culminated in a series called *The Adventures of Jasper Woodbury*. *Jasper* consists of twelve anchors (on videodisc or CD-ROM) that are designed for students in grades five and up. To promote transfer of learning, multiple related anchors are available to provide extra practice on core concepts and problem schemas. Three anchors relate to each of the following topics: statistics and business planning, trip planning, geometry, and algebra. Each anchor contains a short (about fifteen minutes) story on video, which ends in a complex challenge. The adventures are like good detective novels, where all the data necessary to solve the adventure (plus additional solution-irrelevant data) are embedded in the story.

In *The Big Splash*, one of the anchors related to statistics and business planning, the main character is a junior high school student named Chris. Chris's school is having a Fun Fair to raise money to buy a new camera for the school TV station. Chris wants to set up a dunking booth at the fair. Students would buy tickets for the opportunity to try to dunk their teachers in a pool of water. Chris needs to develop a business plan to get his dunking booth project approved by the school and to obtain a loan from the school principal. The plan must include an estimate of revenue and expenses for the dunking booth and must meet constraints set by the principal with respect to the maximum amount of the loan and the requisite profit. The video story shows Chris collecting information for his business plan.

**Design principles.** *Jasper* anchors were designed according to a set of principles. Each is video based. Research indicates that video helps students, especially poor readers, comprehend problems better. Video is also motivating to students. Anchor problems are presented in story form, instead of expository form. Stories are used because they are easy to remember.

Anchors are not simply traditional word problems on video—they are more representative of problems that an expert might solve. They are complex; more than one solution is possible and many steps (and hours) are required to solve them. Traditional story problems explicitly present the problem to be solved (there is usually only a single problem) and the relevant data. Anchors use a generative format. Each story ends with a challenge and students must generate the problems to be solved. For example, in *The Big Splash* many different business plans can be generated, based on the information presented. There are several options for filling the dunking booth with water and each option differs in terms of cost, risk, and the amount of time required. The challenge also involves some important statistical concepts. Chris conducts a survey to collect information on whether students at his school would be interested in dunking a teacher and how much they would pay to do so. Data from the survey can be used to extrapolate an estimate of revenue for the whole school.

All of the data needed to solve each challenge is contained in the story; students revisit the videos on an as-needed basis to look for and record data. Some of the *Jasper* anchors also contain ideas for how to solve parts of the challenge. These are called embed-

ded teaching scenes. The embedded teaching scenes provide students with models for how to approach particular problems that may not be familiar to them.

### Perspective on Pedagogy

Anchored instruction is consistent with a class of instructional theories known as constructivist theories. Constructivism rejects the idea that students learn by passively “soaking up” knowledge that is transmitted to them by teachers or others. Instead they assume students learn more if the teacher engages them in activities, such as defining problems, clarifying misunderstandings, generating solutions, and so forth, instead of lecturing or “telling” students how to solve problems.

Because of their complexity, anchors are effective for use in cooperative learning groups. Depending on the skill level of the class, teachers may structure the small-group work in different ways. If the class is quite skilled, the teacher may simply ask students to solve the challenge posed at the end of the video. For other classes, the teacher may ask groups to work and report on some part of the challenge or may focus the task even more by asking groups to brainstorm and report on ideas for how to solve a part of the challenge. An important aspect of AI pedagogy relates to how teachers mediate group problem solving. Because a goal of AI is for students to be as intellectually autonomous as possible in solving the anchors, it is important for teachers to interact with student in ways that do not usurp this autonomy.

### Research on Anchored Instruction

One of the largest studies on AI involved a field implementation of four anchors from *The Adventures of Jasper Woodbury*. These anchors were used over the course of a school year by teachers in seventeen classes in seven states in the southeastern United States. In the majority of the classes, the *Jasper* instruction took the place of the students' regular mathematics instruction. Ten comparison classes that were matched on key demographic variables, including socioeconomic status, location, gender, minority representation, and mathematical achievement, were included in research. All students were administered a series of tests at the beginning and end of the school year. One test examined students' word-problem-solving skills. In spite of the fact that *Jasper* students had not received additional practice

on written word problems, they performed significantly better than comparison students at the end of the school year. In this way, *Jasper* students were able to transfer the skills they had acquired in the context of solving *Jasper* problems to written word problems.

Students were also administered a series of tests designed to assess their abilities to define and formulate problems. They were given complex story problems in written form and were asked to identify goals that would need to be addressed to solve these problems. They were also shown mathematical formulations and were asked to identify the goal that each formula would satisfy. These aspects of problem solving are unique to the *Jasper* anchors and are not part of traditional problem-solving instruction. As expected, *Jasper* students performed better than comparison students on the posttest.

Finally, self-report measures of students' attitudes were collected. *Jasper* students showed more positive change relative to comparison students in five areas: they showed a reduction in mathematics anxiety, an increase in their beliefs about their ability to perform successfully in mathematics, greater interest in mathematics, greater interest in solving complex problems, and they thought mathematics was more useful in solving problems from everyday life.

The goal of anchored instruction is to help students learn information such that it can be remembered later on and flexibly applied to solve problems. Relevant research suggests that pedagogical approaches such as anchored instruction can enhance students' complex problem solving skills and positive attitudes towards learning.

## CASE-BASED REASONING

Case-based reasoning (CBR) is a kind of analogical reasoning that focuses on reasoning based on previous experience. A previous experience can play several roles, such as:

- suggesting a solution to a new problem or a way of interpreting a situation,
- warning of a problem that will arise, or
- allowing the potential effects of a proposed solution to be predicted.

These are the types of inference necessary for addressing the kinds of ill-defined or complex problems that occur every day in the workplace, at school, and at home. One might, for example, create a new recipe by adapting one made previously. To understand why someone's boss reacted a certain way, one might remember a situation when his own boss reacted similarly. People might persuade themselves that a strategic plan will work based on the similarities between their company's situation and that of another company that is progressing in a similar way.

### Cognitive Foundations

Case-based reasoning views analogical reasoning as the centerpiece of the ability to function as human beings. It posits that the most natural and powerful learning strategies are the automatic ones that situate learning in real-world experience. Previous experience and knowledge are naturally brought to bear in interpreting new situations, trying to explain when things are not as expected (based on the predictions made by previous experiences and knowledge), drawing conclusions based on explanations and on similarities between situations, and anticipating when some new thing just learned might be applicable. To do these things automatically there must be some internal processes and representations that allow a new experience to call up similar ones from memory.

Key to such reasoning is a memory that can access the right experiences (cases) at the times they

are needed (the indexing problem). Case-based reasoning identifies two sets of procedures that allow such recognition to happen. First, at insertion (encoding) time, while engaging in an experience, a reasoner interprets the situation and identifies at least some of the lessons it can teach and when those lessons might most productively be applied. The case is labeled according to its applicability conditions, that is, the circumstances in which it ought to be retrieved. The most discriminating labels on a case will be derived by a reasoner who has taken the time and effort, and who has the background knowledge, to carefully analyze a case's potential applicability. Second, at retrieval time, while engaging in a new situation, a reasoner uses his or her current goals and understanding of the new situation as a probe into memory, looking for cases that are usefully similar to the new one. The extent to which a reasoner is willing or able to interpret the new situation determines the quality of the probe into memory. An uninterpreted situation is likely to yield poorer access to the contents of memory than is one that is more embellished. The more creative a reasoner is at interpreting a situation, the more likely he or she is to find relevant knowledge and experience to use in reasoning about it.

Learning, in the CBR paradigm, means extending one's knowledge by interpreting new experiences and incorporating them into memory, by reinterpreting and reindexing old experiences to make them more usable and accessible, and by abstracting out generalizations over a set of experiences. Interpreting an experience means creating an explanation that connects one's goals and actions with resulting outcomes. Such learning depends heavily on the reasoner's ability to create such explanations, suggesting that the ability and need to explain are key to promoting learning.

Case-based reasoning thus gives failure a central role in promoting learning because failure promotes a need to explain. When the reasoner's expectations fail, he or she is alerted that his or her knowledge or reasoning is deficient. When such failures happen in the context of attempting to achieve a personally meaningful goal, the reasoner wants to explain so that he or she can be more successful. Crucial to recognizing and interpreting failure is useful feedback from the world. A reasoner who is connected to the world will be able to evaluate his or her solutions with respect to what results from them, allowing in-

dexing that discriminates usability of old cases and allowing good judgments later about reuse.

Because one's first explanations might not be complete or accurate, iterative refinement is central to CBR. Explanations (and thus, knowledge) are revised and refined over time. People explain and index any experience the best they can at the time, and later on, when a similar situation comes up, remember and try to apply what was learned from the past experience. The ability to accurately explain develops over time through noticing similarities and differences across diverse situations, suggesting that a variety of experiences with a concept or skill—personal ones and vicarious ones—are necessary to learn it to its full complexity.

### Implications for Promoting Learning

Case-based reasoning suggests five important facilitators for learning effectively from experience:

1. having the kinds of experiences that afford learning what needs to be learned;
2. interpreting those experiences so as to recognize what can be learned from them, to draw connections between their parts so as to transform them into useful cases, and to extract lessons that might be applied elsewhere;
3. anticipating the usefulness of those extracted lessons so as to be able to develop indexes for these cases that will allow their applicability to be recognized in the future;
4. applying what one is learning and experiencing failure of one's conceptions to work as expected, explaining those failures, and trying again (iteration); and
5. learning to use cases effectively to reason.

Case-based reasoning suggests that the easiest kinds of experiences to learn from are those that afford concrete, authentic, and timely feedback, so that learners have the opportunity to confront their conceptions and identify what they still need to learn. It also suggests that learners be given the opportunity to iteratively move toward increasingly better development of the skills and concepts they are learning so as to experience them in a range of situations and under a variety of conditions, and that, with each iteration, they have a chance to explain things that did not go exactly as expected and identify what else they need to learn. According to CBR,

the iterative cycle of applying what is known, interpreting feedback, explaining results, and revising memory explains how expertise is developed and how an expert uses personal experiences and those of others to reason and learn.

### Designing Instruction

Case-based reasoning makes two kinds of suggestions about designing instruction. First it suggests ways of orchestrating and sequencing classroom activities, including the roles teachers and peers can play in that orchestration and ways of integrating hands-on activities, software tools, and reflection. Second it suggests several kinds of software tools for scaffolding and enhancing reasoning and for promoting productive kinds of reflection.

**Design of learning environments.** Case-based reasoning suggests a style of education in which students learn by engaging in problem solving and other activities that motivate the need to learn and that give students a chance to apply what is being learned in ways that afford real feedback. In such an environment students might engage in solving a series of real-world problems (e.g., managing erosion, planning for a tunnel, designing locker organizers) requiring identification of issues that need resolution and knowledge that needs to be learned to address those issues; exploration or investigation or experimentation to learn the needed knowledge; application of that knowledge to solve the problem; and generation and assessment of a solution. Thinking about the problem they are trying to solve should help learners identify what they need to learn; they should have opportunities to learn those things; and they should get to apply what they are learning over and over again, with help along the way aimed at allowing them to successfully solve the problem and successfully learn the targeted knowledge and skills. Two approaches to the design of full learning environments have come from CBR. Roger C. Schank's group at Northwestern University's Institute for the Learning Sciences proposed the notion of a goal-based scenario as a fully automated learning environment. Janet L. Kolodner's group at Georgia Institute of Technology proposes the notion of their trademarked Learning by Design, a way of orchestrating a classroom for combined learning of content and important skills.

**Goal-based scenarios (GBS).** A goal-based scenario is a learning environment that places students in a situation where they have to achieve some inter-

esting goal that requires them to learn targeted knowledge and skills. In *Advise the President*, for example, students play the role of advisers to the president in dealing with a hostage situation in a foreign land, in the process learning about several hostage-taking events, which have happened in history, and also learning some foreign policy. In *Sickle-Cell Counselor* students advise couples about their risk of having children with sickle-cell anemia, in the process learning about genetics in the context of sickle-cell disease. Using *Broadcast News* students put together a news story, in the process learning both history and writing skills. Students learn about history or genetics or writing because they need to learn those things to successfully achieve the challenge set for them. The trick is to design challenges that both engage the students and focus them on whatever content and skills they should be learning.

The student engaged in a goal-based scenario is provided with a case library of videos of experts telling their stories, strategies, and perspectives, which might help them with their task. When they reach an impasse in achieving their goal, they ask a question of the case library, and an appropriate video is retrieved and shown. Sometimes a story will suggest a topic they should learn more about or a skill they need to learn; other times it will tell how that expert dealt with some difficult issue the student is addressing. Based on suggestions made by the case library students move forward with their task—choosing a policy to recommend to the president, choosing a blood test, making recommendations to couples about whether or not they should have children, or deciding how to refer to a leader. The software takes on an additional role to clearly inform students when they have failed at their task. The case library can be consulted again, this time to help with explaining and recovering from a failure.

***Learning by Design.*** Learning by Design is a project-based inquiry approach to middle school science, which uses design challenges as compelling contexts for learning science concepts and skills. Design challenges provide opportunities for engaging in and learning complex cognitive, social, practical, and communication skills. For example students design miniature vehicles and their propulsion systems to learn about forces, motion, and Newton's laws; and ways of managing the erosion near a basketball court to learn about erosion and accretion, erosion management, and the relationship between people and the environment.

Learning by Design's curriculum units are centered on the design and construction of working devices or models that illustrate physical phenomena. Learning by Design's focus on design challenges comes from CBR's suggestion that learning requires impasses and expectation failures. Designing, building, and testing working devices provides the kinds of failure experiences and feedback that promote good learning as well as opportunities for trying again to achieve the challenge based on what's been newly learned.

Case-based learning purports that learning from experience requires reflecting on one's experiences in ways that will allow learners to derive well-articulated cases from their experiences and insert them well into their own memories. Learning by Design includes integration of classroom "rituals" that promote such reflection. "Poster sessions" provide a venue for reporting on and discussing investigative results and procedures. "Pin-up sessions" give small groups the opportunity to share their plans with the whole class and hear other students' ideas. "Gallery walks" provide a venue for presenting one's designs in progress to the rest of the class and explaining why one's device behaves the way it does. Each provides opportunities for students to publicly present the way they engaged in important science skills, to see how others have engaged in those skills, and to discuss the ins and outs of the skills being practiced. Preparing for presentations requires doing the kinds of reflection on their activities that CBR suggests will lead to lasting learning.

Successfully engaging in design and investigative activities and in reflecting on those activities in ways that lead to productive learning requires help, and in Learning by Design, that help is distributed among the teacher, peers, cases, software, and paper-and-pencil tools. Cases that are read as part of the investigation or during design planning help students identify what they need to learn more about and give them ideas for their designs. Paper-and-pencil design diary pages help them keep track of decisions they make and data they collect while designing and testing so that they will be able to remember and reconstruct their experiences. SMILE's (Supportive Multi-User Interactive Learning Environment) Design Discussions help students plan investigative activities, summarize investigative experiences, justify design decisions, and explain design experiences, and its Lessons Learned helps them reflect back on a full design experience (several

weeks long) and articulate what they've learned. The tools act as resources to help students create cases for others to use, help students keep track of what they have been doing, and help students reflect on their experiences and turn them into cases in their own memories. Learning by Design's classroom rituals get students and teachers involved in sharing and discussing experiences, providing advice, and abstracting across the experiences of different groups in a class.

**Design of instructional tools.** Case-based reasoning suggests three types of software tools for promoting learning: (1) case libraries as a resource; (2) supports for reflection; and (3) realistic simulation and modeling environments.

**Case libraries as a resource.** The most common place where CBR has influenced learning tools is in the creation of case libraries. A case library offers the opportunity for students to learn from others' experiences. Case libraries as a resource can offer a variety of different kinds of information of value to learners:

- Advice in the form of stories
- Vicarious experience using a concept or skill
- The lay of the domain and guidance on what to focus on
- Strategies and procedures
- How to use cases

Archie-2, for example, provides cases for architecture students to use while designing. Its cases describe public buildings, focusing on libraries and courthouses. As students work on designing buildings they consult Archie periodically for advice. Another program, STABLE, is designed to help students learn the skills involved in doing object-oriented design and programming. It uses a web-based (hypermedia) collection of cases made from previous students' work. Many goal-based scenarios include case libraries at their cores.

The context in which case libraries are used is critical to their effectiveness. For cases to be a useful resource to students, the students must be engaged in an activity where their impasses might be answered by cases in the case library. If students are facing challenges that arise naturally in problem solving (e.g., "How do I model a situation like this?" or "What's a good starting point for this kind of problem?"), then a case library of relevant situations and problems can help them address those impasses.

Building case libraries can be as valuable educationally as using case libraries, sometimes even more valuable. One of the findings in using Archie-2 was that the graduate students who were *building* the case library seemed to be learning as much or more than the students who were *using* the case library in their design work. The activity of building a case library is frequently motivating for students because it is creating a public artifact whose purpose is to help future students. Cognitively the need to explain to others in a way that will allow them to understand requires reflecting on a situation, sorting out its complexities, making connections between its parts, and organizing what one has to say into coherent and memorable chunks.

**Support for reflection.** Case-based reasoning purports that the most productive reflection for deep and lasting learning includes connecting one's goals, plans, actions, and their outcomes to tell the fully interpreted story of an experience, and then extracting the lessons learned and making predictions about the circumstances when those lessons might be applicable in the future. Several software tools have been designed to help learners engage in such reflection, each asking learners to be authors of cases describing their experiences. Jennifer Turns's Reflective Learner helps undergraduate engineering students write "learning essays" about their design experiences. Its prompting asks students to (a) identify and describe a problem that they had encountered when undertaking the current phase of their design project; (b) describe their solution to the problem; (c) say what they had learned from the experience; and (d) anticipate the kinds of situations where a similar solution might be useful. Amnon Shabo's Javacap and its successor, Kolodner's and Kris Nagel's Storyboard Author, provide structuring and prompts to help middle school students summarize their project-based science experiences, extract from them what they have learned, and write them up as stories for publication in a permanently accessible case library for use by other students. The networked computer creates motivation for the students' reflection; students enhance their own learning as they write summaries, which can act as guides and supports to future students. Nagel and Kolodner's Design Discussions, mentioned earlier, provides prompting to help students write up the results of experiments they've done, ideas about achieving project challenges or solving problems they are

working on, or what happened when they constructed and tested a design idea.

**Realistic modeling and simulation.** Case-based reasoning's model of learning puts emphasis on experiencing failure as a motivation for deep learning. Case-based reasoning thus suggests that learners should have opportunities to try out their conceptions, failing softly when their predictions fail, and getting timely and interpretable feedback that they can use to identify and explain their misconceptions. Thus, the ability to try out and see the results of one's conceptions is fundamental to any learning environment based on CBR's model. Sometimes one can construct artifacts and try them out. For example, in Learning by Design, students design, construct, and test miniature vehicles to learn about combining forces. But often processes have time scales, size, cost, or safety constraints that make authentic feedback impractical. In those situations, CBR suggests making available to students realistic modeling and simulation environments.

### Evidence of Learning

There has not been a great deal of evaluation and assessment of case-based tools and learning environments, but indicators are positive. Teachers and trainers who use CBR-informed materials come back energized. Teachers feel that they are able to reach more of their students with this methodology. Both students at the top and those at the bottom seem to be drawn in more by these activities than they are in a normal aim-toward-the-middle classroom. Concepts and skills are being learned, teachers think, in ways that will encourage students to remember and reuse them. Students surprise the teachers with ideas they come up with and the connections they are able to draw.

Evaluation and assessment in Learning by Design classrooms shows that indeed students are learning, often better than students in a traditional classroom. Results indicate that students who participate in Learning by Design learn the science content as well as or better than students in more traditional science classes. More important, results show that Learning by Design students learn targeted science skills and communication, collaboration, project, and learning practices such that they can apply them in novel situations. Indeed, Learning by Design students in typical-achievement classes perform these skills and practices as well as or better than honors students who have not been exposed to Learning by

Design, while Learning by Design honors students perform the targeted skills and practices almost like experts.

## DIRECT INSTRUCTION

*Instruction* is an illusive term that is often used indiscriminately to describe any presentation of information. In this discussion instruction is limited to those situations that, in addition to providing relevant in-

formation, include the following characteristics: (1) a particular educational goal has been specified; (2) the information has been organized to facilitate the acquisition of the desired knowledge or skill; (3) appropriate practice with feedback has been provided; and (4) guidance is available to assist learners to acquire the desired knowledge or skill.

*Learning* is also a term that is often equated with instruction. Learning occurs in all situations, whether or not there was a deliberate attempt to promote acquisition of a particular goal. Instruction is limited to those situations where there is a deliberate attempt to promote learning of specified knowledge or skill.

*Direct instruction* is a subset of instructional situations in which there is some instructor or instructional agent that is not only providing information but also monitoring the instructional activities of the student and providing guidance and feedback as appropriate. Ruth Clark describes four instructional architectures: receptive, directive, guided discovery, and exploratory. *Receptive instruction* is typified by a lecture where information is provided, but there is no attempt to ensure learning by providing practice or guidance. *Directive instruction*, often called tutorial instruction, involves presenting segments of information followed by appropriate practice with feedback and guidance. This is the type of instruction that is the subject of this entry. *Guided discovery* provides students with problems to solve and engages them in microworlds or simulations of the real world where they can explore a variety of approaches. The amount of guidance provided varies widely in this type of instruction. Highly guided situations are very similar to direct instruction, whereas those with little or no guidance depend more on student discovery of the knowledge or skill being promoted. *Exploratory architectures* are typically unstructured. Learners are provided some problem to solve and given a rich library of resource material. Students must structure their own learning as they investigate various resources and attempt to solve the problem.

### Types of Instructional Models

There are a wide variety of instructional models and theories available to guide the design of directive instructional products. Charles M. Reigeluth includes summaries of more than twenty such models. Robert Tennyson et al. and Sanne Dijkstra et al. include summaries of a number of international models of instruction. David Jonassen includes a number of ar-

ticles summarizing research related to direct instruction. Perhaps the most widely used model for direct instruction is the 1985 work of Robert Gagné, elaborated and extended by David Merrill in 1994. A newer model of some importance is the 4C/ID model of J. J. G. van Merriënboer.

The author has examined the above and other sources to identify instructional principles prescribed by this body of theory and research to which all of these authors would agree. These instructional design models represent a wide range of philosophical orientation and each emphasizes different aspects of the instructional situation. Some of these models apply more directly to architectures other than direct instruction but have implications for direct instruction nevertheless.

Many of these instructional models suggest that the most effective learning situations are those that are problem-based and involve students in four distinct phases of learning: (1) activation of prior experience; (2) demonstration of skills; (3) application of skills; and (4) integration of these skills into real-world activities.

### Principles for Direct Instruction

The various instructional theorists and researchers all seem to agree on the following underlying principles for direct instruction:

1. Learning is promoted when learners are engaged in solving real-world problems.
  - a. Learning is promoted when learners are shown the task that they will be able to do or the problem they will be able to solve as a result of completing a module or course.
  - b. Learning is promoted when learners are engaged at the problem or task level, not just the operation or action level.
  - c. Learning is promoted when learners solve a progression of problems that are explicitly compared to one another.
2. Learning is promoted when relevant previous experience is activated.
  - a. Learning is promoted when learners are directed to recall, relate, describe, or apply knowledge or skill from relevant past experience that can be used as a foundation for the new knowledge or skill.
  - b. Learning is promoted when learners are provided relevant experience that can be used as a foundation for the new knowledge or skill.

- c. Learning is promoted when learners are provided or encouraged to recall a structure than can be used to organize the new knowledge.
3. Learning is promoted when the instruction demonstrates what is to be learned rather than merely telling information about what is to be learned.
    - a. Learning is promoted when the demonstration is consistent with the learning goal: examples and nonexamples for concepts, demonstrations for procedures, visualizations for processes, and modeling for behavior.
    - b. Learning is promoted when learners are provided appropriate learner guidance including some of the following: learners are directed to relevant information, multiple representations are used for the demonstrations, and multiple demonstrations are explicitly compared.
    - c. Learning is promoted when media plays a relevant instructional role.
  4. Learning is promoted when learners are required to apply their new knowledge or skill to solve problems.
    - a. Learning is promoted when the application (practice) and the posttest are consistent with the stated or implied objectives: *information-about practice* is to recall or recognize information; *parts-of practice* is to locate, name, and/or describe each part; *kinds-of practice* is to identify new examples of each kind; *how-to practice* is to do the procedure; and *what-happens practice* is to predict a consequence of a process given conditions, or find faulted conditions given an unexpected consequence.
    - b. Learning is promoted when learners are guided in their problem solving by appropriate feedback and coaching, including error detection and correction, and when this coaching is gradually withdrawn.
    - c. Learning is promoted when learners are required to solve a sequence of varied problems.
  5. Learning is promoted when learners are encouraged to integrate (transfer) the new knowledge or skill into their everyday life.
    - a. Learning is promoted when learners are given an opportunity to publicly demonstrate their new knowledge or skill.
    - b. Learning is promoted when learners can reflect on, discuss, and defend their new knowledge or skill.
    - c. Learning is promoted when learners can create, invent, and explore new and personal ways to use their new knowledge or skills.

## LEARNING COMMUNITIES

At the end of the twentieth century in America there has developed a *learning-communities* approach to education. In a learning community the goal is to advance the collective knowledge and, in that way, to support the growth of individual knowledge. The defining quality of a learning community is the presence of a culture of learning in which everyone is involved in a collective effort of understanding.

There are four characteristics that such a culture must have: (1) diversity of expertise among its members, who are valued for their contributions and given support to develop; (2) a shared objective of continually advancing the collective knowledge and skills; (3) an emphasis on learning how to learn; and (4) mechanisms for sharing what is learned. It is not necessary that each member assimilate everything that the community knows, but each should know who within the community has relevant expertise to address any problem. This marks a departure from the traditional view of schooling, with its emphasis on individual knowledge and performance and the expectation that students will acquire the same body of knowledge at the same time. Classrooms organized as learning communities differ from most classrooms along a number of dimensions.

### Learning Activities

Because the goals focus on fostering a culture of learning, the activities of learning communities must provide a means for (1) both individual development and collaborative construction of knowledge, (2) sharing knowledge and skills among members of the community, and (3) making learning processes visible and articulated. The learning activities described in a learning-communities approach and those found in most classrooms may share some similarities. For instance, methods such as cooperative learning can be used to support a learning community's goals, but they can equally well support

more traditional learning aimed at inculcating particular knowledge among students.

### Teacher Roles and Power Relationships

In a learning-communities approach the teacher takes on roles of organizing and facilitating student-directed activities, whereas in most classrooms the teacher tends to direct the activities. The power relationships shift as students become responsible for their own learning and the learning of others. Students also develop ways to assess their own progress and work with others to assess the community's progress. In contrast, in most classrooms the teacher is the authority, determining what is studied and assessing the quality of students' work.

### Identity

As members of a learning community take on different roles and pursue individual interests toward common goals, students develop individual expertise and identities. In contrast, in most classrooms students work on the same things and are all expected to reach a base level of understanding. Students tend to form their identity through being measured or by measuring themselves against this base level. In a learning-communities approach there is also the notion of a community identity. By working toward common goals and developing a collective awareness of the expertise available among the members of the community, a sense of "who we are" develops.

### Resources

Both a learning-communities approach and many traditional classrooms use resources outside of the classroom, including disciplinary experts, telementors, the Internet, and so forth. However, in learning communities both the content learned and the processes of learning from the outside resources are shared more among members of the community and become part of the collective understanding. A further distinction between learning communities and most classrooms is that in learning communities, both the members themselves and the collective knowledge and skills of the communities are viewed as important resources.

### Discourse

In the learning-communities approach, the language for describing ideas and practices in the community emerges through interaction with different knowledge sources and through co-construction and ne-

gotiation among the members of the community. Also, learning communities develop a common language for more than just content knowledge and skills. The community develops ways to articulate learning processes, plans, goals, assumptions, and so forth. In contrast, in most classrooms the teacher and texts tend to promulgate the formal language to be learned.

### Knowledge

In learning communities the development of both diverse individual expertise and collective knowledge is emphasized. In order for students to develop expertise, they must develop an in-depth understanding about the topics that they investigate. There is also a circular growth of knowledge, wherein discussion within the community about what individuals have learned leads individuals to seek further knowledge, which they then share with the community. In most classrooms the goals tend toward covering all the topics in the curriculum (breadth over depth) and teaching everyone the same thing.

### Products

In a learning-communities approach, members work together to produce artifacts or performances that can be used by the community to further their understanding. There is sustained inquiry and development of products over months. In contrast, most classrooms tend toward individual or small group assignments with little sharing or collective products. Usually work is produced in short periods of time.

A key idea in the learning-communities approach is to advance the collective knowledge of the community, and in that way to help individual students learn. This is directly opposed to the approaches found in most schools, where learning is viewed as an individual pursuit and the goal is to transmit the textbook's and teacher's knowledge to students. The culture of schools often discourages sharing of knowledge by inhibiting students talking, working on problems or projects together, and sharing or discussing their ideas. Testing and grading are administered individually. When taking tests, students are prevented from relying on other resources, such as students, books, or computers. The whole approach is aimed at ensuring that students have all the knowledge in their heads that is included in the curriculum. Thus the learning-community approach is a radical departure from the theory of

learning and knowledge underlying traditional schooling.

### LEARNING THROUGH DESIGN

Design principles, perspectives, and processes in K–12 classroom practice became a topic of educational research during the final decade of the twentieth century. Research was preceded by design-based practices in the classrooms of many K–12 teachers, who engaged students in a variety of design projects and activities, such as proposing environmental strategies, creating plans for future communities, building bridges, designing machines, creating art and theater, and planning for community events. Classroom design projects thrived among teachers, who appreciated their value, but received little notice from researchers of learning. Design activities were the legacy of John Dewey and other progressive influences on schools and teachers, with roots in "experiential education," "learning by doing," and "project work." This entry is concerned exclusively with the nascent research field exploring the cognitive, metacognitive, and social contributions of design-based approaches to learning.

## Research Background and Interests

The research community's interest in design-based approaches to curriculum overlap with several movements in education during the last two decades of the twentieth century. During the 1980s an education policy atmosphere developed that called for connecting what was taught and learned in school with the emerging demands of the work world. At the same time, cognitive and social research on learning evolved in new directions. Finally, research and development efforts with educational technologies emerged, bringing new concerns, tools, and methods to classroom research. In each of these arenas there was interest in problem solving, multidisciplinary approaches to content learning, social aspects of the learning process, applications of school content to the real world, and development of new tools. Because design embodies these qualities, it became a focus of research.

**Policy.** At the policy level, standards documents supported the importance of design-based learning experiences. The national science content standards included a strand titled "Science and Technology Standards," which called for students to engage actively in design work, from stating problems to designing solutions and evaluating them. The standards "emphasize abilities associated with the process of design and the fundamental understandings about the enterprise of science and its various linkages with technology" (National Research Council, p. 106). The *Standards for Technological Literacy* included design activities, stating that design is "as fundamental to technology as inquiry is to science and reading is to language arts" (International Technology Education Association, p. 90). Although not pointing directly to design, other standards documents from the National Council of Teachers of Mathematics supported problem solving, modeling, and connecting schoolwork to real applications. The trend to include design was international as well. In a 1996 multinational examination of science, mathematics, and technology curricula in thirteen countries, Paul Black and J. Myron Atkin identified movement toward design-oriented curricula that coincided with the desire of educators to have relevant, applied contexts as well as contexts for students to develop their practical knowledge and understandings. Although the policy call was clear, there was little account of existing school practices and no evidence of their effectiveness.

**Design-based curricula.** The most comprehensive examination of design-based learning in the United States, a 1997 report by Meredith Davis and colleagues under the umbrella of the National Endowment for the Arts, attempted to find and study design-based curricula to show what teachers and students do in design and the promise it holds for educational reform. The study used an "exploratory, hypothesis-generating approach" because design practices in classrooms were not widespread. Scores of design approaches were discovered and examined. The study's contribution was in providing descriptions of design practice in classrooms and identifying effective models and outcomes for using design. The study emphasized the ways design opens learning opportunities across curriculum subjects for teachers and learners and connects them to the world and a future beyond school.

## Designing for Results

Changes took place in what was of interest to study as well as in the ways social and cognitive researchers approached and conducted research. Concerns about the learning goals of schools and their connections to students' futures as citizens and workers interested cognitive and social-learning researchers. Prior research results indicated that, under the right conditions, children were capable of complicated understandings and skills, and more researchers became interested in identifying and understanding learning in practice. This brought researchers out of laboratories and into the rough and tumble of classroom life. Researchers began to connect with teachers and reformers, expanding the goals, methods, and reach of their research. New models of research became established, such as the "design experiment" and "interactive research and design," both less aimed at researching design-based learning and more focused on researchers designing, implementing, studying, and tweaking classroom activities until they achieved sought-after results. Some researchers partnered with teachers to conduct classroom-based cognitive research and to develop tools and curriculum based on research findings that specifically incorporated design.

**Middle-School Mathematics through Application Project (MMAP).** Research and development of educational technologies became an additional and significant intersection point. Technology and design have a symbiotic relationship. Once technology tools for problem solving were in the hands of teach-

ers and students, design-based activities became a possibility for widespread use. The Middle-School Mathematics through Application Project (MMAP) developed and researched an approach to middle school mathematics that integrated technology as a tool for mathematics learning in the context of design-based projects. Students were introduced to mathematics as they needed it, to solve pre-specified and constrained design problems, such as building a research station in Antarctica or recommending environmental population-control policies. Design contexts were treated as resources for mathematical interaction and explanation, and they led to increasing student engagement with mathematics topics. Design contexts made real-world connections of mathematics obvious to students and gave them situational resources for developing mathematical concepts. Design contexts provided opportunities for problem definition, problem solving, and performance-based assessments.

**Jasper Project.** The Jasper Project incorporated design-based approaches to upper-elementary mathematics learning with technology. The Jasper series focused on mathematical problem finding and solving, reasoning, communications, and making connections to other content areas for elementary students. The Jasper Project encouraged collaborative activity on extended problems over time, while offering deep understanding of mathematical concepts. Both MMAP and the Jasper Project emphasized the emergent aspects of problem solving and the utilization of various mathematical concepts and skills along the way to solving real-world problems. They both emphasized the roles technologies could play in supporting complex, design-based work in the mathematics curriculum and the supports needed for teacher professional development and assessment.

Yasmin Kafai and Mitchell Resnick bring together research from both school and informal technology, using settings to demonstrate how design activities with games, textile patterns, and robots empower children and connect them to important mathematics and science ideas. They examined subject-matter learning and provided compelling cases for how design processes provide meaningful and productive learning settings.

**Learning by Design.** Research independent of technology has concentrated on connections between design contexts and content learning, especially in mathematics and science. The Learning by Design

project employed design approaches in science learning. The researchers based their work on prior results to create environments for learning science concepts and their applicability through a curriculum focused on “design and build challenges.” They studied how, in the context of design work, students gained a conceptual understanding of complex systems and practices and created and field tested pedagogical rituals and processes for making design projects effective.

**Modeling.** With a concentration in both mathematics and science, work by Richard Lehrer and Leona Schauble investigated students’ understanding of modeling, which is central to design work. They studied four schools where teachers were moving away from emphasizing facts and procedures to approaches focusing on constructing, evaluating, and reviewing models. They chronicled the development of models across the K–5 years and outlined key features in teacher professional development. In other analyses, they examined the development of mathematical inscription devices for representing and communicating about data in experiments and designs.

**Geometry.** Several studies of geometry understanding explored design contexts. In a 1998 study on understanding space, Lehrer, Cathy Jacobson, and colleagues examined how the geometric ideas of transformation and symmetry were developed through a quilt-design activity. They found that quilt design provided students with opportunities to explore ideas of symmetry and transformation and that informal knowledge of drawing and aesthetics played a mutual role in mathematical argumentation and notation. James Middleton and Robert Corbett examined the contexts of engineering and architecture to see if realistic situations helped students develop notions of physical structure that they could in turn connect to their understanding of geometry. Students made toothpick models of geometric solids, tested their strengths, then created suspension bridges and tested their stability. Results were mixed, with conceptions of geometric contributions to stability present but applied naively in designs.

### Features of Design-Based Learning under Study by Researchers

A closer look at the features of design ideas and practices reveals what has made them appealing to teachers and researchers and indicates areas for future research. As a collaborative process, design requires

discussion and clarification of goals, problems, sub-problems, and actions. Researchers of learning have interests in problem exploration, the development of organizational skills and logic, and the ways they connect to, or enhance, learning of content and concepts.

Once problems and solution constraints are understood, design-based brainstorming encourages participation because it requires students to offer ideas and suggestions for solving problems in the context of a low-pressure forum. This engages students as stakeholders at the start of a complex set of activities. Brainstorming reinforces equity principles by providing for cultural knowledge to be relevant, brought to the table, and consequential for engagement and participation.

Success and inclusion are encouraged because multiple solutions to design problems are sought and appreciated. Variation is an expected outcome of the design experience. Variation in response to problems requires that students keep track of their decisions and provide rationales for them.

The features mentioned, including problem definition, brainstorming, open access to varied solution paths, and collaborative work, provide support for specific discourse processes in the classroom. Discussion, making and testing conjectures, rationales, argumentation, and explanation are necessary. Students must talk about possibilities, resources, and constraints. The more students discuss the problems they are trying to solve, the more they suggest and assess the viability of specific solutions while trafficking in the vocabulary and discourse practices of the discipline, then the more they are learning.

Design work and its tools require students to interact with multiple media and representations of information and data, and these are an increasing focus of research. Students may have to create constraint lists, flowcharts, data tables, graphs, and drawings as they use numbers and number sense, measurement, and both natural language and symbolic formulas while working from problem definition to solution. Researchers recognize the ability and ease with which technologies and media can put multiple representations of problems and processes on the student's desktop.

Research on design-based approaches creates opportunities for studying performance-based assessment practices. Iterative review processes are part of design work, leaving teachers and students

with more opportunities for performance-based and peer-based assessment. Elaborating and agreeing on goals, evaluating processes, giving and receiving feedback, and prioritizing and making revisions are practices in design and worthwhile assessment practices as well.

In design, students' work with extended real-world problems connects them to practical professions, such as art, architecture, and engineering. Links are created between the real world and models, between simulations and solution processes, giving students access to practical knowledge and general processes of problem solving.

Finally, design-based learning has examined teacher practices. Evidence from MMAP suggests that the design process has the effect of decentering instruction from the teacher, and provides students with more explanation opportunities, more agency, and a more balanced position of power in relation to their work progress.

Barriers to widespread design-based approaches are also evident. Design-based learning is considered difficult to adopt and implement and remains only a specialized classroom practice. Design-based projects and activities are disruptively different from traditional approaches and perspectives. They impact on "business as usual" in the classroom in terms of management, planning, pedagogy, and content focus, disrupting classroom routines and requiring new kinds of work and attention. They are complex and take extended periods of time, making it necessary to reorganize classroom activity structures.

Design projects place new demands on teachers and students. Teachers need professional development to learn how to structure and manage design-based activities and many of the design-focused research projects also depend on teacher learning and preparation. Design work supports new levels of participation from students as well. Students often make strong connections to their design projects, taking extra time and often working at home. This is a positive effect, with implications for supporting partnerships between school, home, and community, but one that needs to be negotiated.

With collaborative work, emergent, complex problems, and real-world distractions, design projects are difficult to grade. Researchers are working to find ways to articulate standards, assessments, and complex learning environments, such as design projects.

## Summary

Design-based approaches to learning have a long-standing place in the K–12 classroom, yet research attention to the role and effects of design-based learning experiences is in its infancy. Recent movements in educational reform, changes in the conduct of social and cognitive research on learning, and the growth of research and development in educational technologies have contributed to design-based learning becoming a topic of interest and inquiry. Current research reports findings from work in the social and cognitive sciences on problem solving, discourse and learning, teaching and learning processes, culture and learning processes, and classroom assessment.

## PEDAGOGICAL AGENTS AND TUTORS

The creation of pedagogical agents is a fairly new enterprise that has emerged from previous work done in autonomous agents, intelligent tutoring systems, and educational theory. *Pedagogical agents* are autonomous agents that occupy computer learning environments and facilitate learning by interacting with students or other agents. Although intelligent tutoring systems have been around since the 1970s, pedagogical agents did not appear until the late 1980s. Pedagogical agents have been designed to produce a range of behaviors that include the ability to reason about multiple agents in simulated environments; act as a peer, colearner, or competitor; generate multiple, pedagogically appropriate strategies; and assist instructors and students in virtual worlds.

### Animated Pedagogical Agents

A new breed of pedagogical agents has begun to appear in learning environments and on websites: *animated* pedagogical agents. The advent of animated pedagogical agents is the result of recent advancements in multimedia interfaces, text-to-speech software, and agent-generation technologies. Some of the more high-profile systems are described below.

- ALI is an automated laboratory instructor that monitors and guides undergraduates as they solve problems while interacting with chemistry simulations.
- ADELE (Agent for Distance Learning—Light Edition) helps students work through problem-solving exercises for courses that are delivered over the Internet. ADELE-based courses have been developed for continuing medical education and geriatric dentistry.
- AutoTutor simulates the dialogue moves of human tutors while participating in conversations with students. AutoTutor is currently designed to help college students learn about topics in computer literacy and conceptual physics.
- Cosmo exploits deictic behaviors to offer problem-solving advice to students learning about network routing mechanisms in the Internet Advisor learning environment.

- Herman the Bug inhabits the Design-A-Plant learning environment and helps children learn about botanical anatomy and physiology.
- PPP Persona provides online help instructions while helping users navigate through web-based materials.
- STEVE (Soar Training Expert for Virtual Environments) interacts with learners in an immersive virtual environment and has been used in naval training tasks such as operating engines on U.S. Navy surface ships.
- Vincent helps workers in shoemaking factories learn about production-line control time.

These agents exhibit lifelike behaviors and have the potential to bolster student-learning outcomes by exploiting both the auditory and visual channels of the learner. In general, animated pedagogical agents are lifelike personas, which execute behaviors that involve emotive responses, interactive communication, and effective pedagogy.

**Emotive responses.** Clark Elliott, Jeff Rickel, and James Lester argue in their 1999 article that animated agents displaying appropriate emotions provide a number of educational benefits to learners. First, agents that appear to care about students' progress may convince students to care about their own progress. Second, agents that are sensitive to learners' emotions (e.g., boredom or frustration) can provide feedback that prevents students from losing interest. Third, agents that convey enthusiasm for the subject matter are more likely to evoke the same enthusiasm in learners. Finally, agents that have rich and interesting personalities make learning more enjoyable for the learner.

Agents can display appropriate emotions through facial expressions, gestures, locomotion, and intonation variations. For example, Cosmo uses a recorded human voice and full-body emotive behaviors to express a wide range of pedagogically appropriate emotions. When a student experiences success in the Internet Advisor learning environment, Cosmo may applaud, point to relevant information on the screen, and provide positive feedback (e.g., "You chose the fastest subnet. Also, it has low traffic. Fabulous!"). Another system, AutoTutor, synchronizes facial expressions and intonation variations to provide feedback that reflects the quality of students' natural language contributions. If a student provides a good answer to a question, AutoTutor may respond simultaneously with an enthusiastic

“Okay!” a fast head nod, and a smile. However, if the student’s answer is only partially correct, AutoTutor may respond with a less enthusiastic “Okay,” a slower head nod, and no smile.

**Interactive communication.** Most educational websites and software packages are designed to be mere information delivery devices that occasionally employ unsophisticated reward systems as metrics of student understanding. Pedagogical agents, however, facilitate interaction in learning environments and force students to be active participants in the learning process. Agents and learners can collaboratively perform tasks, solve problems, and construct explanations. STEVE, the agent that teaches procedural knowledge involved in operating engines on navy ships, demonstrates for learners how to perform tasks and solve problems. A learner may choose to intervene and finish the demonstration. When this happens, STEVE monitors the learner’s actions and a mixed-initiative demonstration occurs. Specifically, learners can take the initiative by asking questions or performing actions, or STEVE can mediate the interaction by providing hints, asking questions, giving feedback, or demonstrating a task. Learning sessions with ADELE are interactive in that ADELE interrupts students when “she” detects student errors and suggests alternative actions to be performed instead (e.g., “Before ordering a chest X ray, it would be helpful to listen to the condition of the lungs.”). Students who reach impasses during problem solving may receive hints and ask “why” questions while interacting with ADELE and STEVE. In other systems, such as AutoTutor, the agent and student have a conversation with each other. Throughout the conversation, AutoTutor simulates human-tutor-dialogue moves (e.g., hints, prompts, assertions, and corrections), which allow the agent and student to jointly construct answers and explanations to deep-reasoning problems.

**Effective pedagogy.** In order to be considered value-added entities of learning environments, pedagogical agents must be effective teachers and, therefore, adaptive and dynamic in their teaching strategies. They must be able to adjust their teaching to fit a particular problem state or learning scenario, and they must be capable of adjusting their pedagogy to accommodate students’ knowledge and ability levels. Pedagogical agents should be able to ask and answer questions, provide hints and explanations, monitor students’ understanding, provide appropriate feedback, and keep track of what has been covered in the

learning session. All of the pedagogical agents mentioned above are, to some extent, capable of each of these functions. Of course the litmus test for any pedagogical agent is whether it produces positive student-learning outcomes.

### Learning Outcomes

It has been well documented that users prefer learning environments with animated agents over those that do not have agents. Specifically, participants assigned to learning conditions with animated agents (even ones that are not particularly expressive) perceive their learning experiences to be considerably more positive than participants assigned to learning conditions that do not include animated agents. This recurring finding is known as the *persona effect*. The persona effect is somewhat enigmatic in that it generally is not related to student outcome or performance measures. That is, most researchers who report evidence of the persona effect also report no differences between agent and no-agent conditions for retention and learning measures.

Several recent empirical studies, however, indicate that pedagogical agents do promote learning on both retention and transfer tasks. Robert Atkinson reported that students who received explanations from an animated agent about how to solve proportion word problems outperformed other learning conditions on both near and far transfer problems. In a study conducted by Roxana Moreno et al., college students and seventh graders attempted to learn about how to design plants that could survive in a number of different environments. One group of students interacted with a pedagogical agent, Herman the Bug, while another group of students received identical graphics and textual explanations but no pedagogical agent. The results indicated that students in the pedagogical agent condition outperformed students in the no-agent condition on transfer tests but not on retention tests. In another study, Natalie Person et al. (2001) reported that the effect size for AutoTutor was .6 compared to the other learning conditions; human tutoring studies typically report effect sizes around .5 compared to other learning controls. Given the results of these learning-outcome studies and the fact that learners perceive their interactions with agents quite favorably, the future for pedagogical agents looks quite promising.

## PROBLEM-BASED LEARNING

Problem-based learning (PBL) is one of a class of instructional methods that situates learning in complex contexts. In PBL, students learn through guided experience in solving complex, open-ended problems, such as medical diagnosis or designing a playground. Developed by Howard Barrows for use in medical schools, it has expanded to other settings such as teacher education and K–12 instruction.

Problem-based learning was designed with five goals: to help students (1) construct flexible knowledge; (2) develop effective problem-solving skills; (3) develop self-directed learning skills; (4) become effective collaborators; and (5) become motivated to learn.

With its emphasis on learning through problem solving and on making key aspects of expertise visible, PBL exemplifies the cognitive apprenticeship model. In this model, knowledge is constructed by learners working on real-world problems. One key

characteristic that distinguishes PBL from other cognitive apprenticeship approaches is its potential for covering an entire integrated curriculum through a well-chosen set of problems. Concepts and thinking skills are used in a variety of problems. This redundancy affords learners the opportunity to construct a deep understanding by revisiting concepts from many perspectives and by experiencing a variety of situations in which skills are applied.

### The Problem-Based Learning Tutorial Process

A PBL tutorial session begins by presenting a group, typically 5 to 7 students, with a small amount of information about a complex problem. From the outset, students question the facilitator to obtain additional problem information; they may also gather facts by doing experiments or other research. At several points, students pause to reflect on the data they have collected so far and generate questions about that data and ideas about solutions. Students identify concepts they need to learn more about to solve the problem (i.e., learning issues). After considering the case with their existing knowledge, students divide up and independently research the learning issues they identified. They then regroup to share what they learned, and reconsider their ideas. When completing the task, they reflect on the problem to consider the lessons learned, as well as how they performed as self-directed learners and collaborative problem solvers.

While working, students use white boards to help guide their problem solving. The white board is divided into four columns to help them record where they have been and where they are going. The columns help remind the learners of the problem-solving process. The white board serves as a focus for group deliberations. Figure 1 shows an example of white board entries made by engineering students working on a chemical release problem. The *Facts* column holds information that the students obtained from the problem statement. The *Ideas* column serves to keep track of their evolving hypotheses about solutions, such as reducing the storage of hazardous chemicals. The students place their questions for further study into the *Learning Issues* column. They use the *Action Plan* column to keep track of plans for resolving the problem or obtaining additional information.

### The Role of the Problem

Cognitive research and experience with PBL suggest that to foster learning, good problems have several

characteristics. Problems need to be complex and open ended; they must be realistic and connect with the students' experiences. Good problems require multidisciplinary solutions and provide feedback that allows students to evaluate the effectiveness of their knowledge, reasoning, and learning strategies. Problems should promote conjecture and discussion and should motivate the students' need to go out and learn. As students generate and defend their ideas, they publicly articulate their current understanding, thus enhancing knowledge construction and setting the stage for future learning.

Each problem requires a final product or performance that allows the students to demonstrate their understanding. For example, PBL has been used to help middle school students learn life science by designing artificial lungs. They conducted experiments and used a variety of other resources to learn about breathing. Their final products were models of their designs.

### The Role of the Facilitator

The term *facilitator* refers to someone trained to facilitate student learning through PBL. In PBL facilitators are expert learners, able to model good learning and thinking strategies, rather than being content experts. The facilitator is responsible for moving students through the various stages of PBL and for monitoring the group process—ensuring that all students are involved and encouraging them to externalize their own thinking and to comment on each other's thinking. The facilitator plays an important role in modeling the thinking skills needed

when self-assessing reasoning and understanding. For example, the facilitator encourages students to explain and justify their thinking as they propose solutions to problems. Their questions help model the use of hypothetical-deductive reasoning as they encourage students to tie inquiry to their hypotheses. Facilitators progressively fade their scaffolding as students become more experienced with PBL, until their questioning role is largely adopted by the students. However, they continue to actively monitor the group, making moment-to-moment decisions about how to facilitate the PBL process.

### **Collaborative Learning in Problem-Based Learning**

Collaborative problem-solving groups are a key feature of PBL. Its small group structure helps distribute the work among the members of the group, taking advantage of individual strengths by allowing the whole group to tackle problems that would normally be too difficult for any student alone. Students often become experts in particular topics. Small group discussions and debate enhance higher-order thinking and promote shared knowledge construction.

### **Reflection in Problem-Based Learning**

Reflection on the relation between doing and learning is needed to help the learners understand that the tasks they are doing are in the service of the questions they have asked and that these questions arise from the learning goals they have set. Thus, each task is not an end in itself but a means to achieve a self-defined learning goal.

One potential danger of PBL is that knowledge may become bound to the problem in which it is learned. Learners need to understand what principles are at play in a given task and further understand how those principles might apply to new problems. To avoid this difficulty, learners must use concepts and thinking skills in multiple problems and to reflect on their learning. Reflection is important in helping students (1) relate their new knowledge to prior understanding; (2) mindfully abstract knowledge; and (3) understand how the strategies might be applied in new situations. Problem-based learning incorporates reflection throughout the tutorial process and when completing a problem. As students make inferences that tie the general concepts and skills to the specifics of the problem that they are working on, they construct more coherent

understanding. The facilitator-guided reflection helps students prepare to take what Gavriel Salomon and David Perkins, in their 1989 study, call the “high road” to transfer as they consider how their new knowledge might be useful in the future and the effectiveness of their learning and problem-solving strategies.

### **Empirical Support for Problem-Based Learning**

Research results are converging to show that some of these goals have been successfully met. Students in problem-based curricula are more likely to use their knowledge during problem solving and to transfer higher-order thinking skills to new situations. Cindy Hmelo has studied PBL in medical students and found that when asked to provide an explanation for a patient problem, the students in problem-based curricula were more accurate in their diagnoses, more likely to apply scientific concepts, and constructed better quality explanations than students in traditional curricula. This study provides evidence that PBL students transfer their knowledge and strategies to new problems. Shelagh Gallagher and William Stepien have studied the effects of PBL on gifted high school students. In one study, they examined the effect of a PBL intervention on content knowledge in social studies and found that students in PBL learned as much content as students in traditional instruction. In another study Gallagher, Stepien, and Hilary Rosenthal, comparing students taking a PBL science and society elective with students taking other classes, found that PBL students became better at problem-finding than comparison students. Most studies of PBL have been conducted either in medical schools or in other highly selected populations such as gifted high school students, but Hmelo, Douglas Holton, and Janet Kolodner conducted a 2000 preliminary study with middle school students learning life science. The students in the PBL intervention learned more than a comparison class, but because the students were not actually able to get feedback by implementing their solution, they did not achieve as deep an understanding as the investigators had expected.

### **Conclusion**

Problem-based learning was designed to help students become flexible thinkers. Although the research on PBL is promising, the effects of PBL need to be examined more widely. The challenge ahead lies in understanding how the potential of PBL can

be harnessed in diverse settings. Understanding the nature of the tutorial process, including the role of the problem and facilitator, collaboration among peers, and the importance of student reflection is necessary to successfully implement PBL and to prepare students to think in the world beyond school.

## INSTRUCTIONAL DESIGN AND COMPUTER-ASSISTED INSTRUCTION

*See:* TECHNOLOGY IN EDUCATION, *subentry on* CURRENT TRENDS.

## INSTRUCTIONAL OBJECTIVES

Most people would agree that the goal of education is learning. Most would also agree that education is likely to be more effective if educators are clear about what it is that they want the learners to learn. Finally, most would agree that if teachers have a clear idea about what learners are expected to learn, they can more easily and more accurately determine how well students have learned.

Enter instructional objectives. Because instructional objectives specify exactly what is supposed to be learned, they are helpful to the teacher as well as the learner throughout the learning process and are invaluable in the evaluation process.

Instructional objectives (also known as *behavioral objectives* or *learning objectives*) are basically statements which clearly describe an anticipated learning outcome. When objectives were first coming into their own in education, they almost always began with the phrase: "Upon completion of this lesson, the student should be able to . . ." This phrase focused on the outcome of learning rather than on the learning process. In fact, one of the criteria for a well-written objective is that it describe the outcome of learning, that is, what the learners can do after learning has occurred that they might not have been able to do before the teaching and learning process began.

### Characteristics of a Well-Written Objective

A well-written objective should meet the following criteria: (1) describe a learning outcome, (2) be student oriented, (3) be observable (or describe an observable product).

A well-written objective should describe a learning outcome (e.g., to correctly spell the spelling words on page seventeen). It should not describe a learning activity (e.g., to practice the words on page seventeen by writing each one ten times). Learning activities are important in planning and guiding instruction but they are not to be confused with instructional objectives.

A student-oriented objective focuses on the learner, not on the teacher. It describes what the learner will be expected to be able to do. It should not describe a teacher activity (e.g., to go over the words on page seventeen with the students, explaining their meaning and telling them how the words are pronounced). It may be helpful to both the

teacher and the student to know what the teacher is going to do but teacher activities are also not to be confused with instructional objectives.

If an instructional objective is not observable (or does not describe an observable product), it leads to unclear expectations and it will be difficult to determine whether or not it had been reached. The key to writing observable objectives is to use verbs that are observable and lead to a well defined product of the action implied by that verb. Verbs such as "to know," "to understand," "to enjoy," "to appreciate," "to realize," and "to value" are vague and not observable. Verbs such as "to identify," "to list," "to select," "to compute," "to predict," and "to analyze" are explicit and describe observable actions or actions that lead to observable products.

There are many skills that cannot be directly observed. The thinking processes of a student as she tries to solve a math problem cannot be easily observed. However, one can look at the answers she comes up with and determine if they are correct. It is also possible to look at the steps a student takes to arrive at an answer if they are written down (thus displaying his thinking process). There are many end products that also can be observed (e.g., an oil painting, a prose paragraph, a 3-dimensional map, or an outline.)

### Characteristics of a Useful Objective

To be useful for instruction, an objective must not only be well written but it also must meet the following criteria: (1) be sequentially appropriate; (2) be attainable within a reasonable amount of time; (3) be developmentally appropriate.

For an objective to be sequentially appropriate it must occur in an appropriate place in the instructional sequence. All prerequisite objectives must already have been attained. Nothing thwarts the learning process more than having learners trying to accomplish an objective before they have learned the necessary prerequisites. This is why continuous assessment of student progress is so important.

A useful objective is attainable within a reasonable time. If an instructional objective takes students an inordinately long time to accomplish, it is either sequentially inappropriate or it is too broad, relying on the accomplishment of several outcomes or skills rather than a single outcome or skill. An objective should set expectations for a single learning outcome and not a cluster of them.

Developmentally appropriate objectives set expectations for students that are well within their level of intellectual, social, language, or moral development. Teachers, parents, and others who are working with preschool or elementary school children should be especially aware of the developmental stages of the children they are working with. No author or researcher has more clearly defined the stages of intellectual development than Jean Piaget. Familiarity with his work as well as with the work of other child development specialists (e.g., Lev Vygotsky's language development, Lawrence Kohlberg's moral development and Erik Erikson's social development) should produce better instructional objectives.

### Kinds of Instructional Objectives

Instructional objectives are often classified according to the kind or level of learning that is required in order to reach them. There are numerous taxonomies of instructional objectives; the most common taxonomy was developed by Benjamin Bloom and his colleagues. The first level of the taxonomy divides objectives into three categories: cognitive, affective, and psychomotor. Simply put, cognitive objectives focus on the mind; affective objectives focus on emotions or affect; and psychomotor objectives focus on the body.

Cognitive objectives call for outcomes of mental activity such as memorizing, reading, problem solving, analyzing, synthesizing, and drawing conclusions. Bloom and others further categorize cognitive objectives into various levels from the simplest cognitive tasks to the most complex cognitive task. These categories can be helpful when trying to order objectives so they are sequentially appropriate. This helps to insure that prerequisite outcomes are accomplished first.

Affective objectives focus on emotions. Whenever a person seeks to learn to react in an appropriate way emotionally, there is some thinking going on. What distinguishes affective objectives from cognitive objectives is the fact that the goal of affective objectives is some kind of affective behavior or the product of an affect (e.g., an attitude). The goal of cognitive objectives, on the other hand, is some kind of cognitive response or the product of a cognitive response (e.g., a problem solved).

Psychomotor objectives focus on the body and the goal of these objectives is the control or manipulation of the muscular skeletal system or some part

of it (e.g., dancing, writing, tumbling, passing a ball, and drawing). All skills requiring fine or gross motor coordination fall into the psychomotor category. To learn a motor skill requires some cognition. However, the ultimate goal is not the cognitive aspects of the skill such as memorizing the steps to take. The ultimate goal is the control of muscles or muscle groups.

### The Role of Objectives in Teaching and Testing

Objectives can be helpful in instructional planning, during the teaching/learning process, and when assessing student progress. Instructional objectives are often either ignored (by both teachers and students) or are, at best, occasionally referred to. However, it can be argued that instructional objectives should guide the teaching and learning process from beginning to end.

Most lesson plan forms include a place for the objectives of the lesson to be recorded. However, to write an objective down and then to plan the lesson around the topic of the lesson rather than around the learning outcomes to be reached is missing the point. There is good evidence in the human learning literature that different kinds of outcomes are learned differently. Robert Gagné was one of the first researchers to articulate this; it follows from his research that instructional planning must take into account the kind of learning the students will be engaged in as they seek to reach an objective. Effective teachers learn to categorize their instructional objectives and then develop the teaching and learning activities that will help students do the kind of thinking required for that kind of learning.

It's time to evaluate. How does an educator know what to measure? Look at the objectives. How does a teacher know what kind of information gathering tools to use (test, rubric, portfolio)? Study the objectives. Any test item, any rating scale or checklist, any technique devised to collect information about student progress must seek to measure the instructional objectives as directly and as simply as possible. Instructional objectives are an extremely valuable teaching tool that guide both teachers and students through the teaching and learning process.

## **INSTRUCTIONAL STRATEGIES**

Since the inception of formal, classroom-based instruction, a fundamental aspect of teaching has been

the way teachers arrange the classroom environment so students can interact and learn. The instructional strategies teachers use help shape learning environments and represent professional conceptions of learning and of the learner. Some strategies consider students empty vessels to be filled under the firm direction of the teacher; other strategies regard them as active participants learning through inquiry and problem solving—still others tell children they are social organisms learning through dialogue and interaction with others.

### **History**

The instructional strategies used in the early twenty-first century began in antiquity. In ancient Greece, Socrates illustrated a questioning strategy intended to facilitate the learner's independent discovery of important truths. An instructional strategy similar to direct instruction was reported by Samuel Griswold Goodrich's account of teaching in a rural Connecticut school during the early eighteenth century.

The children were called up one by one to Aunt Delight, who sat on a low chair and required each, as a preliminary, "to make his manners," which consisted of a small, student nod. She then placed the spelling book before the pupils and with a penknife pointed, one by one, to the letters of the alphabet saying, "What's that?" (Edward and Richey, p. 172).

As education extended beyond society's elite, educators became interested in instructional strategies that would accommodate large numbers of students in efficient ways. One example, the Lancaster Method, popular in the early nineteenth century, consisted of gathering as many as a hundred students in one large room, sorting them into groups of similar abilities, and having monitors (teacher aides) guide pupil recitations from scripted lesson plans. Nineteenth-century instructional strategies were teacher centered, intended mainly to transmit basic information clearly. In the early part of the twentieth century, however, this emphasis started to shift. John Dewey and his disciples of Progressive education left a legacy of student-centered instructional methods aimed at helping students acquire higher-level thinking and problem-solving skills. Of particular importance was the project method that provided the intellectual heritage for such contemporary methods as cooperative learning, problem-

based instruction and other approaches emphasizing active student learning and group interaction.

The early work of the Progressives, fueled later by new theories and research about learning by such eminent theorists as European psychologists Lev Vygotsky and Jean Piaget and Americans Jerome Bruner and Albert Bandura extended thinking in the profession about instructional strategies in the post-*Sputnik* reforms of the 1950s and 1960s. Cognitive psychology and constructivist perspectives produced instructional strategies such as discovery learning and inquiry teaching that were at the center of the curriculum reforms of that era, and the cooperative learning and problem-based strategies popular today became more widely known and used.

In the late 1960s Bruce Joyce began describing the various approaches to teaching that had been developed over the years. He developed a classification system to analyze each approach according to its theoretical basis, the learner outcomes it was designed to accomplish, and the teacher and student behaviors required to make the approach work. Joyce used the term *model* rather than *teaching strategy* to refer to a particular approach to instruction. In his initial work (Joyce and Weil, 1972) more than twenty models were identified. Joyce's conceptualization of the field was a significant contribution and has influenced greatly how educators have thought about instructional strategies worldwide.

### Nature and Categories of Instructional Strategies

In the early twenty-first century there are many instructional strategies. Similarly, there are tactics used by teachers to support particular strategies. The following provides a framework for thinking about instructional strategies, and then provides descriptions of seven strategies used frequently by teachers.

**Instructional organizers, strategies, and tactics.** A number of educators over the years, such as Barrie Bennett and Carol Rolheiser, have developed conceptual frameworks for thinking about instructional strategies. The frameworks most often include instructional organizers, instructional strategies, and tactics. Instructional organizers are at one end of a complexity continuum, and provide the "big ideas" that allow us to think about instructional practices. Examples of instructional organizers would be Howard Gardner's multiple intelligences or Benjamin Bloom's taxonomy for organizing instructional objectives. On the other end of the continuum are what

are often labeled *instructional tactics*. These are specific, and for the most part, simple actions taken by teachers within the confines of particular teaching strategies. Asking questions, checking for student understanding, providing examples or visual representations, or examining both sides of an argument are examples of instructional tactics. Many tactics have grown out of the practices of experienced teachers. In the middle of the continuum are instructional strategies that involve a series of steps, are supported by theory and research, and have been designed to produce certain types of student learning. Examples of instructional strategies would include direct instruction, cooperative learning, and the others described later in this article.

Finally, some teaching strategies are tightly tied to the content of particular lessons. *Pedagogical content knowledge* is a term coined by Lee Shulman in 1987 to describe the relationship between content and strategy and to illustrate how what is being taught influences the way it is taught. For example, an English teacher teaching a Shakespearean tragedy would use different strategies than the biology teacher who is trying to help students understand photosynthesis. Similarly, a fourth-grade teacher would use different methods to teach reading, fractions, or the concept of scarcity.

**Learning environments and instructional strategies.** Classrooms are places where teachers and students interact within a highly interdependent environment. At particular times, some types of learning environments have been deemed more appropriate than others. For example, prior to the mid-twentieth century in the United States, environments that kept students quiet and in their seats were the preferred environment compared to later times when more open and active environments were in vogue. Both formal and informal learning emanates from the particular environments that teachers create, and these are highly influenced by the strategies being used. For instance, lecturing creates a tightly structured learning environment where students are expected to listen, observe, and take notes. On the other hand, if the teacher divides students into cooperative learning groups, an environment is created where students are actively engaged and in charge of their own interactions.

**Instructional strategies and learner outcomes.** Learning is defined as a process where experience (instruction) causes a change in an individual's knowledge or behavior; different learning theories

propound different perspectives about what is important and how learning occurs. Behavioral learning theories generally view the outcome of learning as change in behavior and emphasize the effects of the external environment. Cognitive and constructivist learning theories, on the other hand, view learning as change in cognition and focus mainly on internal mental activity. Instructional strategies used by teachers stem from particular learning theories and in turn produce certain kinds of outcomes. For most of the twentieth century, arguments persisted about which learning theories and which instructional strategies were the most accurate and most effective in affecting student learning. Debates among educators and the general public have surrounded lecture versus discussion; direct instruction versus discovery learning; and phonics versus whole language. These debates led nowhere mainly because the selection of effective instructional strategies can not always be precisely pinpointed, and mainly depends on what the teacher is trying to accomplish.

Contemporary conceptions of instructional strategies acknowledge that the goals of schooling are complex and multifaceted, and that teachers need many approaches to meet varied learner outcomes for diverse populations of students. A single method is no longer adequate. Effective teachers select varied instructional strategies that accomplish varied learner outcomes that are both behavioral and cognitive. To illustrate this point consider strategies teachers might use to teach the Bill of Rights to a group of eighth-grade students. The teacher might begin with a lecture describing each of the ten articles and the reasons they were included as the first ten amendments to the Constitution. Students might then be asked to match each amendment with its purpose. Use of the lecture and direct instruction methods facilitates the transmission of fairly large amounts of information to students in an efficient manner and helps them retain it in memory. However, it does not encourage students to think very deeply or critically about the Bill of Rights, or consider its significance to contemporary life. Nor would listening to a teacher promote the development of social discourse skills. Instead, the teacher might use more interactive strategies such as concept teaching and cooperative learning. If, however, teachers use more interactive methods, they have less time to explain the Bill of Rights. Particular strategies, then, have been designed to achieve particular learner outcomes, but no single strategy can

address them all. Appropriate use of particular strategies depends upon the type of learning outcomes the teacher wants to achieve.

### Taxonomies for Categorizing Instructional Methods

Several taxonomies have been developed that categorize instructional strategies based on the strategy's theoretical underpinnings and on the type of learner outcomes that result from using the strategy. Joyce's taxonomy divided instructional models into four major families: information processing, behavioral, personal, and social. Behavioral strategies are designed to help students acquire basic information and skills. Information processing strategies help the learner process and use information and data. Social strategies help develop a sense of community and facilitate the learning of social skills. Personal methods emphasize the development of personal growth and awareness.

Others have made distinctions among strategies based on achieving learning outcomes most closely associated with behavioral theory as compared to those outcomes that stem from information processing, cognitive, and constructivist theories of learning. Still others have found the student-centered and teacher-centered categorization scheme useful for thinking about the relationship between student learning and instructional strategies. The seven strategies are categorized according to the degree of student versus teacher centeredness and the theoretical basis for the strategy (see Table 1).

### Frequently Used Instructional Strategies

The rationale and theoretical background for each strategy is described in the table, along with the learner outcomes the strategy is intended to produce and the syntax and learning environment required to make the strategy effective. Syntax refers to the steps or phases through which a lesson progresses. Learning environment refers to the classroom context and required teacher and student behaviors. Each strategy described has been subjected to substantial research and evaluation and has been deemed highly effective. Positive effects, however, are sizeable only if the strategy is implemented faithfully.

**Direct instruction.** Direct instruction is a method for imparting basic knowledge or developing skills in a goal-directed, teacher-controlled environment. The teacher identifies clearly defined learning out-

comes, transmits new information or demonstrates a skill, and provides guided practice. Direct instruction is designed to maximize academic learning time through a highly structured environment in which students are “on task” and experience high degrees of success.

Direct instruction has its roots in behaviorism. Behavioral theorists emphasize breaking behaviors and skills into component tasks and mastering each subcomponent. They emphasize the importance of modeling desired behavior and using feedback and reinforcement to guide students toward desired goals. The clearest empirical support for direct instruction came from the teacher effectiveness research of the 1970s and 1980s. By studying the relationship between teaching behaviors and student achievement in classrooms, researchers concluded that direct instruction produced greater time-on-task and higher student achievement, particularly for the acquisition of basic information and skills.

Direct instruction can be used effectively to promote acquisition of knowledge that is well structured and that can be taught in a step-by-step fashion, such as parts of speech, the multiplication tables, or the capitals of the fifty states. It is also effective in teaching how to perform simple and complex skills such as how to subtract, read a map, or swing a golf club. Although direct instruction is widely used, it is not appropriate for teaching concepts and generalizations, higher-level thinking, inquiry, problem solving, group processes, or independent learning.

In general, a direct instruction lesson proceeds through five phases. Teachers begin the lesson with an orientation phase. The teacher clarifies the goals of the lesson, explains why the lesson is important, ties the lesson to previous lessons and students’ prior knowledge, and motivates students. This establishes the students’ mental set and prepares them for the lesson. This initial phase is followed by phase 2, presentation or demonstration. The teacher demonstrates the skill or presents new information. If a skill is being taught, each step must be identified and demonstrated accurately. If new information is being taught, the information must be well organized and logically presented. Effective teachers give multiple examples, provide accurate demonstrations, restate the information often, and use visual models or illustrations.

The third phase is guided practice. The teacher structures the initial practice by walking the students

through, step-by-step, and giving feedback on correct and incorrect responses. When students understand, the teacher moves to guided practice in which students work independently while the teacher monitors student work and gives individual feedback. Guided practice is most effective in short increments repeated over time. At the end of guided practice, phase 4 checks for understanding and provides feedback, informally or formally, verbally or in writing. The most common tactic in this phase of the lesson is teacher questioning, but assessing independent work, giving a quiz, or observing a live or taped performance may also be appropriate. Feedback must be given as soon as possible after practice and be specific and focused on behavior.

The final phase of a direct instruction lesson is extended practice. Extended practice reinforces the knowledge or skill. It can be accomplished through seatwork or homework, but should only be given when students are at or near mastery and timely feedback can be given. Extended practice over time increases retention, transfer, and automaticity.

The learning environment in a direct instruction lesson is highly structured by the teacher. Students are expected to be careful listeners and keen observers.

**Simulation.** Simulation involves students playing roles in simulated situations in order to learn skills and concepts transferable to “real life.” Students make decisions and learn from successes and failures. Simulations enable the learning of complex concepts or mastery of dangerous tasks in more simple and safe environments. Simulations include hands-on games such as Monopoly (real estate), social-political-economic role-playing or problem

solving (model United Nations or feeding a family of four on \$100 a week), software games (“Where in the World Is Carmen Sandiego?” for geography) and experiments (chemical changes), and simulators (driving a car or landing a plane). Although some simulations are done individually (such as driving), others occur in groups.

Simulation is grounded in a branch of behavioral psychology called cybernetics, which holds the perspective that learning occurs in an environment in which the learner receives immediate feedback, experiences the consequences of behavior, and continually self-corrects until mastery occurs. When learning to land a plane in a flight simulator, for example, the “pilot” receives feedback on the speed, height, and angle of descent, and corrects (or under- or over-corrects) until the plane “lands” or “crashes.” With continued practice, corrective behaviors become automatic until the “pilot” lands the plane safely each time.

Simulations are effective for teaching complex skills or concepts. Simulations can be used to practice skills such as driving, to teach concepts such as how political, social, and economic systems work, or to discern scientific principles through simulated experiments. Additional outcomes include problem solving, decision making, cause-effect relationships, cooperation or competition, and independent learning. Simulations are not effective for teaching large amounts of fact-based information.

Simulation has four phases. The teacher begins the lesson by explaining the purposes of the simulation and providing an overview of how it will proceed. This is followed by phase 2, where students are trained in the rules, procedures and goals of the simulation and provided time for abbreviated practice.

During phase 3, the simulation itself, the teacher serves as a coach, giving feedback, clarifying misconceptions, and maintaining the rules. The teacher does not tell students what to do or provide direct assistance. The debriefing aspect of the simulation, phase 4, allows time to describe and analyze experiences, make comparisons to real world situations, and relate the experience to the subject they are studying. The teacher’s role is critical at this final phase in helping students make sense of the simulated experience and tie it to course content.

The teacher structures and facilitates the learning environment fairly tightly; however, students are active in determining their own experiences during

the simulation. Students work individually or cooperatively in a nonthreatening atmosphere in which feedback comes from the simulation or from peers. The teacher helps students apply their learning to real world situations.

**Presentation using advance organizers.** Presentation (or lecture) is among the most commonly used strategies for knowledge acquisition and retention. But presentation is more than teachers talking. An effective presentation requires a highly structured environment in which the teacher is an active presenter and students are active listeners and thinkers. Teachers use advance organizers—powerful concepts to which subordinate ideas and facts can be linked—to provide structure and then involve students in processing the new information.

The presentation strategy is grounded in information processing theory, which describes how learning occurs and how the mind organizes knowledge. The brain utilizes short-term memory for complex thought processes and long-term memory for information storage. Stored information is organized according to hierarchically ordered concepts and categories called cognitive structures. New information must be processed actively in short-term memory and tied to students’ existing cognitive structures in long-term memory. Just as the mind has cognitive structures, every discipline has an organizational structure. Presentations should be organized around key ideas and structures and these structures should be made explicit to students.

Presentation enables teachers to organize and convey large amounts of information efficiently. It is an appropriate strategy for instructing students about the key ideas in a subject, for acquisition and retention of factual information linked to these ideas, and for comparing similarities and differences among ideas. Presentation is less appropriate for higher-level thinking, problem solving, and inquiry, although it may be used prior to such activities to ensure that students have the necessary foundational information.

There are four phases in a presentation lesson. The teacher begins the presentation by explaining the goals, sequence, and expectations of the lesson, and by helping students retrieve appropriate prior knowledge. In phase 2 the advance organizer is presented. Advance organizers are “scaffolds” that help learners link new information to what they already know. Advance organizers may be expository, com-

parative (relationships), or sequential (steps), and work best when accompanied by graphic or visual representations.

Phase 3 is the presentation itself. As new learning material is presented, the teacher pays particular attention to order and clarity, and provides concrete examples and illustrations that help students make required connections to what they already know.

In the final phase of a presentation, the teacher checks for student understanding and helps them integrate what they have learned. The teacher asks questions to encourage precise and critical thinking. Effective questions might involve asking for summaries, definitions, examples, comparisons, descriptions, analysis, or connections to the advance organizer. It is in this final phase that students integrate the new knowledge into their prior knowledge, build more complex cognitive structures, and develop understanding of complex relationships.

The teacher carefully structures the learning environment during a presentation so students can hear and see the presentation, uses procedures to ensure a smooth and effective pace, and addresses off-task behaviors immediately.

**Concept teaching.** Concept teaching helps students learn concepts and develop higher level thinking skills. Concepts (such as round and integer in mathematics, scarcity and freedom in social studies, energy and motion in science, and comedy and tragedy in literature) serve as the foundation for knowledge, increase complex conceptual understanding, and facilitate social communication. There are several different approaches to concept teaching. The approach described here is called concept attainment and is an inductive process in which students construct, refine, and apply concepts through teacher-directed activities using examples and nonexamples and in which students learn to classify, recognize members of a class, identify critical and noncritical attributes, and define and label particular concepts.

Cognitive theorists such as Jean Piaget and Jerome Bruner and information processing psychologists such as Robert Gagne emphasized that thinking is organized around conceptual structures. Children begin learning concepts very early through interaction with concrete objects. Conceptual structures continue to develop with increasing complexity and abstraction throughout life. Concept formation requires students to build categories (an island is land

surrounded by water; a noun is a name for a person, place or thing). Concept attainment requires students to figure out the attributes of a category (e.g., a triangle has three sides and three angles; an adjective describes a noun). Young children can categorize using one rule or attribute (a bird has feathers), but students gradually develop the ability to use multiple rules or attributes (birds have feathers, lay eggs, have feet, and are warm-blooded) and to distinguish noncritical attributes (some birds fly, but not all birds). Examples and nonexamples are used to help students construct new concepts (a diary is a primary source, but a novel is not).

The primary purpose of concept teaching is to learn new concepts. It is also effective for teaching higher-level thinking, including inductive reasoning, hypothesis formation, logical reasoning, concept building strategies, and taking multiple perspectives (Is a slave's concept of slavery different from a master's concept?). Although not designed to convey large amounts of information, students must process information as they formulate new concepts.

Concept teaching has four phases. In phase 1 the teacher explains the purposes of the lesson, describes why concepts are important, and gets students ready to learn. The second phase consists of presentation of examples and nonexamples of the concept. The teacher gives examples and nonexamples, and the students strive to discover the concept and its attributes through inductive reasoning.

After the concept has been discovered, the teacher gives more examples and nonexamples, then asks students to provide examples and nonexamples. The purpose of this tactic is to test student understanding of the concept and its attributes. A concept lesson concludes with the teacher asking students to analyze their thinking patterns, strategies, and decisions in order to develop more effective thinking skills and to help students integrate the new concepts into existing knowledge.

The learning environment for concept teaching has a moderate degree of structure in that the teacher controls the first three phases of the lesson rather tightly. The fourth phase is more open and student interaction is encouraged. As students gain more experience with concept learning, they can assume increasing responsibility for how the lesson proceeds.

**Discussion.** Discussion is central to all aspects of teaching. Classroom discussion may serve as a strategy in itself or as part of another strategy. Teachers

and students talking about academic content and students displaying their ideas and thinking processes to the teacher and to each other characterize discussions. Effective discussions go beyond question-and-answer recitations. The more involved students are in the discussion, the more effective the learning.

Theoretical support for classroom discussions stems from the study of language and patterns of discourse and from constructivist psychologists, such as Lev Vygotsky, who believed that most learning occurs through language-based social interactions.

Discussion is an appropriate strategy for improving student thinking; promoting engagement in academic content; and learning communication and thinking skills in a social environment. Discussion is particularly appropriate for topics that are subjective or controversial and that involve several points of view, such as the causes of World War I or funding of stem-cell research.

Classroom discussion proceeds through five phases. The teacher introduces the discussion by providing a clear purpose for the discussion and engaging students so they will become involved. This is followed by phase 2 where the teacher sets the ground rules, then poses a question, raises an issue, or presents a puzzling situation.

Phase 3 is the discussion itself. The teacher asks questions, uses wait-time, responds to students' ideas, and enforces the ground rules. The teacher keeps the discussion focused and encourages all students to participate. Using visual cues and posting a written record of main ideas keeps the discussion focused. Skillful, well-planned questioning is critical, and each discussion should include a mixture of factual and thought-provoking questions. Pairing students or putting them in small groups can increase their participation during a discussion.

The teacher provides closure in phase 4 by (1) summarizing; (2) asking students to summarize the content and meaning of the discussion; and (3) tying it back to the initial question or problem. Finally, the teacher debriefs the process of the discussion by having students examine their thinking processes and reflect on their participation.

The teacher focuses and moderates the discussion, but broad and active student participation characterizes the learning environment. The atmosphere is one of open communication in which students feel free to express their ideas and ask

questions. Teaching students to have high regard for other's ideas and to use interpersonal communication skills improves cognitive and social learning.

**Cooperative learning.** In cooperative learning students work together in small groups on a common learning task, coordinate their efforts to complete the task, and depend on each other for the outcome. Cooperative learning groups are characterized by student teams (of 2–6) working to master academic goals. Teams are normally comprised of learners of mixed ability, ethnicity, and gender. Rewards systems (grades) are designed for the group as well as individuals.

Cooperative learning is rooted in two theoretical traditions. First, it is based on the progressivism of John Dewey, particularly his idea that the school should mirror the values of the society and that classrooms should be laboratories for learning democratic values and behaviors. Students are prepared for civic and social responsibilities by participating in democratic classrooms and small problem-solving groups. Cooperative learning also has roots in constructivist theory and the perspective that cognitive change takes place as students actively work on problems and discover their own solutions. Particularly important is Lev Vygotsky's theories that students learn through language-based interactions with more capable peers and adults.

Cooperative learning has three distinct goals: academic achievement, acceptance of diversity through interdependent work, and development of cooperative social skills.

There are numerous approaches to cooperative learning and each proceeds in slightly different ways. However, in general, a cooperative learning lesson has six phases. The teacher begins the lesson by presenting the goals of the lesson, motivating students, and connecting the forthcoming lesson to previous learning. Procedures, timelines, roles and rewards are described. Required group processes or social skills may also be taught at the beginning of a cooperative learning lesson.

In phase 2 the teacher facilitates the acquisition of the academic content that is the focus of the lesson. This may be done verbally, graphically, or with text. The teacher during phase 3 explains how the teams are formed and helps students make transitions into their groups. Phase 4 is teamwork. Students work together on cooperative tasks and the teacher assists students and groups, while reminding them of their interdependence.

The final phases of a cooperative learning lesson consists of phase 5 (assessment) and phase 6 (recognition). The teacher tests student knowledge or groups present their work. Individual students and groups are assessed on cooperation as well as academic achievement. The effort of individuals and groups are recognized through displays, newsletters, presentations, or other public forums.

The learning environment for cooperative learning differs markedly from the traditional individualistic classroom environment. Students assume active roles and take responsibility for their own learning. The social atmosphere is collaborative and respectful of differences. Students learn group processes and problem-solving skills and become increasingly independent in using them. Students construct their own learning through active engagement with materials, problems, and other students. The teacher forms the teams, structures the group work, provides materials, and determines the reward structure, but the students direct their own work and learning.

**Problem-based instruction.** In problem-based instruction students are presented with authentic, meaningful problems as a basis for inquiry and investigation. Sometimes called project-based instruction, inquiry learning, or authentic investigation, this strategy is designed to promote problem solving and higher-level thinking skills. All problem-based instruction strategies include more or less the following features: a driving question or problem, interdisciplinary focus, authentic investigation, production of artifacts or exhibits, and collaboration. This strategy is designed to involve students in the kinds of real-world thinking activities they will encounter outside of school from childhood through adulthood. Sample problems include the following:

- Why did the settlers at Jamestown die?
- How can we recycle in the school cafeteria?
- What causes clouds to form different shapes?
- How much peanut butter does our school need for a year and how much would it cost?
- Why did some civilizations thrive while others died out?
- What will happen if the world population doubles in five years?

Like cooperative learning, problem-based instruction has its roots in the progressivism of John Dewey and the constructivism of Jean Piaget, Lev

Vygotsky, and Jerome Bruner. Dewey argued that learning should be relevant and engaging through the involvement of students in group projects of their own interest. Piaget theorized that learning occurs through active investigations of the environment in which students construct personally meaningful knowledge. Vygotsky stressed the importance of social, language-based learning. Bruner emphasized the importance of learners working with their own ideas and finding meaning through active involvement and personal discovery.

The primary goal of problem-based instruction is learning content through inquiry that can be applied in authentic situations. Students learn to think and behave like adult workers, scholars, and problem solvers and to regulate their own learning. They learn collaboration skills and research and inquiry strategies, and gain an understanding of knowledge as complex, multifaceted, and uncertain.

Problem-based instruction involves five phases similar to those in cooperative learning. A lesson may extend over several days or even weeks. Phase 1 is orientation to the problem. The teacher presents the problem or driving question, provides the parameters for student inquiry, and motivates students to engage in problem-solving activities. In phase 2 the teacher assists students in forming study groups and assists the groups in defining, planning, and organizing tasks and timelines, and by clarifying roles and responsibilities.

During the students' investigation, phase 3, the teacher encourages, questions, and assists students in data/information gathering, hypothesis formulation and testing, and the generation of explanations and solutions. Guiding and coaching is emphasized, not directing and telling.

Problem-based lessons are brought to conclusion through student presentation of products and exhibits, phase 4, and through reflection, phase 5. The teacher assists students in planning, preparing, and presenting products that share their work with others. These might include reports, videos, multimedia presentations, murals, plays, reenactments, models, diaries, or computer programs. After presentations, the teacher helps students reconstruct and analyze their thinking processes and integrate their learning.

Problem-based instruction is the most student centered of the strategies presented. Students work actively and independently on problems that interest

them. This requires an environment that is open and safe for asking questions, forming hypotheses, and sharing ideas. The teacher's role is to pose problems, ask questions, facilitate investigation and dialogue, and provide support for learning.

## INTELLECTUAL PROPERTY RIGHTS

Intellectual property law, once thought of as an arcane and unpopular area of law, came to the forefront of legal disciplines in the 1990s, in large part due to the increased use of computers and the commercialization of the World Wide Web. Because of the widespread use of technology and computers to conduct research and teach, intellectual property law greatly impacts the educational enterprise in the early twenty-first century. The use of computer networks and the Web to create classrooms in cyberspace, communicate with students and faculty, write and publish scholarly material, and conduct research is considered the norm for many educational institutions. And each of these activities involves the use of copyrighted information. As a consequence educators and administrators need to have a basic understanding of copyright in order to avoid misusing copyrighted material.

### Copyright Framework and Exclusive Rights

Intellectual property in the United States is a property right created by the law in intangible property. Specifically, *copyright* is a subset of *intellectual prop-*

erty, which protects creative works such as literature and art. Other types of intellectual property are patents, which protect inventions and processes, and trademarks, which protect names and logos.

Copyrights and patent rights originate from the Patent and Copyright Clause of the United States Constitution, which states “The Congress shall have power to . . . promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries” (Art. 1, sec. 8, clause 8). The policy behind the copyright framework, embodied in this clause, is that economic incentive, in the form of monopoly rights in an author’s work, is needed to generate new creative works in society and thus promote “the progress of science and useful arts.”

The monopoly rights that authors possess are outlined in section 106 of the Copyright Act of 1976 (the Act). These rights include the right to make copies, create derivative works, and distribute, display, and perform works publicly. The copyright owner is entitled to exercise and authorize these rights, and prevent others from exercising these rights. Unless a use is exempted or considered fair, users must seek the permission of copyright owner and/or pay license fees to use a copyrighted work.

The digital environment implicates the exclusive rights of authors quite easily. For example, every time a person saves a work to a disk, the right to make copies is invoked. Scanning, digitizing, uploading, downloading, and file transfer all involve the right to make copies. A work is publicly displayed each time someone posts copyrighted information on a bulletin board, website, or online class. When a display or performance is done through a digital network transmission, temporary RAM copies are made in computers through which the material passes.

### Copyright Protection and the Public Domain

In order to qualify for copyright protection, a work must meet the statutory requirements set out in section 102(s) of the Act. The work must be an original work of authorship fixed in a tangible medium of expression. Copyright protection exists from the moment of fixation in a tangible medium. The protection is automatic and notice is not required; however, registration carries certain benefits and is required to bring a lawsuit. Section 102 of the Copy-

right Act of 1976 includes eight categories of subject matter that fall under copyright protection: literary works; musical works; dramatic works; pantomimes and choreographic works; pictorial, graphic, and sculptural works; motion pictures and audiovisual works; sound recordings; and architectural works. Examples of copyrighted expression also include computer programming, animations, video footage, java applets, web pages, and photographs.

An important aspect of the copyright framework is that facts, ideas, and government works are not protected. Those items are generally considered within the public domain and freely available for use without permission or payment of license fees. The logic behind this is clear. If facts and ideas in particular were considered copyrighted information, then the process of innovation, research, and scholarship would be considerably slowed due to the increased time and monetary costs of getting permission and paying fees. Moreover, the possibility of great constraint of academic freedom would be quite high under those circumstances because those who exercised control over controversial facts or ideas might be hesitant to grant access to those materials. Facts, ideas, government information, and items with expired terms of copyright are also within the public domain. To determine whether a copyright term has expired, one should consult Chapter 3 of the Copyright Act. Another helpful resource is a chart developed by Laura N. Gasaway of the University of North Carolina School of Law that helps determine when works pass into the public domain. The chart can be found online at <[www.unc.edu/~unclng/public-d.htm](http://www.unc.edu/~unclng/public-d.htm)>.

### Copyright Ownership

The exclusive rights in copyright are initially given to the owner of the copyrighted work. Although the author may transfer the copyright to someone else, any analysis of copyright ownership should begin with the principle that the author is the owner. Section 201 of the Act provides four types or categories for ownership: (1) author; (2) joint ownership; (3) collective works; and (4) works made for hire.

The primary exception to the *author is owner* approach is the *work-for-hire* category. When a work is made for hire, the employer, not an employee, is considered the owner/author of a work. Section 101 of the Act outlines two ways a work is made for hire: (1) the employee creates the work within the scope of his or her employment; or (2) the work meets the

statutory criteria of being an independently contracted work made for hire.

The work-for-hire doctrine has always played a role in academic production. Many institutions have asserted ownership over research and other scholarly works by claiming the work is made for hire. However, an exception to this rule was developed in the common law for things such as syllabi, lectures, textbooks, and articles that professors write. There is no such explicit exception in the Copyright Act of 1976.

The factors to be considered in determining whether or not a person is an employee were outlined in the Supreme Court's decision in *Community for Creative Non-Violence (CCNV) v. Reid* (1989). The CCNV factors applied by the U.S. Court of Appeals for the Second Circuit in *Aymes v. Bonelli* include: the right of the hiring party to control the manner and means of creation; employee benefits provided by the hiring party; whether the hiring party has the right to assign more projects to the hired party; tax treatment of the hired party; and skill required to complete the project.

If a creator is not an employee, but is hired to create something, and both parties sign a written contract before the work begins that states the work is a work made for hire, and if the work fits into one of the statutory categories, it will be considered a work made for hire and the hiring party will own the work. The statutory categories are: contribution to a collective work; part of a movie or other audiovisual work; a translation; a supplementary work; a compilation; an instructional text; a test; answer material for a test; an atlas.

The controversy over the availability of the academic exception under the 1976 act has been exacerbated by the onset of digital distance education. Many educators claim that distance-education courses delivered online are nothing less than lecture notes, and that these items have historically been the property of faculty. Institutions counter that online courses are not developed in isolation, but that various persons help to develop them, and the institution therefore has an ownership interest in such courses. Because of the lack of clarity in this area, it is very important that colleges and universities develop copyright policies. University copyright policies can affect the application of copyright law by designating certain activities as being outside the scope of employment and/or incorporating the traditional academic exception.

## Copyright Limitations and Exemptions

Although copyright owners have exclusive rights in their creations, these exclusive rights are limited by certain statutory exemptions and defenses. The most used and notable of these for the education community are: fair use, library copying, first sale, and the educational *performance and display* exemptions. The primary limitation in copyright on the exclusive rights of copyright owners is *fair use*. The fair use privilege allows for the reasonable use of a copyrighted work without permission or payment of license fees if the use is fair pursuant to statutory factors. Section 107 of the Act includes four factors that must be weighed to determine whether or not a use is fair: (1) the purpose and character of the use; (2) nature of the copyrighted work; (3) the amount and substantiality of the portion used; and (4) the effect of the use on the potential market for, or value of, the copyrighted work. All four factors are weighed or balanced, and no one factor ensures a finding of fair use. Fair use is critical to the teaching and research that takes place in educational institutions. If fair use did not exist, then the research process would be greatly frustrated, since many small and relatively inconsequential research uses copyrighted material that could be considered unlawful reproductions such as photocopying a page from a journal in order to write a research paper.

Exemptions that are directly applicable to the classroom and to distance education are located in Section 110 of the Copyright Act. The classroom exemption, 110(1), allows for the performance and display rights to be used in the course of "face to face" teaching at a nonprofit educational institution. The use must be within a "classroom or similar place devoted to instruction." The right to public display may occur whenever a picture, graphic, text, or chart is shown directly or by means of a projecting mechanism. A performance may occur when a work is recited or acted, or when an audiovisual work, such as a videotape, is played. Thus, in the course of teaching students in the classroom one can read text out loud, sing a song, or play a movie.

The types of activities permitted in the course of face-to-face instruction under the act, as of May 2002, may not be permitted in an online class, pursuant to the distance education exemption. The distance education exemption, 110(2), allows for the performance only of nondramatic literary or musical works or the display of a work if: (1) the use is part of "systematic instructional activities" of a nonprofit

educational institution or governmental body; (2) the use is “directly related and of material assistance to the teaching content of the transmission;” and (3) the transmission must be “primarily” for “reception in classrooms or similar places normally devoted to instruction,” or for persons whose disabilities or other special circumstances prevent their coming to classrooms.

The distance education provision was created in the 1970s and does not address the issues involved in transmitting content in the online classroom. This exemption does not provide for the use of audiovisual works such as educational videos, theatrical films, and film clips. The U.S. Copyright Office documented some of the limitations in 110(2) in a report given in 1999. The copyright owner and user communities have attempted to negotiate an amendment to Copyright Act, known as the Technology Education and Copyright Harmonization Act (TEACH Act). As of May 2002, the TEACH Act had yet to be adopted by Congress.

### **Infringement and Liability**

Use of a copyrighted work without permission, unless it is covered under an exemption, infringes on the exclusive rights of the author outlined in Section 106 of the Copyright Act. Infringement can be direct, vicarious, or contributory. Direct infringement occurs when someone violates any of the exclusive rights of the copyright owner. Vicarious infringement occurs when one has the right to control the infringement of another or profits from infringement. This type of liability is based on the relationship with the direct infringer. Contributory infringement occurs when a person has knowledge of infringing activity and/or induces, causes, or contributes to infringing conduct. Educational institutions and faculty may be liable under all three types of liability.

### **Digital Millennium Copyright Act**

Educational institutions that are heavily networked with high student and faculty use of computers need to become well versed in the liability limits in the Digital Millennium Copyright Act (DMCA), a 1998 amendment to the Copyright Act. Specifically, the DMCA limits liability for Internet Service Providers (ISPs) and provides safe harbors from liability for conduit activities, system caching, hyperlinks, directories, and location tools and stored material on an ISP system. There are specific requirements that

must be met in order to get statutory protection, however. Service providers qualifying for these limits in subsections (a)–(d) are shielded from damage awards. Section 512(j) limits the availability of injunctive relief.

The DMCA has a specific provision for nonattribution of infringing conduct by graduate students and faculty of nonprofit educational institutions. This provision, 512(e), applies to the conduct of graduate students and faculty involved in teaching and research if: (1) the activities do not involve online access to instructional materials that are required or recommended for a course taught at the institution within the preceding three-year period; (2) within that same three-year period, the institution received two or fewer DMCA notifications that a particular faculty member or graduate student engaged in infringement and no actionable misrepresentations were made in connection with such notifications; and (3) the institution provides information on copyright compliance.

### **Anti-Circumvention**

The DMCA also adds sections 1201–1205 to the Copyright Act, implementing the World Intellectual Property Organization treaty provisions prohibiting the circumvention of technological copyright protection measures and protecting the integrity of copyright management information. Section 1201 defines circumvention of technological measures and prohibits circumvention of technological measures that restrict access to a copyrighted work and trafficking in the means to circumvent protective measures restricting access to a copyrighted work. A technological measure that controls access is defined as one in which the authorized access to a copyrighted work requires either application of information (such as a password) or a process or treatment—with the authority of the copyright owner. Circumvention occurs whenever such technological measures are avoided, bypassed, deactivated, or impaired without the authority of the copyright owner.

Section 1201(d) exempts nonprofit libraries, archives, or educational institutions that circumvent technological measures controlling access to a protected work that is not reasonably available in another form. Such conduct must be for the sole purpose of making a good faith determination of whether to acquire that work. This exemption does not apply to acts that fall under section 1201(a)(2) or 1201(b)(1), which prohibit trafficking in a product or service

that is intended to circumvent technological copyright protection measures.

There is also a narrowly limited reverse-engineering exception, found in section 1201(f), for circumvention of technological measures controlling access to a computer program. The exception exists for the sole purpose of identifying and analyzing those elements of a copyrighted work necessary to achieve interoperability with other independently created programs. *Interoperability* is defined as the ability of computer programs to exchange and share information. This section does not exempt acts of reverse engineering, but merely the circumvention of measures controlling access.

### Computer Software

The issue of reverse engineering as copyright infringement was litigated before the Court of Appeals for the Ninth Circuit in *Sega Enterprises Ltd. v. Accolade* (1992). The court observed that “intermediate copying of computer object code may infringe the exclusive rights granted to the copyright owner in section 106 of the Copyright Act regardless of whether the end product of the copying also infringes those rights.” The court held, however, that disassembly of copyrighted object code was a fair use, since it was a necessary step in the examination of unprotected ideas and functional concepts. The court recognized that there is no “settled standard” for identifying protected expression and unprotected ideas involved in determining copyright infringement of computer software.

## TRIARCHIC THEORY OF INTELLIGENCE

Robert J. Sternberg

## EMOTIONAL INTELLIGENCE

The term *emotional intelligence* was introduced in a 1990 article by Peter Salovey and John D. Mayer. They described emotional intelligence as a set of skills that involve the ability to monitor one's own and others' feelings and emotions, to discriminate among them, and to use this information to guide one's thinking and action. Salovey and Mayer introduced the term as a challenge to intelligence theorists to contemplate an expanded role for the emotional system in conceptual schemes of human abilities, and to investigators of emotion who had historically considered the arousal of affect as disorganizing of cognitive activity. In the spirit of Charles Darwin, who, in his 1872 book *The Expression of the Emotions in Man and Animals*, viewed the emotional system as necessary for survival and as providing an important signaling system within and across species, Salovey and Mayer emphasized the functionality of feelings and described a set of competencies that might underlie the adaptive use of affectively charged information.

### Associated Concepts and Formal Definition

The idea of an emotional intelligence was anticipated, at least implicitly, by various theorists who argued that traditional notions of analytic intelligence are too narrow. Emotional intelligence adds an affective dimension to Robert Sternberg's 1985 work on practical intelligence, is consistent with theorizing by Nancy Cantor and John Kihlstrom (1987) about social intelligence, and is directly related to research on children's emotional competencies by Carolyn Saarni (1999) and others. Emotional intelligence is most similar to one of the multiple intelligences characterized by Howard Gardner in *Frames of Mind* (1983). Gardner delineated *intrapersonal intelligence* as awareness of one's feelings and the capacity to effect discriminations among these feelings, label them, enmesh them in symbolic codes, and draw upon them as a means of understanding and guiding one's behavior.

Mayer and Salovey described emotional intelligence more specifically in 1997 by outlining the

competencies it encompasses. They organized these competencies along four branches: (1) the ability to perceive, appraise, and express emotion accurately; (2) the ability to access and generate feelings when they facilitate cognition; (3) the ability to understand affect-laden information and make use of emotional knowledge; and (4) the ability to regulate emotions to promote growth and well-being.

Individuals can be more or less skilled at attending to, appraising, and expressing their own emotional states. These emotional states can be harnessed adaptively and directed toward a range of cognitive tasks, including problem solving, creativity, and decision-making. Emotional intelligence also includes essential knowledge about the emotional system. The most fundamental competencies at this level concern the ability to label emotions with words and to recognize the relationships among exemplars of the affective lexicon. Finally, emotional intelligence includes the ability to regulate feelings in oneself and in other people. Individuals who are unable to manage their emotions are more likely to experience negative affect and remain in poor spirits.

### Measures and Findings

There are two types of measures of emotional intelligence: self-report questionnaires and ability tests. Self-report measures essentially ask individuals whether or not they have various competencies and experiences consistent with being emotionally intelligent. Ability tests require individuals to demonstrate these competencies, and they rely on tasks and exercises rather than on self-assessment. Self-report and ability measures may yield different findings, because asking people about their intelligence is not the same as having them take an intelligence test.

Self-report measures include relatively short scales, such as Niccola Schutte and colleagues' (1998) scale, intended to assess Salovey and Mayer's original model of emotional intelligence, and the Trait Meta-Mood Scale (TMMS), designed to assess people's beliefs about their propensity to attend with clarity to their own mood states and to engage in mood repair. More comprehensive self-report inventories, such as the Bar-On Emotional Quotient Inventory (EQ-i) encompass a larger number of subscales that tap into personality and other traits related to emotional experience and self-reported, noncognitive competencies.

The advantage of self-report measures is that they provide a global self-evaluation of emotional

competence. They draw upon a rich base of self-knowledge and reflect people's experiences across different settings and situations. However, these measures have important limitations: they measure perceived, rather than actual, abilities; and they are susceptible to mood and social desirability biases, as well as deliberate or involuntary self-enhancement. Moreover, self-report measures overlap substantially with personality, and it is unclear whether they contribute to the understanding of social and emotional functioning over and above what personality traits might explain.

To overcome such problems, Mayer, David Caruso, and Salovey (1999) developed an ability test of emotional intelligence. Their first test, called the Multidimensional Emotional Intelligence Scale (MEIS), paved the way for a more reliable, better normed, and more professionally produced test, the Mayer, Salovey, and Caruso Emotional Intelligence Test (MSCEIT). This test asks people to process emotional information and use it to solve various problems, and to rate the effectiveness of different strategies for dealing with emotionally arousing situations. It consists of eight tasks, including decoding facial expressions and visual displays of emotion, understanding blends of emotions and emotional dynamics, integrating emotional information with other thinking processes, and managing emotions for purposes of self-regulation and social interaction. The test can be scored using either expert or consensus norms, and Mayer and his colleagues demonstrated in 2001 that these scoring methods yield similar results.

Ability tests of emotional intelligence avoid the self-enhancement and other biases that plague self-report measures, and they are very different from personality inventories. These are substantial advantages. However, these tests also have limitations. To assess emotional regulation, the MSCEIT evaluates people's knowledge of appropriate strategies for handling various situations, rather than their actual skill in implementing these strategies. It is not known to what extent the abilities assessed by ability tests generalize across situations and social or cultural contexts. While they are intended to assess skills, relying on consensus scoring can make it difficult to distinguish enacted skills from adjustment or conformity, especially because emotionally intelligent behavior necessarily reflects attunement to social norms and expectations.

Evidence suggests that emotional intelligence, assessed through ability tests, represents a coherent and interrelated set of abilities, distinct from (but meaningfully related to) traditional measures of intelligence, and developing with age. Initial studies also suggest that ability measures of emotional intelligence are associated with a range of positive outcomes, including lower peer ratings of aggressiveness and higher teacher ratings of prosocial behavior among school children; less tobacco and alcohol consumption among teenagers; higher self-reported empathy, life satisfaction, and relationship quality among college students; and higher manager ratings of effectiveness among leaders of an insurance company's customer claims teams. Emotional intelligence also seems to explain the perceived quality of social relationships over and above what personality traits and traditional measures of intelligence might explain.

Stronger evidence that emotional skills are associated with social adaptation comes from studies with children, using very different measures. In a large number of studies, children's abilities to read emotions in faces, understand emotional vocabulary, and regulate their emotions have been associated with their social competence and adaptation, as rated by peers, parents, and teachers.

### **Emotional Intelligence in the Schools**

During the 1980s and 1990s, the idea that the social problems of young people (e.g., dropping out of school, illicit drug use, teenage pregnancy) can be addressed through school-based prevention programs became popular among educational reformers. Earlier programs focused primarily on social problem-solving skills or conflict resolution strategies. After the 1995 publication of a best-selling trade book on the topic of emotional intelligence by science writer Daniel Goleman, the concept of emotional intelligence gained enormous popular appeal, and school-based programs of social and emotional learning multiplied. These programs usually deal with emotions explicitly, and they can help children to build a feelings vocabulary, recognize facial expressions of emotion, control impulsive behavior, and regulate feelings such as sorrow and anger.

There is evidence that programs of social and emotional learning that are well designed and well implemented can promote children's social and emotional adjustment. Programs such as Promoting Alternative Thinking Strategies (PATHS), the Seattle

Social Development Project, and Resolving Conflict Creatively have been evaluated through studies that track children's development over time. Benefits from these programs may include gains in children's social and emotional bonding to school, lowered dropout rates, a reduced incidence of aggressive or risky behaviors, and improvements in cognitive and emotional functioning. However, social and emotional learning programs usually address a very broad range of competencies, and it is not known to what extent the benefits observed in these studies can be attributed specifically to the training of emotional skills. Moreover, the success of these interventions depends on many factors, including the quality and motivation of the teachers, as well as their capacity to promote informal learning and generalization of skills.

Researchers associated with the Collaborative to Advance Social and Emotional Learning (CASEL) and others have drafted useful guidelines to help educators choose, adapt, and implement effective social and emotional learning programs. Important questions remain to be addressed, however. In dealing with others, people draw upon a very wide range of social and emotional skills, and it may be difficult to address all these competencies through formal or explicit instruction. It is not clear exactly what skills to emphasize, what are the best ways of teaching these skills, and to what extent they generalize across settings and situations.

Emotional skills may contribute to academic achievement in various ways. The ability to perceive and understand emotions may facilitate writing and artistic expression, as well as the interpretation of literature and works of art. Emotional regulation may help children to handle the anxiety of taking tests, or the frustrations associated with any pursuit requiring an investment of time and effort. It may also facilitate control of attention, sustained intellectual engagement, intrinsic motivation, and enjoyment of challenging academic activities.

## MEASUREMENT

Introductory treatments of the measurement of intelligence often begin with a discussion of three pioneers in the field: the French psychologist Alfred Binet (1857–1911), the English psychologist Charles Spearman (1863–1945), and the American psychologist Lewis Terman (1877–1956). Binet initiated the applied mental measurement movement when, in 1905, he introduced the first test of general mental ability. Spearman offered support for a psychologically cohesive dimension of general intellectual ability when, in 1904, he showed that a dominant dimension (called *g*) appears to run through heterogeneous collections of intellectual tasks. And Terman championed the application of intelligence testing in schools and in the military. Subsequently, Terman also illustrated how tracking intellectually talented youth longitudinally (i.e., via long-term studies) affords fundamental insights about human development in general.

### Binet: The Testing of Mental Ability

Binet was not the first to attempt to measure mental ability. Operating under the maxim of the fourth century B.C.E. Greek philosopher Aristotle, that the mind is informed to the extent that one's sensory systems bring in clear and reliable information, the English scientist Francis Galton (1822–1911) and others had aimed to measure intellect through fundamental psychophysical procedures that indexed the strength of various sensory systems. In contrast, Binet examined complex behaviors, such as comprehension and reasoning, directly. In doing so, his methods could not compare to psychophysical assessments in terms of *reliability*. But Binet more than made up for this in the *validity* of his assessment procedure in predicting school performance. Binet's insight was to use an external criterion to validate his measuring tool. Thus, he pioneered the empirically keyed or external validation approach to scale construction. His external criterion was chronological age, and test items were grouped such that the typical member of each age group was able to achieve 50

percent correct answers on questions of varying complexity. With Binet's procedure, individual differences in scale scores, or mental age (MA), manifested wide variation around students of similar chronological age (CA). These components were synthesized by William Stern to create a ratio of mental development: MA/CA. This was later multiplied by 100 to form what became known as the intelligence quotient ("IQ"), namely  $IQ = MA/CA \times 100$ .

### Spearman: The Discovery of *g*

While Binet was creating the first valid test of general intellectual functioning, Spearman was conducting basic research that offered tangible support for the idea that a psychologically cohesive dimension of general intelligence (*g*) underlies performance on any set of items demanding mental effort. In a groundbreaking publication from 1904 called "General Intelligence: Objectively Determined and Measured," Spearman showed that *g* appears to run through all heterogeneous collections of intellectual tasks and test items. Ostensibly, items aggregated to form such groupings were seen as a hodgepodge. Yet when such items are all positively correlated and they are summed, the signal received by each is successively amplified and the noise carried by each is successively attenuated. And the total score paints a clear picture of the attribute under analysis.

Spearman and William Brown formalized this property of aggregation in 1910. The Spearman-Brown Prophecy formula estimates the proportion of common or reliable variance running through a composite:  $r_{tt} = kr_{xx} \div 1 + (k - 1)r_{xx}$  (where:  $r_{tt}$  = common or reliable variance,  $r_{xx}$  = average item intercorrelation, and  $k$  = number of items). This formula reveals how a collection of items with uniformly light (weak) positive intercorrelations (say, averaging  $r_{xx} = .15$ ) can create a composite dominated by common variance. If fifty  $r_{xx} = .15$  items were available, for example, their aggregation would generate an individual differences measure having 90 percent common variance (and 10 percent random error). Stated another way, aggregation amplifies signal and lessens noise. As Bert Green stated in his 1978 article "In Defense of Measurement," "given enough sow's ears you can indeed make a silk purse" (p. 666). A large number of weak positive correlations between test items is, in fact, the ideal when measuring broad psychological attributes.

## Terman: The Application of IQ

Binet's approach to assessing mental ability was impressive because, unlike psychophysical assessments of sensory systems, his test forecasted teacher ratings and school performance. And Spearman's work identified the dominant dimension responsible for the validity of these forecasts. Subsequently, Terman cultivated the new enterprise of applied psychological testing. For example, he played a key role in America's military effort when he combined forces with the American psychologist Robert Yerkes (1876–1956) to facilitate personnel selection during World War I. The U.S. armed forces needed an efficient means to screen recruits, many of whom were illiterate. One of Terman's students, Arthur Otis, had devised a nonverbal test of general intelligence, and his work was heavily drawn on to build one of the two group intelligence tests used for the initial screening and the appropriate placement of recruits: the Army Alpha (for literates) and Beta (for illiterates). The role that mental measurements played in World War I and, subsequently, in World War II constitutes one of applied psychology's great success stories. Even today, an act of the U.S. Congress mandates a certain minimum score on tests of general mental ability, because training efficiency is compromised prohibitively at IQs less than or equal to 80 (the bottom 10% of those tested).

Following World War I, Terman was one of the first to draw a generalization between the utility of military intellectual assessments and problems in America's schools. In the early 1920s, Terman developed one of the most famous longitudinal studies in all of psychology, exclusively devoted to the intellectually gifted (the top 1%). Terman, a former teacher himself, was aware of the ability range found in homogeneous groupings based on chronological age and became an advocate of homogeneous grouping based on mental age. Drawing on solid empirical findings from his study of 1,528 intellectually precocious youth (a study that continued after his death in 1956 and into the twenty-first century), he proposed that, at the extremes (say, two standard deviations beyond either side of IQ's normative mean), the likelihood of encountering special student needs increases exponentially. Terman noted that structuring educational settings around chronological age often results in classes of students with markedly different rates of learning (because of markedly different mental ages). Optimal rates of curriculum presentation and complexity vary in gradation

throughout the range of individual differences in general intelligence. With IQ centered on 100 and a standard deviation of 16, IQs extending from the bottom 1 percent to the top 1 percent in ability cover an IQ range of approximately 63 to 137. But because IQs are known to go beyond 200, this span covers less than half of the possible range. Leta Stetter Hollingworth's classic 1942 study, *Children above 180 IQ*, provided empirical support for the unique educational needs of this special population. These needs have been empirically supported in every decade since.

## The Modern Hierarchical Structure of Mental Abilities

Modern versions of intelligence tests index essentially the same construct that was uncovered at the turn of the twentieth century in Spearman's 1904 work, "General Intelligence: Objectively Determined and Measured"—albeit with much more efficiency and precision. For example, *g* is a statistical distillate that represents approximately half of what is common among the thirteen subtests comprising the Wechsler Adult Intelligence Scale. As noted by intelligence researcher Ian J. Deary in "Intelligence: A Very Short Introduction," the attribute *g* represents the research finding that "there is something shared by all the tests in terms of people's tendencies to do well, modestly, or poorly on all of them" (p. 10). In 2001 Deary's team published the longest temporal stability assessment of general intelligence to date (covering a span of sixty-six years, from age eleven to age seventy-seven); they observed a correlation of .62, which rose to over .70 when statistical artifacts were controlled.

John B. Carroll and other modern psychometricians have come to a consensus that mental abilities follow a hierarchical structure, with *g* at the top of the hierarchy and other broad groups of mental abilities offering psychological import beyond *g*. Specifically, mathematical, spatial-mechanical, and verbal reasoning abilities all have demonstrated incremental (value-added) validity beyond *g* in forecasting educational and vocational criteria. Although mathematical, spatial, and verbal reasoning abilities do not have the breadth or depth of external correlates that *g* does, the incremental validity they offer makes them especially important for educational and vocational planning.

## Psychological and Social Correlates of *g*

Psychologists at poles of the applied educational-industrial spectrum, such as Richard Snow and John Campbell, respectively, have underscored the real-world significance of general intelligence by incorporating it in lawlike empirical generalizations, as in the following two passages:

Given new evidence and reconsideration of old evidence, [*g*] can indeed be interpreted as “ability to learn” as long as it is clear that these terms refer to complex processes and skills and that a somewhat different mix of these constituents may be required in different learning tasks and settings. The old view that mental tests and learning tasks measure distinctly different abilities should be discarded. (Snow, p. 22)

General mental ability is a substantively significant determinant of individual differences in job performance for any job that includes information-processing tasks. If the measure of performance reflects the information processing components of the job and any of several well-developed standardized measures used to assess general mental ability, then the relationship will be found unless the sample restricts the variances in performance or mental ability to near zero. The exact size of the relationship will be a function of the range of talent in the sample and the degree to which the job requires information processing and verbal cognitive skills. (Campbell, p. 56)

Modern research on general intelligence has sharpened validity generalizations aimed at forecasting educational outcomes, occupational training, and work performance. But empiricism also has escalated in domains at the periphery of general intelligence’s network of external relationships, such as aggression, delinquency and crime, and income and poverty. For some benchmarks, general intellectual ability covaries .70–.80 with academic achievement measures, .40–.70 with military training assignments, .20–.60 with work performance (higher correlations reflect greater job complexity), .30–.40 with income, and around .20 with law-abidingness.

An excellent compilation of positive and negative correlates of *g* can be found in a 1987 work by Christopher Brand that documents a variety of weak correlations between general intelligence and diverse

phenomena. For example, *g* is positively correlated with altruism, sense of humor, practical knowledge, responsiveness to psychotherapy, social skills, and supermarket shopping ability, and negatively correlated with impulsivity, accident-proneness, delinquency, smoking, racial prejudice, and obesity. This diverse family of correlates is especially thought-provoking because it reveals how individual differences in general intelligence “pull” with them cascades of direct and indirect effects.

Charles Murray’s 1998 longitudinal analysis of educational and income differences between siblings is also illuminating. Murray studied biologically related siblings who shared the same home of rearing and socioeconomic class yet differed on average by 12 IQ points. He found that the differences in IQ predicted differences in educational achievement and income over the course of 15 years. His findings corroborate those of other studies that use a similar control for family environment, while not confounding socioeconomic status with biological relatedness.

Experts’ definitions of general intelligence appear to fit with *g*’s nexus of empirical relationships. Most measurement experts agree that measures of general intelligence assess individual differences pertaining to “abstract thinking or reasoning,” “the capacity to acquire knowledge,” and “problem-solving ability.” Naturally, individual differences in these attributes carry over to human behavior in facets of life outside of academic and vocational arenas. Abstract reasoning, problem solving, and rate of learning touch many aspects of life in general, especially in the computer-driven, information-dense society of the United States in the early twenty-first century.

## Biological Correlates of *g*

General intelligence may be studied at different levels of analysis, and, as documented by Arthur Jensen in “The *g* Factor,” modern measures of *g* have been linked to a variety of biological phenomena. By pooling studies of a variety of kinship correlates of *g* (e.g., identical and fraternal twins reared together and apart, and a variety of adoption designs), the heritability of general intelligence in industrialized nations has been estimated to be between 60 and 80 percent. These estimates reflect genetic factors responsible for individual differences between people, not overall level of *g*. In addition, research teams in molecular genetics, led by Robert Plomin, are working to uncover DNA markers associated with *g*.

Using magnetic resonance imaging technology, total brain volume covaries in the high .30s with *g* after removing the variance associated with body size. Glucose metabolism is related to problem-solving behavior, and the highly gifted appear to engage in more efficient problem-solving behavior that is less energy expensive. Also, highly intellectually gifted individuals show enhanced right hemispheric functioning, and electroencephalographic (EEG) phenomena have been linked to individual differences in *g*. Finally, some investigators have suggested that dendritic arborization (the amount of branching of dendrites in neurons) is correlated with *g*.

### A Continuing Field of Debate

The above empiricism is widely accepted among experts in the measurement/individual differences field. Yet, it has been common for empiricism pertaining to general intelligence (and interpretative extrapolations emanating from it) to stimulate contentious debate. Indeed, psychologists can be found on all sides of the complex set of issues engendered by assessing individual differences in general intelligence. But this is not new, and it is likely to continue. Because psychological assessments are frequently used for allocating educational and vocational opportunities, and because different demographic groups differ in test score *and* criterion performance, social concerns have followed the practice of intellectual assessment since its beginning in the early 1900s. In the context of these social concerns, alternative conceptualizations of intelligence, such as Howard Gardner's theory of multiple intelligences, Daniel Goleman's theory of emotional intelligence, and Robert Sternberg's triarchic theory of intelligence have generally been positively received by the public. Yet, measures of these alternative formulations of intelligence have not demonstrated incremental validity beyond what is already gained by conventional measures of intelligence. That is, they have not yet demonstrated incremental validity beyond conventional psychometric tests in the prediction of important life outcomes such as educational achievement, occupational level, and job performance. This is not to say that there is no room for improvement in the prediction process. Innovative measures of mental abilities, however, need to be evaluated against existing measures before one can claim that they capture something new.

## MULTIPLE INTELLIGENCES

The theory of multiple intelligences (MI) was developed by Howard Gardner, a professor of cognition and education at Harvard University. Introduced in his 1983 book, *Frames of Mind*, and refined in subsequent writings, the theory contends that human intelligence is not a single complex entity or a unified set of processes (the dominant view in the field of psychology). Instead, Gardner posits that there are several relatively autonomous intelligences, and that an individual's intellectual profile reflects a unique configuration of these intelligences.

### Definition of Intelligence

In his 1999 formulation of MI theory, *Intelligence Reframed*, Gardner defines intelligence as “a biopsychological potential to process information that can be activated in a cultural setting to solve problems or create products that are of value in a culture.” By considering intelligence a potential, Gardner asserts its emergent and responsive nature, thereby differentiating his theory from traditional ones in which human intelligence is fixed and innate. Whether a potential will be activated is dependent in large part on the values of the culture in which an individual grows up and the opportunities available in that culture, although Gardner also acknowledges the role of personal decisions made by individuals, their families, and others. These activating forces result in the development and expression of a range of abilities (or intelligences) from culture to culture and also from individual to individual.

Gardner's definition of intelligence is unique as well in that it considers the creation of products such as sculptures and computers to be as important an expression of intelligence as abstract problem solving. Traditional theories do not recognize created artifacts as a manifestation of intelligence, and therefore are limited in how they conceptualize and measure it.

**Criteria for intelligences.** Gardner does not believe that the precise number of intelligences is known, nor does he believe that they can be identified

through statistical analyses of cognitive test results. He began by considering the range of adult end-states that are valued in diverse cultures around the world. To uncover the abilities that support these end-states, he examined a wide variety of empirical sources from different disciplines that had never been used together for the purpose of defining human intelligence. His examination yielded eight criteria for defining an intelligence:

- Two criteria derived from biology: (1) an intelligence should be isolable in cases of brain damage, and (2) there should be evidence for its plausibility and autonomy in evolutionary history.
- Two criteria derived from developmental psychology: (3) an intelligence has to have a distinct developmental history along with a definable set of expert end-state performances, and (4) it must exist within special populations such as idiot savants and prodigies.
- Two criteria derived from traditional psychology: (5) an intelligence needs to be supported by the results of skill training for its relatively independent operation, and (6) also by the results of psychometric studies for its low correlation to other intelligences.
- Two criteria derived from logical analysis: (7) an intelligence must have its own identifiable core operation or set of operations, and (8) it must be susceptible to encoding in a symbol system—such as language, numbers, graphics, or musical notations.

To be defined as an intelligence, an ability has to meet most, though not all, of the eight criteria.

**Identified intelligences.** As of 2001, Gardner has identified eight intelligences:

1. Linguistic intelligence, exemplified by writers and poets, describes the ability to perceive and generate spoken or written language.
2. Logical-mathematical intelligence, exemplified by mathematicians and computer programmers, involves the ability to appreciate and utilize numerical, abstract, and logical reasoning to solve problems.
3. Musical intelligence, exemplified by musicians and composers, entails the ability to create, communicate, and understand meanings made out of sound.
4. Spatial intelligence, exemplified by graphic

designers and architects, refers to the ability to perceive, modify, transform, and create visual or spatial images.

5. Bodily-kinesthetic intelligence, exemplified by dancers and athletes, deals with the ability to use all or part of one's body to solve problems or to fashion products.
6. Naturalistic intelligence, exemplified by archaeologists and botanists, concerns the ability to distinguish, classify, and use features of the environment.
7. Interpersonal intelligence, exemplified by leaders and teachers, describes the ability to recognize, appreciate, and contend with the feelings, beliefs, and intentions of other people.
8. Intrapersonal intelligence, apparent when individuals pursue a particular interest, choose a field of study or work, or portray their life through different media, involves the ability to understand oneself—including emotions, desires, strengths, and vulnerabilities—and to use such information effectively in regulating one's own life.

Gardner does not claim this roster of intelligences to be exhaustive; MI theory is based wholly on empirical evidence, and the roster can therefore be revised with new empirical findings. In the MI framework, all intelligences are equally valid and important, and though significantly independent of one another, they do not operate in isolation. Human activity normally reflects the integrated functioning of several intelligences. An effective teacher, for example, relies on linguistic and interpersonal intelligences, and possesses knowledge of particular subject areas as well.

### Relationship to Other Theories

MI theory bears similarities to several other contemporary theories of intelligence, yet it remains distinct. Although it shares a pluralistic view of intelligence with Robert Sternberg's triarchic theory, MI theory organizes intelligences in terms of content areas, and no single cognitive function, such as perception or memory, cuts across all domains. The triarchic theory, in contrast, posits three intelligences differentiated by functional processes, and each intelligence operates consistently across domains.

Daniel Goleman's theory of emotional intelligence resonates with MI theory in that both ac-

knowledge the social and affective aspects of intelligence. Whereas Goleman views intelligence from a moral and ethical perspective, however, Gardner regards all intelligences as value-free: He does not judge individuals as inferior or superior based on their configuration of intelligences, nor does he judge cultures as inferior or superior because they value one intelligence over another.

MI theory has been criticized on two grounds. First, some critics contend that psychometric research finds correlations, not autonomy, among abilities. Gardner has argued that these correlations are largely due to the use of psychometric instruments designed to measure only a given set of abilities. Second, critics have suggested that human intelligence is different from other human capabilities, such as musical talent. Gardner believes that such a narrow use of the word *intelligence* reflects a Western intellectual mind-set that does not recognize the diversity of roles that contribute to society.

### Implications for Educational Practice

The primary intent for developing MI theory was to chart the evolution and topography of the human mind, not to prescribe educational practice. Nonetheless, MI theory has been discussed widely in the educational field and has been particularly influential in elementary education, where it has provided a useful framework for improving school-based practice in the areas of curricula, instruction, and assessment.

**Curricula and instruction.** From an MI perspective, curricula, particularly for young children, should encompass a broad range of subject areas that include (but go beyond) reading, writing, and arithmetic, because all intelligences are equally valuable. The visual arts, for example, are a serious domain in and of themselves, and not just as a means to improve reading scores. According to MI theory, the talented artist is just as intelligent as the excellent reader, and each has an important place in society. In *The Disciplined Mind*, Gardner cautions that an authentic MI-based approach goes beyond conveying factual knowledge about various domains: He stresses the importance of promoting in-depth exploration and real understanding of key concepts essential to a domain.

Because each child's biopsychological potential is different, providing a broad range of subject areas at a young age also increases the likelihood of discov-

ering interests and abilities that can be nurtured and appreciated. Educators who work with at-risk children have been particularly drawn to this application of MI theory, because it offers an approach to intervention that focuses on strengths instead of deficits. By the same token, it extends the concept of the gifted child beyond those who excel in linguistic and logical pursuits to include children who achieve in a wide range of domains.

MI theory can be applied to the development of instructional techniques as well. A teacher can provide multiple entry points to the study of a particular topic by using different media, for example, and then encouraging students to express their understanding of the topic through diverse representational methods, such as pictures, writings, three-dimensional models, or dramatizations. Such instructional approaches make it possible for students to find at least one way of learning that is attuned to their predispositions, and they therefore increase motivation and engagement in the learning process. They also increase the likelihood that every student will attain at least some understanding of the topic at hand.

**Assessment.** When applied to student assessment, MI theory results in the exploration of a much wider range of abilities than is typical in the classroom, in a search for genuine problem-solving or product-fashioning skills. An MI-based assessment requires “intelligence-fair” instruments that assess each intellectual capacity through media appropriate to the domain, rather than through traditional linguistic or logical methods. Gardner also argues that for assessment to be meaningful to students and instructive for teachers, students should work on problems and projects that engage them and hold their interest; they should be informed of the purpose of the task—and the assessment criteria as well; and they should be encouraged to work individually, in pairs, or in a group. Thus, the unit of analysis extends beyond the individual to include both the material and social context.

MI-based assessments are not as easy to design and implement as standard pencil-and-paper tests, but they have the potential to elicit a student’s full repertoire of skills and yield information that will be useful for subsequent teaching and learning. As part of Project Spectrum, Gardner and colleagues developed a set of assessment activities and observational guidelines covering eight domains, including many often ignored by traditional assessment instruments,

such as mechanical construction and social understanding. Project Spectrum’s work also included linking children’s assessments to curricular development and bridging their identified strengths to other areas of learning.

### **Evidence of the Value of the Theory**

MI theory has been incorporated into the educational process in schools around the world. There is much anecdotal evidence that educators, parents, and students value the theory, but, as of 2001, little systematic research on the topic has been completed. The main study was conducted by Mindy Kornhaber and colleagues at Harvard University’s Project Zero in the late 1990s. They studied forty-one elementary schools in the United States that had been applying MI theory to school-based practice for at least three years. Among the schools that reported improvement in standardized-test scores, student discipline, parent participation, or performance of students with learning differences, the majority linked the improvement to MI-based interventions. Kornhaber’s study also illuminates the conditions under which MI theory is adopted by schools and integrated into the educational process.

The difficulty of research on MI theory in education is correlating changes specifically to the theory, since schools are complex institutions that make it difficult to isolate cause-and-effect relationships. Indeed, since MI theory is meaningful in the context of education only when combined with pedagogical approaches such as project-based learning or arts-integrated learning, it is not possible to study the precise contribution of the theory itself to educational change, only the effect of interventions that are based on it or incorporate it.

## MYTHS, MYSTERIES, AND REALITIES

Intelligence and intelligence tests are often at the heart of controversy. Some arguments concern the ethical and moral implications of, for example, selective breeding of bright children. Other arguments deal with the statistical basis of various conclusions such as whether tests are biased, or how much of intelligence is genetically determined. What one hears less often is discussion of the construct of intelligence itself: What is intelligence? How does it grow? How and why do people differ intellectually? Questions like these, along with many others, which are central to any discussion of intelligence and intelligence testing, are less often raised, much less answered.

### Historical Roots of Intelligence Tests

Intelligence testing began as a more or less scientific pursuit into the nature of differences in human intellect. However, it soon acquired practical significance as a tool for predicting school achievement and selecting individuals for various educational programs. Sir Francis Galton’s work in the late 1800s formed the background for much of the research and theory pursued during the twentieth century on the assessment of individual differences in intelligence.

Galton believed that all intelligent behavior was related to innate sensory ability but his attempts to

empirically validate that assumption were largely unsuccessful. In France, Alfred Binet and Victor Henri (1896) criticized the approach advocated by Galton in England and James McKeen Cattell in the United States and argued that appropriate intelligence testing must include assessment of more complex mental processes, such as memory, attention, imagery, and comprehension. In 1904, Binet and Théodore Simon were commissioned by the French Minister of Public Instruction to develop a procedure to select children unable to benefit from regular public school instruction for placement in special educational programs. In 1905 Binet and Simon published an objective, standardized intelligence test based on the concepts developed earlier by Binet and Henri. The 1905 test consisted of thirty subtests of mental ability, including tests of digit span, object and body part identification, sentence memory, and so forth. Many of these subtests, with minor modifications, are included in the Stanford-Binet intelligence test of the early twenty-first century.

In 1908 and again in 1911, Binet and Simon published revised versions of their intelligence test. The revised tests distinguished intellectual abilities according to age norms, thus introducing the concept of *mental age*. The subtests were organized according to the age level at which they could be successfully performed by most children of normal intelligence. As a result, children could be characterized and compared in terms of their intellectual or mental age. The Binet and Simon intelligence test was widely adopted in Europe and in the United States. Lewis Terman of Stanford University developed the more extensive Stanford-Binet test in 1916. This test has been used extensively in several updated versions throughout the United States.

A major change in intelligence testing involved the development of intelligence tests that could be simultaneously administered to large groups. Group tests similar to the original Binet and Simon intelligence test were developed in Britain and the United States. During World War I, group-administered intelligence tests (the Army Alpha and Army Beta tests) were used in the United States to assess the abilities of recruits who could then be selected for various duties based on their performance. In England, from the 1940s to the 1960s, intelligence tests were administered to all children near the age of eleven years to select students for different classes of vocational training.

An enormous number of “mental” tests are available in the early twenty-first century and are typically divided into those involving group versus individual administration. Whereas IQ (the intelligence quotient) was originally reported as the ratio of an individual’s mental age to chronological age multiplied by 100 ( $100 \times \text{MA/CA}$ ), IQ has long been based upon normative score distributions for particular age groups. All individual and group tests currently yield such deviation IQs where 100 typically represents the 50th percentile and 68 percent of all scores fall between 85 and 115.

### Factor Theories of Intelligence

What is intelligence and what do these tests actually assess? Very early in the psychological study of intelligence, Charles Spearman (1904) sought to empirically determine the similarities and differences between various mental tests and school performance measures. He found that many seemingly diverse mental tests were strongly correlated with each other. This led him to postulate a general factor of intelligence, *g*, that all mental tests measure in common while simultaneously varying in how much the general factor contributes to a given test’s performance. On the basis of correlational studies, Spearman argued that intelligence is composed of a general factor that is found in all intellectual functioning plus specific factors associated with the performance of specific tasks. Spearman’s theoretical orientation and methods of analysis served as the foundation of all subsequent factor analytic theories of intelligence. Spearman (1927) later developed a more complex factor theory introducing more general “group factors” made up of related specific factors. However, he adhered to his main tenet that a common ability underlies all intellectual behavior. For lack of a better definition, he referred to this as a mental energy or force.

The concept that intelligence is characterized by a general underlying ability plus certain task- or domain-specific abilities constitutes the basis of several major theories of intelligence, including those offered by Cyril L. Burt (1949), Philip E. Vernon (1961), and Arthur Jensen (1998). Quite distinct from theories of intelligence that emphasize *g* are those that emphasize specific abilities that can be combined to form more general abilities. Lloyd L. Thurstone (1924, 1938) developed factor analytic techniques that first separate out specific or primary factors. Thurstone argued that these primary factors

represent discrete intellectual abilities, and he developed distinct tests to measure them. Among the most important of Thurstone’s primary mental abilities are verbal comprehension, word fluency, numerical ability, spatial relations, memory, reasoning, and perceptual speed.

Raymond Cattell (1963, 1971) attempted a rapprochement of the theories of Spearman and Thurstone. In an attempt to produce a *g* factor, he combined Thurstone’s primary factors to form secondary or higher-order factors. Cattell found two major types of higher order factors and three minor ones. The major factors were labeled *gf* and *gc*, for fluid and crystallized general intelligence. Cattell argued that the fluid intelligence factor represents an individual’s basic biological capacity. Crystallized intelligence represents the types of abilities required for most school activities. Cattell labeled the minor general factors *gv*, *gr*, and *gs* for visual abilities, memory retrieval, and performance speed, respectively. Cattell’s initial theory has been substantially extended by individuals such as John L. Horn (1979, 1985).

The most recent psychometric research supports a hierarchical model of intellect generally in accord with the outlines of the Cattell-Horn theory. At the top of the hierarchy is *g* and under *g* are broad group factors such as *gf* and *gc*. Below these broad group factors are more specific or narrow ability factors. The majority of intelligence tests focus on providing overall estimates of *g* (or *gf* and *gc*) since this maximizes the prediction of performance differences among people in other intellectual tasks and situations, including performance in school.

### Alternative Theoretical Perspectives

The hierarchical model of human intelligence that has evolved from the psychometric or measurement approach is not the only influential perspective on human intellect. A second view of intelligence, that provided by developmental psychology, stems from the theory of intellectual development proposed by the Swiss psychologist Jean Piaget. This tradition is a rich source of information on the growth and development of intellect. A third view on intelligence, the information-processing or cognitive perspective, is an outgrowth of work in cognitive psychology since the 1970s. It provides elaborate descriptions and theories of the specific mental activities and representations that comprise intellectual functioning. The three perspectives are similar with regard to the

general skills and activities that each associates with “being or becoming intelligent.” For all three, reasoning and problem-solving skills are the principal components of intelligence. A second area of overlap among the three involves adaptability as an aspect of intelligence.

The differences and separate contributions of the three perspectives to an understanding of human intellect also stand out. The emphasis on individual differences within the psychometric tradition is certainly relevant to any complete understanding of intelligence. A theory of intelligence should take into account similarities and differences among individuals in their cognitive skills and performance capabilities. However, a theory of human intellect based solely on patterns of differences among individuals cannot capture all of intellectual functioning unless there is little that is general and similar in intellectual performance.

In contrast, the developmental tradition emphasizes similarities in intellectual growth and the importance of organism–environment interactions. By considering the nature of changes that occur in cognition and the mechanisms and conditions responsible, one can better understand human intellectual growth and its relationship to the environment. This requires, however, that one focus not just on commonalities in the general course of cognitive growth, but consider how individuals differ in the specifics of their intellectual growth. Such a developmental-differential emphasis seems necessary for a theory to have adequate breadth and to move the study of intelligence away from a static, normative view, where intelligence changes little over development, to a more dynamic view that encompasses developmental change in absolute levels of cognitive power.

Finally, the cognitive perspective helps to define the scope of a theory of intelligence by further emphasizing the dynamics of cognition, through its concentration on precise theories of the knowledge and processes that allow individuals to perform intellectual tasks. Psychometric and developmental theories typically give little heed to these processes, yet they are necessary for a theory of intelligence to make precise, testable predictions about intellectual performance.

No theory developed within any of the three perspectives addresses all of the important elements and issues mentioned above. This includes the more recent and rather broad theories such as Howard

Gardner’s multiple intelligences theory (1983, 1999) and Robert J. Sternberg’s triarchic theory (1985). Both theories represent an interesting blending of psychometric, developmental, and cognitive perspectives.

### Uses and Abuses of Tests

Above it was noted that testing was developed in response to pragmatic concerns regarding educational selection and placement. The use of intelligence tests for educational selection and placement proliferated during the decades from the 1930s through 1960s as group tests for children became readily available. Since the early 1980s, however, general intelligence testing has declined in public educational institutions. One reason for diminished use of such tests is a trend away from homogeneous grouping of students and attendant educational tracking. A second reason is that achievement rather than aptitude testing has become increasingly popular. Not surprisingly, such tests tend to be better predictors of subsequent achievement than aptitude or intelligence tests. Even so, it is an established fact that measures of general intelligence obtained in childhood yield a moderate 0.50 correlation with school grades. They also correlate about 0.55 with the number of years of education that individuals complete.

Intelligence and aptitude tests continue to be used with great frequency in military, personnel-selection, and clinical settings. There are also two major uses of intelligence tests within educational settings. One of these is for the assessment of mental retardation and learning disabilities, a use of tests reminiscent of the original reason for development of the Binet and Simon scales in the early 1900s. The second major use is at the postsecondary level. College entrance is frequently based upon performance on measures such as the SAT, first adopted in the United States by the College Entrance Examination Board in 1937. Performance on the SAT, together with high school grades, is the basis for admission to many American colleges and universities. The ostensible basis for using SAT scores is that they moderately predict freshman grade point average—precisely what they were originally designed to do. However, considerable debate has arisen about the legitimacy and value of continued use of SAT scores for college admission decisions.

Throughout the history of the testing movement, dating back to the early 1900s and extending to the early twenty-first century, there has been con-

trovercy concerning the (mis)use of test results. One of the earliest such debates was between Lewis Terman, who helped develop the revised Stanford-Binet and other tests, and the journalist Walter Lippman. A frequent issue in debates about the uses and abuses of intelligence tests in society is that of bias. It is often argued that most standardized intelligence tests have differential validity for various racial, ethnic, and socioeconomic groups. Since the tests emphasize verbal skills and knowledge that are part of Western schooling, they are presumed to be unfair tests of the cognitive abilities of other groups. As a response to such arguments, attempts have been made to develop culture-fair or culture-free tests. The issue of bias in mental testing is beyond this brief review and Arthur R. Jensen (1980; 1981) can be consulted for highly detailed treatments of this topic. Evidence in the 1990s suggests that no simple form of bias in either the content or form of intelligence tests accounts for the mean score differences typically observed between racial and ethnic groups.

### Factors Affecting Test Scores

Much of the research on intelligence has focused on specific factors affecting test scores. This includes research focused on environmental versus genetic contributions to IQ scores, related issues such as race differences in IQ, and overall population trends in IQ.

One of the most extensively studied and hotly debated topics in the study of intelligence is the contribution of heredity and environment to individual differences in test scores. Given a trait such as measured intelligence on which individuals vary, it is inevitable for people to ask what fraction is associated with differences in their genotypes (the so-called heritability of the trait) as well as what fraction is associated with differences in environmental experience. There is a long history of sentiment and speculation with regard to this issue. It has also proven difficult to answer this question in a scientifically credible way, in large measure due to the conceptual and statistical complexity of separating out the respective contributions of heredity and environment. Adding to the complexity is the need to obtain test score data from people who have varying kinship and genetic relationships, including identical and fraternal twins, siblings, and adoptive children with their biological and adoptive parents. Nonetheless, evidence has slowly been gathered that heritability is sizeable and that it varies across popu-

lations. For IQ, heritability is markedly lower for children, about 0.45, than for adults where it is about 0.75. This means that with age, differences in test scores increasingly reflect differences in the genotype and in individual life experience rather than differences in the families within which they were raised. The factors underlying this shift as well as the mechanism by which genes contribute to individual differences in IQ scores are largely unknown. The same can be said for understanding environmental contributions to those differences. A common misconception is that traits like IQ with high heritability mean that the results are immutable, that the environment has little or no impact, or that learning is not involved. This is wrong since heritable traits like vocabulary size are known to depend on learning and environmental factors.

Perhaps no topic is more controversial than that of race differences in IQ, especially since it is so often tied up with debates about genetics and environmental influences. It is an established fact that there are significant differences between racial and ethnic groups in their average scores on standardized tests of intelligence. In the United States, the typical difference between Caucasians and African Americans is 15 points or one standard deviation. A difference of this magnitude has been observed for quite a long period of time with little evidence that the difference has declined despite significant evidence that across the world IQ scores have risen substantially over the last fifty years. The latter phenomenon is known as the "Flynn Effect," and it, like so many other phenomena associated with test scores, begs for an adequate explanation.

There is a tendency to interpret racial and ethnic differences in mean IQ scores as being determined by genetic factors since, as noted above, IQ scores in general have a fairly high level of heritability and the level of heritability seems to be about the same in different racial and ethnic groups. There is, however, no logical basis on which to attribute the mean difference between racial groups to either genetic or environmental factors. As one group of researchers stated, "In short, no adequate explanation of the differential between the IQ means of Blacks and Whites is presently available" (Neisser et al., p. 97).

### Age and Intelligence

Although most intelligence tests are targeted for school-age populations, there are instruments developed for younger age groups. Such tests emphasize

the assessment of perceptual and motor abilities. Unfortunately, measures of infant and pre-school intelligence tend to correlate poorly with intelligence tests administered during the school years. However, there appears to be a high degree of stability in the IQ scores obtained in the early primary grades and IQ scores obtained at the high school level and beyond. Often this is misinterpreted as indicating that an individual's intelligence does not change as a function of schooling or other environmental factors. What such results actually indicate is that an individual's score relative to his or her age group remains fairly constant. In an absolute sense, an individual of age 16 can solve considerably more difficult items and problems than an individual of age 8. Comparing IQ scores obtained at different ages is akin to comparing apples and oranges since the composition of tests changes markedly over age levels.

Research has also studied changes in IQ following early adulthood. A frequent conclusion from research examining age groups ranging from 21 to 60 and beyond is that there is an age-related general decline in intellectual functioning. However, there are serious problems with many such studies since they involve cross-sectional rather than longitudinal contrasts. In those cases where longitudinal data are available, it is less obvious that intelligence declines with age. John L. Horn and Cattell (1967) presented data indicating a possible differential decline in crystallized and fluid intelligence measures. Crystallized intelligence measures focus on verbal skills and knowledge whereas fluid intelligence measures focus on reasoning and problem solving with visual and geometric stimuli. The latter also often place an emphasis on performance speed. Fluid intelligence measures tend to show substantial declines as a function of age, whereas crystallized intelligence measures often show little or no decline until after age 65. Research in the 1990s based on combinations of longitudinal and cross-sectional samples supports the conclusion that there are age-related declines in intelligence, which seem to vary with the type of skill measured, and that the declines are often substantial in the period from age 65 to 80.

### Future Outlook

After more than 100 years of theory and research on the nature and measurement of intelligence there is much that researchers know but even more that they don't understand. Still lacking is any agreed upon

definition of intelligence and many of the empirical findings regarding intelligence test scores remain a puzzle. In their summary paper "Intelligence: Knowns and Unknowns," Ulric Neisser and colleagues (1996) stated:

In a field where so many issues are unresolved and so many questions unanswered, the confident tone that has characterized most of the debate on these topics is clearly out of place. The study of intelligence does not need politicized assertions and recriminations; it needs self restraint, reflection, and a great deal more research. The questions that remain are socially as well as scientifically important. There is no reason to think them unanswerable, but finding the answers will require a shared and sustained effort as well as the commitment of substantial scientific resources. (p. 97)

## TRIARCHIC THEORY OF INTELLIGENCE

The triarchic theory of intelligence is based on a broader definition of intelligence than is typically used. In this theory, intelligence is defined in terms of the ability to achieve success in life based on one's personal standards—and within one's sociocultural context. The ability to achieve success depends on the ability to capitalize on one's strengths and to correct or compensate for one's weaknesses. Success is attained through a balance of analytical, creative, and practical abilities—a balance that is achieved in order to adapt to, shape, and select environments.

### Information-Processing Components Underlying Intelligence

According to Robert Sternberg's proposed theory of human intelligence, a common set of universal mental processes underlies all aspects of intelligence. Although the particular solutions to problems that are considered "intelligent" in one culture may be different from those considered intelligent in another, the mental processes needed to reach these solutions are the same.

*Metacomponents*, or executive processes, enable a person to plan what to do, monitor things as they are being done, and evaluate things after they are done. *Performance components* execute the instructions of the metacomponents. *Knowledge-acquisition components* are used to learn how to solve problems or simply to acquire knowledge in the first place. For example, a student may plan to write a paper (metacomponents), write the paper (performance components), and learn new things while writing (knowledge-acquisition components).

### Three Aspects of Intelligence

According to the triarchic theory, intelligence has three aspects: analytical, creative, and practical.

**Analytical intelligence.** Analytical intelligence is involved when the components of intelligence are applied to analyze, evaluate, judge, or compare and contrast. It typically is involved in dealing with relatively familiar kinds of problems where the judgments to be made are of a fairly abstract nature.

In one study, an attempt was made to identify the information-processing components used to solve analogies such as: A is to B as C is to: D1, D2, D3, D4 (e.g., lawyer is to client as doctor is to [a] nurse, [b] medicine, [c] patient, [d] MD). There is an *encoding* component, which is used to figure out what each word (e.g., *lawyer*) means, while the *inference* component is used to figure out the relation between *lawyer* and *client*.

Research on the components of human intelligence has shown that although children generally become faster in information processing with age, not all components are executed more rapidly with age. The encoding component first shows a decrease in processing time with age, and then an increase. Apparently, older children realize that their best strategy is to spend more time in encoding the terms of a problem so that they later will be able to spend less time in making sense of these encodings. Similarly, better reasoners tend to spend relatively more time than do poorer reasoners in global, up-front metacomponential planning when they solve difficult reasoning problems. Poorer reasoners, on the other hand, tend to spend relatively more time in detailed planning as they proceed through a problem. Presumably, the better reasoners recognize that it is better to invest more time up front so as to be able to process a problem more efficiently later on.

**Creative intelligence.** In work with creative-intelligence problems, Robert Sternberg and Todd Lubart asked sixty-three people to create various kinds of products in the realms of writing, art, advertising, and science. For example, in writing, they would be asked to write very short stories, for which the investigators would give them a choice of titles, such as “Beyond the Edge” or “The Octopus’s Sneakers.” In art, the participants were asked to produce art compositions with titles such as “The Beginning of Time” or “Earth from an Insect’s Point of View.” Participants created two products in each domain.

Sternberg and Lubart found that creativity is relatively, although not wholly, domain-specific. In other words, people are frequently creative in some domains, but not in others. They also found that correlations with conventional ability tests were modest to moderate, demonstrating that tests of creative intelligence measure skills that are largely different from those measured by conventional intelligence tests.

**Practical intelligence.** Practical intelligence involves individuals applying their abilities to the kinds of problems that confront them in daily life, such as on the job or in the home. Much of the work of Sternberg and his colleagues on practical intelligence has centered on the concept of tacit knowledge. They have defined this construct as what one needs to know, which is often not even verbalized, in order to work effectively in an environment one has not been explicitly taught to work in—and that is often not even verbalized.

Sternberg and colleagues have measured tacit knowledge using work-related problems one might encounter in a variety of jobs. In a typical tacit-knowledge problem, people are asked to read a story about a problem someone faces, and to then rate, for each statement in a set of statements, how adequate a solution the statement represents. For example, in a measure of tacit knowledge of sales, one of the problems deals with sales of photocopy machines. A relatively inexpensive machine is not moving out of the showroom and has become overstocked. The examinee is asked to rate the quality of various solutions for moving the particular model out of the showroom.

Sternberg and his colleagues have found that practical intelligence, as embodied in tacit knowledge, increases with experience, but that it is how one profits, or learns, from experience, rather than experience *per se*, that results in increases in scores. Some people can work at a job for years and acquire relatively little tacit knowledge. Most importantly, although tests of tacit knowledge typically show no correlation with IQ tests, they predict job performance about as well as, and sometimes better than, IQ tests.

In a study in Usenge, Kenya, Sternberg and colleagues were interested in school-age children’s ability to adapt to their indigenous environment. They devised a test of practical intelligence for adaptation to the environment that measured children’s infor-

mal tacit knowledge of natural herbal medicines that the villagers used to fight various types of infections. The researchers found generally negative correlations between the test of practical intelligence and tests of academic intelligence and school achievement. In other words, people in this context often emphasize practical knowledge at the expense of academic skills in their children's development.

In another study, analytical, creative, and practical tests were used to predict mental and physical health among Russian adults. Mental health was measured by widely used paper-and-pencil tests of depression and anxiety, while physical health was measured by self-report. The best predictor of mental and physical health was the practical-intelligence measure, with analytical intelligence being the second-best measure and creative intelligence being the third.

### **Factor-Analytic Studies**

Factor-analytic studies seek to identify the mental structures underlying intelligence. Four separate factor-analytic studies have supported the internal validity of the triarchic theory of intelligence. These studies analyzed aspects of individual differences in test performance in order to uncover the basic mental structures underlying test performance. In one study of 326 high school students from throughout the United States, Sternberg and his colleagues used the so-called Sternberg Triarchic Abilities Test (STAT) to investigate the validity of the triarchic theory. The test comprises twelve subtests measuring analytical, creative, and practical abilities. For each type of ability, there are three multiple-choice tests and one essay test. The multiple-choice tests involve verbal, quantitative, and figural content. Factor analysis on the data was supportive of the triarchic theory of human intelligence, as it was measured relatively separate and independent analytical, creative, and practical factors. The triarchic theory also was consistent with data obtained from 3,252 students in the United States, Finland, and Spain. The study revealed separate analytical, creative, and practical factors of intelligence.

### **Instructional Studies**

In another set of studies, researchers explored the question of whether conventional education in school systematically discriminates against children with creative and practical strengths. Motivating this work was the belief that the systems in most schools

strongly tend to favor children with strengths in memory and analytical abilities.

The Sternberg Triarchic Abilities Test was administered to 326 high-school students around the United States and in some other countries who were identified by their schools as gifted (by whatever standard the school used). Students were selected for a summer program in college-level psychology if they fell into one of five ability groupings: high analytical, high creative, high practical, high balanced (high in all three abilities), or low balanced (low in all three abilities). These students were then randomly divided into four instructional groups, emphasizing memory, analytical, creative, or practical instruction. For example, in the memory condition, they might be asked to describe the main tenets of a major theory of depression. In the analytical condition, they might be asked to compare and contrast two theories of depression. In the creative condition, they might be asked to formulate their own theory of depression. In the practical condition, they might be asked how they could use what they had learned about depression to help a friend who was depressed.

Students who were placed in instructional conditions that better matched their pattern of abilities outperformed students who were mismatched. In other words, when students are taught in a way that fits how they think, they do better in school. Children with creative and practical abilities, who are almost never taught or assessed in a way that matches their pattern of abilities, may be at a disadvantage in course after course, year after year.

A follow-up study examined learning of social studies and science by 225 third-graders in Raleigh, North Carolina, and 142 eighth-graders in Baltimore, Maryland, and Fresno, California. In this study, students were assigned to one of three instructional conditions. In the first condition, they were taught the course they would have learned had there been no intervention, which placed an emphasis on memory. In the second condition, students were taught in a way that emphasized critical (analytical) thinking, and in the third condition they were taught in a way that emphasized analytical, creative, and practical thinking. All students' performance was assessed for memory learning (through multiple-choice assessments) as well as for analytical, creative, and practical learning (through performance assessments).

Students in the triarchic-intelligence (analytical, creative, practical) condition outperformed the other students in terms of the performance assessments. Interestingly, children in the triarchic instructional condition outperformed the other children on the multiple-choice memory tests. In other words, to the extent that one's goal is just to maximize children's memory for information, teaching triarchically is still superior. This is because it enables children to capitalize on their strengths and to correct or to compensate for their weaknesses, allowing them to encode material in a variety of interesting ways.

In another study, involving 871 middle-school students and 432 high school students, researchers taught reading either triarchically or through the regular curriculum. At the middle-school level, reading was taught explicitly. At the high school level, reading was infused into instruction in mathematics, physical sciences, social sciences, English, history, foreign languages, and the arts. In all settings, students who were taught triarchically substantially outperformed students who were taught in standard ways.

### Conclusion

The triarchic theory of intelligence provides a useful way of understanding human intelligence. It seems to capture important aspects of intelligence not captured by more conventional theories. It also differs from the theories of Howard Gardner, which emphasize eight independent multiple intelligences (such as linguistic and musical intelligence), and from the theory of emotional intelligence. The triarchic theory emphasizes processes of intelligence, rather than domains of intelligence, as in Gardner's theory. It also views emotions as distinct from intelligence. Eventually, a theory may be proposed that integrates the best elements of all existing theories.

## INTERDISCIPLINARY COURSES AND MAJORS IN HIGHER EDUCATION

---

Interdisciplinary studies, broadly defined, is the process of answering a question, solving a problem, or addressing a problem that is so broad or complex that it cannot be addressed through a single discipline or field. In higher education in the United States, interdisciplinary studies are conducted through individual courses, including independent studies; in specific programs of study such as major or minor concentrations; as part of a student's general education requirements; through practica, internships, and other educational experiences that focus on the application of theory and knowledge to the workplace and society; and occasionally through honors programs. In a few cases entire colleges or universities are organized in interdisciplinary units that replace discipline- or field-based departments or divisions.

The goal of most interdisciplinary courses and programs is to integrate the contributions of different academic disciplines or fields of study so that topics, problems, and phenomena under study are better understood. (*Disciplines* have traditionally been defined as specializations within the arts and sciences; the term *fields* is often used to distinguish disciplines from professional fields, such as business, education, law, and medicine, which draw their content and methods from a number of different disciplines.) However, some scholars such as Jean Francois Lyotard contest the usefulness of academic disciplines as ways of organizing and generating knowledge, and thus challenge the idea that disciplines are the basis for interdisciplinarity. These scholars consider interdisciplinarity to be a critique of the disciplines; in their view, the goal of interdisciplinarity is to subvert, rather than to utilize, the disciplines as they are currently organized.

### Rationale for Interdisciplinary Courses and Programs

Arguments favoring interdisciplinary teaching emphasize the need to bring multiple disciplinary perspectives to bear on real-world issues. Proponents of interdisciplinarity argue that the disciplines arbitrarily fragment the world and allow their adherents to select only those dimensions of a problem that their discipline can adequately address, thus leaving important dimensions of the problem unaddressed.

The views offered by the disciplines are therefore considered partial; they provide a single lens or perspective from which to study and understand complex phenomena or issues. Advocates of interdisciplinarity argue that disciplinary approaches to education are therefore reductionist; they divide knowledge rather than generate comprehensive explanations of the world. Although many if not most proponents of interdisciplinarity believe that disciplines are necessary for the advancement of knowledge, they view overspecialization, in the form of increasing disciplinary isolationism, as impeding communication and understanding among disciplinary experts, their students, and the larger public that might be consumers or beneficiaries of their work.

Those who encourage interdisciplinary education seek holistic understandings of the social and natural worlds. Real-world problems, they argue, are not separated into disciplinary components; rather, they are complex, hard to define, challenging to solve, and often have more than one right answer. Such problems require that individuals know what kinds of information are needed and where to find that information. By requiring students to work on such problems, the argument proceeds, interdisciplinary education develops a number of intellectual skills. These include skills in problem solving, critical thinking, evaluation, synthesis, and integration. In addition, interdisciplinary courses are believed to develop the ability to see and employ multiple perspectives; to encourage tolerance and respect for the perspectives of others; to expand students' horizons or perspectives; to increase their willingness and capacity to question assumptions about the world and about themselves; to promote the ability to think in creative and innovative ways; and to create sensitivity to disciplinary and other biases. As a result, advocates argue, interdisciplinary study is excellent preparation for the role of citizen and worker in a pluralistic, technological, and democratic society.

Proponents such as James R. Davis, William H. Newell, and William J. Green also claim that interdisciplinary curricula are more engaging, capturing students' intellectual interests and encouraging them to make connections among the disparate realms of information provided by discrete disciplines. Even scholars, this argument continues, need to know about developments in other disciplines so that they may adapt or incorporate these into their own work as appropriate. Interdisciplinary training has there-

fore been recommended by Joseph Klockmans as a way to build bridges to overcome disciplinary isolation. Others argue that interdisciplinary courses can improve faculty morale by revitalizing instructors' interest in teaching introductory or survey courses that are not closely related to their areas of specialization. Similarly, supporters contend that interdisciplinary courses promote faculty development, offering instructors the opportunity to explore new areas of interest and collaborate with colleagues and thereby expand their repertoire of knowledge and skills.

Arguments, such as Thomas C. Benson's, opposing undergraduate interdisciplinary courses and programs typically focus on perceived detriments to student learning. Interdisciplinary study, opponents argue, cannot be effective unless students are first adequately schooled in at least one of the disciplines contributing to an interdisciplinary course or program. Without this foundation, students cannot marshal arguments, methods, or insights from the disciplines in an interdisciplinary course. Critics also assert that substantial commitment to interdisciplinary study as an undergraduate student, as is required in a minor or major program, may impede a student's development of disciplinary competencies. A third argument—that interdisciplinary courses are shallow and lacking in intellectual rigor—builds on the previous arguments. This criticism maintains that because students do not have the foundational knowledge of the involved disciplines that allows them to participate in demanding intellectual discussions in interdisciplinary courses, instructors emphasize what is entertaining and most accessible to the majority of students. Opponents also argue that interdisciplinary courses are costly because they often rely on team-teaching, independent studies, and low faculty-student ratios.

### **Interdisciplinary Study in U.S. Higher Education**

The first interdisciplinary courses in U.S. colleges and universities were part of the general education, or core, requirements of the undergraduate curriculum. (General education is that component of the undergraduate curriculum intended to provide students with the knowledge, skills, and values required for life as a contributing member of society.) Although general education has a long history in higher education, interdisciplinary general education courses in the United States did not appear until the twentieth century when World War I prompted

U.S. colleges and universities to institute general education courses designed to strengthen Americans' sense of cultural and national identity and responsible citizenship. These comprehensive survey courses, which relied on a number of disciplines for their subject matter, attempted to sustain the content and values of Western civilization. The courses required instructors who could effectively synthesize knowledge and make it accessible to undergraduates and therefore highlighted the need for interdisciplinary approaches to education. Despite concerns about disciplinary fragmentation and academic overspecialization, only a few institutions offered more than a handful of interdisciplinary survey courses; the Experimental College at the University of Wisconsin, which lasted only from 1928 to 1932, is perhaps the most famous example of an institution committed to an extensive interdisciplinary general education.

During the 1930s and 1940s, war again influenced interdisciplinary curricula as institutions developed area studies programs designed to provide knowledge about foreign cultures and peoples involved in World War II. Although international education was spurred by private foundation support before the war, these efforts diversified during and after World War II as programs focused on more and more geographic areas. By 1988, there were more than 600 area studies programs on American campuses.

The social and cultural transformations of the 1960s and 1970s inspired additional interdisciplinary educational efforts. As the civil rights, women's liberation, and Vietnam War protests created demands for more personally and socially relevant, student-centered curricula, institutions responded by offering interdisciplinary courses and programs in a variety of areas. While a few institutions developed interdisciplinary organizational models, most institutions developed interdisciplinary courses and programs that supplemented the usual disciplinary offerings. By the 1970s, interdisciplinary minor and major programs in Black, Chicano, Environmental, Urban, and Women's Studies appeared on campuses across the United States. In the year 2000 Barrie Thorne reported there were more than 700 women's studies programs in U.S. institutions. According to a report published by the National Center for Education Statistics in 2001, in 1998 more than 6,200 associate and baccalaureate degrees were conferred in area, ethnic, and cultural studies. In addition more

than 35,000 students earned associate's or baccalaureate degrees in multi/interdisciplinary studies.

During the 1980s concerns about general education heightened and curricular reform in this area was often motivated by a desire to create more meaningful and less fragmented educational experiences for college students. General education distribution requirements, typically filled by allowing students to choose from a variety of introductory courses in selected disciplines, were replaced by a core of interdisciplinary courses common to all students in an institution. Proponents believed the goals of general education would be better served if students engaged in a common conversation regarding cultural and societal issues rather than haphazardly choosing courses from approved lists with little concern for their connection to one another. Interdisciplinary general education requirements often include multicultural studies, environmental studies, Western Civilization, and the Great Books. In the final decades of the twentieth century, the number and type of interdisciplinary curricula greatly increased as programs in cultural studies, interdisciplinary science fields (e.g., neuroscience, molecular biology, and environmental sciences), human ecology, information technology, public policy, and legal and labor studies gained prominence in U.S. colleges and universities.

### **Interdisciplinary Courses**

A distinction is often made between multidisciplinary and interdisciplinary courses, although the difference is more likely one of degree. In multidisciplinary courses, instructors present disciplinary perspectives, often one at a time, without special attention to integrating those perspectives or examining their assumptions. In contrast, instructors in interdisciplinary courses not only examine the underlying assumptions of the disciplines that contribute to the course, but also assist students in integrating the separate disciplinary contributions that have been brought to bear on a topic into an inclusive understanding.

Typically an interdisciplinary course is organized around a topic, broadly defined as an issue, theme, problem, region, era, institution, person, or idea. Different disciplinary (and potentially other) perspectives on the topic are incorporated into readings and assignments. Interdisciplinary courses take a variety of formats and espouse a number of purposes. First-year seminar courses can provide a com-

prehensive orientation to a field or fields of study, often by probing a single issue, problem, or question. Advanced seminars usually have an integrative purpose, serving as culminating or capstone courses in which students refine analytical and critical methodologies. Fieldwork, internship, service learning, and travel-study courses may also employ interdisciplinary approaches to assist students in connecting life experiences with classroom learning.

Individual instructors often plan and teach interdisciplinary courses, but teams of two or more faculty members from different disciplines or fields of study are also common. Collaboration among faculty teaching interdisciplinary courses can involve course planning, content integration, teaching, and assessment. All members of the faculty team may be involved in planning a course or a single individual can take primary responsibility for this role. Responsibility for instruction can also vary. In some team-taught courses, all members are present in the classroom for each session; they may all contribute to each class session or team members may take responsibility for specific components of the course. In other team-based courses, a core of faculty supplement their lectures and discussions by inviting guest lecturers to provide instruction in a specific area of interest. In a dispersed team model, large classes of students meet together for one class session per week in which all members of the faculty team are present. Subsequent weekly meetings take place in smaller sections taught by a single faculty member. No matter what delivery model is used, team members must make decisions about how student work will be assessed. Faculty may share this task, with each team member reading and commenting on all student work, or they may divide the task among them.

Coordinated studies and learning community models are a variation on the team-taught course. In these models, members of a faculty team coordinate two or more courses that focus on a prearranged theme or topic rather than teaching about that theme or topic in the context of a single course. Each coordinated course is designed to contribute to a wide-ranging understanding of the subject under study; in addition to coordinating content across these courses, instructors may also coordinate course activities and assignments to enhance the learning experience. The multiple-course format is intended to achieve the goal of depth of learning; a few institutions seek to further enhance depth by ex-

tending coordinated courses over an academic year rather than confining them to a single semester.

Instructors who teach interdisciplinary courses alone rather than in a team must present disciplinary information and perspectives that are not part of their area of specialization in order to teach an interdisciplinary topic. Most proponents of interdisciplinary courses and programs argue that faculty must have a broad background in the disciplines that are engaged in a particular interdisciplinary course before they can teach it without assistance from other disciplinary experts; faculty teaching an interdisciplinary course must be able to present their own, as well as different, disciplinary perspectives accurately and in depth. Until instructors develop the requisite base of knowledge and skills, proponents of this view believe that “solo” efforts should be discouraged. Faculty development in the form of seminars in which faculty teach one another their disciplines can provide the kind of faculty development needed to support interdisciplinary courses, but can be costly in terms of human and financial resources.

Many interdisciplinary courses are never taught in teams; individual faculty design and teach all the perspectives needed in the course. Faculty trained in interdisciplinary programs may have the necessary background for teaching such courses. Others develop expertise once asked to teach an interdisciplinary course. Interdisciplinary programs sometimes offer incentives to persuade and reward faculty who serve the program. These incentives can take the form of salary stipends, teaching or research assistants, travel money, or funding for the purchase of books or other materials. These incentives provide helpful resources for course preparation and also recognize the time and effort dedicated to the preparation and teaching of an interdisciplinary course.

Team-taught courses are frequently used for general education course sequences and in interdisciplinary programs in which the variety of disciplinary perspectives engaged are disparate, each requiring in depth knowledge of a specific set of methods or concepts, such as in environmental sciences, biochemistry, or urban planning. Individually taught interdisciplinary courses are particularly common in the humanities, women’s studies, cultural studies, and ethnic studies, and often include a critique of disciplinary knowledge.

## **Interdisciplinary Programs**

Interdisciplinary major and minor programs take a number of organizational forms, but three forms are prominent: (1) established programs with permanent staffs and program budgets; (2) interdepartmental committees, programs, or colleges with defined curricula but no faculty members appointed solely to the unit; and (3) individually designed majors or other programs that permit students to design, with faculty guidance, customized degree programs to meet their educational needs.

Typically, established programs have a full- or part-time director who provides administrative leadership and who also teaches in the program. Individual faculty in established programs may hold joint appointments with the interdisciplinary program and with one or more departments related to their area of expertise. They may also be appointed for a fixed term to serve an interdisciplinary program (for a portion or all of their time). The number of faculty associated with such programs can vary, but this mode provides stability to the interdisciplinary program because it guarantees at least a portion of a faculty member’s time will be dedicated to program responsibilities at a given time.

In interdepartmental committees, programs, or colleges, the program director is either full- or part-time and is responsible for arranging courses to be taught by faculty from different departments. These faculty are not permanent members of the program but are rather borrowed temporarily from their home departments. Such budgetary arrangements leave interdisciplinary programs vulnerable in times of resource and financial stress. Advocates of interdisciplinarity note however that the closer the interdisciplinary program is tied to the mission of the institution, the less likely it is to suffer financially during difficult periods in an institution’s history.

## **Interdisciplinary Colleges and Universities**

Most institutions that adopt an interdisciplinary approach value team teaching, student and faculty involvement in curriculum development and in governance, and active participation by the students both in the classroom and in external research or work internships. Academic departments based on disciplinary affiliations are either nonexistent or more fluid than in other institutions. “Great Books” colleges, characteristically small institutions such as St. John’s College of Maryland and of Santa Fe, are

often labeled interdisciplinary because they explore the foundational ideas and questions that distinguish a civilization. The few Great Books colleges in the U.S. organize their curricula around reading and discussion of what they believe to be a set of classic texts of Western civilization. Proponents of this approach believe that students are best prepared for life when they interact and wrestle with the greatest minds of our civilization, and they opt for a nondisciplinary structure because “neither the world nor knowledge of it is arbitrarily divided up as universities are” (Hutchins, p. 59).

Other interdisciplinary institutions organize curricula around specific societal or environmental issues, and encourage individualized programs of study developed collaboratively by students and faculty. In 1965 the Wisconsin legislature chartered the University of Wisconsin-Green Bay to devise a future-oriented innovative curriculum. Influenced by the ecology movement of the time, Green Bay offered an interdisciplinary curriculum focused on the relationships between humans and their environment. The university organized its colleges around environmental themes rather than academic disciplines and divided its curriculum into nine problem-centered concentrations. Over time, however, Green Bay added disciplinary majors and interdisciplinary minors to its original structure. A smaller institution, the College of the Atlantic, established in Bar Harbor, Maine, in 1969 maintained its commitment to one primary issue. It offers individually tailored bachelor’s and master’s degrees in human ecology, a field that emphasizes the interrelationships between humans and their social and physical environments.

Other institutions, such as Evergreen State College in Olympia, Washington, offer a more extensive interdisciplinary curriculum. In 1967 Evergreen opened as a nontraditional liberal arts college. Its coordinated studies program allows students to participate in full-time interdisciplinary study through a combination of team-taught programs and student-designed areas of concentration. Hampshire College in Massachusetts also offers students the opportunity to create individualized programs of study built upon a core multidisciplinary curriculum. The number of colleges and universities offering exclusively interdisciplinary curricula is relatively small; the majority of higher education institutions in the United States either prescribe or offer interdisciplinary tracks within their general education offerings.

## INTEREST GROUPS

See: EDUCATIONAL INTEREST GROUPS.

## INTERGOVERNMENTAL RELATIONS IN EDUCATION

Relationships between branches and levels of government are important in the administration and delivery of educational services in all countries. National ministries of education may wish to control all phases of education, but they inevitably must delegate significant aspects of the operation and delivery of educational services to lower levels of government. The more decentralized the governance system, and the more branches and levels of government there are, the more complex intergovernmental relationships may be. But, even in nations with highly centralized approaches to governance, the re-

lationship between the central ministry of education and schools and colleges is important. Any government's policies are only as effective as their design and implementation permit, and effective implementation is heavily influenced by the character of the relationship that exists between branches and levels of government.

### Governance Structures

Most nations have a unitary government, which means that the central government holds sovereign power over all lower levels of government. The lower levels of government are subordinate to the national government, which can overrule or even abolish them. By contrast, some nations have adopted federal governance systems, in which power is shared between the national government and state or regional units, which cannot be abolished. These federations with constitutions developed in nations, such as Australia, Canada, Germany, and the United States, where regional differences are important and where former colonies or semiautonomous states banded together out of common interest. In federal systems, education usually is the legal responsibility of the state governments rather than the national government. Still, even in federal systems, national interests in such matters as equality of opportunity and educational adequacy and excellence inevitably cause the national governments to play a role in education.

Whether control over a nation's government is democratic or autocratic, and whether a unitary or federal system is used, there can be significant variation in the degree to which the government is centralized or decentralized. By definition, one expects decentralization in federal systems, but this is not always the case. For example, until the mid-1980s Australia's states ran highly centralized statewide education systems in which all but the simplest decisions were made in the state ministries of education in the capitol cities. For the most part, Germany's states continue to run highly centralized education systems.

Beginning in the 1980s, a reform movement advocating decentralization and much greater decision-making at the school level (school-based management or "self-managing schools") began to spread across the world, especially the English-speaking world. School-based management sought to restructure the decision-making chain of command by shifting authority from highly centralized bureaucracies to the school site level. New Zealand

adopted this approach completely, and some Australian states have moved in this direction. Britain presents a complex and interesting example of these trends. It has reduced the power of the local education authorities (roughly equivalent to American and Canadian school districts) and given schools much more decision-making authority, but the entire system operates under a powerful central government in London. In the United States, more than one-third of all school districts have implemented some version of school-based management, and at least five states—Colorado, Florida, Kentucky, North Carolina, and Texas—have legislated participatory decision-making at each school.

The high degree of decentralization in the structure of educational governance in the United States is unusual. The kind of local control that exists in the United States, through the delegation by states of substantial decision-making power to elected school boards of lay citizens in some 15,000 local school districts, is rare. Most nations have far more centralized arrangements. In European nations, such as France and Germany, civil servants operating within highly bureaucratized agencies or ministries of education tightly control the education system. In these settings, local citizens have little or no voice in decision-making for schools, and a highly professionalized (or at least bureaucratized) cadre of educators hold sway.

The stark contrast between, on the one hand, highly centralized and bureaucratized systems of governance and, on the other hand, decentralized systems that allow for local and lay participation in educational policy-making raises the question of how best to structure the governance of education. Here, it is common to see a tension between competing values. Efficiency, it can be argued, is best served by a centralized system that can better ensure consistent standards throughout a nation than a decentralized system. On the other hand, centralized systems are prone to develop bureaucratic rigidities that can ultimately impede efficiency, not to mention liberty and democracy. Debates about the proper governance of public services, in fact, often seem to revolve around the tension between the competing values of democracy and efficiency. Unfortunately, by themselves neither centralized nor decentralized approaches to government can guarantee either democracy or efficiency.

### **Standards, Accountability, and Capacity-Building**

Many nations require students to pass national examinations in order to advance in school or exit from the school system. These high-stakes exams and the accompanying national curriculum provide a common standard for all students and schools and help establish a coherent educational system. In the United States, however, a debate continues over curriculum standards, testing, and accountability measures and over which level of government (local, state, or federal) should be responsible for these measures. The long tradition of local control over education impedes state and national efforts to impose standards and accountability systems. Further, high-stakes examinations conflict with American beliefs in freedom, individualism, and multiple opportunities for success. Inevitably, national goals, individual and minority rights, and regional differences conflict and contribute to tensions in intergovernmental relations.

Most U.S. states have established academic and curricular standards with testing and other accountability requirements, and many have experienced increasingly tense intergovernmental relations. The highly publicized takeover of the academically and fiscally distressed School District of Philadelphia by the Commonwealth of Pennsylvania in December 2001 illustrates how volatile intergovernmental conflicts can become when serious consequences are attached to school accountability measures. When higher levels of government intervene in or take over failing schools or school districts, the assumption is that the higher levels have the capacity to correct the problems. But, owing to underinvestment, state education departments sometimes lack the capacity to provide the technical assistance and professional development necessary to reinvigorate failing schools. Many schools lack the organizational capacity to respond effectively to the demands of higher academic standards, so staff professional development and capacity-building efforts are key activities in which higher levels of government need to assist them.

### **The Financing of Schools and Intergovernmental Relations**

The costs of professional development efforts, not to mention the basic costs of operating and maintaining schools, lead to the important question of intergovernmental arrangements for the finance of education, including the relative share of the costs different levels of government should contribute.

Ideally, there are provisions, such as in Australia, to ensure that the same amount of government tax money is provided to finance a child's education regardless of where the child lives. But arrangements can be far less logical and equitable than that. The tradition of local control of education in the United States has produced a situation in which the funding of schools is heavily influenced by the wealth of individual communities. Even though American states try to equalize funding through contributions of state funds to augment local property tax revenue, many states still allow large disparities to exist between the levels of spending in local school districts that vary in wealth. Since the 1960s, this inequitable pattern has been challenged in numerous court cases, and reformers have succeeded in reducing the disparities in some states.

The funding of schools is likely to become even more complicated as governmental agencies are now having to determine who is responsible and at what level for the costs of educating students who no longer attend local schools but instead receive their education through "cyber schools" over the Internet. Cyber schools and other technological advances pose new challenges to intergovernmental relations and raise new politically charged questions. Policy-makers must determine, for example, if cyber schools—in which students primarily stay home and access materials online with little direct contact with teachers—should be counted and financed as public education. Further, cyber schools raise new questions about school funding for which there have been no clear answers. Who should pay? What amount should come from local funds and what from state or national? Beyond fiscal questions, cyber schools also raise accountability and regulatory issues.

### **Intergovernmental Relations and School-Linked Social-Services Coordination**

Children worldwide face a multitude of modern problems that include increased incidents of substance abuse, inadequate and unaffordable housing, racism, sexism, child abuse and family violence, sexual promiscuity and teen pregnancy, poverty, hunger, and limited or poor health care. These problems place children at risk and put schools at the epicenter of interconnected social problems. Yet the services needed to respond to these problems are typically fragmented across a variety of uncoordinated government agencies. Consequently, many Westernized

nations are increasingly adopting policies to have schools and external agencies collaborate to help meet students' nonacademic needs and provide more comprehensive support services for at-risk students and their families.

School-linked social-services efforts illustrate the complicated nature of intergovernmental relations in education. Although each school, social-service agency, or branch of the government seeks to assist those in need, jurisdictional and organizational problems can limit their ability to work together to find sustainable solutions that help those most at risk. Coordinated, school-linked services create new expectations and complexities and introduce new actors, thereby increasing organizational demands, ambiguities, and, potentially, loss of control. A fundamental challenge in intergovernmental collaborative efforts is to overcome the barriers created by the effects of competing institutional interests that emphasize protecting jobs, budgets, programs, facilities, and the agency's "turf" and clientele.

Organizational and professional differences among various government and nonprofit agencies, including schools, create barriers that include a lack of a common outlook and professional language, communication problems, licensure issues, and confidentiality issues. Also problematic are issues such as space and facilities management; funding issues and resource mingling; differing salary and personnel policies; new roles and relationships between educators and other agency personnel; leadership issues; deficits and differences in professional preparation programs and training; information sharing and retrieval; and control and legal issues. Research indicates that these are significant barriers that can impede intergovernmental/interagency collaboration.

## INTERNATIONAL ASPECTS OF EDUCATION COMMERCE

---

The use of government financial resources to support public basic-education provision is well estab-

lished and widely accepted across the globe. However, since 1990 there has been a noticeable shift in the traditional ways that provision of higher education and, to a lesser extent, secondary education is regulated. In different contexts there are new financing strategies being implemented in the public sector, with a view toward generating additional revenues from public assets, mobilizing additional resources from students and their families, encouraging donations from third-party contributions, and involving the private sector in the provision of essential services to educational institutions. Future demand for private provision of education services, especially at the higher levels of education, is predicted to grow even more in the first decade of the twenty-first century.

All governments are concerned about investment in human capital, and, despite significant improvements in education coverage in developing countries, there is still a large unmet demand for both access and quality education at all levels.

The private sector's role as a potential partner with the public sector in both the provision and financing of education is widely recognized in the early twenty-first century. There is substantial evidence to show that the private sector can: (1) ease the pressure on governments' financial constraints; (2) encourage and demonstrate efficiency, effectiveness and innovation; (3) promote social mobility and contribute to the growth of an emerging middle class; (4) expand educational diversity; and (5) increase access and quality across all education levels and societal groups.

### Private Higher Education

In higher and continuing education, private-sector provision has become a practical way for economies to scale up their investment in human capital, especially in developing countries. More than 2.3 billion people, or 53 percent of the total population of the developing world, live in the poorest countries—those that have annual per capita incomes of less than \$885. These countries have a small proportion (12 million students) of the global tertiary education market (90 million). Innovative action has been necessary in these lower-income countries to provide an acceptable standard of tertiary education in order to provide the education needed to generate economic growth. In these settings, low-income countries are providing positive legal frameworks where private, specialized two- or three-year tertiary education in-

stitutions (such as technical institutes or community colleges) can provide training for technicians and applied specialists.

Studies done between 1998 and 2000 show that the size of the private higher-education sector varied significantly across developing countries. Levels of private-sector ownership included:

- 100 percent of professional training market in Cote d'Ivoire
- 44 percent of skills training market in The Gambia
- 75 percent of tertiary colleges in India
- 1,274 private institutions, with 4 million students, in China
- 37 tertiary institutions in Ghana
- 60 percent of tertiary institutions in Brazil

A common characteristic of private higher-education provision is that tuition fees are the main source of revenue. Private institutions also serve both the rich and poor, which often includes *second chance* students who cannot gain admission to public universities. These institutions also exist in different forms, including franchises, school groups, sole proprietorships, for-profit companies, nonprofit institutions, and religious organizations. Some higher-education institutions may also offer a limited range of professional and practically oriented courses (e.g., accounting, management, English information technology), often using part-time staff (including trained professionals, practitioners, or professors from public institutions).

Student loan schemes are also emerging in places where positive regulatory conditions are in place for banks to provide for an individual student's access to credit. This is particularly the case at postsecondary levels, where private financial institutions can use students' increased expected earnings from their education as future collateral to provide individual credit.

### Private Schools

Evidence shows that, in many cases, private schools can introduce and encourage better effectiveness in terms of education outcomes. A 2000 study by Arjun Bedi and Ashish Garg on the effectiveness of private versus public schooling in Indonesia showed a positive correlation between increased labor market earnings (as a proxy for more effective education) and private school attendance. Results from the Do-

minican Republic, the Philippines, Tanzania, and Thailand show evidence of better education results, at lower costs, for private schools—through better management practices, more efficient use of inputs, and the introduction of innovative cost-saving techniques. Likewise, two studies in India concluded that private initiatives provide better education at lower costs. The Fé y Alegria School network in Latin America is also known to provide more effective schooling than its public-sector counterparts; its per student costs are only 60 percent of those in the public sector; yet many of the schools achieve similar or better learning outcomes.

### For-Profit and Nonprofit Institutions

Many countries regulate that private schools only be operated on a not-for-profit basis, while others are more liberal and allow for both nonprofit and for-profit institutions to operate and compete freely in the same markets. There has been an emergence of more for-profit institutions across the globe. Typically, but not always, they will serve urban-based middle- to upper-class families, and the tuition fees they charge can vary considerably. These schools are normally registered by public authorities, are subject to socially based regulatory requirements, and in some cases they receive public subsidies. Such is the case in many eastern European countries and South Africa, where subsidies are paid on a sliding scale based on the levels of tuition fees charged to students.

The main difference between the two categories of private schools is that nonprofit entities are not traditionally obliged to pay any taxes on surpluses they may generate, whereas for-profit entities are required to pay taxes on the profits they earn.

In countries where all private schools are required by regulation to be nonprofit entities, it is typical for investors to establish for-profit entities that can *parent*, or own, a school's physical assets and deliver essential services, usually on preferred commercial terms. While the education institution preserves its status by complying with the not-for-profit regulations, the parent entity can operate on a for-profit basis, selectively deriving income from the school's operations on favorable terms. Using these for-profit vehicles, proprietors are generally able to find more flexible mechanisms to minimize the tax impact on their earnings, and at the same time provide satisfactory social and financial returns to investors.

### **Public-Private Partnerships**

Partnerships between the public sector and the private sector have provided a basis for positive collaboration between governments and private-sector interests. In some developed countries where effective decentralization has taken place (e.g., Chile, New Zealand), greater autonomy at the institution level has had a positive impact on institution efficiency and accountability. Depending on the degree of outsourcing in each case, traditional services such as teacher payroll, school transport, financial services, and professional development have been successfully outsourced to the private sector. In cases where sensitivity to privatization exists, governments are actively seeking ways to outsource the design, building, and management of selected facilities, while retaining the ownership and control of all academic operations.

### **Supply of Textbooks and Ancillary Services**

Traditional private-sector supply of textbooks, curriculum, and other learning materials to both public and private schools has been in place for many years. Food service, catering, cleaning, and building and general maintenance services are also typically provided by the private sector.

### **Public Schools Managed by Private Companies**

Private-sector management of publicly owned schools (e.g., in Chile and the United States) under contract to the state has begun to earn public acceptance. Although it is still too early to know whether delivery of curriculum and learning outcomes improve in these situations, professional staff and many of their school communities are known to be supportive of these initiatives, with communities having greater inputs into school operations and development. In 2001, the Edison Schools network in the United States consisted of 136 schools in 53 cities, covering 22 states and serving approximately 75,000 students. This meant that Edison Schools were servicing approximately one out of every 700 K–12 students.

### **Private Tutoring Services**

Across the globe, private tutoring services have developed into a burgeoning industry. They thrive on supplementing the curriculum delivered in public institutions, are often highly skills-based in nature, and are sometimes staffed by teachers or subject specialists as a second job. In Asia alone there is more

than U.S. \$20 billion spent annually on English lessons.

### **Accreditation, Quality Reviews, and Inspections**

Independent accreditation services for colleges and universities are the norm in the United States. There is also a growing interest in many countries for quality reviews of schools and tertiary institutions to be carried out by the private sector. Many U.S. agencies, for example, are providing accreditation and quality-assurance services internationally. In Oman, a private British group undertakes operational and quality reviews of public schools.

### **Education on Internet Portals**

The private sector also plays an important role in education, improving access to new technologies through the development of resources and services that the public sector would find difficult to sustain. Private-sector interests will continue to dominate the development of information and communications technology (ICT) resources for the education sector throughout the world. Core curriculum materials and programs developed for use with ICT have, in a few cases, remained the preserve of public education. It is in the future interest of ICT development in education in both developed and developing countries that public- and private-sector education interests work in close partnership with private-sector ICT companies for the benefit of future education development. The private sector has the capability of making the significant investments required to keep pace with the continuous technological changes that are happening in the ICT sectors across the globe.

Education sites on the Internet can take on different forms of ownership. Private-sector sites and resources are common in the United States, India, Canada and elsewhere. In New Zealand, the development and management of the public education Internet portal was outsourced to the private sector. But in each case, consultation with the public sector regarding the linking of resources to the local curriculum was important.

Relevant use of the Internet will help democratize education, giving all students, even those in poor communities, access to global libraries and teachers around the world. A majority of the ICT resources developed to support electronic learning, or to add value to the delivery of curriculum into the classroom, have been developed by the private sector.

Education authorities in both developed and developing countries do not have the capability of making the significant investments required to keep pace with the continuous technological changes that are happening in the ICT sectors.

## OVERVIEW

International comparisons of student achievement involve assessing the knowledge of elementary and secondary school students in subjects such as mathematics, science, reading, civics, and technology. The comparisons use test items that have been standardized and agreed upon by participating countries. These complex studies have been carried out since 1959 to explicitly compare student performance among countries for students at a common age. To participate in such a comparative study, a country must demonstrate that it has had prior experience in conducting empirical studies of education.

Comparing student achievement between countries has several goals. To policymakers, country-to-country comparisons of student performance help indicate whether their educational system is performing as well as it could. To a researcher of education issues, the studies provide a basis for hypothesizing whether some policies and practices in education are necessary or sufficient for high student performance (such as requiring all teachers to obtain college degrees in the subject area they teach). To teachers and school administrators, international studies provide examples of behavior that may be a source of new forms of practice and self-evaluation.

### Types of Study Results

The results of a large international study in 1995 showed that eighth-grade teachers in the United

States are often not involved in decisions about the content areas of their teaching, as teachers are in other nations. U.S. teachers work longer hours than those in most other countries, they do not have as much time during the day to prepare for classes, and their daily classroom teaching is disrupted more often by things such as announcements, band practice, and scheduling changes. Moreover, the organization of curriculum used by elementary and middle schools in the United States appears not to be focused on topics that will propel students toward a more advanced understanding of mathematics. Comparisons with other countries show that U.S. students are just as interested in science and mathematics as other students, they study as long, and they watch just as much television.

### Organizational History

Education researchers and policymakers from twelve countries first established a plan for making large-scale cross-national comparisons between countries on student performance in 1958 at the UNESCO Institute for Education in Hamburg, Germany. The first successful large-scale quantitative international study in mathematics was conducted in 1965 by the International Association for the Evaluation of Educational Achievement (IEA) and included Australia, Belgium, England, Finland, France, Germany, Israel, Japan, Netherlands, Scotland, Sweden, and the United States. Since then, studies in fourteen or more countries have been conducted periodically in several subject areas of elementary and secondary education.

Between 1965 and 2001 the IEA sponsored studies of mathematics in 1965, 1982, 1995, and 1999; science in 1970, 1986, 1995, and 1999; reading in 1970, 1991, and 2001; civics in 1970 and 1998; and technology in 1990 and 1999. The Educational Testing Service conducted an International Assessment for Education Progress in science and mathematics in 1990. The Adult Literacy and Lifeskills survey is a large-scale comparative survey designed to identify and measure prose literacy, numeracy, and analytical reasoning in the adult population (those between sixteen and sixty-five years of age). This survey was conducted in 1994 and 2001.

Studies such as these require the development of a set of test items, which are translated into the languages of the participating countries. The translated items are checked for proper translation and they are pretested in each country to determine

whether they have misunderstandings or errors that would make the items unsuitable for use in the final study (about three times as many items are written as are finally used). The participating countries collectively agree upon a framework to define critical aspects of the topic area. For example, an elementary mathematics test would include items in numbers, geometry, algebra, functions, analysis, and measurement, and would also have items that represented different aspects of student performance, such as knowing the topic, using procedures, solving problems, reasoning, and communicating. However, no single assessment could cover comprehensively an entire topic for all countries.

The tests are administered to a sample of students in 100 to 200 schools, which are selected to represent all students in the country. An international referee monitors the school selection process to insure that all countries follow correct sampling procedures. The test items are scored according to internationally agreed-upon procedures and are analyzed at an international center to insure cross-national comparability. Countries that do not meet high standards of participation are not included in the comparisons.

### Problems of Comparability

Some educators believe that learning is too elusive and culturally specific to be measured in a statistical survey. They believe that the outcomes of education are too diverse, indirect, and unpredictable to be measured in a single instrument. Others believe that comparisons are “odious” because practices that work in one culture may not be appropriate in another culture due to differences in social context and history.

The first IEA study planners were not confident that cross-national comparisons would be valid. They were concerned that the curriculum of different countries would stress different aspects of mathematics, science, or reading, and that any test of student performance might not reflect what students had been taught. To recognize national differences in teaching, the first studies measured the degree to which topics that were emphasized in the school system were actually covered. Curriculum differences were categorized as *intended*, *implemented*, or *attained* curriculum in order to separate the policies of the school district from classroom presentations and actual student performance. The amount of coverage of a topic became an important explanato-

ry variable for between-school and between-country differences in achievement. The analysis showed that students in every country cover the same topics, but that they were often covered in a different order, and with a different emphasis, thus showing that international comparisons of student achievement do reflect the same content areas as other countries and thus they do make sense.

Education practices in the countries studied have been found to have more similarities than differences. The differences can be studied, however, and give important insights into which practices can be improved. International studies have helped policymakers understand that student performance is strongly determined by how schools articulate the content areas they are responsible for.

For example, a study conducted in 1965 showed significant differences in how countries approached the teaching of mathematics. Subsequent studies showed which topics of mathematics each country considered important, at what age they were introduced, and how the topics were sequenced. These studies led educators to pay closer attention to the underlying curriculum and the training of teachers in the United States. They also led to the earliest efforts by the mathematics education professionals to develop a single set of standards for mathematics teaching.

Studies of writing have had difficulty in achieving standards that permit comparison across countries. After several attempts to develop a standard set of principles for grading the writing of students across countries, the IEA gave up its efforts to evaluate writing across cultures. However, a study of reading achievement was successfully conducted in elementary and middle school grades in 1970, and studies are being conducted by the IEA and the Organisation for Economic Co-operation and Development (OECD). International studies have shown that U.S. elementary school students have a high performance level in reading compared with the rest of the participating countries, but only moderate performance at grade nine. These results indicate that U.S. students begin school with sufficient ability to read and interpret texts.

### Forms of Inquiry

Comparative studies of student achievement require carefully designed statistical surveys for the statistical measurement aspect of the comparison. The popula-

tions must be defined in a common way for each country, even though definitions of a grade might differ from country to country. For example, one way to insure comparability is to select a careful sample of all students who attend whatever grade is common for fourteen-year-old students. These surveys involve students taking a test for about an hour and filling in a background questionnaire of their attitudes toward school. Teachers are asked to complete questionnaires about the curriculum topics they cover and their own professional training.

Since the 1990s studies have sometimes involved the use of videotape technology to collect information on teaching practices and student activities. For example, large national samples of mathematics classrooms were videotaped in 1995 in Japan, Germany, and the United States, and classrooms for other subjects were videotaped, in additional countries, in 2000. Videotape methods permit a more careful description of teaching practices than classroom surveys, and they provide a check on the validity of teachers' self-reporting of their practices. Detailed case studies of educational practices in several countries have also provided information about the social context in which students are taught.

### International Assessments in the Twentieth Century

The first international studies were carried out by university research centers unaffiliated with government agencies. The results of those studies were published in academic journals, technical volumes, and academic books. During the 1980s these studies influenced policies in American education. Beginning in 1989 government agencies decided that they should have a larger role in organizing and supporting the studies and improving their quality. The National Center for Education Statistics (NCES), an agency of the U.S. Department of Education, and the National Science Foundation provided the leadership and funding support for creating international assessments. The U.S. National Academy of Sciences established an oversight committee called the Board on International Comparative Studies in Education to monitor the progress of these studies.

By 1995 international comparative studies had become an accepted continuing aspect of describing the status of the educational outcomes and were being carried out regularly by the NCES. Many countries originally participated in these studies in order to conduct an analysis of a single subject area

in a single year. They have since shifted toward a more strategic plan to develop consistently measured trends in educational achievement with international benchmarks.

### International Assessments in the Twenty-First Century

The complexity of conducting standardized comparisons of student achievement in many countries will always challenge researchers, yet they have become institutionalized in many countries. The OECD, which is based in Paris, has gained support from at least twenty-five governments for a continuing series of international comparisons of reading, mathematics, and science. These comparisons began in 2000. Also in 2000 UNESCO established the International Institute of Statistics to further institutionalize a process for improving the use of comparative statistics for policymaking.

Studies on the use of technology in schools are being developed to provide new information on forms of instructional technology that are becoming widespread in schools. Schools all over the world have introduced the use of computers and other forms of technology to classroom instruction, and studies seek to determine how educational practices are being altered by these systems.

## INTERNATIONAL ASSOCIATION FOR EDUCATIONAL ASSESSMENT

The International Association for Educational Assessment (IAEA) was conceived as an international association of measurement agencies in 1974 at a meeting at Educational Testing Service (ETS) in Princeton, New Jersey. Later that same year a preparing committee, representing various geographic regions, met at CITO, the Institute for Educational Measurement in the Netherlands, to formulate the plans for the association.

In 1976 the United Nations Educational, Scientific and Cultural Organization (UNESCO) admitted IAEA to C (information sharing) status as a nongovernmental organization (NGO). In 1981 UNESCO admitted IAEA to B (consultative) status.

### Purpose and Objectives

The broad purpose of IAEA is to assist educational agencies in the development and appropriate application of educational assessment techniques to improve the quality of education. IAEA's main objectives are to:

- improve communication among organizations interested in educational assessment through the sharing of professional expertise, conferences, and publications, while providing a framework that includes cooperative research, training, and projects involving educational assessment;
- make expertise in assessment techniques readily available for the solution of problems in the field of educational evaluation;
- cooperate with other organizations and agencies having complementary interests;
- engage in other activities leading to the improvement of assessment techniques and their appropriate use by educational agencies throughout the world.

### Membership

IAEA has mainly three groups of membership: primary organizations, affiliate organizations, and individuals. Primary organization members are not-for-profit organizations, often associated in one way or another with ministries of education, which have educational assessment as their primary function. Affiliate organizations are those that make a major use of educational assessment techniques, or financial

agencies that devote a large part of their budgets to work involving educational assessment. Individual members are those with a professional interest in assessment who may not be associated with an organization that has educational assessment as a primary concern. An executive committee whose officers and members are elected by the primary organization members governs IAEA. A subscription to the journal *Assessment in Education: Principles, Policy and Practice* is included with membership.

### Activities and Projects

IAEA organizes annual conferences on assessment themes of international significance. Rotated on a geographic basis, a primary organization member in a region assumes responsibility for organizing the conference. IAEA has focused on topics such as standard setting, school-based assessment, public examinations, and admission to higher education.

In cooperation with UNESCO, IAEA organizes roundtables on the impact of assessment on education. The roundtables bring experts from designated geographic areas together to share information about topics of mutual interest, such as "The Impact of Evaluation and Assessment on Educational Policy," "The Impact of Examination Systems on Curriculum Development," and "International Comparisons of Student Achievements." Since its inception IAEA has conducted through its members a number of projects for UNESCO and the World Bank.

The executive Secretaryship of IAEA is located at CITO, The Netherlands.

## INTERNATIONAL ASSOCIATION FOR THE EVALUATION OF EDUCATIONAL ACHIEVEMENT

The International Association for the Evaluation of Educational Achievement (IEA), founded in the late 1950s, conducts international comparative studies in which educational achievement is assessed in relation to student background, teacher, classroom, and school variables. At the time of the IEA's founding, there was a growing awareness among international

agencies of the role of formal education in social and economical development while indicators for educational “productivity” were lacking. A group of researchers, among them Torsten Husén and his colleagues, decided in the early 1960s to undertake a first study of mathematics achievement in twelve countries to explore the feasibility of international comparative achievement studies. This first study marked the birth of the IEA.

After starting as a group of researchers, the IEA soon became a cooperative of research institutes with a primarily academic research focus. Since the early 1980s the IEA has begun to focus more specifically on the interests of policymakers, and an increasing number of member countries are represented by their ministry of education and no longer by a leading research institute. The current membership of the IEA comprises almost sixty countries from all regions of the world, and these are represented in a policymaking body, the IEA General Assembly, that is supported by the Secretariat in Amsterdam. Each IEA study is managed by three bodies: the International Coordinating Centre (ICC), which is responsible for the conduct of the research at the international level; the International Steering Committee (ISC), which monitors the quality of the research and is responsible for the general policy directions; and the International Study Committee, which consists of the National Research Coordinators (who are responsible for the study at the national level), the ISC, and the ICC.

Over the years the IEA has conducted many survey studies of basic school subjects. Most of the studies were curriculum driven and measure educational outcomes (the attained curriculum) on the basis of an analysis of the “official” curricula (the intended curricula) of the participating countries. All these studies evaluate school and classroom process variables (the implemented curriculum), as well as teacher and student background variables. Examples are the studies of mathematics and science, reading literacy, civics education, and English and French as foreign languages. The IEA also conducts studies that are not curriculum based, such as the Pre-Primary Project and the Computers in Education study. In a typical IEA study, data are collected in the third and/or fourth grade, the seventh and/or eighth grade, and the final year of secondary schooling, although some studies do not include all three populations. IEA’s best-known study is the Third International Mathematics and Science Study (TIMSS),

conducted between 1992 and 1999 for all three populations, in which more than forty countries participated. This study was designed to assess achievement in mathematics and science in the context of national curricula, instructional practices, and the social (and learning) environment of students.

To allow countries a longitudinal international comparative perspective, the IEA in the late 1990s initiated a basic cycle of studies in which the association studies, in alternating years, mathematics and sciences (through TIMSS—now called Trends in Mathematics and Science Study) and reading literacy (through the Progress in International Reading Literacy Study). Additionally, the IEA conducts other studies such as the Civic Education Study, which was completed in 2002, and the Second Information Technology in Education Study, which started in the fall of 1997.

### **Purposes and Functions of IEA Studies**

IEA’s mission is to enhance the quality of education. Its studies have two main purposes: (1) to provide policymakers and educational practitioners with information about the quality of their education in relation to relevant reference countries; and (2) to assist in understanding the reasons for observed differences among educational systems.

Given these purposes, the IEA strives for two kinds of comparisons in its studies. The first one consists of straight international comparisons of effects of education in terms of scores (or subscores) on international tests. The second relates to how well a country’s official curriculum is implemented in the schools and achieved by students.

As a result, IEA studies have a variety of functions for educational policymakers, practitioners, and researchers:

- describing the national results in an international context
- analyzing the information about the status of the achievement of pupils against the results of one or more other countries or against the results in the country of interest in an earlier study (“benchmarking”)
- analyzing data to contribute to recommendations for changes when and where needed (“monitoring”)
- analyzing data with the purpose of understanding the reasons for observed performances either in a national context or within an international comparative perspective

- promoting a general “enlightenment”—that is, there is not a direct link to decisions but rather a gradual diffusion of ideas into the sphere of organizational decision-making

Many national and international reports on IEA studies illustrate the usefulness of IEA studies for educational policy and practice. For example, in Australia, Hungary, Ireland, Japan, New Zealand, and the United States, specific curriculum changes have been attributed to IEA findings.

### Considerations in Planning IEA Studies

IEA studies are very complex endeavors and are conducted with attention to quality at every step of the way. The first question to be answered in planning an IEA study is “what questions do we want to address through this study.” The leading research questions become very compelling because there are a variety of competing perspectives in realizing a study. In order to obtain valid and useful data and indicators, high-level scientific and technical standards have to be met for each component of the study, such as the development of a conceptual framework; determining target populations; curriculum analysis; instrument development (including pilot testing, translation, etc.); sampling; data collection, cleaning and file building; quality control in participating countries of each component; data analysis; and report writing.

Many countries participate in IEA studies (e.g., in TIMSS more than forty countries), and according to its mission the IEA aims to create opportunities for each country to conduct its own cross-national analysis in order to enhance the understanding of the functioning of its educational system at all levels. The varying interests of participating countries contribute to the dilemma between desirability and feasibility (many stakeholders want an array of data, while there are practical limitations in collecting data in schools), and in these types of studies compromises have to be found among the interests of all participating countries. The IEA aims for a design and for instruments that are as equally fair as possible to all participating countries, while also allowing for national options. For example, in the 1999 TIMSS study in South Africa, where the majority of pupils receive instruction in a language other than the home language, a language proficiency test was included to allow for investigating relationships between language and achievement.

A final point that requires careful attention is the organizational and logistical complexities of the IEA studies. For instance, the 1995 TIMSS study involved the following: achievement testing in mathematics and science in forty-five countries; five grade levels (third, fourth, seventh, eighth, and final year of secondary school); more than half a million students; testing in more than thirty languages; more than 15,000 participating schools; nearly 1,000 open-ended questions, generating millions of student responses and performance assessments; questionnaires from students, teachers, and school principals containing about 1,500 questions; and many thousands of individuals to administer the tests and process the data.

### Conclusions

IEA studies do not lead to easy answers to complex educational problems, but they contribute to the body of knowledge of how educational systems work and of optimal conditions for teaching and learning. An example can be found in a 1992 report by T. Neville Postlethwaite and Kenneth N. Ross, who determined on the basis of cross-national analysis of the IEA Progress in International Reading Literacy Study that a large number of variables (including school, teacher, teaching, and student variables) influenced reading achievement. Their analyses illustrate how IEA studies can contribute to informed decision-making by policymakers and create an awareness of the rich variety of educational settings and approaches around the world. On the other hand, the types of studies conducted by the IEA have some limitations and also receive criticism. Technical criticisms have largely been addressed in the recent studies, and critiques have become increasingly political.

Finally, reflecting on nearly half a century of IEA activities, a number of developments have occurred and benefits have emerged. IEA studies have moved beyond simply international comparative assessment scores and contextual information. They have contributed to the national and international education community in various ways. They have provided possibilities of addressing regional issues as part of an international comparative study, linking national assessments to international assessments, and for developing countries, in particular, the opportunity to collect baseline data on education. Important benefits of the international comparative IEA studies have been the development of education research ca-

capacities in many countries, culminating in the development of a network of researchers and specialists who can be drawn from by both governments and other agencies both nationally and internationally.

TJEERD PLOMP

#### IEA AND OECD STUDIES OF READING LITERACY

Globalization, increased worker mobility, and competition between knowledge-based economies have led to a growth in demand for studies to measure and compare the achievement outcomes of education systems. Given its importance in students' educational development and in everyday life, it is not surprising that reading has featured in a number of these studies. Reflecting a concern with functional aspects of learning, the assessment of reading was expanded from one that mainly focused on decoding and comprehension skills to one that addressed the ability to understand and use written language forms required by society and valued by the individual.

The International Association for the Evaluation of Educational Achievement (IEA), a nongovernmental organization, pioneered international assessment studies in the early 1960s. The number

of education systems (mostly in the industrialized world) participating in its reading studies increased from fifteen in 1970–1971 to thirty-two in 1991–1992 and to thirty-six in 2001. In the studies assessment instruments were developed by international panels, translated into national languages, and administered to representative samples of nine- or ten-year-old students and thirteen- or fourteen-year-old students in participating countries. A variety of correlates of reading proficiency, including students' opportunity to learn and resources for reading, were identified.

The Organisation for Economic Co-operation and Development (OECD), responding to concern among member governments about the preparedness of young people to enter society and the world of work, has supported the development of the Programme for International Student Assessment (PISA), which is designed to monitor the achievements of fifteen-year-old students in reading literacy (as well as in mathematics and science). Thirty-two countries participated in the first survey in 2000. The ability to comprehend forms of prose organized as continuous and noncontinuous text, such as lists and forms, and to retrieve and evaluate information were assessed.

In the 1990s a number of countries (eventually twenty) joined with Statistics Canada in studies, later involving OECD, to assess the ability of adults (sixteen to sixty-five years old) to understand and employ written information in daily activities at home, at work, and in the community. Reading tasks were based on text from newspapers and brochures, maps, timetables, and charts; basic arithmetic tasks were also included. Proficiency was found to be negatively related to age and, in eighteen countries, respondents' level of education was its strongest predictor.

Although international studies were initially planned to improve understanding of the educational process and to provide information relevant to policymaking and educational planning, the media have generally interpreted their findings in a competitive context, focusing on countries' relative performances, without considering the social, economic, and educational conditions that affect student learning.

## IEA STUDY OF TECHNOLOGY IN THE CLASSROOM

Prior to 1980 few teachers utilized information technology (IT) in the classroom. But the global diffusion of personal computers in the 1980s generated considerable interest in educational circles around the world, leading the International Association for the Evaluation of Educational Achievement (IEA) to initiate the first international comparative study of IT or computers in education. This study was named the Computers in Education Study and sometimes called CompEd.

### IEA Computers in Education Study

Twenty-two countries participated in the first stage of the Computers in Education Study and in 1989 conducted school surveys, as documented by Pelgrum and Plomp. Surveys were conducted in elementary, lower secondary, and upper secondary schools, and within each school sample, questionnaires were completed by the principal, computer coordinator, and several teachers. In 1992 the second stage of the study repeated the surveys of the first stage and added a student assessment, according to Willem Pelgrum and colleagues and Robert E. Anderson.

An assessment was designed to measure the ability of students to generally understand and use information technology. The performance of students in this assessment depended largely on the extent to which school curricula in each country provided opportunity to learn such skills. A number of countries already had instituted an informatics curriculum at the middle- or upper-secondary levels. Perhaps the most important finding of the study was that teachers in general lacked opportuni-

ties for the type of training that would enable them to integrate technology into their instruction.

The terminology for information technology has changed since the 1980s. Whereas information technology was called computers or IT during that decade, by the late 1990s educators in most countries referred to it as ICT to stand for the phrase *information and communication technology*. However, in some countries, most notably the United States, educators refer to information technology simply by the word *technology*.

### Second IEA Study

The rapid diffusion of the Internet and multimedia technology during the mid-1990s generated an interest in a new study that among other things could investigate the changes in the curricula and classrooms since IEA's earlier study. The Second International Technology in Education Study (SITES) was initiated in 1996 by the IEA and school surveys were conducted in 1998. The SITES study consists of three modules as summarized in Table 1.

Although the study was approved by the IEA in 1996, the survey data of module 1 were collected in 1998. The module 2 case study visits to the school sites were conducted during 2000 and 2001, and the reports will be released in 2002 and 2003. Module 3 was launched in 2001, but the data for the surveys and student assessments will be collected during 2004, with the results released in 2005 and 2006. Each of the three modules will be described briefly in turn.

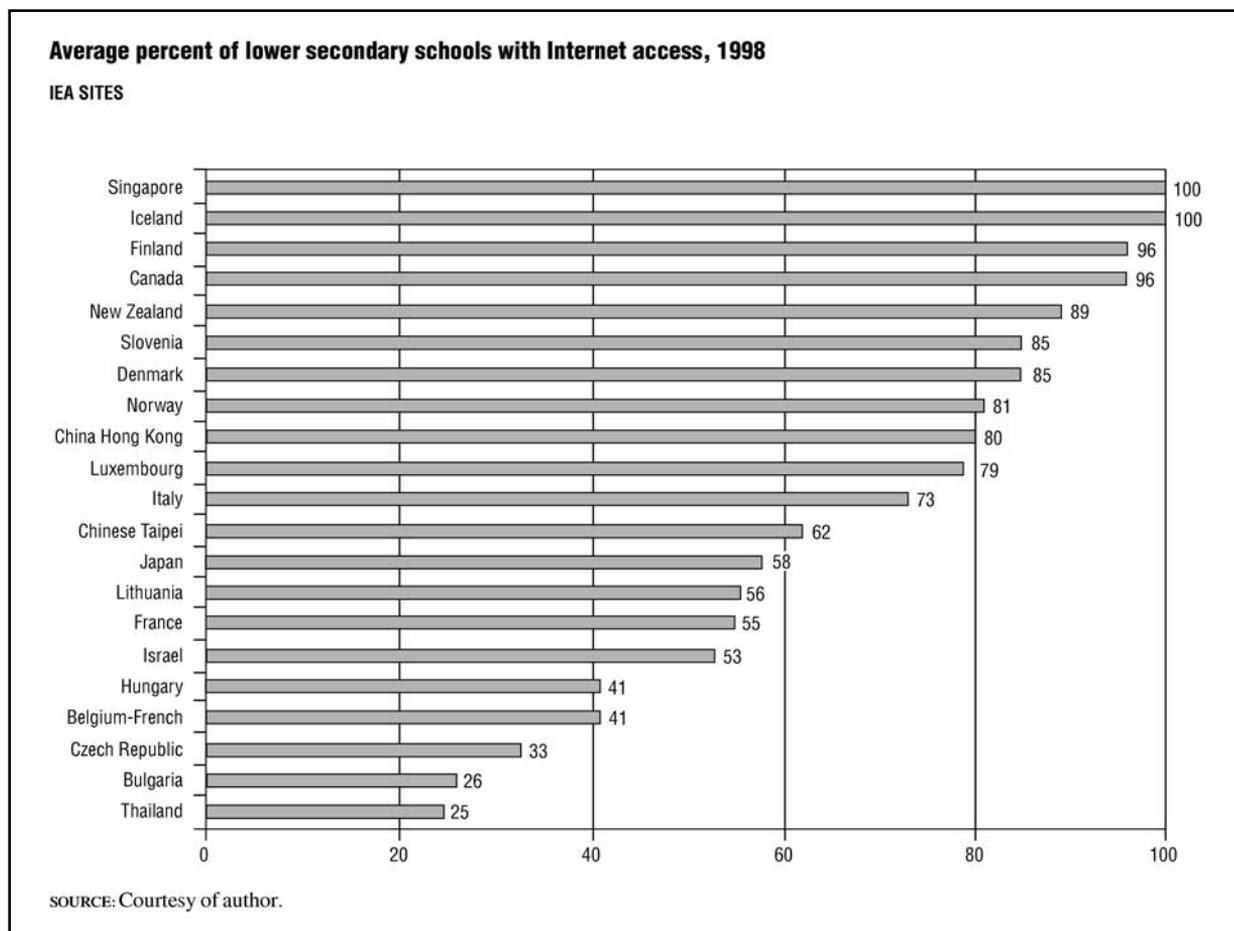

**School Survey Module.** In 1998 data were collected using a questionnaire survey of principals and one

of technology coordinators or their equivalents. Twenty-six countries participated by conducting these surveys in one or more of these three school levels: primary, lower secondary, and upper secondary. As reported by Pelgrum and Anderson, this module produced findings on the following phenomena:

- the extent to which ICT is used (and by whom) in education systems across the globe
- the extent to which education systems have adopted, implemented, and realized the results from objectives that are considered important for education in a knowledge society
- teaching practices that principals consider to be innovative, important, effective, and satisfying
- existing differences in ICT-related practices both within and between education systems and what lessons can be learned from this.

The findings on school Internet access were representative of the heterogeneous pattern of cross-national adoption of new ICT practices. Figure 1 shows that while 100 percent of the schools in Singapore and Iceland had access, some countries had only about a fourth of their schools connected. Most of the other countries had connected more than 50 percent of their schools. What is so remarkable about this pattern is that even in populations that do not speak English—the dominant language of the Internet—most of their countries' schools had been connected and many of the students were using the Internet in school. This rapid connection of schools to the Internet occurred within only about five years or less.

FIGURE 1

**Case Studies Module.** Nearly thirty countries conducted in-depth case studies during the last half of 2000 and the first half of 2001. The focus of this qualitative research is innovative pedagogical practices that use technology (IPPUT). The main purposes are to understand what sustains these practices and what outcomes they produce. To accomplish this investigation, each case study describes and analyzes classroom-based processes and their contexts. These case studies are intended to provide policy analysts and teachers with examples of “model” classroom practices and offer policymakers findings regarding the contextual factors that are critical to successful implementation and sustainability of these exemplary teaching practices using ICT.

The twenty-eight countries participating in this module of SITES were Australia, Canada, Chile, China Hong Kong, Chinese Taipei, Czech Republic, Denmark, England, Finland, France, Germany, Israel, Italy, Japan, Korea, Latvia, Lithuania, the Nether-

lands, Norway, Philippines, Portugal, Russian Federation, Singapore, Slovakia, South Africa, Spain (Catalonia), Thailand, and the United States. As each country will conduct four to twelve case studies, the total number of cases for analysis is expected to be more than 150.

One noteworthy preliminary finding was that the students used the Internet as part of nearly every innovative practice selected. Another preliminary finding of perhaps greater importance is that the students involved in these innovative pedagogical practices often engaged in activities that could be considered “knowledge management” in that they frequently constructed knowledge products. Typically such activities were called projects and included the tasks of searching, organizing, and evaluating knowledge. For instance, Germany’s first case study found that students “turned into providers of knowledge.” Portugal’s pilot case reported that the teachers wanted their students to be “constructors

rather than receptors of mathematical knowledge.” In Norway and the USA the case studies found students working collaboratively with ICT tools to complete projects yielding diverse types of knowledge.

**Assessment Module.** This module builds upon these findings from the leading-edge classrooms of the case studies. Specifically, the school survey, teacher survey, and student assessment will include indicators to determine the difference between the innovative and the typical learning contexts. The study will measure the ICT-supported knowledge management competencies of students, including their abilities to retrieve, organize, critically evaluate, communicate, and produce knowledge. In addition, the study will determine the readiness of schools and teachers to provide a learning environment where students can develop these abilities. In addition, this module will follow up the school survey module by having a school survey administered to principals and ICT-coordinators to measure trends of technology availability and use in schools.

All countries participating in the assessment module will study fourteen-year old students; the target population will be the grade with the most students of age fourteen. An optional population will be the grade with the most ten-year-old students. Each country will be expected to attain a sample of a minimum of 200 randomly selected schools per population. In at least 100 of these participating schools, one intact class will be sampled from all classes in the target grade. In addition to surveying the teacher of the sampled class, three additional teachers will be sampled and surveyed from those teaching the target grade.

Guiding the development of the student assessment is a framework that considers different types of knowledge management and types of tools. The categories of knowledge and tools are shown in Table 2 with the cells that illustrate sample performance tasks.

In the student assessment there will be a paper-and-pencil assessment administered to all students in the sample, and an optional Internet-based performance assessment given to four students in each class, provided that they are Internet-“literate.” Students in the sampled class will be administered a survey questionnaire and a short paper-and-pencil assessment during a single class period. The assessment will include a short Internet screening test.

Students will not be eligible for participation in the performance assessment unless they pass the screening test. If at least half of the students pass the Internet screening test, then the school will be eligible for participation in the performance assessment.

Despite highly diverse national educational systems around the world, almost every country has established policies regarding ICT in education. SITES in its first two modules found many different approaches across countries to the ICT challenge in education. Yet there are common threads such as widespread and rapidly growing access to the Internet. There is every reason to believe that this trend, as well as the large digital divide across countries, will continue in the early twenty-first century. It is anticipated that the assessment module with its focus on knowledge management will capture significant trends in information technology and the changing role of knowledge in society.

## IEA THIRD INTERNATIONAL MATHEMATICS AND SCIENCE STUDY

The Third International Mathematics and Science Study (TIMSS) is the largest and most ambitious educational assessment ever done under the auspices of the International Association for the Evaluation of Educational Achievement (IEA). The TIMSS data collection in 1995 involved testing more than a half-million students in more than forty educational systems (usually countries) around the world. Students were assessed at five different grade levels, and students, as well as their teachers and principals, were given questionnaires about their backgrounds, attitudes, and practices. The TIMSS data collection in 1999 focused on eighth-grade students in thirty-eight countries.

The TIMSS study resulted in many provocative findings, which are published in the TIMSS international reports. The results showed that the averages of students of participating Asian nations (Hong Kong, Japan, Korea, and Singapore) were higher

than those of students of other nations in mathematics at both the elementary and middle school levels. Japan and Korea also did very well in science at these levels, although Australia, Austria, and the United States also performed highly at the elementary level, and the Czech Republic performed well at the middle school level.

Testing was also done at the end of secondary school, where a sample of the total population of students was assessed in mathematical and scientific literacy. In addition, samples of students taking advanced mathematics or physics courses were tested on those subjects. The Asian countries were not among the twenty countries that participated in this assessment. The average scores of the Netherlands, Sweden, Iceland, Norway, and Switzerland were highest in mathematical and scientific literacy; the average achievement in advanced mathematics was highest in France and Russia; and the average physics test scores were highest in Norway, Sweden, and Russia.

The TIMSS results have been widely reported in the press and in numerous public reports. All TIMSS reports, including those cited above, are available on the Internet. TIMSS's website also contains technical reports that contain the details of the TIMSS methodology, and the raw TIMSS data are available at this site for those who would like to use the data to investigate different educational questions or research methodologies.

The study was administered by the International Study Center at Boston College and by the International Coordinating Centre at the University of British Columbia. TIMSS has been funded by the participating countries along with major contributions by the Government of Canada, the National Science Foundation (U.S.), and National Center for Education Statistics (U.S.).

### The Aim of TIMSS

The TIMSS was established to improve the teaching and learning of mathematics and science in school systems around the world through a comparison of the curricula and practices of different countries, and to relate this information to the performance of their students. The research questions included not only what students in the participating countries had learned, but also how the curricula varied in different countries and what facilities and opportunities were made available for students to learn what was in their curricula. The relationships of students' performance to their curricula, educational opportunities, and backgrounds were also to be investigated.

### IEA Studies of Mathematics and Science

The IEA has been involved in comparing the educational systems of various countries for many years. Four previous IEA studies of mathematics or science led up to TIMSS:

- First International Mathematics Study (FIMS), 1959–1960.
- First International Science Study (FISS), 1970.
- Second International Mathematics Study (SIMS), 1980–1982.
- Second International Science Study (SISS), 1982–1986.

TIMSS, which included both mathematics and science, was conducted in the Northern Hemisphere in 1995 and in the Southern Hemisphere in both 1994 and 1995. A second round of TIMSS, involving only eighth-grade students, was conducted in 1999. A third assessment is planned for 2003.

### TIMSS Design

The design of TIMSS grew out of discussions in the late 1980s by many researchers who were involved in SIMS, and these discussions led to the Study of Mathematics and Science Opportunity (SMSO), which explored the curricula and teaching practices of a few countries around the world and initiated the

development of the tests and questionnaires for TIMSS. The final design and its instrumentation were developed and approved by the participating countries in conjunction with mathematics and science education specialists and specialists in educational assessment.

### Populations and Sampling

TIMSS defined three populations of students for assessment:

- Population 1—all students enrolled in the two adjacent grades that contain the largest proportion of students nine years old at the time of testing. In most participating countries, grades three and four fit this definition.
- Population 2—all students enrolled in the two adjacent grades that contain the largest proportion of students thirteen years old at the time of testing. In most participating countries, grades seven and eight fit this definition.
- Population 3—all students in their final year of secondary education, including students in vocational education programs. In most countries, this was grade twelve. Population 3 included two subpopulations: students taking advanced courses in mathematics and students taking advanced courses in physics.

In Populations 1 and 2, an early decision was made to sample intact mathematics classrooms so that information about teachers and students could be matched and studied. The students who were not enrolled in any mathematics class were treated as a separate classroom, and thus they could be selected for the sample. In Population 3, students were not sampled by classroom, but were classified according to their mathematics and science courses, and then individually sampled for assessment. All participating countries were required to assess Population 2, but assessments of Populations 1 or 3 were optional.

### TIMSS Tests and Questionnaires

The TIMSS tests were constructed using mathematics and science frameworks that were agreed upon by the participating countries and subject-matter specialists. TIMSS included multiple-choice, short answer, extended response, and performance items. Countries were not required to administer the performance items.

In order to widen the curriculum coverage of TIMSS, a form of matrix sampling was used in which

students in a population received different test items, except for a few items that were common to all booklets. In Populations 1 and 2, there were eight different booklets of items administered along with student questionnaires. Teachers and school questionnaires were also administered. In Population 3, nine test booklets were administered, with the particular booklet to be used dependant on the courses in which a student was enrolled. The teacher questionnaires were omitted because intact classrooms were not sampled. The booklets in Populations 1 and 2 required about an hour of student time, whereas the booklets for Population 3 required about ninety minutes.

### Administration and Quality Monitoring

TIMSS was administered by personnel from the participating countries, and the TIMSS administrators were given extensive training to assure the high quality and comparability of the TIMSS data. International quality-control monitors were hired and trained to visit the national research centers and to review their procedures. The translations were also checked centrally to detect and avoid differences in the presentation of assessment questions.

### Analysis and Reporting

The basic TIMSS database was constructed in the participating countries and then given extensive statistical scrutiny at the IEA Data Processing Center in Germany. Any unusual occurrences in the database were noted and adjudicated with the participating countries. The data were then sent to Statistics Canada for a review of the sampling and construction of sampling weights. The data also went to the Australian Council for Educational Research for scale development. The scaling was done using a variation of the Rasch model. The scaled database then went to the International Study Center at Boston College for analysis and reporting.

TIMSS was a very complex study that required the cooperation of the many countries and contracting organizations involved. Cooperation was critical to assure that the tests were appropriate for all countries and that the administration of TIMSS was uniform. The coordination required many meetings in which strategy and tactics were discussed and decided. Many training sessions were required to assure that all phases of the TIMSS were carried out successfully. The flow of data from the participating countries to Germany, then Canada, Australia, and

finally to the United States required careful monitoring. Finally, the final reports were designed and approved by the participating countries before the data were available. The details of the procedures are given in the TIMSS technical reports.

## POLITICAL DEMOCRACY AND THE IEA STUDY OF CIVIC EDUCATION

In examining the contributions of education to political democracy researchers have considered shared decision-making, use of extracurricular activities to promote civic awareness, and policies designed to enhance educational equity. School curricula (especially in history, civics and government, and the social sciences/social studies) and the atmosphere of classroom discussion are also dimensions of education that contribute to students' acquisition of an understanding of and willingness to participate in political democracy. Citing empirical findings from a massive international study of civic education, evidence about these dimensions of education will be examined. The special focus is on how classroom practices contribute to what fourteen-year-old students know and believe about democratic processes and institutions.

## The 1999 IEA Civic Education Study

The International Association for the Evaluation of Educational Achievement (IEA), headquartered in Amsterdam, is a consortium of research institutes and agencies in more than fifty countries. Since the late 1950s IEA has carried out nearly twenty large, cross-national studies of educational achievement in various curriculum areas. The 1999 Civic Education Study, the first IEA study in this subject area since 1971, was ambitious both in concept and in scope. About 90,000 fourteen-year-old students from twenty-eight countries as well as approximately 10,000 teachers and thousands of school principals participated in the study.

The countries participating in the test and survey of fourteen-year-olds in 1999 included Australia, Belgium (French-speaking), Bulgaria, Chile, Colombia, Cyprus, the Czech Republic, Denmark, England, Estonia, Finland, Germany, Greece, Hong Kong (SAR), Hungary, Italy, Latvia, Lithuania, Norway, Poland, Portugal, Romania, the Russian Federation, the Slovak Republic, Slovenia, Sweden, Switzerland, and the United States. Fifteen of these countries and Israel surveyed an older population of students, primarily in 2000.

## Design of the IEA Civic Education Study

Through an international consensus process involving representatives from the participating countries and reflecting observations from structured national case studies conducted during the first phase of this study, three domains were identified as important topics in civic education across democracies: Democracy, Institutions, and Citizenship; National Identity and International Relations; and Social Cohesion and Diversity. Test and survey items were then written to assess students' knowledge and skills as well as attitudes in these three domains. Specifically, students were tested on their knowledge of democratic processes and institutions and their skills at interpreting political communication (e.g., interpreting the message of a political cartoon and an election leaflet). In addition, students were surveyed on their concepts of democracy and citizenship, their attitudes toward their countries and political institutions, the political rights of women and immigrants, and their expected civic participation. Background information was also collected from the students, including the activities in which they participated both in and out of school, the books avail-

able to them at home, and their perceptions of classroom climate.

The test and survey were administered to fourteen-year-olds by national research teams in accordance with IEA technical policies and guidelines. Teachers and school principals were also surveyed. The data provide a rich and complex picture of the civic development of young adolescents and the views of their teachers.

### The Importance of Classroom Climate

The extent to which students experience their classrooms as places to discuss issues and express their opinions as well as hear the opinions of their peers has been identified as a vital element of civic education. Because of its importance, a scale was developed to measure students' perceptions of the classroom climate for open discussion in the 1999 IEA Civic Education Study. Students were asked how frequently (never, rarely, sometimes, or often) they were encouraged to make up their own minds about issues, how often they felt free to disagree with their teachers about political and social issues during class, and the extent to which teachers respected student opinions and encouraged their expression during class. Students were also asked how often teachers presented several sides of an issue and whether the students felt free to express opinions even when the issues might be controversial.

The students' responses to these statements proved to be a significant predictor of both student knowledge and attitudes. For example, single level path analyses show that a democratic classroom climate where discussion takes place and teachers encourage multiple points of view was an important predictor of students' knowledge of democratic processes and institutions and skills in interpreting political communication. The only factors more closely related to knowledge were the home literacy resources available to the students and their plans for future education. Classroom climate was also positively associated with students' plans to vote as adults—an essential element of democracy. Furthermore, positive classroom climate was related to students' trust in government institutions, their confidence in school participation, and positive attitudes toward immigrants and women. In short, findings from students tested in 1999 in the IEA Civic Education Study show that when schools model democratic values by providing an open climate for discussing issues, they enhance their effec-

tiveness in promoting students' civic knowledge and engagement.

Although open classroom climate seems to enhance democratic learning and engagement, this classroom approach is not the norm in many countries. Across the twenty-eight countries in the IEA Study, about one-third of the students reported that they were often encouraged to voice their opinions in the classroom, but an almost equal proportion said that this rarely or never occurred (especially when the issues were potentially controversial). Teacher responses confirmed the students' perceptions. They reported that teacher-centered methods of instruction, such as the use of textbooks, recitation, and worksheets were dominant in civic-related classrooms in most of the countries, although there were also opportunities for classroom discussion of issues.

### Conclusion

Classrooms where students feel free to express their views on issues, and where multiple perspectives can be heard, seem to foster both knowledge about democratic principles and processes as well as positive attitudes toward civic engagement and the rights of others. Yet, these classroom practices are not the norm in some democratic countries. An emphasis on the transmission of factual knowledge through textbooks and worksheets seems to be dominant in many (though certainly not all) classrooms. Research closely tied to the design of professional development programs could help to illuminate the ways in which classrooms might better reflect democratic practices and thereby enhance civic learning and engagement.

## INTERNATIONAL ASSOCIATION FOR EDUCATIONAL ASSESSMENT

See: INTERNATIONAL ASSESSMENTS, *subentry*  
on INTERNATIONAL ASSOCIATION FOR  
EDUCATIONAL ASSESSMENT.

## INTERNATIONAL BACCALAUREATE DIPLOMA

The international baccalaureate (IB) diploma program is a curriculum whose time has come. Growing out of a perceived need in the 1960s, the IB diploma—as it is commonly known—has gone from strength to strength in creating a role for itself as a major player on the world education stage.

## The Establishment of the IB Diploma

The IB diploma was first developed in international schools and, in particular, the International School of Geneva. Reportedly the oldest international school in existence, this bilingual (French/English) school was founded in 1924 primarily as a means of providing education for the offspring of employees of the League of Nations. As the number of international schools grew over the following thirty-year period, in response to increasing ease of international travel and global mobility of professional parents, this school remained at the forefront of educational development. In 1951 it took the lead in founding the International Schools Association (ISA), which was set up "to help the growing number of international schools all over the world with their common problems" (Peterson, p. 15). As Peterson describes, one of the most pressing of these problems was that of providing adequate university preparation for their older students, destined as they were to seek university places in many different countries of the world. In 1962 a group of teachers from the International School of Geneva, with a small amount of funding from the United Nations Educational, Scientific, and Cultural Organization (UNESCO), organized a conference of social studies teachers from international schools to investigate the possibility of developing an international social studies program. With sponsorship from the Twentieth-Century Fund and the Ford Foundation, and central involvement of Atlantic College in Wales, the United Nations International School in New York, and Oxford University's department of educational studies in England, the program was launched. Developments led to the setting of a first full examination paper in 1971 and generation of a program that would, on the one hand, provide "an education that would facilitate the admission of students into the universities of their choice in different countries, without having to engage in the lengthy and uncertain process of obtaining equivalence agreements"; and, on the other, have as a major purpose "promoting international understanding and world peace" (Fox, p. 65).

## The Early Twenty-First Century

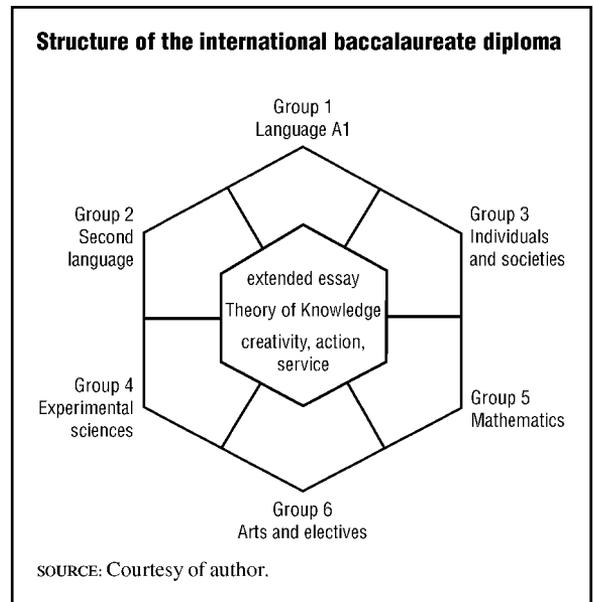

The IB diploma of the early twenty-first century is based on essentially the same structure as was developed originally, which is represented by Figure 1. Students are required to engage in study of six subjects, with at least one selected from each of groups one to five, and a sixth choice, which may be from

any of the six groups. Either three or four subjects must be studied at higher level and the others at standard level, while students must also complete a course in the theory of knowledge, write an extended essay of some four thousand words, and engage in the creativity, action, service (CAS) program. The IB diploma program can be shown to have four main characteristics, as follows:

- **Breadth:** By requiring the study of a range of disciplines to pre-university level, the diploma avoids the narrowness of programs such as the English “Advanced” (“A”) Level, where students commonly study no more than three or four subjects at the ages of 16 to 18, often in very restricted areas of the curriculum.
- **Depth:** The availability of two levels of study, taken alongside the possibility of studying a second subject from groups one to five and of writing an extended essay in a chosen area of interest, “allows for a specialist element within the context of overall breadth” (Hayden and Wong, p. 351).
- **Coherence:** Two elements at the center of the hexagon model serve to support the notion of the IB diploma as a coherent program, as opposed to simply a collection of subjects. The theory of knowledge program “has often been seen as the ‘cement’ or ‘glue’ that binds together the different curricular areas of the IB Diploma hexagon” and has “been viewed as the sort of meta-learning that can give meaning to knowledge acquired in the subjects which students must study” (Mackenzie, p. 46), while the CAS program promotes the affective as well as cognitive dimensions of the student experience.
- **Internationalism:** The mission statement of the International Baccalaureate Organization (IBO) includes reference to strong emphasis being placed upon “the ideals of international understanding and responsible citizenship” (IBO web site), and subject programs are designed to encourage students to consider issues from a number of perspectives as they become “global citizens” (Hill dissertation).

Schools may opt to offer the program in one or more of three working languages (English, French, and Spanish) in which all curriculum materials are produced and examinations are set. All subjects are graded on a scale from one (low) to seven (high), with a further total of three points potentially avail-

**FIGURE 1**

able for the theory of knowledge and extended essay, leading to a maximum possible score of forty-five points. A minimum score of twenty-four points with achievement of a number of other conditions (including satisfactory completion of the nonassessed CAS program) leads to the award of the diploma. As an alternative to the diploma, students may elect to register for one or more individual certificates, which are also awarded if conditions for the award of the diploma are not met.

The IBO head office is in Geneva, the Curriculum and Assessment Centre is in Cardiff Wales, and its Research Unit is based at the University of Bath in England. It also has regional offices in New York, Geneva, Buenos Aires, and Singapore. The curriculum is developed by examiners and teachers worldwide, and some 3,400 examiners and assessors for the program are similarly located in many different countries. The number of schools offering the IB diploma program has grown steadily: as of May 2001 some 960 schools in more than one hundred countries were authorized to offer the diploma program, through which some 40,000 students were assessed in 2001.

According to former students, the advantages of studying the IB diploma program include “its breadth-depth balance, its academic rigour and its suitability as a preparation for university-level study . . . (and its) contribution to world peace and understanding” (Hayden and Wong, p. 352). The IB

diploma is accepted by universities worldwide, including those in Europe, North America (where advanced placement may be offered for diploma holders), and all other continents.

### Issues for the Future

In a relatively short period of time, the IB diploma program has come to satisfy varying needs of different constituencies. Clearly it continues to provide an appropriate curriculum for those international schools worldwide that seek to promote an “international education” that is not associated with a particular national system. Additionally, in more recent years the program has been adopted by a number of schools in national education systems, which are attracted to it for a variety of reasons. Some of those in England and Wales, for instance, undoubtedly favor its breadth compared with the narrowness of the national (“A” level) system. The many American high schools that offer the program are attracted to the combination of an international perspective with the rigor and high academic standards that the IB diploma represents. In some cases it serves as a basis on which to promote programs for particularly able students and in others as a means of assisting state or public schools in their efforts to help students to meet state or provincial standards. Schools in still other systems are undoubtedly influenced by what might be termed *credentialism* where local elites respond to a “stiffening of the local positional competition on the one hand and a globalization of that competition on the other. As more people gain local educational qualifications, those who can afford to do so seek a new competitive edge by taking qualifications that they hope will give them a local advantage” (Lowe, pp. 24–25). A major challenge, then, to the IB diploma in the twenty-first century is the continued development of its attraction to national as well as international schools as it moves from being “a programme for international schools” to being “an international programme for schools” (Hagoort, p. 11).

A further and related challenge is that of determining the appropriate linguistic base for a program that is now so widely used internationally. Forty-five different languages are available as languages A1 (the student’s “best language”), each including a study of world literature, and in principle an A1 examination can be set in any language with a sufficient body of written literature. The Eurocentric nature of the IBO’s English, French, and Spanish working lan-

guages, however, is an issue currently being addressed in terms of how many—and which—working languages a program should offer before it can claim to be truly “international.” Although new subjects have been added to the program since its inception, an interesting development is the current trialing of a small number of transdisciplinary subjects, which cross existing subject boundaries. A further important development in recent years has been the extension of the IB organization’s provision to younger students by the development of the IB middle-years program (designed for ages eleven to sixteen, added in 1994 with 184 schools authorized to offer the program in May 2001) and the IB primary-years program (designed for ages three to twelve, added in 1997 and offered by fifty-nine authorized schools in May 2001). As a program now catering, therefore, to the entire pre-university age range, which is increasingly being offered within national systems as well as by international schools, the international baccalaureate seems likely to have interesting and challenging times ahead.

## BILATERAL AGENCIES

An official bilateral development or aid agency is responsible to a single government. It is usually a ministry or part of a government ministry dedicated to advancing foreign policy goals while contributing to the economic and social development of recipient countries. This discussion will review the history, legacy, importance, and current role of some of the more important bilateral agencies with regard to education.

### U.S. Agency for International Development (USAID)

As an agency within the U.S. State Department, the United States Agency for International Development's mandate includes assisting countries with disaster recovery, poverty reduction, and the expansion of democratic reforms. USAID education and training support activities fall within this mandate and cover six major areas: basic education, learning technologies, higher education, workforce development, participant training, and telecommunications reform and applications.

USAID's current efforts in basic education include activities such as the Demographic and Health Surveys Education Data for Decision-Making (DHS EdData), which builds on population-based demographic surveys and provides data for planning and evaluation of education policies worldwide; the Global Education Database (GED), a computer-based database of international statistics; and Basic Education and Policy Support (BEPS). Learning technologies consist of activities such as Global Information Network in Education (GINIE). Higher education includes activities such as the Higher Education Partnerships and Development and Advanced Training for Leadership and Skills (ATLAS). Workforce development entails activities such as Global Workforce in Transition. Participant training includes activities such as Global Training for Development and the Training Resources and Information Network (TraiNet). Telecommunications reform and applications entail activities such as the Telecommunications Leadership Program.

USAID was created by executive order in 1961 when U.S. President John F. Kennedy signed the Foreign Assistance Act. It was the first U.S. foreign assistance organization whose primary emphasis was on long-range economic and social development assistance efforts. The agency faced early criticisms fueled by opposition to the Vietnam War, concern that aid was too focused on short-term military considerations, and concern that aid, particularly development aid, was a giveaway program producing few foreign policy results for the United States. Thus in 1972 and 1973 the Senate rejected the foreign-assistance bill authorizing funds. In 1973 the House Committee on Foreign Affairs restructured aid to focus on “functional categories,” including “education and human resources development.” Since then, USAID has faced concerns about its administration and structure, and there have been multiple efforts to officially restructure the administration and control of the agency. In 1998 the Foreign Affairs Reform and Restructuring Act placed the agency under the direct authority and foreign policy guidance of the secretary of state. In 2001 the George W. Bush administration reorganized USAID into three spheres of influence: global health, economic growth and agriculture, and conflict prevention and developmental relief. The second sphere captures most education funding.

USAID has continually tried to define its education policy. Policy papers from the mid-1980s established the priorities for USAID funding of “basic education and technical training.” First, a 1982 statement proclaimed that “assisting countries to establish more efficient systems of education” was an essential component of an “effective development strategy.” These efforts would include raising the levels of basic education and relating technical-training systems more effectively to productive employment. A 1984 paper stated the policy of improving primary education enrollment, program efficiency, and diversification of training. In the 1990s a USAID–higher education community consultation was designed (1) to enhance the U.S. foreign assistance program by incorporating the experience and knowledge of higher education institutions to develop better USAID policies, country and sector strategies, and activity designs and implementation; (2) to collaborate constructively in the delivery of development and humanitarian assistance when interests are compatible; and (3) to increase the transparency of USAID’s decision and

polycymaking processes relevant to higher education institutions. In 1997 the agency released a strategic plan listing seven goals to support USAID’s mission, the third of which was “to build human capacity through education and training.” Still, the \$7.7 billion total 2002 fiscal-year budget request allocated a mere 3 percent to education and training.

### **Canadian International Development Agency (CIDA)**

The Canadian International Development Agency assists in issues from health, education, and agriculture to peace building, governance, human rights, land mines, and information technology. CIDA works with a variety of partners, both inside and outside of Canada, and it supports projects in more than 150 countries. Partners include nongovernmental organizations (NGOs), the private sector, and academic institutions—in Canada and in recipient countries—as well as a number of international organizations and institutions. Some projects are run bilaterally, while others are carried out through multilateral organizations. According to CIDA, its primary objective regarding development assistance is “to support sustainable development in developing countries in order to reduce poverty and contribute to a more secure, equitable, and prosperous world.” In funding education projects, CIDA has chosen to define education as “the acquisition of knowledge, skills, and training through formal, non-formal, and informal systems and activities” (Isaac, p. 2).

CIDA has its official origins as Canada’s External Aid Office, created in 1960 to reduce poverty and promote growth. The office’s primary functions were to administer assistance programs funded by the Department of External Affairs, coordinate operations with other agencies, consult with international agencies and Canadian NGOs, and coordinate Canadian efforts to obtain aid for countries affected by disasters. Edward T. Jackson et al., in a 1996 report, note that most bilateral organizations, such as CIDA, spent the 1950s and 1960s focusing on initiatives to increase national production through industrial growth and paid little attention to income distribution within countries. However, as the spirit of such organizations started to change in the late 1960s, Canada complied with international guidelines and replaced “Office” with “Agency” and “Aid” with “International Development,” becoming the Canadian International Development Agency in

1968. Education became more of a focus in the 1970s, as growth was promoted through equity by targeting interventions at the poor and meeting “basic human needs.” The 1980s were characterized by structural adjustment policies, forcing developing nations to reduce deficits, privatize and deregulate industry, and promote exports. With the 1990s came an emphasis on “accountability and value-for-money spending.” In 1990 Canada co-chaired the United Nations World Summit for Children, and it set a ten-year agenda for improving the well-being of children. Goals included attaining a basic education for all children and achieving at least an 80 percent completion rate of primary education for all boys and girls. However, rising public debt and nationwide unemployment forced Canada to cut social programs in the 1990s and also led the country to emphasize development programs that best served Canadian trade and competitiveness objectives. During this time CIDA faced some criticism for having “no comprehensive, official policy on basic human needs,” having out-of-date “sub-priority” policies on areas such as education, having an “underdeveloped” management information system, a tendency to “underestimate, undervalue, or ignore altogether the record of engagement in basic human-need by the nongovernmental sector,” and a need to boost accountability assessments (Jackson et al., section 5.25).

In 2001 CIDA released *Social Development Priorities: A Framework for Action*, in which budgetary allocations for social development programs, including education, increased from 19 percent to 38 percent. The plan called for quadrupling funding for basic education to \$164 million annually. The additional financial commitment provides support for activities that promote the development and reform of the basic education sector in selected countries, strengthen the integration of locally driven education efforts, and improve the quality of basic education. The two stated goals were to increase gender equality and to achieve universal primary education by 2015. The plan called for improving programming, investing in girls’ education, strengthening action against HIV/AIDS, integrating efforts of local communities and NGOs, and strengthening global political commitment.

### **Swedish International Development Cooperation Agency (SIDA)**

The Swedish International Development Cooperation Agency handles Sweden’s bilateral international

development cooperation and much of its relationship with central and eastern Europe. SIDA attempts to raise the standard of living among poorer populations throughout the world while also addressing geographical concerns, such as security and the environment, through cooperation with countries in central and eastern Europe. Although SIDA contributes financial resources and skill development, it holds partner countries responsible for their own general development and improvement.

SIDA supports development through nine operational areas, including social development that encompasses education. According to the 1997 annual report, SIDA gives priority to programs that have a direct effect on classrooms, particularly textbooks and teacher training. While SIDA’s main task is to promote the development of international partners, it also promotes Swedish interests in a variety of ways. First, solving global problems holds direct appeal for both Sweden and its partners. In education, this has included funding primary education in rural areas and building education centers in villages. Second, development cooperation (such as research, business, and volunteerism) helps strengthen relations of value to Swedish society. SIDA has supported the privatization of textbook production in Tanzania and worked with many Swedish university departments to enable Swedish students to perform minor field studies during their senior years. Finally, by contracting with domestic companies and using Swedish goods, SIDA contributes to both the short- and long-term growth of the country. About 300 Swedish NGOs receive support, and 60 percent of SIDA’s budget goes ultimately to Swedish companies and foundations in the form of consultancy assignments, higher levels of employment, construction contracts, and sales orders. One-third of SIDA’s cooperation is channeled through various multilateral organizations (such as the United Nations agencies and the World Bank).

For many years Swedish aid focused on nations that had advanced the most toward a planned economy. In the first part of the 1990s, total Swedish aid declined, thus affecting development program aid. In 1999 Howard White’s *Dollars, Dialogue, and Development: An Evaluation of Swedish Programme Aid* noted SIDA had an excessive bureaucratic burden, which acted as a constraint to SIDA’s operations. Also, SIDA supported anti-inflationary policies, which some felt might be “detrimental for long-run growth by undermining investment in human capi-

tal” programs, such as education and training. Questions also arose about how well Swedish program aid (which comprised about 12% of total aid in the 1990s) supported policy change in recipient countries.

At the turn of the century, SIDA began to reduce the number of projects by 25 percent in order to maintain quality and efficiency. SIDA also determined that certain countries had developed sufficiently to warrant replacing development grant aid with other types of cooperation. Indeed, the 1997 annual report mentioned phasing out “one-sided giving” in favor of development that “creates mutual benefits and from which all parties gain.” According to SIDA, at the center of all development cooperation is developing knowledge and skills, but major efforts in education will not succeed unless other important functions in society, such as public administration, trade, and industry work properly.

### **The Department for International Development (DFID)**

The Department for International Development is the British government entity responsible for promoting development and reducing poverty. DFID has six divisions (Africa, Asia, eastern Europe, western hemisphere, International, and Resources) and seven advisory groups or departments, of which education is one. The majority of DFID’s assistance goes to the poorest countries in Asia and sub-Saharan Africa.

The current department was created in 1997, with policy outlined in the *White Paper on International Development*. DFID replaced Britain’s Ministry of Overseas Development, which was created in 1964. The transformation was in response to increasing globalization of the world economy and a “review of aspirations.” According to the *White Paper*, the 1970s and 1980s had produced inadequate economic policies that benefited only a small portion of the population, and those years produced external factors, such as high oil prices, which particularly affected developing countries.

Thus the new DFID established the goals of contributing to the elimination of poverty in poorer countries through bilateral and multilateral development programs, as well as intergovernmental cooperation. One of the three initial objectives was to improve education, health, and opportunities for poor people. In particular this meant promoting ef-

fective universal primary education, literacy, access to information, and life skills. It created targets based on the United Nations conventions and resolutions, which aimed for universal primary education in all countries by 2015 and the elimination of gender disparity in primary and secondary education by 2005. DFID’s stated priority was “to achieve the full participation of all children and adults in quality education at all levels.”

DFID focuses its education support on access, quality, retention, and equity. Initial strategies included strengthening and extending partnerships by involving local communities in managing schools, reconstructing school systems in poor countries, and promoting research to improve understanding of how education can contribute to the elimination of poverty. Early spending reviews suggested DFID needed to become more selective and focused on poverty reduction in its assistance.

### **French Agency for Development (AFD)**

The French Agency for Development is a public, industrial, and commercial institution and a component of France’s official development assistance. The AFD financially supports public and private job-creating projects in developing countries. Some projects are financed completely by the AFD, while others are cofinanced with partner-funding agencies. In addition, the AFD deploys and administers structural adjustment aid allocated by the French government.

The AFD functions as a group of domestic and foreign entities, including two domestic subsidiaries and fourteen banking, financial, and real estate subsidiaries operating in the overseas departments and territories. Although the AFD itself manages state treasury loans, grants, and other government funding, it has two domestic subsidiaries: the Society of Promotion and Participation for Economic Cooperation (Proparco) and the Center for Finance, Business, and Banking Studies (CEFEB).

Proparco was established in 1977 as a limited company owned by the AFD, and originally it was concerned mainly with risk capital. The AFD converted Proparco to a financial company in 1990, and it currently works entirely with private-sector funding.

CEFEB focuses purely on education and training. Founded in 1963, it is based in Marseilles, France. CEFEB provides continuing education and

training for personnel from France and developing countries with current or future careers in senior posts in economic or financial public services, financial development institutions, and public or private enterprises. CEFEB's principal activities are: (1) an annual diploma course for approximately seventy trainees; (2) specialized short-duration seminars in France; and (3) training missions abroad. In addition, in cooperation with the University of Aix-Marseilles or Hautes Etudes Commerciales (HEC), CEFEB runs two master's-level courses for senior executives—one for human resources managers and the other for managers of operational or functional units. Finally, CEFEB is also involved in running in-service training for AFD staff and courses for the Ministry of Foreign Affairs.

The AFD operates in more than eighty countries and has a network of forty-three local offices and agencies around the world. In 1941 General Charles de Gaulle created the Caisse Centrale de la France Libre in London. In 1992 the Caisse Française de Développement was established by decree to succeed the Caisse Centrale de la France Libre, and six years later the name was changed to the Agence Française de Développement, or the French Development Agency. Under a French law established in the 1980s, the AFD is classed as a "specialized financial institution," which is a credit institution with a permanent public-service mission. The AFD's commitments, the terms of those commitments, and the company accounts are submitted for approval to its supervisory board. As a public institution the AFD is subject to control by the French Court of Auditors and, as a specialized financial institution, by the French Banking Commission.

The AFD plays a role in both bilateral and multilateral programs. Bilateral aid is directed mainly toward countries with strong historical and political ties. Countries in Africa and French-speaking countries worldwide have traditionally been given special attention by the AFD and its predecessors. About 75 percent of AFD aid is handled on a bilateral basis. The other 25 percent is handled at a multilateral level, within international and European organizations. As a whole, the AFD has designed its development cooperation to be compatible with other members of the Organisation for Economic Cooperation and Development (OECD) and to have a European context through investments in central and eastern Europe.

The AFD's program activity can be divided into fourteen sectors, of which the educational infrastructure is one. After becoming the AFD in 1998, almost 60 percent of project aid went to sub-Saharan Africa. However, the government directed the agency to expand, and more aid started to move into the Mediterranean region and Lebanon. Still, only about 1 percent of all project aid went to education-specific projects. Conversely, about 50 percent of all project aid at the beginning of the new millennium went to support rural development and urban infrastructure.

### **Japan International Cooperation Agency (JICA)**

The Japan International Cooperation Agency was created in 1974 to handle Japan's bilateral Official Development Assistance (ODA). As Japan's governmental aid agency, JICA has a stated goal of "helping people to help themselves." Japan handles official development assistance through a program devised in 1954 as a part of the Colombo Plan to assist Asian countries. That program has three components: (1) bilateral grants; (2) bilateral loans; and (3) multilateral assistance. JICA is responsible for most of the first component, bilateral grants, which are composed of grant aid and "technical cooperation." The agency also conducts surveys and helps execute a capital-grant assistance program on the part of Japan's Ministry of Foreign Affairs. In addition, JICA has helped create a long-term training program to allow foreign students to obtain academic degrees in Japan as well as a grant-aid program to support foreign students.

One of JICA's education contributions is through this capital-grant assistance program. These projects may hold public value but are not highly profitable, as grant aid involves financial assistance without obligation of repayment and is focused upon basic human needs. There are three types of grant aid: general, aid for fisheries, and aid for increased food production. Education projects are funded through general grant aid, and projects include construction of education-related facilities such as school buildings, expansion of broadcast education services, and training and retraining of educators. Aid is also provided for specific local needs.

In addition, JICA provides for training through technical cooperation activities. In essence, technical cooperation refers to the fostering of human and socioeconomic development through the exchange of technology and knowledge. JICA engages in techni-

cal cooperation with developing countries in six basic ways: (1) by providing training in Japan; (2) dispatching Japanese experts to provide training abroad; (3) supplying equipment; (4) providing technical assistance in the development of projects; (5) conducting economic development studies; and (6) dispatching Japanese volunteers to work in developing countries. Training, expert dispatch projects, and volunteer dispatch each have educational elements. Training courses include both group and individual courses, and many group courses have been implemented in the field of education (such as "The Practice of Science Education"). The volunteer dispatch program sends Japan Overseas Cooperation Volunteers (JOCV) to primary and secondary educational institutions. The expert dispatch sends experts to education-related agencies and vocational-training programs in Japan and overseas. Finally, project cooperation is directed at universities through such programs as agriculture, engineering, and medicine.

The Japanese government's interest in assisting developing countries grew after receiving aid from the World Bank in the 1950s for its own reconstruction. In 1954 Japan established Official Development Assistance (ODA), and according to JICA, Japan's development assistance has expanded annually since that time. Initially, Japan focused on funding Asian countries, but toward the end of the twentieth century began expanding aid to eastern and central Europe. By 1992 it was the major donor in twenty-five countries. With the creation of JICA in 1974, Japan's ODA started taking a more country- and issue-specific approach. As the cold war came to a close, certain development issues, such as education, the environment, and population began to receive more global attention, and this was reflected in JICA projects. Beginning with the 1990 World Conference on Education for All in Jomtien, Thailand, Japan adopted the international goals of extending primary education and eliminating gender inequality in education. Consequently, a much larger portion of JICA's contributions have gone to primary schools whereas until 1990 higher education had received greater emphasis.

### **Norwegian Agency for Development Cooperation (NORAD)**

The Norwegian Agency for Development Cooperation aims to assist developing countries in improving political, economic, and social conditions.

Headquartered in Oslo, Norway, NORAD is a Norwegian directorate under Norway's Ministry of Foreign Affairs. NORAD is responsible for bilateral and long-term aid, while the Ministry of Foreign Affairs handles the administration of multilateral projects. The education sector became a higher priority in the late 1980s and 1990s, with funding nearly tripling during that time. Asia receives the most Norwegian educational support.

NORAD focuses on six major areas of development: social development; economic development; peace, democracy, and human rights; environment and natural resource management; humanitarian assistance in the event of conflict or natural disasters; and gender equality. NORAD gives priority to education funding, and most of these six major areas have educational objectives. For example, by providing assistance for multilingual education and cultural diversity, NORAD attempts to support human rights and democracy.

In addition, NORAD invests in knowledge and human resource development in order to assist in the health and education sectors. A variety of programs support the development of knowledge management, research-based planning, support for international involvement in centers of knowledge, institutional development at universities and colleges in partner countries, the development of financial plans for research and higher education, and cooperation in research and education.

Although Norway has been involved in international development activities since the late 1940s, NORAD was created in 1968. Norway's first bilateral education project began in 1952, as a component of the India Fund's "Kerala Project." The project was designed to promote economic and social development of the people of India and had a number of programs, including "fishery colleges." In the 1960s programs extended to other countries in Asia and Africa, and in 1968 NORAD took over aid activities and obtained a broader range of objectives. In essence, NORAD became the sole agency responsible for coordinating and preparing Norway's official development aid. Before 1990 most of NORAD's education aid went to tertiary education. In 1991 a Norwegian white paper endorsed the goals of "education for all," established at the 1990 Jomtien World Declaration of Education for All conference. Since that time, NORAD's orientation to development has evolved from a project approach to more sectorwide programs, such as the Basic Primary Ed-

ucation Project in Nepal, and the Basic Education Sub-Sector Investment Program in Zambia.

Norway conducts annual evaluations, available to the public, of its foreign aid program. Suggestions for NORAD's education programs have included improving donor coordination and ensuring that recipient countries play a stronger role in coordinating aid, improving information management, conducting specific evaluations of education programs, and funding educational research in beneficiary countries.

### **Netherlands Organization for International Cooperation in Higher Education (Nuffic)**

The Netherlands Organization for International Cooperation in Higher Education was created in the 1950s to promote an accurate image of Dutch higher education around the world. Its mission states four major areas of interest: development cooperation, internationalization of higher education, credential evaluation, and positioning Dutch higher education worldwide. Within these four areas, human resource and institutional development receives the most funding, followed by international academic relations, communication, and finally, international credential evaluation.

Higher education in the Netherlands has three branches: (1) the universities of professional education; (2) the remaining universities; and (3) international education institutes. Nuffic's board consists of members appointed by organizations representing each of these branches. Nuffic also has three secretariats: the National Commission for UNESCO, the Netherlands Development Assistance Research Council, and the Steering Committee of the Netherlands Israel Development Research Program. In addition to these three autonomous secretariats, Nuffic began conducting language courses for both foreigners and Dutch people in 1966. Participants in this program include students, foreign employees and their partners, embassy staff, au pairs, and classroom groups.

One of Nuffic's initial programs in the 1950s was international credential evaluation. Essentially, Nuffic offers advice regarding the relative value of foreign higher education diplomas in the Netherlands and vice versa. Nuffic publishes a manual, *Evaluation of Foreign Credentials in the Netherlands*, to help clients in this regard. An Internet resource describing procedures of higher education qualifica-

tions earned within the European Union (EU) and the European Economic Area Countries (EEA) is also maintained. As internationalization grew throughout the world in the mid-1980s, Nuffic assumed a role of encouraging cooperation between Dutch institutions and other industrialized countries. The goal was to improve Dutch higher education and broaden its dimensions. The primary method of promoting internationalization was the exchange of Dutch students and staff, and these efforts were supported by grants and scholarships.

Nuffic's primary source of difficulty has been the confrontation between different academic and cultural traditions, which has resulted in delays and irritation among participants. Nuffic has published various books in an effort to help program participants deal with issues arising from these differences.

Development cooperation represents one of Nuffic's main activities. At the end of the 1990s Nuffic reduced its concentration to a smaller number of countries to install a sectorwide approach, which emphasizes human resource development. This change represents a philosophical shift within the agency in which education is regarded as integral to all areas of development, and thus development cooperation receives the greatest amount of Nuffic's expenditures. Nuffic administers and finances education programs, initiates communication, and helps develop policy in beneficiary countries. Programs are categorized as human resource development, such as fellowships and scholarships, or institutional development, such as the Joint Financing Program for Cooperation in Higher Education (MHO) and Cooperation between the Netherlands and South Africa (CENESA).

In 1999 Nuffic adopted a more succinctly worded mission regarding knowledge export, by stating the goal "to position Dutch higher education on emerging markets." That same year, Nuffic set up the Project Office for Positioning Higher Education, to coordinate and support efforts of Dutch higher education institutions with the goal of recruiting institutional partners and foreign students. Three nations were targeted: Taiwan, China, and Indonesia. In 1998 Nuffic established the Network for the Export of Higher Education, in which nearly forty higher education institutions join to exchange information and coordinate activities.

### **The German Organization for Technical Cooperation (Deutsche Gesellschaft für Technische Zusammenarbeit) (GTZ)**

The German Organization for Technical Cooperation is owned by the Federal Republic of Germany, and it operates as a service enterprise for international development cooperation. Established in 1975 as a private-sector enterprise with a development-policy mandate, the GTZ supports international development, reform, and technical cooperation on behalf of the Federal German Ministry for Economic Cooperation (BMZ) and other German ministries, partner-country governments, and international organizations. Education represents one of the GTZ's sector-related themes, and it has four major components: educational aids, basic education, vocational training, and universities/scientific and technical institutions.

The first educational area, education aids, operates by the name of the Crystal project. Crystal provides teachers' aids such as textbooks and materials, specialist literature, and consulting. Consulting services are provided for vocational training, work-oriented training, and development cooperation (such as the application of new media and education aids). Services and materials are free to developing countries, and many of them are described in a Crystal catalog.

In the second area of basic education, the GTZ serves in an advisory role. The GTZ advises developing government partners on ways to improve their basic education systems. The suggestions focus upon quality, efficiency, and relevance through the design of programming methods and system structures. The GTZ's educational philosophy supports a decentralized approach utilizing parents and communities. Three major basic education activities include: (1) developing and introducing appropriate curricular elements and relevant learning and teaching materials; (2) institution building; and (3) systems consulting.

Vocational training encompasses the GTZ's third education area. These services are aimed at policymakers, industry, research and planning institutions, state and private training institutions, and in-company training facilities. The GTZ serves a consulting and planning role for the general vocational field as well as individual institutes of further and advanced training and vocational agencies. Specific services include concept design, planning, and

evaluation, along with the establishment and commissioning of agencies and staff.

Finally, the GTZ provides consulting for universities and scientific and technical institutions. The goals of this higher education theme are to improve the performance capacity of education and research systems, to boost training performance and research capacity, and to encourage an exchange of ideas and experience at the academic level through international linkages. The GTZ provides services such as developing education and research systems, developing institutions, consulting on program conduct and efficiency, and the promotion of cooperation in training and research.

When the GTZ was developed, most services were conducted out of the head office. Though the head office is still the major interface between the government and project implementation abroad, in an effort to cut costs, the organization began to emphasize decentralization and regionalization in the late 1980s and early 1990s. This shifted responsibility to the field offices in more than sixty partner countries. The GTZ has also focused most heavily on advisory services. The late 1980s figured prominently in the GTZ's development because of German reunification. This required Eastern bloc nations, including the former East Germany, to make the transition to a market economy. Since the changes in Germany both drove and were affected by globalization, the GTZ decided to expand its cooperation with other organizations. In addition, the GTZ took on a larger role in the promotion of democracy worldwide.

### **Summary**

Overall, bilateral agencies have been expanding their education and training goals since the early 1990s. The opening of eastern Europe, the fall of state socialism, and the 1990 Jomtien World Conference on Education for All were among the main factors shaping education policy regarding the geography and the goals of bilateral aid. Still, in the late 1990s, actual overall aid budgets had begun to decline, especially across the member countries of the OECD. Indeed, though policies have had lofty objectives, the reality often has not been as positive. According to Therien and Lloyd, bilateral aid agencies have faced issues such as dwindling resources, the loss of donors and a rationale for aid because of the end of the cold war and the dismantling of the Soviet Union, greater support of domestic aid instead of foreign development assistance, and an overall decrease in

public support. As interests of donors have taken precedence over the interests of recipients, development aid has suffered. Other issues facing bilateral agencies include problems working through recipient governments, the inconsistency between economic and social development objectives (which span countries), and inconsistent foreign policy goals (with regard to specific countries). Some examples of these issues include French aid to francophone Africa, U.S. aid to Egypt and Israel, and Nordic aid to its program countries. Furthermore, globalization and development assistance received much scrutiny at the beginning of the new millennium, as groups questioned whether or not programs were actually reducing poverty.

ANDREW J. FINCH

#### REGIONAL INSTITUTIONS

Official regional development agencies are those whose mandate confines them to serve regional ob-

jectives. Some are part of regional governments, such as the European Union (EU), while others are managed by groups of individual national governments with common interests, like the Organisation for Economic Co-operation and Development (OECD). This entry will review the history, legacy, importance, and role of some of the more important regional institutions with regard to education.

### **Organisation for Economic Co-operation and Development (OECD)**

**Purpose.** Originally founded as the Organisation for European Economic Co-operation (OEEC), OECD was formed to administer American and Canadian aid for the reconstruction of Europe under the Marshall Plan after World War II. In 1961 the organization was renamed the Organisation for Economic Co-operation and Development to promote economic growth and global trade. Since then, its mandate has been to build strong economies in member countries, improve efficiency, hone market systems, expand free trade, and contribute to development in industrialized and developing countries. It also groups the thirty member countries in an organization that provides a setting in which governments develop economic and social policy. Increasingly nongovernmental organizations and civil society are included in policy and thematic discussions. OECD is well known for its publications and statistics, which cover economic and social issues including education, the environment, social policy, and science and technology.

**Structure.** OECD's internal governance consists of each member country having a permanent representative, usually of ambassadorial rank, who sits on the council, the governance body. The council, meeting in sessions of ministers or permanent representatives, makes all major decisions on budgetary issues and the work programs of each committee.

**Projects and activities.** OECD does not generate operational development projects, but rather focuses on information-generating projects, such as collecting statistical indicators across OECD countries and writing publications. For example, OECD's Directorate of Education, Employment, Labor, and Social Affairs (DEELSA) undertakes work in the following five areas: (1) education and skills; (2) employment; (3) health; (4) international migration; and (5) social issues.

DEELSA undertakes research and policy work in education as well as other areas. The emphasis with-

in education is on lifelong learning, from early childhood to adulthood, which is considered important for social integration and a tool in the battle against social exclusion, from both society and the labor market. However, the work of DEELSA spans the range from early childhood development to higher education, including adult learning and literacy, education indicators, education policies, finance of lifelong learning, higher education management, human and social capital, information and communication technology (ICT) and the quality of learning, inclusion and equity, knowledge and learning, a program for international student assessment, schooling for tomorrow, and the transition from initial education to working life. The directorate produces host meetings and conferences to discuss these issues and provides online documents, newsletters, and publications pertaining to each area. In addition, the directorate works in close cooperation with the thirty member countries and draws on the expertise of the secretariat and external consultants, who provide advice and guidance through their national delegations and ministerial meetings. The resulting work is intended to meet the needs of member countries and their citizens.

Within DEELSA is the Centre for Educational Research and Innovation (CERI), which carries out studies and promotes an international dialogue about education across OECD countries. It is a source of information and publications on the topic of education. It strives to establish links between research, policy innovation, and practice, to enhance knowledge about educational trends internationally, and to actively engage educational researchers, practitioners, and government officials in cross-national discussions.

**Statistical improvements.** One of the first efforts to improve education statistics was the creation, in 1990, of the Indicators of National Education Systems (INES) with support in part from the U.S. Department of Education. OECD embraces the importance of statistics as a means of achieving

informed policymaking. The INES program responds to the need to standardize the collection of statistics on a given aspect of education. For example, in the area of students with disabilities or learning or behavior problems, each member country uses a different definition for a particular term. The INES program works to establish

uniformity in the definition and collection of indicators.

More recently, the World Education Indicator (WEI) project, a joint endeavor of OECD and the United Nations Educational, Scientific and Cultural Organization (UNESCO), has become an important initiative to expand the indicators system beyond OECD countries. Begun in 1997 as a pilot project for a small group of countries invited by OECD and UNESCO, the primary aim of the project is to develop a small but critical mass of policy-oriented education indicators, which measure the current state of education in an internationally valid, timely, and efficient manner. The project received funding from the World Bank for organization and administration, but participating countries provided their own resources for assembling and reporting data.

During the first year, the eleven countries that initially agreed to participate identified common education issues of concern, agreed upon an indicator set and the definitions and classifications to be used in the data collection, and assembled and provided the data. OECD processed the data and results, which were subsequently presented in the annual publication *Education at a Glance*. During the second year of the project, OECD and UNESCO agreed to add a number of countries that had expressed an interest in joining the pilot group, bringing the number of participating countries to sixteen. Indicators prepared from the data submissions over the two-year period served as the basis for a separate WEI report released in 2000. In 2001 the project produced *Teachers for Tomorrow's Schools: Analysis of the World Education Indicators*, a second volume that analyzes education indicators developed through the WEI project.

In addition to the basic data collection to derive the indicators, a number of special-interest groups assembled to research areas requiring data development and make recommendations based on their research of additions to the indicator set. World Bank funding permits pilot projects in six selected countries to develop national education indicators systems that both respond to national policy information needs and are compatible with education indicators used at the international level. The result of these pilot projects is a number of national education indicator publications that are disseminated to policymakers within national ministries and development agencies.

## European Union (EU)

**Purpose.** The European Union, formed by the Maastricht Treaty of 1993, expanded European integration through the establishment of a common foreign and security policy and standards of justice, and improved police protection. A twenty-member European Commission represents the policymaking arm and executive body for the fifteen countries that comprise the EU. The Council of the European Union (not to be confused with the Council of Europe, which is a separate regional institution) is comprised of one representative of ministerial level from each member country, and it represents the legislative body of the EU. Along with the European Parliament, the council makes legislative and budgetary decisions for the EU.

In the formation of the EU, education was suggested to remain a national enterprise. Article 149 of *The Treaty Establishing the European Community* notes, "The Community shall contribute to the development of quality education by encouraging cooperation between Member States and, if necessary, by supporting and supplementing their action, while fully respecting the responsibility of the Member States for the content of teaching and the organization of education systems and their cultural and linguistic diversity." However, although education itself is thus not an official function of the EU mandate, EU literature still claims education and vocational training were "two cornerstones of the Commission's commitment to securing investment in people" ("Education—Training—Youth"). In fact, education programs were inaugurated to improve the prospects of European integration in culture, science, technology, and labor markets.

The EU's education policy has six basic components: (1) education; (2) vocational training; (3) recognition of diplomas and comparability of vocational qualifications; (4) training and mobility; (5) youth; and (6) international cooperation. The education component contains programs dealing with quality, access, and the teaching of languages. There have been four main programs—Tempus, Socrates, Erasmus, and Lingua—and European integration was the rationale for each.

**Erasmus program.** Erasmus (1987), Lingua (1989), and Tempus (1990) were each established before the official creation of the EU in 1993, as projects of the European Community, a precursor to the EU. The Erasmus program was adopted in June 1987 and

amended in December 1989, and its focus was the mobility of university students within the European Community. The steps included establishing a European university network among the member states, the creation of grants to assist with travel and the cost-of-living differential, recognition and mobility of diplomas and periods of study, and the financing of promotional activities to create awareness of work throughout the European Community. In 1994, its final year as an independent program, Erasmus received European Currency Unit (ECU) 96.7 million.

**Lingua program.** Lingua went into effect in January 1990 and lasted independently for five years. It was an attempt to bolster foreign-language competence within the EU. Specifically, it focused upon Danish, Dutch, English, French, German, Greek, Irish, Italian, Luxembourgish, Portuguese, and Spanish. The program operated at various levels: citizens, teachers, university students, and organizations. The focus was on promotion, increasing learning opportunities, and innovative training. Lingua's budget was set at about 200 million euros. In its five years, Lingua provided services for 120,000 youth through educational projects, 30,000 students through interuniversity cooperation, and 30,000 teachers through training grants. In addition, projects promoting languages in economics and business were established. In 1995 Lingua activities were integrated into other EU programs.

**Tempus program.** Tempus was first established in May 1990, with a second phase adopted in April 1993, and a third phase adopted in April 1999. The third phase was scheduled to last from 2000 through 2006. Tempus was designed to help develop higher education systems for the "eligible countries" operating as partners with EU member states, and funding was established at ECU 95 to 100 million per year. Eligible countries include a number of republics in central and eastern Europe and central Asia. Its stated objectives were to develop new teaching programs, purchase equipment, encourage mobility of university professors, create periods of study in member states, and promote the learning of European Community languages. The overall goal of each of these objectives was to assist in the transfer to a market economy. The second and third phases added more countries to the list of eligible nations and further refined its features. The third phase aimed to adapt higher education to the socioeconomic and cultural needs of the new democracies. By phase three, the focus had become the reform

of higher education structures, linking training to industry, and strengthening citizenship and democracy.

**Socrates program.** While Tempus was continually updated as its own program, both Lingua and Erasmus were melded into the Socrates program, the only one of the four to be established first as an EU program. Socrates was inaugurated in March 1995 and moved into a second six-year phase in January 2000. Socrates had a much more general aim to actually create an open European educational area through access, mobility, and language knowledge. It incorporated higher education (Erasmus), school education (Comenius), and adult education initiatives (Grundtvig), as well as language learning (Lingua), distance learning and technology education (Minerva), and information exchanges (Arion and Eurydice). Socrates also extended beyond the member states into some central and eastern European countries and former Soviet republics. Phase two had a budget of 1.85 million euros.

**Program evaluation.** Criticism and difficulties of the four programs included the divergence among the legacies of the various nations, especially the newly independent states; coordination and communication between nations; and monitoring and evaluation of projects. However, there have also been some indirect side effects, including the improvement of quality, coverage, and content of local and national systems.

**The remaining components.** Vocational training involves access to training, analyzing qualification requirements, quality of training, and promotion of apprenticeship. The EU has run a variety of programs and organizations to handle vocational training. These have included Comett and Eurotecnet to promote technology and human resource training, IRIS (Inter-Regional Information Society) to promote equality of opportunity, Petra to boost the status of vocational education and encourage transnational cooperation, Force to encourage investment in vocational education, and Leonard da Vinci to promote lifelong learning and EU cooperation.

Recognition of diplomas and qualifications and training and mobility both attempt to facilitate unity with the EU. This has involved creating mechanisms for the recognition of diplomas and the establishment of comparable training. It has also meant the removal of barriers to mobility, such as recognition

of training abroad and the continuation of health insurance.

Youth programs have included volunteer service, social inclusion, and youth exchange programs, such as “Youth for Europe.” Finally, international cooperation programs have involved the United States and Canada.

The EU has its origins in the European Federalists Union, designed in 1946. The following year, the Marshall Plan was signed, and a variety of unionist movements began, culminating in the International Coordination of Movements for the Unification of Europe Committee in December 1947. Some of those involved in the movement wanted a federation, and others wanted simply cooperation. In 1950 French Foreign Minister Robert Schuman proposed a union of countries to pool coal and steel resources. Six nations (Belgium, France, Germany, Italy, Luxembourg, and the Netherlands) ultimately subscribed to the Schuman Plan, forming the European Coal and Steel Community (ECSC) in 1951. These six nations ratified the Treaty of Rome in 1953, thus officially starting the path toward a European union forty years later. This community developed from a tax, customs, and quantity regulator into a full-fledged political institution, dealing with trade, human rights, labor, economics, agriculture, and energy. In 1967 the ECSC merged with the European Economic Community and Euratom to form the European Communities (EC). In November 1976 a council was held in The Hague, and a statement was published regarding the possible construction of a “European Union.” In 1983 the Ministers of Education held their first joint meeting with the Ministers of Employment and Social Affairs. A ruling on non-discriminatory enrollment fees was handed down in 1985. Following the fall of the Berlin Wall and the subsequent opening of eastern Europe, a council held in Maastricht, the Netherlands, drafted a Treaty on the European Union in 1991, which was ratified in 1993 with twelve member nations. Just before ratification, the commission published a green paper on creating a “European dimension of education.” In 1995 Austria, Sweden, and Finland joined the EU, bringing the number to fifteen, with a number of eastern European newly independent states awaiting ratification. A council in Brussels in 2001 outlined a ten-year strategic education and training plan with three main objectives: (1) increase quality and effectiveness of education in the EU; (2) facilitate access; and (3) open up education and training systems “to

a wider world” through research, mobility, and exchanges.

### **The Council of Europe (COE)**

The Council of Europe is distinct from—and larger than—the European Union. As of 2001 the COE comprised forty-three member states, including all fifteen of the European Union states. Established in 1949 and headquartered in Strasbourg, France, the COE is a regional organization that essentially makes recommendations (through conventions, studies, and activities) to member states. The COE holds no legislative authority over its members, and this allows it to consider a large breadth of issues. The COE has developed programs involving human rights, economics, health, culture, sport, the environment, education, and many others, not including defense. It also tries to ensure that citizens of one nation, who are residents of another, will receive the same social benefits as the nationals. The requirements for membership in the COE are less stringent than the EU, as nations basically must accept “the principle of the rule of law” and guarantee “human rights and fundamental freedoms to everyone under its jurisdiction” (Council of Europe website 2001).

The COE was born from the 1948 Congress of Europe. While some nations favored a European union or federation, others felt more comfortable with basic intergovernmental cooperation. These nations (along with five of the six eventual charter members of the ECSC) formed the COE in 1949. One of the earliest COE conventions included education. In 1950 the ten original member states signed the European Cultural Convention, which established a framework for education, as well as youth, culture, and sport.

With so many nations involved in discussions, the breadth of issues considered by the COE has also stretched the specific area of education. The COE has considered educational projects in primary, secondary, higher, and adult education; research and promoting links and exchanges; recognition of educational qualifications throughout Europe; publishing handbooks for policymakers and educators; and cooperating with European institutions and non-governmental organizations. In addition, with the opening of central and eastern Europe, educational programs to assist the new democracies took hold in the 1990s. The COE has been active in promoting democratic citizenship and, toward the end of the 1990s, social cohesion.

Regarding higher education, the COE established the Higher Education and Research Committee for the exchanges of views and experience among member-state universities. Other higher education activities have included mobility, recognition of qualifications, lifelong learning, citizenship, cultural heritage, access, research, and social sciences. In 1971 the COE established the European Documentation and Information System for Education (EUDISED), which pools education research from throughout Europe and is available via the Internet. EUDISED is a joint project with the EU's European Commission. In addition, the Legislative Reform Program (LRP) helps new member states reform their higher education laws.

The variety of cultures and languages represented by the COE presents challenges for any cooperative effort, thus language learning and social science have been the focus of many programs, such as the Council for Cultural Cooperation's Modern Language Project and the European Center for Modern Languages. The COE's cultural work has also involved democracy, human rights, minorities, history teaching, and "Europe at School," an annual Europe-wide competition for school children.

### **Organization for Security and Cooperation in Europe (OSCE)**

The Organization for Security and Cooperation in Europe is the largest regional security organization in the world with fifty-five participating states from Europe, Central Asia, and North America. It is active in early warning, conflict prevention, crisis management, and postconflict rehabilitation.

The OSCE approach to security is comprehensive and cooperative. It deals with a wide range of security-related issues, including arms control, preventive diplomacy, confidence- and security-building measures, human rights, democratization, election monitoring, and economic and environmental security. It is cooperative in the sense that all OSCE participating states have equal status, and decisions are based on consensus.

The OSCE headquarters are located in Vienna, Austria. The organization also has offices and institutions located in Geneva, Switzerland; The Hague, Netherlands; Prague, Czech Republic; and Warsaw, Poland. The organization employs about 4,000 staff in more than twenty missions and field activities located in southeastern Europe, the Caucasus, eastern

Europe, and Central Asia. They work "on the ground" to facilitate political processes, prevent or settle conflicts, and promote civil society and the rule of law.

The organization's attention to education is twofold; it comprises (1) internal and external training efforts, and (2) an emphasis on voter and civic education.

Given the considerable increase in the number and size of OSCE field activities in the 1990s, the OSCE's training efforts must be able to adapt to the changing environment. The OSCE participating states regard training as a tool for enhancing the ability of the organization's institutions and missions to carry out their mandate. This is the underlying principle behind the *OSCE Strategy on Capacity-Building and Training* adopted by the OSCE Permanent Council in March 1999. Participating states have acknowledged the need for training in two main spheres: first, training as a component of human resources management within the organization; second, training as an instrument to achieve the goals of the OSCE in conflict prevention, crisis management, and postconflict rehabilitation.

Within the areas of voter and civic education, training is emphasized. The OSCE deems it necessary for election observers to be able to assess the extent and effectiveness of voter and civic education. Sufficient voter and civic education is necessary to ensure that participants in the electoral process are fully informed of their rights and responsibilities as voters. These efforts can also generate knowledge and interest about the election process and build a climate for open debate. Voter education is focused on the particular election and should inform voters of when, how, and where to vote. It is therefore essential that this information be provided in a timely manner, allowing voters sufficient time to make use of the information. Civic education is a long-term process of educating citizens in the fundamentals of democratic society and civic responsibility. It may focus on the choices available to the voter and the significance of these choices within the respective political system.

Although political parties and civic organizations may contribute to voter and civic education efforts, it is ultimately the responsibility of the government and the election authorities to ensure that voters receive objective and impartial information, which should be provided to all eligible voters,

including traditionally disenfranchised segments of the population, such as minorities.

### **Southeast Asian Ministers of Education Organization (SEAMEO)**

The Southeast Asian Ministers of Education Organization promotes cooperation in education, science, and culture in Southeast Asia. The SEAMEO was established in 1965 in Bangkok, Thailand, and it has a mission to establish networks and partnerships, to provide a forum for policymakers and experts, and to develop regional “Centers of Excellence” for human resource development. Some specific education project areas include education technology, language, higher education, science and mathematics, vocational and technical education, distance learning, history, and education management.

The SEAMEO has ten member countries from Southeast Asia, six associate member countries from Australia, North America, and Europe, and one donor country, Japan. Each member and associate member assigns a representative to the SEAMEO Council. There are eleven centers that focus upon various sectors.

Each of the centers involves education to some degree. The Center for the Impact on Tropical Biology builds capabilities and provides grants and training. It also is developing a postgraduate degree program in information technology in natural resource management. The Center for the Impact on Educational Innovation and Technology provides training in educational leadership, curriculum and policy development, technology, literacy, nonformal education, and community development. The Center for the Impact on Education in Science and Mathematics provides research and teacher training in science and mathematics instruction. The Center for the Impact on Language Education provides teacher training in language instruction through pedagogy, testing, and textbooks. The Center for the Impact on Higher Education Development promotes recognition of qualification in Southeast Asia and conducts networking and policy development in higher education. The Center for the Impact in Indochina runs a regional training center in Ho Chi Minh City, Vietnam, which provides English training and planning for vocational and technical school directors. The Center for the Impact on Open Learning/Distance Education provides computer resources and training to promote distance learning. The Center for the Impact on Graduate Study and

Research in Agriculture provides graduate study, training, and research, and it adopted an elementary school through the Community Outreach Program. The Center for the Impact on Archaeology and Fine Arts develops theories of standard practices and scholarship on regional culture, arts, archaeology, and heritage. The Center for the Impact of Tropical Medicine and Public Health was established for training and research, and it grew into a forum on policies and sector needs. Finally, the Center for the Impact on Vocational and Technical Education conducts training programs and provides an education database.

SEAMEO emerged from a 1965 meeting between education ministers from Thailand, Singapore, Malaysia, Laos, and the Republic of South Vietnam (now Vietnam). Advisers from UNESCO and the United States were also involved. Indonesia and the Philippines joined in 1968, followed by Cambodia in 1971, Brunei Darussalam in 1984, and Myanmar in 1998. Its first thirty-five years saw numerous challenges within the region in the form of various social and political transitions, some of them violent, and an extreme economic downturn in the 1990s. Also, SEAMEO has faced cultural diversity that has created both tension and programs.

### **Inter-American Development Bank (IDB)**

The Inter-American Development Bank, the oldest and largest regional multilateral development institution, was established in December 1959 to help accelerate economic and social development in Latin America and the Caribbean. The bank’s operations cover the entire spectrum of economic and social development. In the past, IDB lending emphasized the productive sectors of agriculture and industry, the physical infrastructure sectors of energy and transportation, and the social sectors of environmental and public health, education, and urban development. Current lending priorities include poverty reduction and social equity, modernization and integration, and the environment.

IDB provides financing for projects in the education sector for the purpose of promoting greater integration of educational activities within the national development strategy of the member countries. The loans and technical cooperation from the bank for education have the following objectives:

- Training of human resources for development to contribute to the formation of technical and

scientific skills that enable people to efficiently carry out the occupational tasks of promotion and management needed for the economic and social development of the country.

- Equality of educational opportunities to facilitate national efforts for introducing conditions of fairness in access to education opportunities for the entire population.
- Efficiency of investments in education to stimulate and support national efforts for rational planning of education systems and the essential reforms in content, teaching methods, organization and administration of programs, and institutions and systems, to achieve more positive results within the financial possibilities of the country.

IDB gives preference for financing development projects in the following educational areas:

1. Higher education programs at the professional, postgraduate, and scientific and technological research level and the training of specialized technicians in short-duration courses. The bank will support the role of higher education in the training of management teams needed in the development process and will stimulate the strengthening, at the national and regional levels, of institutions with high academic standards capable of showing the way in critical development areas.
2. Programs on technical education and professional training to turn out skilled workers and middle-level technicians in occupations needed for productive activities and to assure their participation in the social and cultural benefits of their communities, including reform and adaptation of middle-level education programs, which provide training in technical occupations without sacrificing the opportunity of acquiring basic education.
3. Education programs to provide a minimum of social and work skills to young persons and adults who did not have access to formal education, thus equipping them to find employment in rural development programs or rehabilitation of urban areas.
4. Programs to introduce substantive reforms in curriculum, teaching methods, structure, organization, and functioning of basic,

formal, and nonformal education at the primary and secondary level. These programs can include education research, training and retraining of teachers and auxiliary technical staff, nontraditional forms of education, and the design, production, and evaluation of institutional materials, equipment, and communication systems of proven effectiveness. The basic objective of these programs is to improve the quality and efficiency of education activities and to expand the levels of participation without considerable increase in cost.

5. Programs to improve efficiency and fairness in the application of funds intended for financing education and promoting the creation of additional sources of financing by improving student loan systems, social security, business support, scholarships for priority professional fields, and such other systems as appropriate.

#### **Asian Development Bank (ADB)**

The Asian Development Bank, a regional multilateral development institution established in 1966, provides loans and investments for developing countries; technical assistance for development projects, programs, and services; facilitation of public and private capital investment for development; and assistance in policy coordination and planning. The ADB has fifty-nine member countries, with Japan and the United States as the largest shareholders (combining for almost one-third of the shares). The ADB has a stated primary goal of reducing poverty in Asia and the Pacific, and its headquarters are in Manila, Philippines.

One of the ADB's objectives is supporting human development, and education is one of the major means to this end. Noting that education is a basic human right recognized in the 1948 Universal Declaration of Human Rights, the ADB states, "Education helps lay the foundation for the three pillars of poverty reduction: human development, equitable economic growth, and good governance" (Asian Development Bank 2001). However, it was not until 1988 that the ADB formally stated in a policy paper that basic education was a human right. According to its own historical accounts, the ADB invested \$4.6 billion in education between 1970 and 2000, with about two-thirds of that investment occurring in the 1990s. During its initial years, the ADB followed a

“manpower planning” and economic growth philosophy and funded facilities and equipment for vocational and technical education. In 1988 the ADB published its first education sector policy paper, which called for investment in primary and secondary education to foster human and social development. In 1990 the ADB adopted the goals set down by the World Conference on Education for All, held in Jomtien, Thailand, which called for universal education and gender equity. With these goals came an emphasis on basic education, teacher training, and curriculum planning. The ADB also moved deeper into policy, research, and capacity-building activities. However, education represented only about 6 percent of the ADB’s total investments during the 1990s.

The ADB’s 2001 education policy paper called for the ADB to support programs in literacy and nonformal education, early childhood development, basic education, secondary education, higher education, and skills training. It also called for reducing poverty, enhancing the status of women, and facilitating economic growth.

Critique of the ADB has included a narrow focus on “schooling as opposed to education in the broader sense” (Asian Development Bank 2001), uneven distribution of support (three countries accounted for two-thirds of the total education lending between 1970 and 2000), an early focus on traditional project technical assistance, education as a relatively small proportion of the ADB’s overall investment portfolio, sector reform not always guided by clear policy goals and strategies, and overall education investment not reaching its impact potential because of weak sector analysis.

### **The Economic Commission for Africa (ECA)**

The Economic Commission for Africa is a United Nations regional institution designed to foster economic and social development and promote regional integration and cooperation in Africa. Established in 1958, the ECA has its headquarters in Addis Ababa, Ethiopia, and it reports directly to the United Nations Economic and Social Council. The fifty-three African countries comprise the ECA’s member states, and it serves four main modal functions: (1) advocacy and policy analysis; (2) convening stakeholders and building consensus; (3) technical cooperation and capacity building; and (4) enhancing the United Nation’s role in Africa. In approaching edu-

cational and other policy issues, the ECA essentially reports on social situations and influences policy.

Because of Africa’s size, political situations, and economic extremes, education in the continent provides a variety of challenges. A 1995 conference of ministers’ report (United Nations Economic Commission for Africa 2001) outlined many of the educational issues the ECA has faced and documented during its existence. According to the report, “the crisis in African education” intensified in the 1980s and 1990s, because of rapid population growth and cuts in public spending. Many African countries during this period offered little funding for primary education, and primary school enrollments declined while total enrollment increased. Together with these issues were declining standards, overcrowding, lack of teaching materials, and declining teacher morale. Inadequate facilities and “deteriorating” educational quality also plagued secondary education during the period. Girls were not served at the same level as boys, and fewer girls stayed in school through tertiary education. Higher education as a whole faced low salaries, political issues, lack of materials, student and professor unrest, and university closures. Finally, the number of adult illiterates rose considerably during the last two decades of the twentieth century.

The ECA has served a number of roles in handling educational issues and other sector situations. It helped create the African Development Bank in 1964, and it has assisted in the establishment of a number of other regional organizations and technical institutions. The ECA also helps member nations communicate and cooperate in efforts to tackle issues. Through analyses and reports, the ECA tries to suggest and implement strategical approaches to problem areas, and it also helps evaluate the progress of implemented programs.

As economic development strategies moved away from primarily physical or structural developments and recognized the importance of education and human capital in capacity building, many of the ECA member states adopted international conventions on educational development. A 2001 ECA strategy noted eight “sub-programs,” including facilitating economic and social policy analysis, promoting trade and mobilizing finance for development, enhancing food strategy and sustainable development, strengthening development management, harnessing information for development, promoting regional cooperation and integration,

promoting the advancement of women, and supporting subregional activities for development.

### The African Development Bank (AfDB)

The African Development Bank, a regional multilateral development bank, was established in 1964 and began operations in 1966. The AfDB has seventy-seven shareholder states, including each of the fifty-three African countries and twenty-four nations in Asia, Europe, North America, and South America. As a development bank, the AfDB provides: (1) loans and investments for developing countries; (2) technical assistance for development projects, programs, and services; (3) facilitation of public and private capital investment for development; and (4) assistance in policy coordination and planning. Education is one of the AfDB's major sectors of support, and financing includes specific projects, loans, private-sector support, and cofinancing with bilateral and multilateral institutions.

The AfDB did not support an education project during its first nine years of operation. The first education project occurred in Mali in 1975. From 1975 through 1998, education lending represented 6.7 percent of the total lending to all sectors. During that period, over 80 percent of the AfDB's lending in education went to hardware, such as equipment and furniture. In addition to funding hardware, the AfDB has funded training for teachers, administrators, and planners, and construction and rehabilitation. The AfDB has also supported both regional and national projects.

Three publications/conferences had major effects on AfDB educational policy. First, the AfDB published an *Education Sector Policy Paper* in 1986. Before that time, education accounted for just under 60 percent of the AfDB's social-sector lending. After the policy paper, education accounted for an average of 70 percent of all social-sector spending (from 1985 to 1998). A second milestone was the 1990 Jomtien World Conference on Education for All, which called for gender equality and universal basic education. Prior to 1990 nearly half of all funding went to secondary, general, vocational, and technical education or teacher-training projects. After the Jomtien conference (1991–1998), however, 52.8 percent of the total lending went to basic education.

As Africa's education issues evolved in the last years of the 1990s, the AfDB tried to address challenges, such as globalization, the growth of informa-

tion technology, the increased role of the private sector, deepening poverty, high unemployment, low human-capital production, extreme population growth, HIV/AIDS and malaria, armed conflicts and population displacement, and unequal access to education. Recognizing that education could both affect and was affected by these issues, the AfDB released a new *Education Sector Policy Paper* in 1999. This paper listed three priority areas: (1) quality education for all; (2) provision of middle- and high-level skills; and (3) organization and management of the education sector. The paper also listed five strategies of improvement: (1) access; (2) equity; (3) quality of instruction and output; (4) management and planning; and (5) financing mechanisms. It also suggested the AfDB's approach would shift from a project-orientation to a sectorwide approach focused on joint financing with governments and institutional partners. Among the areas of interest that had grown since 1986 were girls' education, technology and distance learning, environmental education, population and AIDS education, and peace education.

Some of the areas in need of improvement within education-sector funding, according to the policy paper, included the need to balance qualitative and quantitative approaches, coordinating projects at the community level, participation of beneficiaries and stakeholders, maintenance and sustainability of building and equipment, supervision of projects, and monitoring of evaluations. In addition, Njoki Njoroge Njehũ, the director of 50 Years Is Enough: U.S. Network for Global Economic Justice, a coalition "dedicated to the profound transformation of the World Bank and the International Monetary Fund" ("Hearing on U.S. Policy," 2001), noted that the conditions in Africa had not improved substantially during the first thirty-five years of bank lending and that the AfDB, "as it recovers from its management crisis of the 1990s, is losing relevance to most of the people of the continent" by lending to "very few sub-Saharan countries."

**UNITED NATIONS AND INTERNATIONAL AGENCIES**

Official multilateral development agencies are those that are responsible to and governed by representatives of worldwide organizations. The United Nations (UN), a multilateral organization with a variety of institutional mandates, has many organizations under its umbrella. Other organizations have a single mandate but are similarly broad in scope. A distinction should be made between the multilateral development banks—such as the World Bank—whose projects take the form of loans, and the other multilateral development agencies—such as United Nations Educational, Scientific and Cultural Organization (UNESCO)—whose projects take the form of nonreimbursable grants. This entry will describe the history, legacy, importance, and role of international agencies with regard to education.

**The World Bank (or the International Bank for Reconstruction and Development)**

The World Bank is an international bank established in 1944 to help member nations reconstruct and develop by guaranteeing loans. The organization has members (both donors and borrowers) who own shares in the bank, although each member nation does not have a vote. Rather, the governance structure is representative in nature, such that one representative may vote on issues for a cluster of nations. It provides loans and technical assistance in many sectors—including education—to reduce poverty and advance sustainable economic growth. There are several types of loans: project loans, macro-policy loans, and sector-policy loans. For each project bank staff work carefully with country counterparts to establish a project covenant or loan

agreement, which stipulates the government's commitments, to reform, for example. As part of the loan agreement, when the bank and the country meet to negotiate the loan contract, the bank can establish conditionalities or parameters that commit the country to accomplishing certain changes. Should these benchmarks not be reached, then the bank, according to the terms set out in the contract, can take action.

**Educational mission.** Education is a cornerstone in the bank's overall mission to help countries fight poverty. The World Bank's mission in education is to assist clients to improve access to relevant learning opportunities, use education resources wisely and fairly, and build stronger institutional capacity. More specifically, the bank works with national ministries of education to identify and implement the countries' strategic steps in order to provide access for all to quality education. The institution works in partnership with the client (or government) as well as other stakeholders, including bilateral-aid agencies, nongovernmental organizations (NGOs), and other members of civil society.

The long-term goal in education is to ensure that everyone completes a basic education of adequate quality, acquires foundation skills (literacy, numeracy, reasoning, and social skills such as teamwork) and has further opportunities to learn advanced skills throughout life, in a range of postbasic education settings.

At the beginning of the twenty-first century the bank draws upon four decades of experience in education with approximately 600 projects in 115 countries totaling \$26 billion. Although the focus of early projects was on building school infrastructure, increasingly the focus is on improving access to schooling, student attendance, and the quality of education once students are there. Concern for the adequacy of the education has led to greater emphasis on teaching quality and learning achievement. In addition, the concern about a greater demand on limited resources has precipitated a concern about efficiency, including the need for building the institutional capacity required to implement and sustain improvements.

The World Bank made its first loan for education in 1963, and the bank is now the largest single source of external financing for education in developing countries. Since 1980 the total volume of lending for education has tripled, and its share in overall

bank lending has doubled. The primary and secondary levels of education are increasingly important; in the fiscal years from 1990 to 1994 these levels represented half of all World Bank lending for education. Early bank lending for education concentrated on Africa, East Asia, and the Middle East, but at the beginning of the twenty-first century lending is significant in all regions. Girls' education is at the forefront, and increasing attention is being given to the educational needs of ethnic minorities and indigenous people. World Bank funds are used less for buildings and more for other educational inputs. The narrow project focus of the past is increasingly giving way to a broad sectoral approach.

The World Bank is strongly committed to continued support for education. However, even though bank funding now accounts for about a quarter of all aid to education, this funding still represents only about 0.5 percent of developing countries' total spending on the sector. Therefore, the World Bank sees its key contribution as advice or technical assistance, designed to help governments develop education policies suitable for the circumstances of their countries. Bank financing will generally be designed to leverage spending and policy change by national authorities. According to World Bank documents, future operations are expected to adopt a more explicit sectorwide policy focus to support changes in educational financing and management. Because of the need to consult key stakeholders, this strategy may increase both the resources and the time needed to prepare projects. In increasingly decentralized contexts, the stakeholders will include not only central governments but also other levels of government, as well as communities, parents, teachers, and employers. Donor cooperation is expected to extend to broad policy advice, as well as investment coordination.

**Programs.** World Bank programs encourage governments to make education and education reform a higher priority, particularly as economic reform becomes a permanent process. Projects will take more account of outcomes and their relation to inputs, making explicit use of cost-benefit analysis, participatory methods, learning assessments, and improved monitoring and evaluation. The share of basic education in total World Bank lending for education is expected to continue to increase, especially in the poorest countries, which receive International Development Association (IDA) funds. The bank emphasizes a sectoral approach that recognizes the

importance of each level of the education system, the interdependencies among levels, and the need to focus bank assistance in areas where the bank can be most useful in the particular circumstances of each country.

At the outset of the twenty-first century, World Bank-supported projects have paid greater attention to equity. This is especially the case in education for girls, for disadvantaged ethnic minorities, and for the poor—and consequently for early childhood education. Projects will support household involvement in school governance and in school choice through an increased emphasis on the regulatory framework for education, on quality-enhancing mechanisms such as outcome monitoring and inspection, on recurrent cost financing, and on demand-side financing mechanisms such as targeted scholarships for the poor, stipends for girls, and student loan schemes for higher education. They will encourage flexible management of instructional resources, complemented by national assessment and examination systems to provide incentives. In all these areas, bank-supported projects are expected to focus more intently on institutional development, including strengthening educational administration and appropriate financial mechanisms, and the bank's staff will pay increased attention to implementation.

**Criticism.** Criticisms of the World Bank emanate from across the political spectrum, from NGOs as well as committees of the U.S. Congress (e.g., the Meltzer Commission), and are strikingly similar in nature. Critics from the conservative right, such as the Meltzer Commission, argue that institutions such as the World Bank should stop the business of lending and instead serve as development agencies. Critics from the left contend that the bank does not alleviate poverty, but rather condemns citizens of poor nations to chronic debt. Both ends of the political spectrum have registered criticism of the need for reform, restructuring, and revisiting the mission of the bank, an increase in transparency and access to information, and the creation of an independent audit and evaluation unit. Another area of criticism revolves about the issue of conditionalities. The criticisms leveraged by NGOs include mention of the unreasonable restrictions and demands placed on countries by the multilateral development banks, including the World Bank.

### **The United Nations Children's Fund (UNICEF)**

The United Nations Children's Fund is an affiliated agency of the United Nations. It was originally established in 1946 as the United Nations International Children's Emergency Fund. UNICEF is concerned with assisting children and adolescents throughout the world, particularly in devastated areas and developing countries. Unlike most United Nations agencies, UNICEF is financed through voluntary contributions from governments and individuals, rather than by regular assessments. National UNICEF committees collaborate with UNICEF in various projects. UNICEF was awarded the Nobel Peace Prize in 1965.

UNICEF was created at the end of World War II to relieve the suffering of children in war-torn Europe. It continues to respond rapidly in crises, helping recreate a sense of stability and normalcy, reopening schools and establishing safe spaces for children when armed conflict, war, flood, and other disruptions occur.

The mandate of UNICEF confines its activities and operations to projects intended to benefit children and youth. Unrestricted donations to its budget permit UNICEF to provide assistance on a grant basis and to operate wherever it deems most necessary, independent of political or governmental influence. As part of its mission, UNICEF is committed to the notion that the survival, protection, and development of children are universal imperatives, integral to human progress.

UNICEF currently works in more than 160 countries, areas, and territories on solutions to the problems plaguing poor children and their families and on ways to realize their rights. Its activities vary according to the local challenges presented. They include encouraging the care and stimulation that offer the best possible start in life, helping prevent childhood illness and death, making pregnancy and childbirth safe, and combating discrimination and cooperating with communities to ensure that girls as well as boys attend school. UNICEF works on behalf of children's well-being in other ways. It supports National Immunization Days in the global effort to eradicate polio. It encourages young people to prepare for and participate in issues affecting them. It helps youth resist the onslaught of HIV/AIDS. UNICEF is out in the field at the local level and at the fore, bringing ideas, resources, strategies, and support to bear when and where they are needed most.

UNICEF strives through its country programs to promote the equal rights of girls and women and to support their full participation in the political, social, and economic development of their communities.

### **United Nations Educational, Scientific and Cultural Organization (UNESCO)**

United Nations Educational, Scientific and Cultural Organization is the agency charged with instituting and administering programs for cooperative, coordinated action in education, science, and the arts. The agency promotes education for all, cultural development, protection of the world's natural and cultural heritage, press freedom, and communication. The internal governance structure grants each member nation one representative in the decision-making body of UNESCO and one vote.

Within UNESCO is an International Bureau of Education (IBE) that is responsible for holding conferences on both broad and specific topics within education. This includes international, regional, and country-specific work, including research, technical assistance projects, the provision of data banks and publications to be used by professionals in international organizations, NGOs, ministries of education, and others.

The IBE Documentation and Information Unit has two main tasks: (1) the Internet site with its data banks, and (2) the Documentation Center. The unit manages the IBE's website in general and, to increase the relevance of its services to decision-making processes in member states and to the needs of educational practice, has developed several data banks, which are accessible and regularly updated on the website: (1) INNODATA—innovative projects in the fields of educational content, methods, and teacher education; (2) world data on education; (3) educational profiles—descriptions of national education systems; (4) national reports—full texts of reports presented to the International Conference on Education in 1996; and (5) country dossiers—a compilation of various sources on education. The data banks provide wider access to materials gathered and analyzed at the IBE. These materials are available for local consultation in the Documentation Center. UNESCO is heavily involved in numerous education-related endeavors, which include associated schools, the production of basic learning materials, drug-abuse prevention programs, early childhood and family development programs, pro-

motion of Education for All, educational facilities, e-learning, emergency assistance, girls and women in Africa, higher education, HIV/AIDS work, the literacy decade project, poverty eradication, primary education, science and technology, special needs education, street and working children, sustainable future, and technical and vocational education.

In addition, it provides more than half a dozen networks for communication among practitioners, policymakers, and people interested in education-related topics. UNESCO also works to build partnerships among key stakeholders in the education policy process, including intergovernmental organizations (IGOs), NGOs and other UN agencies.

A learning materials project, the Basic Learning Materials Initiative (BLM) is based on the premise that successful materials-development strategies must include mechanisms for generating a wide range of printed materials needed by a reading society. The development of a viable local publishing industry in each country is a necessary element of such strategies. The creation of a well-functioning system for the production and distribution of basic learning materials may be a first step toward creating a literate society and a market for books and other printed materials. This project seeks to address the scarcity of books, magazines, newspapers, and even posters in the developing world and to provide learning materials for the classroom environment, which is often the only place where children encounter words in written form. Textbooks provide the main resource for teachers, enabling them to animate the curricula and give life to the subjects taught in the classroom. The importance of books to the quality of education and rates of educational achievement has been well documented. But the goal of Education for All also involves the development of literate societies in the developing world and cannot be attained solely by providing quality learning materials to schools. If people are to stay literate, they must have access to a wide variety of written materials and continue the habit of reading in their adult lives.

Like any large organization, UNESCO has not been immune to controversy. In the 1980s it suffered accusations of mismanagement, which precipitated the withdrawal of three nations: the United States, the United Kingdom, and Singapore. Although the latter two have returned, UNESCO closed its Washington, DC, office definitively in 2001.

### **International Labor Organization (ILO)**

The ILO formulates policies and programs to improve working conditions and employment opportunities and defines international labor standards as guidelines for governments. It settles labor disputes and establishes guidelines for acceptable labor practices. In the field of education, the ILO is involved in issues regarding teaching personnel, including initial preparation, further education and recruitment of teachers, the conditions of employment and work, and the extent of teacher's participation in decision-making processes of public and private educational authorities that affect teaching and learning. The internal governance structure grants each member nation one representative in the decision-making body of ILO and one vote. The philosophical basis of all ILO operations is the equal tripartite partnership of labor, business, and government, with representatives of all three on most internal commissions.

The ILO established the InFocus Program on Strengthening Social Dialogue to strengthen and promote the practice of social dialogue in ILO-member states as a means of sharing information among labor administrations, trade unions, and employers' associations, as well as developing consensus on policy approaches and practical measures to ensure equitable social and economic development. Social dialogue is understood to include all types of negotiations, consultations, or exchange of information between or among the tripartite and bipartite partners on issues of common interest relating to economic and social policy. As such, it plays a pivotal role in identifying the important labor and social issues of the ILO's constituents and in realizing fundamental principles and rights at work promoted by the ILO.

### **World Health Organization (WHO)**

The World Health Organization is the international directing and coordinating authority for information on international health work, which strives to bring the highest quality health to all people. Health is defined in the WHO constitutions as a state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity. In support of its main goal, the WHO works to promote technical cooperation; assist governments at their behest to strengthen health services, to provide appropriate technical assistance and, in emergencies, necessary aid; to stimulate and advance work on the

prevention and control of epidemic, endemic, and other diseases; and to promote, in cooperation with other specialized agencies, the improvement of nutrition, housing, sanitation, recreation, economic or working conditions, and other aspects of environmental hygiene. The internal governance structure grants each member nation one representative in the decision-making body of WHO and one vote.

As part of an educational mission of sorts, the WHO works to promote and coordinate biomedical and health services research. It also promotes improved standards of teaching and training in health, medical, and related professions.

The WHO conducts numerous health-education programs for the benefit of health care professionals and health care beneficiaries. Such health-education programs include, for example, teaching medical students about diarrheal diseases, programs to prevent and reduce the use of tobacco, and health education in food safety. The role of education at the WHO is to aptly disseminate information about ways to prevent and cure disease.

The WHO serves as a conduit to numerous sources of health and medical information as well as health initiatives. The WHO Global School Health Initiative, for example, seeks to mobilize and strengthen health and education activities at the local, national, regional, and global levels. The initiative is designed to improve the health of students, school personnel, families, and other members of the community through schools. Another example is that of the WHO Healthy Cities Project in which attention is given to the principle that health can be improved by modifying living conditions, that is, the physical, environmental, social, and economic factors that affect or determine people's health. The home, the school, the village, the workplace, or the city are all places or settings where people live and work. Health status is often determined more by the conditions in these settings than by the provision of health care facilities.

The WHO has extended collaboration with a number of organizations. One such example is WHO's collaboration with the Industry Council for Development (ICD) and the International Life Sciences Institute (ILSI), both NGOs in official relations with WHO. Some of their joint activities include (1) the Second Asian Conference on Food Safety; (2) Hazard Analysis Critical Control Point training in several countries; (3) training of nutri-

tionists in food safety in Indonesia; and (4) development of a food safety program in Indonesia.

### **Food and Agriculture Organization of the United Nations (FAO)**

The Food and Agriculture Organization of the United Nations is an intergovernmental, multilateral organization created to boost standards of living through improving nutrition, agricultural productivity, and the conditions of rural populations. This is accomplished through development strategies and projects undertaken in cooperation with both national governments and other organizations. The FAO is the largest of the many specialized organizations in the UN system. The FAO's 180 member states and one member organization, the European Community, form the FAO Conference, which meets every two years to determine policy and approve a budget. Each member nation has one representative at the conference. The conference also elects a council of 49 member nations, which form the executive organ of the organization. The council meets at least three times between each conference session, and each of the 49 member nations has one vote. Council representatives are selected for three-year terms.

Founded in 1945, the FAO moved its headquarters from Washington, DC, to Rome, Italy, in 1951. The FAO has eight departments: Administration and Finance, Agriculture, Economic and Social, Fisheries, Forestry, General Affairs and Information, Sustainable Development, and Technical Cooperation. Education programming falls primarily under the control of the Sustainable Development department.

The Sustainable Development (SD) department has four main components: communication for development, education, extension, and research and technology. According to the FAO, it gives priority to basic education through promoting and supporting initiatives aimed at improving children's health and capacity to learn, using technology and distance education, educating rural girls and women, and promoting lifelong education and skills for life in a rural environment. However, the SD expands beyond basic education to improve the quality of all levels of education by supporting curriculum development and teacher training. The FAO tries to respond to the needs of farmers and rural communities by assisting agricultural universities to better serve farmers and to interact with basic and second-

ary educators. In addition, the SD encourages debate on future trends in education and training in agriculture, rural development, and food security; researches practices and case studies; supports partnerships for education for rural development; and provides technical assistance for the training of policymakers and managers.

Youth programming includes a Youth Network for Food and Security and various exchange programs. The goal is to provide education and training to prepare future farmers and community planners.

The SD agriculture extension service does much of its work through universities and extension-research-education linkages. This involves fostering interaction between academic staff and students, with members of local farming communities, and supporting collaborative problem solving.

The FAO further assists in human-resource capacity building through efforts to improve literacy, health and nutrition, and economic well-being. The FAO Nutrition Education and Training Group works with governments to provide training about nutrition and dietary habits. The Policy Assistance Division assists with capacity building through policymaker training.

A 1997 FAO report available on the FAO Internet site in the SD area titled "Agricultural Education and Training: Issues and Opportunities" outlines some of the changes that have affected agricultural education. These include advances in communications technology, decreasing proportions of economically active populations dependent upon agriculture and an increasing marginalization of agriculture and rural life, population increases, scientific progress, changing market demands and employment opportunities, and the increasing recognition of the roles of women in the sector.

### **The United Nations High Commissioner for Refugees (UNHCR)**

The United Nations High Commissioner for Refugees helps resettle people who have left their home countries due to a fear of persecution and who either do not want to or cannot return to their homelands. The UNHCR has two basic goals. First, it aims to protect refugees, and second, it tries to help refugees normalize their lives again. According to the UNHCR women, children, and the elderly comprise 80 percent of the typical refugee population, and the organization attempts to meet their basic needs. For children, this includes education projects.

The UNHCR views education services as meeting psychological needs; restoring structure to children, families, and communities; and helping prevent conflict by providing alternatives to joining armed groups. The UNHCR funds governments and NGOs to construct, rebuild, and operate schools for children and adolescents. Many of these projects are small-scale, quick-impact projects of building and repairs. Although most of the UNHCR's activities are focused on primary and secondary schools, it also provides for literacy classes and vocational training for adults.

The UNHCR tries to use familiar languages and the curriculum from refugees' home countries. In some instances, refugee status might be long-term, and in those cases the UNHCR combines curriculum from countries of origin and the host countries. In cases where a host country forbids education of refugee youth, the UNHCR negotiates on behalf of the refugees.

Beyond direct assistance to refugees and their teachers, the UNHCR also provides information and curriculum materials for teachers worldwide. These resources are provided with the goal of expanding awareness of historical issues and current refugee situations. These efforts can be preventive and build assistance possibilities.

The UNHCR was established with a three-year mandate in 1950 to help resettle refugees left homeless in Europe following World War II. The UN has extended the mandate every five years. It began as a small agency and gradually expanded to offices in 120 countries. It has faced resistance from some countries either unwilling to provide assistance to fleeing civilians or willing to help only temporarily.

## INTERNATIONAL EDUCATION

In the late 1970s a course on international education at the University of Chicago included a series of readings that seemed to fall into the following types of materials. First, there were references to some of the nineteenth-century travelers—Horace Mann, Mathew Arnold, Joseph Kay—who brought back impressions of education in foreign lands for domestic consideration. Second, there were references to some who tried to systematize the results of these kinds of impressions—Michael Sadler, Isaac Kandel, George Bereday. Third, there were references to great minds drawn from philosophy or from the social sciences generally that were of interest to comparative education as well as to many other lines of inquiry—Plato, Leo Tolstoy, Max Weber, Émile

Durkheim, Clifford Geertz, Edward Shils, Stuart Eisenstadt, and David Apter. Either they had thought about education, or they were contributors to compelling theories in which education played a role—in modernization, tradition, center and periphery, economic development, civic culture, and stratification. Fourth, there were references to those who had begun to measure and estimate what it was about education that seemed to make a difference in society—Philip Foster, Torsten Husén, Alex Inkeles, Yuri Bronfenbrenner, Edward Denison, and John McClelland. The purpose of these figures was to study education as though it were like any other social function—religion, law, or medicine, for instance. They were curious about whether education's role and function were similar around the world and why. And last, there were individuals who helped “plan” education's effects—Fredrick Harbison and Charles Myers, Neville Postlethwaite, Benjamin Bloom, Charles Havighurst, James Coleman, C. Arnold Anderson, and Mary Jean Bowman.

Readings by and about these figures constituted “the literature” in the late 1970s. The field, however, was greater. Attending meetings of the Comparative and International Education Society were representatives of various foundations and public agencies who took a keen interest in the field and the society itself. The conferences included scholars from anthropology, political science, public administration, comparative literature, sociology, and regional area studies—Africa, Asia, Latin America, and the Middle East—linked by a common interest in education.

By the early twenty-first century, the major interdisciplinary programs at Stanford University and at the University of Chicago had closed, and the level of international development assistance to education in developing countries continued to decline. Was there less interest in the field than twenty-five years previous? Is international education at risk in the early twenty-first century? Where is international education headed?

### **International Education: More but Different**

There is more written in the early twenty-first century concerning international education than was written in the 1970s. One reference system of public policy issues shows 34 entries on international education in the 1970s and 155 ten years later, a nearly fivefold increase. Another reference system, which includes formal articles and publicly presented papers, shows a substantial level of production of 478

entries in the 1970s, compared to 2,125 ten years later.

Both systems exclude the many and varied internal reports from public agencies, such as the World Bank, the Inter-American Development Bank, the Asian Development Bank, the United Nations Educational, Scientific and Cultural Organization (UNESCO), and the United Nations Children's Fund. There were, for example, 33 World Bank education sector reports produced annually during the 1970s and almost four times that level (123) ten years later, going from 1 in 1972 and 1975, to 10 in 1977, to 12 in 1978, to 17 in 1981 and 1985, to a high of 24 in 1992. The current average is about 20 per year.

The U.S. federal government changed too. Out of more than 3,000 research projects sponsored by the federal government on adolescence and youth in 1974, only one had anything to do with international education. Moreover, the agency sponsoring this particular study (the National Institute of Education) made some effort to underplay its existence for fear of being scrutinized by a congressional committee as being frivolous.

For education, the rise in oil prices in 1974 became a “second *Sputnik*.” Rightly or wrongly it was widely believed that the United States was “behind” in some fundamental way, motivating local demands for more information. These came, for instance, from the offices of state governors in Tennessee, South Carolina, Kentucky, and Washington. Questions about international information began coming from the National School Boards Association, the National Governors Association, the National Educational Association, the American Federation of Teachers, the Council of Chief State School Officers, and the National Association of Manufacturers. This demand for answers to “what's wrong?” led to the 1983 publication of *A Nation at Risk*, a report by the National Commission on Excellence in Education that led to a significant increase in the demand for more international information on education and more reliable information.

The year after the publication of *A Nation at Risk*, there was an acrimonious meeting of the board of directors of the Center for Educational Research and Innovation (CERI). The U.S. delegate pushed for the Organisation for Economic Co-operation and Development (OECD) to be engaged in a project collecting and analyzing statistical education “in-

puts” and “outcomes”—quantifiable information on curricular standards, costs and sources of finance, learning achievements on common subject matter, employment trends, and the like. The reaction among the staff of CERI was one of shock and suspicion. Many thought that generalizations about education were confined to individual cultures, and hence that it was unprofessional to try and quantify education processes or results. They believed that the process of quantification would oversimplify and misrepresent a nation’s educational system. Perhaps more importantly, some suspected that the demand for such information would shift as soon as the political party of the U.S. president changed.

A common European mistake has been to rely primarily on traditional central ministries of education for information. Europeans traveled to the United States to do primary source research on education only sparingly, and they often assumed that the structure and policies were settled in a manner closely resembling their own experience.

The point is that this common European mistake has become less common. Since the 1970s there has been a growth in demand and in sophistication concerning international educational information on both sides of the Atlantic. From the European side, they have learned that the demand for better and more reliable data was not coming exclusively from a single president or a single political party. It was coming, in fact, from educational consumers and grassroots interests, from parts of the society and the educational system over which Washington had no control, and to which political leaders in any democracy had no choice except to respond.

By the early twenty-first century, the OECD’s publication on education indicators was being published in French and English and constituted the most widely circulated publication in OECD history. New projects have been launched on academic achievement, adult literacy, and the use of technology in education. Supported by the World Bank and UNESCO, the World Education Indicators project has expanded to include seventeen non-OECD countries, including China, Brazil, and India, allowing the OECD indicators to claim that they are now representative of the majority of the world’s education systems.

There have been four Nobel prizes dealing with human capital issues (awarded to Edward Dennison, Jan Tinbergen, T. W. Schultz, and Gary Becker).

There has been a flurry of reports on the status of education issued by international agencies in the early 1980s onward. There have been two meetings of heads of state on international educational issues: the Education for All meeting held in Jomtien, Thailand, in March 1990; and the World Summit for Children, which took place in New York City in September 1990. There are three new educational boards of the U.S. National Academy of Sciences and major new research initiatives from the General Accounting Office, the Office of Technology Assessment, various congressional committees, and the Carnegie, Spencer, Ball, and Soros Foundations. There is an ongoing cooperative effort among the donors to assist African education. This is, of course, in addition to the many new efforts in Europe and Asia. The Japanese initiated an important fund to assist human resources in developing countries. The ministers of education from fourteen nations in Asia and North America have decided to pool resources on projects having to do with curriculum requirements and teacher certification. These resources are not classified as foreign aid; instead, they come out of ministry of education budgets. This is also characteristic of the Dutch CROSS (Coordination Dutch-Russian Cooperation in Education) Program, which is designed to assist Russian education. It is justified on grounds that Dutch educational officials have something significant and unique to offer the Russians in the fields of educational management, educational publishing, and assessments of learning achievement and educational examinations and standardized testing, and that the Dutch can themselves learn equally from the cooperative effort. The British Council is also assisting Russian educators with studies and analytic resources. The British Know How Fund is assisting eastern Europeans with studies of the “textbook sector”; the Swedish and the American academies of sciences are assisting higher education and research capacity in the former Soviet Union, as is the European Union. Perhaps unique, though, is an effort led by the chancellor of the State University of New York to provide high-quality advice in comparative education to the minister of higher education in Russia.

These efforts, and the many publications rapidly emerging from them, are not isolated. From a low point of the National Institute of Education’s fear that their one comparative education project would be seen as a waste of resources in 1974 has emerged

a new industry of international education initiatives and projects.

### **Quality of International Education Information**

The international education questions coming from public authorities reveal new sophistication. No longer is thinking confined to “Why Johnny cannot read as well as Ivan.” No longer are the interests of public officials confined to that of an Olympic finish. This increasing sophistication is not uniform, but the kinds of questions being asked in the early twenty-first century cover a much wider spectrum of comparative educational endeavors. The staff of congressional committees ask increasingly about teaching and organizational techniques, types of salary incentives, and the methods of teaching children racial and ethnic tolerance. Questions concern the arts, the system of finance and management, morals, culture, language, and ethnicity. It is now (almost) normal for U.S. political figures to appreciate that political leaders and educators from other countries are not necessarily interested in the exact same questions and problems that interest Americans. Only infrequently does one find the “marble syndrome” of educational politics (if they are not interested in my game and my rules, I go home); rather, there is an appreciation that educational research and the gathering of educational statistics is a natural and normal part of diplomacy. For example, the United States remained in an (expensive, publicly financed) international study of computer literacy even though it was felt there was not very much to learn from other countries. The reason it remained was because it was felt that other countries wanted to learn from the United States. Similarly, the United States lowered its expectations of international research on educational standards with the Asia-Pacific Economic Conference in lieu of the Asian nations’ need to learn about moral education and the teaching of national consensus building. It has become understood that the Japanese may wish to learn about diversified curriculum from the United States, that Russians wish to learn about the teaching of democracy with a heterogeneous school population, and that all societies want to know more about techniques of local management and local finance—all of which are areas in which the United States is not “behind.”

Is it possible that Americans are showing signs of international tolerance and understanding in the field of education? Is it possible that Americans are coming out of their long-held tradition of localism

and educational isolationism? It may be too early to make firm conclusions. But the diversity and sophistication in the kinds of questions being asked by public authorities has increased so dramatically that at times one has the sense that nearly every social science issue on the comparative education reading list the early 1970s seems to be coming of age and into maturity—civic culture and governance, the complexity of human capital theory, stratification and cultural integration, the need for tradition as well as economic development. In every sense, the new century may be a “golden age” for international education.

### **Why Interest in International Education Is Growing**

Some changes come about suddenly and have an immediate worldwide impact. In 1999 Thomas L. Friedman suggested that this is the case with respect to the Internet. Other changes are glacial in the speed by which they are recognized, yet in terms of impact are no less profound. Such is the case with respect to education issues and their shift from local to international relevance.

Significant shifts have affected the governance of education and, hence, the character of international education. These include: the globalization of social and economic forces; the shift to mass education, including mass higher education; the spread of democracy to new areas of the world; the mismatch between education objectives and fiscal capability; the demands placed on the systems to attract high-level talent in terms of international students and faculty; the urgent demands of technology; the new efforts to systematically provide sources of cross-national statistical information; the pressures to create a level playing field in terms of international trade in education services; and the new demands for education to influence social cohesion.

In the 1970s and 1980s governments often determined economic investments, and foreign aid frequently was the dominant source of development capital for middle- and low-income countries. By the early twenty-first century, transfers of private capital far outstripped public investments. A future computer manufacturing plant might be located in Nashville, Tennessee, Northern Ireland, or southern Italy; a textile plant in Bangalore, India, or Sonora, Mexico; a farm for winter fruit in Florida or Chile. What determines the choice of where to invest? Investment capital flows to one or another location on

the basis of many factors—taxation policy, freedom to repatriate profit, labor productivity, labor cost, and social stability. The latter three are heavily influenced by education and by the success of local education systems. Hence, the demands for economic growth and prosperity help determine that pressures on education systems to perform are similar.

In the 1960s the central education representatives were often the sole representatives. Education in the early twenty-first century is frequently a decentralized activity with many new decision makers. Local authorities increasingly drive budgets and policy priorities. This is particularly evident in Brazil, Mexico, India, Russia, Nigeria, and other federal systems; but it is also evident in France, Indonesia, and Malaysia, which had been traditionally centralized. Local states and communities increasingly evaluate their own program innovations, initiate their own research projects, and review their own policies. Local or administrative initiative is often a leading force in centralized education systems as well. Local business and community groups, industries, and nongovernmental organizations increasingly influence policymakers as well as educational authorities. In higher education and private education, where policy decisions are increasingly the responsibility of individual institutions, these institutions are involved in international relations on their own. Educational software companies, publishers, and corporate training firms are ever more active and are demanding new and current information on the size of the educational markets in many countries. Taken together these new categories of participants have deeply affected the vision and the expressed interests of the traditional education authorities.

### **The Influence of Democracy on Educational Governance**

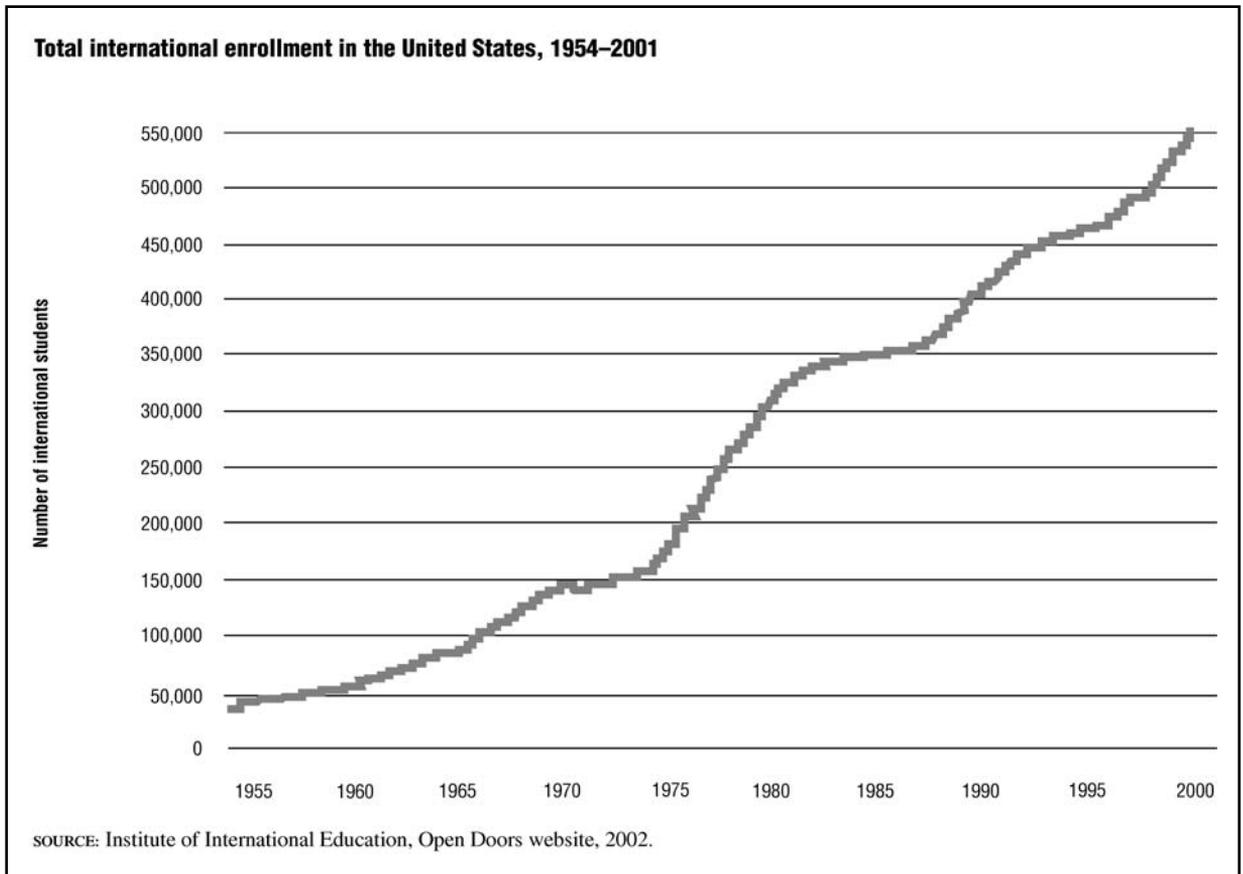

Under autocratic governments, there was little need to explain education policy to the public. Educational policy consisted of edicts of intent and orders for administrative action that may or may not have been carried out effectively. Mechanisms for public debate did not exist. The performance of educational institutions was not open to public scrutiny. Data and other information on program effectiveness were not required. The curriculum was imposed; the goals of civics and history were decided unilaterally. If problems occurred, public officials were not held accountable.

New democracies have emerged in South Africa, Europe and Central Asia, Latin America and the Caribbean, and East Asia. With democracy, the requirements of educational management shift. The effectiveness of educational institutions is open to public scrutiny for the first time, and education policy is the subject of heated public debate. To be effective, policy requires public awareness and consensus prior to any announcements. Institutions have come to be in the position of competing for new resources, new faculty, and new curricula to keep abreast of quickly changing public demands.

Educational systems in the new democracies are faced with problems even more serious than that of efficient management. In many countries, curricular authority has been localized to the region or the local school. In some instances, such as in Bosnia, this has led to serious disagreements over the role of the school itself. Such disagreements have included the content of history and civics, the use of pedagogy counterproductive to interethnic harmony, and the existence of barriers to the equality of educational opportunity for particular ethnic and social groups. In many instances, schools and school systems have been engaged in performing functions exactly the opposite of their traditional intent. Instead of resolving differences across social groups, schools have been used to exacerbate those differences.

### **The Influence of Financial Austerity on Educational Governance**

School systems differ from one country to another, but all share certain characteristics. All school systems share the universal struggle to balance the rapidly changing demands for improvement with the equally problematic realities of fiscal constraints, a permanent and unsolvable dilemma. The demand for mass access, higher levels of equity (for the socially excluded), and higher quality (for everyone) inevitably exceeds financial capacity. These universal demands make all schools and all school systems conscious consumers of educational policy innovations. The key difference in the early twenty-first century, compared to two decades previous, is the growing recognition that relevant innovations may emerge from anywhere; they are not necessarily local or even domestic. This new era in international education is led by the burgeoning realization from active consumers—teachers, school and university managers, and system administrators—that their success may well depend on having the most com-

**FIGURE 1**

pellling innovations, and that they are quite capable of making their decisions on whether geographical origin is a critical factor or not.

As a result, new policies have become common in widely disparate localities—including such policies as focusing on the quality and relevance of teaching materials that are procured from an open and competitive market; developing a professional force in which more effective teachers receive higher compensations; conducting research that allows for transparent comparisons that are available to the public; and securing financing from multiple sources to maximize local investment without abrogating equity. Educational managers around the world have become focused on common problems such as school-based management, teacher incentives, multicultural education, civic responsibilities, tracking, curriculum depth, individualized instruction, fair testing and assessment, special learning problems, and communications with the public.

Higher education has become mass education—it is no longer only for the elite. In the 1960s, in no

country in western Europe was more than 9 percent of the age cohort enrolled in higher education; by the early twenty-first century, however, no country in the region enrolled fewer than about 35 percent of the age cohort. This shift has been associated with common, if not identical, fiscal and administrative pressures. These in turn have generated demand for creative policy reforms. Demand exists for innovations in institutional efficiency in terms of student–faculty ratios, judicious use of new technologies, efficiency in generating contractual outsourcing of traditional functions, department-based budgeting, marketing of university copyrights, and attention to the problems of international trade in education commerce.

In terms of size, the U.S. education system accounts for less than 5 percent of world enrollment. Together, industrialized countries account for about 17 percent. The remaining 83 percent of the world’s enrollments are located in the middle-income and developing countries, with 57 percent enrolled in East and South Asia. Each of these “nonindustrial-

ized” countries is changing rapidly. As economies grow, more is spent on students. Unit expenditures across the world doubled between 1980 and 1994, but different regions showed different rates of growth. Expenditures doubled in the United States, but they increased by 135 percent in Europe and 200 percent in East Asia. In terms of challenges and dilemmas, the world’s education systems share more than ever before.

These common challenges imply several things. First, the demand for innovative policies in education is growing rapidly, and their source is no longer confined to one country’s experience. This is particularly important for the United States, which has a high demand for policy innovation, yet a small portion of the world’s education experience from which to draw lessons. To attain excellence today the education profession must keep abreast of relevant innovations and educational experience from wherever they derive.

But these trends imply something else as well. With the common decentralization of decision-making, the client for educational research and policy innovation is not limited to central or public authorities. There are many different demands for good ideas and information, and therefore many different clients to decide what is relevant. Local school officials in Minnesota, for example, have opted to join international studies of academic achievement so they might compare their educational performance with Sweden and Singapore. The American Federation of Teachers has studied the degree to which American high-stakes tests compare with those in Europe and Asia. These examples illustrate

that traditional notions of what is relevant to local school systems are constantly being retested with new information but are also in the hands of an increasingly diverse set of local educational clients and decision makers.

### **The Influence of International Students on Education Policy**

In 1960 there were only 50,000 international students in the United States. The number of international students in the United States rose steadily thereafter, reaching a record high of 549,000 in 2001 (see Figure 1). Final year expenditures on tuition and fees by international students in the United States reached \$11 billion in 2001. Of those expenditures, approximately 66 percent were derived from personal and family sources. At the undergraduate level (i.e., for 254,000 students), family support accounted for 81 percent (see Table 1). While American higher education may be expensive by world standards, a large number of families outside the United States can afford it. Because of its potential, international education is now classified as a traded service by the U.S. Department of Commerce and has become the nation’s fifth-largest service export.

More than one-half of the foreign students in the United States come from Asia, with students from China and India together accounting for more than 25 percent alone (see Table 2). Most are in the United States to study for utilitarian purposes. The proportion of international students studying humanities is only 2.9 percent; fine arts, 6.2 percent; and social sciences, 7.7 percent. Almost one-half of the foreign students are “crowded” into three fields:

TABLE 2

**International students in the United States by leading country of origin**

Place of Origin	1999–2001	2000–2001	Percent Change	Scholar Total
World Total	74,571	79,651	6.8	
China	13,229	14,772	11.7	18.5
Japan	5,460	5,905	8.2	7.4

19.4 percent are in business and management, 15.2 percent in engineering, and 12.4 percent in mathematics and computer sciences. Human resources are becoming more popular, with health at 4.1 percent and education at 2.6 percent of the total (see Table 3). Just as demand is growing for students to study in the United States, demand by American students to study abroad, even temporarily, is growing. From 1985 to 1999, the number of American students studying abroad increased from 45,000 to 140,000 (see Figure 2). These figures reflect high demand. But is the demand for higher education institutions in the United States as high as it is for higher education institutions outside the United States? In other words, in terms of attracting international students, does U.S. higher education continue to be competitive with higher education elsewhere?

In fact the trade in higher education outside the United States is growing faster. Since 1990 the share of international students studying within the United States dropped from 40 percent to less than 30 percent. And as a proportion of the overall student population, in 2001 the international student population in the United States (3.9%) was not that much greater than it was in 1954 (1.4%). As a percentage of the overall student population, in fact, the United States

ranked twelfth among OECD countries in 1998. The international student proportion in Switzerland that year was 16 percent; in Australia, more than 12 percent; in Britain, about 11 percent; in Germany, about 8 percent; and in France, about 7 percent (see Figure 3).

These figures suggest that international education has become openly competitive and that the United States does not have as large an advantage as it once did. The figures would also suggest that given their proportion of the overall student population, the “impact” of international students in the United States is modest by comparison to the situation that some of its trading partners face.

### Cross-National Sources of Statistical Information

In spite of the inevitable political emphasis on the Olympic nature of cross-national studies, countries are beginning to participate because the lessons derived have proven to be insightful and to stimulate new questions and ideas for improvement. Many have learned that the lessons in one country are not identical to the lessons elsewhere. For example, with respect to the Third International Mathematics and Science Study (TIMSS), Americans drew conclusions about the curriculum being “a mile wide and an inch deep” (Schmidt, p. 3), but Colombians drew conclusions about the range of age within each grade level; Latvians drew conclusions about differences between Latvian and minority students. All countries seemed to draw conclusions about the manner in which subject matter is sequenced. Moreover, it is common to sponsor reanalyses of the datasets, which often result in new insights. For instance, Americans must now ponder why their disadvantaged perform worse than the disadvantaged in other participating countries and why school resources are more inequitably distributed than in other countries.

International standards have been greatly enhanced by the procedures and the results of cross-national studies. Achievement studies around the world have learned from the three different elements used in TIMSS: what one expects to be learned, what has been taught, and what has been learned. The new studies have tried to include case examples and videotape episodes, as well as both cross-sectional and time-series surveys. This experience has helped mitigate the long-standing unproductive battles between quantitative and qualitative evidence; all evidence

TABLE 3

has its strengths and weaknesses, and the principles governing the use of data have become largely understood to be universal. International standards of data collection, reporting, quality control, sampling, the impartiality of questionnaire design, first proposed by the authorities within the United States, have been established and widely accepted, and this has led to questioning and then strengthening of the international institutions that support education data collection and dissemination.

### Future Issues

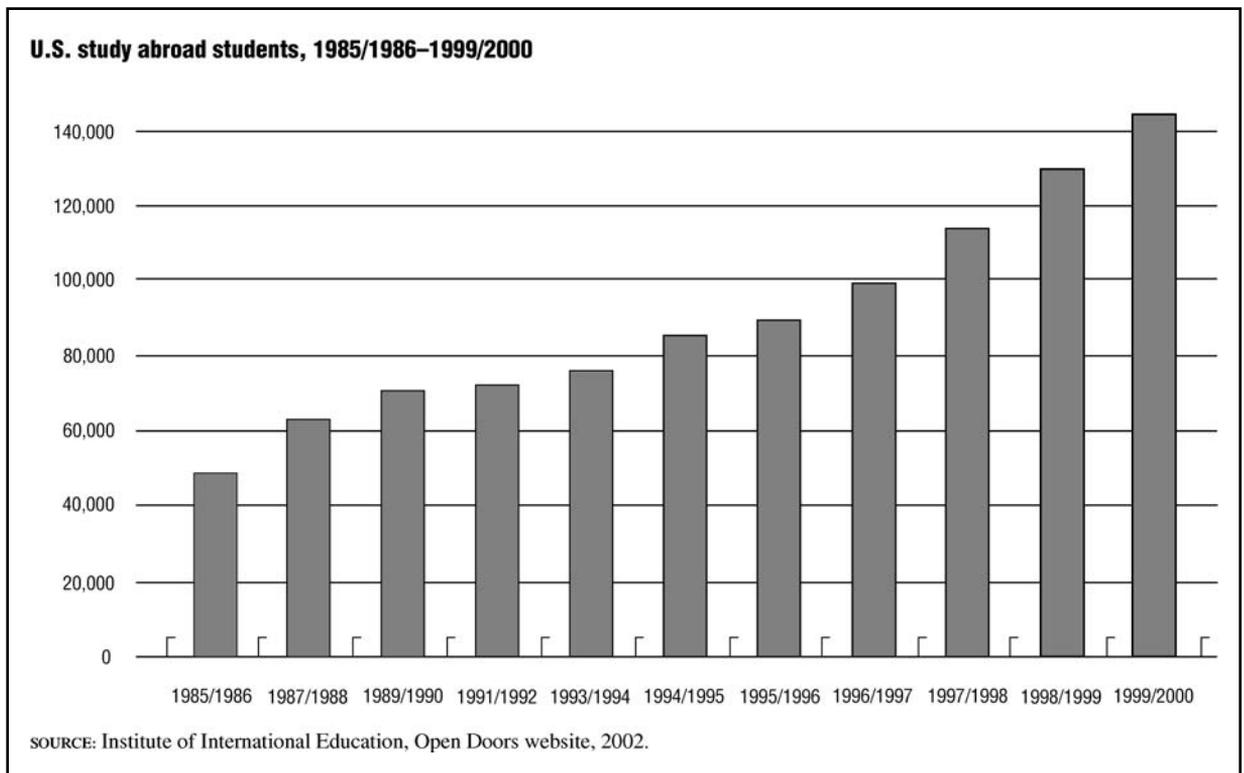

The institutional structure underpinning international education data collection remains fragile. There is no consensus about how financial support for international data collection should be obtained in a fashion that is fair to all countries. Now considered a trade good, education is the source of debate surrounding the World Trade Organization. Are there indeed barriers to the trade in education, or is education a “cultural good” falling within the purview of each nation independently? It is clear that as a separate field of study, international education has shifted. No longer is it viable as an esoteric field of study. Instead, international experience is becoming a normal part of all fields of study—curriculum, administration, human development, and pedagogy. But graduate schools of education, particularly in the United States, are not well-equipped to respond to this new set of demands and will have to undergo a significant, and perhaps painful, adjustment to catch up with the field itself.

## INTERNATIONAL EDUCATION AGREEMENTS

---

The term *international agreement* refers to an international treaty, declaration, or recommendation adopted by the governments of many different countries in order to set out certain principles or courses of action in a selected field, or set of fields, of mutual interest. Countries sign international agreements on many things, such as travel and health regulations, telecommunications, air and ship navigation, and labor practices. The earliest such agreements in the field of education were adopted in the period between the first and second world wars, and many more have been adopted since then. Most

have their origins in the work of international organizations. In some cases they form part of broader agreements that also cover other fields, as in the case of the Universal Declaration of Human Rights (1948). Broadly speaking, their purposes and scope reflect the context of international relations prevailing at the time they were drawn up.

An analysis of these agreements could take any one of several alternative approaches. A historical approach is used here in order to draw attention to both the accumulation of these agreements over time and the possibility that countries have found it easier to adopt new agreements than to implement old ones. The focus is on agreements that are basically worldwide in scope, and not just confined to countries in a particular geographical region. The full texts of all the agreements specifically mentioned here can be consulted at the websites of the United Nations and the United Nations Educational, Scientific and Cultural Organization (UNESCO).

### International Agreements in General

International agreements can be classified according to the level or degree of commitment that countries formally accord each agreement's implementation. The most demanding level is that of an *international treaty*, sometimes referred to as an *international convention* or *covenant*. Treaties typically require a formal signature by representatives of the countries concerned, and they are considered, under international law, to be legally binding on the countries (states) that ratify (accede to) them. The countries that are party to an international treaty normally need to ensure that the terms or provisions of the treaty are reflected in their national legislation.

Certain international treaties have as their purpose the setting up of an intergovernmental organization. An example is the treaty signed in San Francisco in 1945 that set up the United Nations. Another example is the treaty drawn up and adopted by a group of countries in London in 1945 that established UNESCO. Countries that accede to the United Nations and UNESCO treaties undertake to pay dues (assessed financial contributions) to these organizations, and to abide by these organizations' constitutions.

International treaties are normally drawn up and adopted by international conferences of states (so-called diplomatic conferences). They usually come into effect when an agreed number of states in

each case has formally ratified them, which can sometimes be several years after the treaty was originally adopted, depending on how rapidly individual states are able to incorporate the treaty in their national legislation. In the case of education, most international treaties since 1945 have been drawn up and adopted by diplomatic conferences convened either by the United Nations or by UNESCO. No international treaty concerning education was adopted before 1945.

International treaties usually include a provision for states to report to a *treaty body* on measures taken to ensure their implementation. In the case of treaties adopted under the auspices of the United Nations, for example, the latter has established committees, such as the Human Rights Committee and the Committee on Economic, Social and Cultural Rights, to serve as treaty bodies.

Diplomatic conferences are also convened from time to time for the purpose of drawing up and adopting less demanding forms of agreement, such as an international *declaration* or *recommendation*. Broadly speaking, declarations tend to focus on principles that should guide action, while recommendations tend to focus on courses of action, although this distinction is not always clearly apparent. The states concerned formally undertake to make their best efforts to abide by the provisions of the declaration or recommendation in question, without necessarily agreeing to adopt specific legislative measures as might be required by a treaty. The declarations, recommendations, and treaties adopted by international conferences of states are generally referred to in diplomatic parlance as international *normative instruments*.

Other types of agreement include resolutions adopted by the member states of international organizations, as well as international declarations and recommendations of an essentially nonformal character that representatives of countries have expressed their support for without formally committing their respective states to abide by. The latter are typically drawn up and adopted by consensus at nondiplomatic conferences that have a mixed composition of participants, often including representatives of international organizations and nongovernmental organizations as well as of governments. Probably the best-known example in the field of education is the World Declaration on Education for All, adopted by the World Conference on Education for All, held in Jomtien, Thailand, in 1990. Such

conferences have also tended to adopt a plan or program of action for implementation of the declaration or recommendation specifying how the various parties concerned will work towards the agreed goals or objectives. In some cases, agreement has also been reached on the establishment of a mechanism to monitor implementation.

### The Years between the Wars, 1918–1939

With two or three exceptions, the international education agreements adopted during the period between the two world wars were generally of a nonformal character. The exceptions were in the form of resolutions adopted by the General Assembly of the League of Nations, the forerunner of the United Nations set up by the peace conference that followed World War I. The majority were in the form of recommendations adopted by successive international conferences organized by the International Bureau of Education (IBE), a hybrid nongovernmental/intergovernmental body established in Geneva in 1926.

The idea of governments adopting agreements concerning education emerged from the broader movement of opinion among the leaders of the major industrial countries after World War I in favor of new approaches to the challenge of fostering international understanding and peace. The League of Nations was conceived in this spirit as a permanent mechanism of consultation between states, essentially for the purpose of overcoming misunderstandings and disagreements before they could develop into armed conflict. A key concept of the League was that such consultation should not be just a matter of diplomatic contacts between ministries of foreign affairs, but should also include contacts between the national administrations responsible for matters that were often the basic sources of misunderstanding and disagreement between countries, such as commerce and trade, communications, travel, employment, and health. Various subsidiary organs of the League were established in order to facilitate cooperation between countries in certain of these fields.

Education was not specifically mentioned in the treaty setting up the League, although at the peace conference that drew up the treaty, some countries had favored its inclusion. Others felt that education was mainly an internal matter. Nevertheless, at its first session in 1920 the League's General Assembly adopted a resolution calling for the League's (execu-

tive) Council to examine a closely related question, that of “international intellectual co-operation,” which the resolution’s sponsors (Belgium and France) considered to be highly relevant to the task of developing a spirit of understanding, cooperation, and peace among nations. In the following year the League established an International Commission on Intellectual Co-operation, composed of eminent personalities in the sciences and humanities from different countries and charged with advising the council on measures that governments could take with a view to stimulating international cooperation among scientists, artists, philosophers, writers, and other groups of intellectuals, in furtherance of the League’s overall objectives.

This opened a door for the League of Nations to enter somewhat indirectly into educational matters. Thus, one of the early actions taken by the League’s General Assembly was its adoption in 1923 of a resolution calling upon countries to encourage the teaching of the goals of the League and the ideals of international cooperation to young people. However, in the absence of a formal mandate in education, the scope for further initiatives by the League in this field was limited. In the years remaining up until the outbreak of World War II, the only other instance of such an agreement being reached by the League’s General Assembly was the adoption of a resolution in 1935 calling upon countries to encourage the teaching of history for peaceful purposes.

In the meantime, however, the French government (with the League’s blessing, though not its financial support) had set up a body, the International Institute of Intellectual Co-operation, for the purpose of carrying out operational activities in areas of concern to the commission. These indirectly had an educational dimension, if only because international intellectual cooperation partly concerned international cooperation between educational institutions, such as universities, that in most countries were the main centers of intellectual life. The institute became active in promoting exchanges between researchers in different countries, in both the sciences and humanities, and in promoting international cooperation between universities, particularly with regard to teacher and student exchanges and the mutual recognition of degrees and diplomas. Much of this work was to be taken up after World War II by UNESCO.

The absence of a mandate for the League of Nations to get involved in educational matters did not

preclude the League’s members from showing an interest in another framework of cooperation in this field, which came to be provided by the IBE. The IBE was established in Geneva in 1926 as an offshoot of the University of Geneva’s School of Education (Institut Jean-Jacques Rousseau), one of the main centers in Europe of the New Education movement, a body of educational thinking closely associated with the ideas of John Dewey and the Progressive education movement in the United States. Originally conceived as an international nongovernmental clearing-house of educational research and documentation, the IBE revised its statutes in 1929 so as to permit governments to become members, and it was soon discovered that there was widespread latent support for the creation of some kind of forum in which national educational policymakers could exchange views and experiences concerning educational developments in their respective countries.

From 1934, therefore, the IBE undertook to organize an annual conference, the International Conference on Public Education, open to any country that wished to participate. More than thirty countries sent delegations to the first conference, and the attendance increased at subsequent conferences. Delegations were invited to present reports on recent educational developments in their countries, and to participate in a general debate on educational themes selected by the IBE for examination by the conference. The themes (usually three) were selected with a view to addressing current policy issues of concern to conference participants. At the first Conference, for example, the themes were Compulsory Education and the Raising of the School Leaving Age; Admission to Secondary Schools; and Economies in the Field of Public Education. Later conferences examined themes such as The Professional Training of Elementary School Teachers (1935); School Inspection (1937); and The Organization of Preschool Education (1939). In order to give a structure to the debates, the IBE also prepared ahead of the conference a draft recommendation on each theme setting out policies that the conference could consider as likely to help advance the development of education. At the end of its proceedings, the conference would adopt by consensus a final version of each recommendation, taking into account any amendments suggested during the debate.

The spirit that drove the conferences was basically that of the New (or Progressive) Education thinking associated with the IBE: expansion of edu-

cational opportunities and the promotion of more child-centered pedagogies. The recommendations were nonformal and purely advisory, and it was accepted that countries would adapt them to their individual circumstances. Their usefulness for participants (generally ministries of education) probably lay in the broad stamp of international approval that they accorded to policies that most countries were inclined to pursue anyway. Significantly, the majority of the recommendations concerned the organizational and administrative aspects of education rather than its contents, which would have been more difficult to handle politically.

### **Agreements since the End of World War II**

The success of the IBE's conferences was probably a factor in the interest among a number of countries, even before the war was over, in the possibility of future international cooperation on educational matters. Towards the end of the war, at the initiative of the British government, a standing Conference of Allied Ministers of Education was formed in London to discuss the tasks of educational reconstruction and cooperation that countries would need to undertake after the war. This body soon coalesced around proposals for establishing an intergovernmental educational and cultural organization, with scientific cooperation being added later. In the meantime, the United States had initiated a process of international negotiations and discussions with a view to setting up the United Nations Organization, the purposes of which were envisaged in Article I of the organization's charter to include, besides the maintenance of "international peace and security" and the development of "friendly relations among nations," the achievement of "international cooperation in solving international problems of an economic, social or humanitarian character, and in promoting and encouraging respect for human rights and for fundamental freedoms for all without distinction as to race, sex, language, or religion." The San Francisco treaty containing the charter came into force in October 1945. The London treaty containing the constitution of UNESCO came into force in November 1946.

Under Article I of its constitution, UNESCO was basically conceived by its founders as complementary to the United Nations:

The purpose of the Organization is to contribute to peace and security by promoting collaboration among the nations through

education, science and culture in order to further universal respect for justice, for the rule of law and for the human rights and fundamental freedoms which are affirmed for the peoples of the world, without distinction of race, sex, language or religion, by the Charter of the United Nations.

In accordance with their founding instruments, the United Nations and UNESCO have been responsible for initiating most of the international agreements concerning education that have been adopted since the end of World War II. However, in one important respect their founding instruments were incomplete, because the U.N. Charter in particular (to which the UNESCO Constitution refers) does not actually spell out anywhere what the "human rights and fundamental freedoms" are that the United Nations is mandated "to achieve international cooperation . . . in promoting and encouraging respect for." This task was considered at the time to be too complex for the San Francisco conference to handle, and was therefore deferred until a later date. It was taken up by the United Nations itself shortly after the organization came into being, and was to result in the proclamation of the Universal Declaration of Human Rights by the U.N. General Assembly in December 1948.

In adopting the declaration, the opening words of which affirm that "recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family is the foundation of freedom, justice and peace in the world," countries have accepted a set of principles, covering a vast range of human endeavor, that the organizations of the United Nations system are required under their statutes to encourage member states to put into practice. The principles directly relating to education are set out in the declaration's Article 26:

(1) Everyone has the right to education. Education shall be free, at least in the elementary and fundamental stages. Elementary education shall be compulsory. Technical and professional education shall be made generally available and higher education shall be equally accessible to all on the basis of merit. (2) Education shall be directed towards the full development of the human personality and to the strengthening of respect for human rights and fundamental freedoms. It shall promote understanding, tolerance and friendship among all nations,

racial or religious groups, and shall further the activities of the United Nations for the maintenance of peace. (3) Parents have a prior right to choose the kind of education that shall be given to their children.

Virtually all international agreements concerning education adopted since 1948 have owed at least part of their contents to this article, whether or not the agreement has been specifically focused on human rights or on related questions of international concern such as peace and development.

The agreements fall into two groups: those that deal with education along with several other fields, and those that essentially are confined to education. The former correspond broadly to the agreements adopted under the auspices of the United Nations, and the latter to those adopted under the auspices of UNESCO. A comprehensive listing of the various agreements follows, with brief comments on selected aspects of their contents. Particular attention is given to the treaties, since they represent the strongest degree of commitment by countries.

**United Nations agreements.** The agreements adopted under the United Nations' auspices are considered first, beginning with the treaties. The three main treaties that contain provisions concerning education are the International Covenant on Economic, Social and Cultural Rights (1966), the Convention on the Elimination of All Forms of Discrimination against Women (1979), and the Convention on the Rights of the Child (1989). Another treaty, the Convention on the Elimination of All Forms of Racial Discrimination (1965), requires the states parties (nations that have ratified a covenant or convention) to eliminate "racial discrimination in all its forms" in regard to "the right to education and training," among several other rights, but does not elaborate further on the matter.

The International Covenant on Economic, Social and Cultural Rights (1966) has a much broader scope than the other treaties. It emerged directly from the process of drawing up the Universal Declaration of Human Rights, following a decision of the United Nations Economic and Social Council that the principles enunciated in the declaration should be transformed into treaty provisions establishing legal obligations on the part of each ratifying state. The prevailing view was that two separate treaties or covenants were needed, one dealing with civil and political rights, and the other with economic, social,

and cultural rights, the rationale being that civil and political rights could, in principle, be secured immediately, whereas economic, social, and cultural rights could be achieved only progressively, according to each state's available resources. The preparation of the International Covenant of Civil and Political Rights and the International Covenant of Economic, Social and Cultural Rights was very laborious, given the legal issues involved for each member state, and took nearly eighteen years. The covenants were adopted in their final form by the General Assembly in December 1966. Another decade was to pass before they came into force. They have substantially influenced all subsequent international treaties relating to human rights.

The Covenant of Civil and Political Rights mentions education in paragraph 4 of its Article 18, which declares that "The States Parties to the present Covenant undertake to have respect for the liberty of parents and moral education of their children in conformity with their own convictions." Article 13 of the Covenant on Economic, Social, and Cultural Rights basically restates paragraph 4 of Article 18 of the Covenant on Civil and Political Rights. However, there are certain differences. Thus, it provides for "the progressive introduction of free education" in secondary and higher education, and requires the states parties to the covenant "to have respect for the liberty" of parents and guardians "to choose for their children schools, other than those established by the public authorities, that conform to such minimum educational standards as may be laid down or approved by the State." It also requires the states parties to recognize that "the development of a system of schools at all levels shall be actively pursued, an adequate fellowship system shall be established, and the material conditions of teaching staff shall be continuously improved." Under Article 14, the states parties that have not already instituted a system of free and compulsory primary education undertake to do so "within a reasonable number of years." As of February 8, 2002, the covenant had been ratified by 145 states.

The other two treaties mentioned above were intended to focus on particular categories of persons deemed to be especially in need of support and protection. The Convention on the Elimination of All Forms of Discrimination against Women (1979) deals with education in its Article 10. The provisions of this article are based in part on the Covenant on Economic, Social and Cultural Rights, as well as an

earlier UNESCO convention (the 1960 Convention against Discrimination in Education), but they enumerate in detail specific conditions that the states parties shall apply in order to “ensure” to women “equal rights with men,” such as “the same conditions for career and vocational guidance, for access to studies and for the achievement of diplomas in educational establishments of all categories, . . . access to the same curricula, the same examinations, teaching staff with qualifications of the same standard and school premises and equipment of the same quality, . . . the elimination of any stereotyped concept of the roles of men and women at all levels and in all forms of education,” as well as several other conditions of a similar nature. As of February 8, 2002, this convention had been ratified by 168 states.

The Convention on the Rights of the Child (1989) deals with education in Articles 28 and 29. Article 28 is largely a development of Article 13 of the International Covenant on Economic, Social and Cultural Rights, while focusing specifically on the child (essentially defined as a person below eighteen years of age). However, it differs from the covenant by certain omissions and additions. A significant omission is any mention of the “progressive introduction of free education” in respect to higher education. The convention states simply that higher education shall be made “accessible to all on the basis of capacity by every appropriate means.” A significant addition is the requirement that states parties take action with a view to achieving the right of the child to education “on the basis of equal opportunity,” a notion that first appeared in an international instrument in UNESCO’s constitution. Another addition is the requirement that “States Parties shall take all appropriate measures to ensure that school discipline is administered in a manner consistent with the child’s human dignity and in conformity with the present Convention.” Yet another addition is the requirement that “States Parties shall promote and encourage international cooperation in matters relating to education, in particular with a view to contributing to the elimination of ignorance and illiteracy throughout the world and facilitating access to scientific and technical knowledge and modern teaching methods. In this regard, particular account shall be taken of the needs of developing countries.” Article 29 deals mainly with the purposes of education. It basically reiterates the provisions of the covenant, but adds that “States Parties

agree that the education of the child shall be directed to . . . the development of respect for the child’s parents, his or her own cultural identity, language and values, for the national values of the country in which the child is living, the country from which he or she may originate, and for civilizations different from his or her own,” as well as “the development of respect for the natural environment.” As of February 8, 2002, this convention had been ratified by 191 states—all the member states of the United Nations except for Somalia and the United States of America.

The main declarations adopted by the United Nations containing provisions concerning education are the Declaration of the Rights of the Child (1959); the Declaration on the Promotion among Youth of the Ideals of Peace, Mutual Respect and Understanding between Peoples (1965); the Declaration on the Elimination of Discrimination against Women (1967); the Declaration on Social Progress and Development (1969); the Declaration on the Rights of Mentally Retarded Persons (1971); the Declaration on the Rights of Disabled Persons (1975); the Declaration on the Rights of Persons Belonging to National or Ethnic, Religious and Linguistic Minorities (1992); the Declaration and Programme of Action on a Culture of Peace (1999); and the Millennium Declaration (2000). In addition, certain other declarations containing provisions concerning education have been adopted by international conferences of states convened by the United Nations, notably the Proclamation of Teheran adopted by the International Conference on Human Rights (1968); the Rio Declaration on the Environment and Development (1992); the Vienna Declaration and Programme of Action of the World Conference on Human Rights (1993); the Declaration and Programme of Action of the World Summit for Social Development (1995); and the Beijing Declaration and Platform of Action of the Fourth World Conference on Women (1995).

As their titles indicate, the various declarations fall into two broad categories: those focusing on human rights as such and/or the rights of a particular class of persons (e.g., children, women, mentally retarded and disabled persons, persons belonging to various kinds of minorities) deemed to be especially in need of protection and support; and those focusing on particular aspects of the international context (e.g., peace, development, and the environment). Certain of the declarations in the first category were followed up later by treaties (e.g., Rights of the

Child, Elimination of Discrimination against Women). The declarations in the second category have been less amenable to follow-up by treaties, in part because they deal with matters that have been much more open to ideological and political disagreement among countries. Particularly during the cold war, declarations and resolutions of the United Nations concerning peace were open to controversy over the relative priority, if any, to be accorded to peace versus human rights. The declarations relating to the environment and social development, however, have been relatively free of controversy.

The United Nations General Assembly has also from time to time adopted resolutions proclaiming an *International Day, Year, or Decade* relating to education, the purpose being to focus world opinion on a particular aspect of education considered to be deserving of attention and support. Examples include International Literacy Day (September 8), World Teachers Day (October 5), International Literacy Year (1990), and United Nations Decade for Human Rights Education (1995–2004).

**UNESCO agreements.** Turning to the international agreements adopted under UNESCO's auspices, it may first be noted that UNESCO undertook to convene the International Conferences on Public Education jointly with the IBE from 1947 onwards, thus assuming a share of the responsibility for the recommendations adopted by these conferences. The IBE was formally incorporated into UNESCO in 1969, after which the conferences were convened biennially (as International Conferences on Education) up until 1997, and irregularly since then. The International Institute of Intellectual Co-operation, which had been partly involved with education before the war, closed down at the end of 1946.

UNESCO has adopted three international and several regional treaties directly concerning education. The international treaties are the Convention against Discrimination in Education (1960); the Protocol Instituting a Conciliation and Good Offices Commission to Be Responsible for Seeking the Settlement of Any Disputes which may Arise between States Parties to the Convention against Discrimination in Education (1962); and the Convention on Technical and Vocational Education (1989). The regional treaties are agreements relating to the recognition of studies, diplomas, and degrees in higher education.

Two early treaties indirectly relating to education may be noted: the so-called Beirut and Florence

Agreements adopted by UNESCO's General Conference at its third and fifth sessions held, respectively, in those two cities. Their titles indicate their nature: the Agreement for Facilitating the International Circulation of Visual and Auditory Materials of an Educational, Scientific and Cultural Character (1948); and the Agreement on the Importation of Educational, Scientific and Cultural Materials (1950). Although both are designed to promote international cooperation in education, science and culture, they are essentially concerned with reducing tariff, tax, currency, and trade obstacles to the international circulation of the materials indicated in their titles, and thus are, in effect, tariff and trade instruments falling within the scope of the World Trade Organization. With the expansion of electronic commerce in education (cross-border distance education), the two instruments are likely to become better known to national educational policymakers in the future.

The Convention against Discrimination in Education (1960) was the first international treaty to be adopted concerning education as such, except for the London treaty that established UNESCO. It was basically designed to transform the principle of non-discrimination contained in Article 2 of the Universal Declaration of Human Rights into legal obligations pertaining specifically to education, while also taking into account the provisions of the declaration's Article 26 concerning the right to education, as well as the principle of "equality of educational opportunity" affirmed in UNESCO's constitution. The convention influenced the provisions relating to discrimination in education that subsequently came to be included in all international treaties concerned wholly or partly with education, from the Convention on the Elimination of All Forms of Racial Discrimination (1965) down to the Convention on the Rights of the Child (1989). It was also the first international treaty to contain provisions dealing with parental choice and the rights of minorities in education, and in this regard its provisions remain the most comprehensive of any international treaty. As of February 8, 2002, this Convention had been ratified by eighty-four states. The protocol associated with the convention provides for the setting up of a mechanism for dealing with any charges that might be leveled by one country against another accusing it of bad faith in ratifying the convention but not attempting to implement it. As of February 8, 2002, the protocol had been ratified by thirty states.

The Convention on Technical and Vocational Education (1989) is the only international convention ever adopted concerning a specific level or sub-field of education. It was partly inspired by the provision in Article 26 of the Universal Declaration of Human Rights affirming that “technical and professional education shall be made generally available,” and partly by an earlier initiative of the International Labour Organization, which in 1975 had adopted a Convention and Recommendation on Vocational Guidance and Vocational Training. At that time, UNESCO had already adopted (in 1974) its Revised Recommendation concerning Technical and Vocational Education, but not yet a convention. Many of the provisions of UNESCO’s convention are in the nature of prescriptions or recommendations, rather than actions that the states parties specifically agree to undertake. As of February 8, 2002, this convention had been ratified by twelve states.

Aside from the treaties, and unlike the United Nations, UNESCO has historically tended to adopt recommendations rather than declarations. The main recommendations concerning education adopted by UNESCO’s General Conference are the Recommendation concerning the International Standardization of Educational Statistics (1958); the Recommendation against Discrimination in Education (1960; adopted at the same time as the Convention mentioned above); the Recommendation concerning Technical and Vocational Education (1962); the Recommendation concerning the Status of Teachers (1966); the Recommendation concerning Education for International Understanding, Cooperation and Peace and Education relating to Human Rights and Fundamental Freedoms (1974); the Revised Recommendation concerning Technical and Vocational Education (1974); the Recommendation on the Development of Adult Education (1976); the Revised Recommendation concerning the International Standardization of Educational Statistics (1978); the Recommendation on the Recognition of Studies and Qualifications in Higher Education (1993); and the Recommendation concerning the Status of Higher Education Teaching Personnel (1997). The purpose of these recommendations, as of those adopted by the International Conferences on (Public) Education, has essentially been to encourage countries to adopt wise policies and good practices in the relevant fields. Their adoption by UNESCO’s General Conference has been intended to give them more weight and validity than

the recommendations of the International Conferences on (Public) Education, since the former body is a conference of states, while the latter are basically just conferences of ministers of education. As indicated in the titles of some of the recommendations, it has been understood that the recommended policies and practices might need to be reconsidered later in the light of experience and changes in national and international circumstances.

From time to time UNESCO’s General Conference has also adopted resolutions that amount in effect to revised recommendations, though without being formally declared as such. In 1997, for example, it endorsed a new International Standard Classification of Education (ISCED-97) intended to replace an earlier version that had been endorsed by the Revised Recommendation concerning the International Standardization of Educational Statistics (1978).

UNESCO did not issue any recommendations concerning education during the 1980s. This was a period of controversy for the organization, marked by the withdrawal of the United States from the organization at the end of 1984 and the United Kingdom and Singapore at the end of 1985, in protest against what U.S. Secretary of State George Schultz, in his letter of withdrawal, said were “trends in the policy, ideological emphasis, budget and manpower of UNESCO [that] were detracting from the organization’s effectiveness [and were leading the organization] away from the original principles of its constitution.” A definitive study of the merit of these charges has never been made, although in regard to education it may be noted that after the end of the cold war UNESCO became more active in seeking to collaborate with other international organizations for the purposes of advancing its program in areas such as education for development and education for human rights. Two significant international agreements that were to result from this were the World Declaration on Education for All (1990) and the World Plan of Action on Education for Human Rights and Democracy (1993), adopted by the International Congress on Education for Human Rights and Democracy, held in Montreal. The Salamanca Statement (Declaration) on Special Needs Education (1994), adopted by the World Conference on Special Needs Education (jointly convened by UNESCO and the Spanish government in Salamanca, Spain, in June 1994) may also be noted, as well as a follow-up declaration (the Dakar Declaration on Education for

All) to the Jomtien Declaration mentioned above, adopted by the World Education Forum, an international conference convened by UNESCO jointly with its Jomtien partners in Dakar, Senegal, in April 2000.

### Implementation and Impact

A comprehensive study of the implementation and impact of the various international education agreements indicated above has never been undertaken. Since there are so many of these agreements, all of them overlapping to some extent, and all of them having varying degrees of support from the countries of the world, such a study would in any case be an extremely complex undertaking. Although UNESCO, under its constitutional mandate, could undertake such a study, it has largely confined its monitoring activity to the agreements adopted directly under its auspices. Monitoring of the various agreements adopted by the United Nations has been undertaken by the several treaty bodies established by the United Nations for that purpose. Their activities can be consulted at the website of the United Nations High Commissioner for Human Rights.

There are limits to the effectiveness of the existing monitoring mechanisms. The main ones are the dependence of these mechanisms on government-supplied information and the different degrees of readiness and capability of governments to supply information. Indeed, with the growing number of international agreements in education and other fields, there are signs of a *reporting overload* on governments. Thus, questionnaire surveys addressed by the monitoring bodies to the states parties to some of these agreements rarely elicit responses from more than half the countries concerned. Neither the United Nations nor UNESCO can do much about this, since the agreements are, in the last resort, purely voluntary, and both organizations are bound by their constitutions not "to intervene in matters which are essentially within the domestic jurisdiction of any state." It is only in countries with highly developed legal systems, as in western Europe, that ordinary citizens can effectively challenge their governments on questions relating to the implementation of international agreements, whether in education or other fields.

What, then, do they all add up to? Have the agreements had any effect on the worldwide development of education? Probably. The development that has occurred over the years since the Universal

Declaration of Human Rights was proclaimed has certainly been dramatic. In the late 1940s, only a minority of the world's young people had access to any kind of formal education, and little more than half the world's adults could read and write a simple passage about their everyday lives. In the early twenty-first century the great majority of the world's young people go to school, with nearly half of them enrolled in formal education beyond the elementary and fundamental stages, while around four out of five of the world's adults (though a larger percentage of men than of women) are estimated to have acquired at least some simple literacy skills. Doubtless much of this development would have occurred without any international agreements concerning education, but it is reasonable to suggest that the steady accumulation of such agreements, constituting, in effect, a broadly coherent body of international opinion committed to the expansion and equalization of educational opportunities, would have reinforced any secular trends (for example, rising income levels) tending to favor such development. The more that such agreements keep coming, each one affirming one or another aspect of the right to education, then the more difficult it becomes morally for countries to disregard this right.

Nevertheless, it is apparent that there is considerable variation among individual agreements in the degree of commitment that countries accord to their implementation, even among the treaties. Compare, for example, the Convention on Technical and Vocational Education (1990), with only twelve ratifications to date, and the Convention on the Rights of the Child, adopted in the same year, with 191 ratifications. It is also apparent that some agreements basically restate long-standing, but not fully implemented, earlier commitments. For example, both the Dakar Declaration on Education for All (2000) and the United Nations' Millennium Declaration (2000) expect universal primary education to be achieved in all countries by the year 2015, although the World Declaration on Education for All (1990) had earlier targeted the year 2000. The danger here is of a progressive devaluation of all education agreements if new ones are too readily adopted ahead of significant progress in implementing earlier ones.

### THE USE OF INDICATORS TO EVALUATE THE CONDITION OF EDUCATION SYSTEMS

Thomas M. Smith

David P. Baker

### OVERVIEW

Comparisons between the education system in the United States and the systems of other countries have become an established element of the public discussion about education policy and practice in the United States. Publications aimed at the education profession often include articles describing approaches in other countries that are relevant to education in the United States, such as a discussion of tuition tax credits in Canada in *Education Week* and a special section in the *Phi Delta Kappan* about early childhood education in Europe.

Why is this information useful? Simply put, countries outside the United States provide something akin to a natural social laboratory in which one can observe education policy, practices, and outcomes under a variety of different conditions and environments. Knowing whether education in one country is the same or different from education in other countries provides a useful perspective for better understanding a country's system, and is also a useful source of ideas. Comparisons of learning outcomes provide a measure of the effectiveness not possible with any other approach. Given the prominent role of statistics and indicators for policymaking in the United States, it is not surprising that statistics have become an important source of information for these comparisons. At the beginning of the twenty-first century rich sources of statistics are available that can be used to compare education in the United States with education in other countries. But this is a relatively new development.

## The Demand for International Education Statistics

As is the case for many aspects of history of education in the United States since the mid-1980s, the publication of *A Nation at Risk* in 1983 was a key event for setting the stage for change—in this case for strengthening international education statistics. A steady decline in national test scores during the 1960s and 1970s, coupled with the perception that foreign industrial and consumer products were superior, had led many Americans to question the performance of U.S. schools. An international perspective was central to the argument of *A Nation at Risk*, chief among the many reports prepared to document the problem. Citing the superiority of new manufactured goods from Japan, South Korea, and Germany, as well as the level of worker skill that these foreign products represented, the report proclaimed: “If an unfriendly foreign power had attempted to impose on America the mediocre educational performance that exists today, we might well have viewed it as an act of war” (p. 5). When presenting its list of indicators of the risk facing the country, the poor performance of U.S. students in international studies of achievement was the first item.

A second major event that increased the importance of international comparisons was the adoption of the National Education Goals in 1990. One of the six goals adopted by President George H. W. Bush and the nation’s governors was that “by the year 2000, United States students will be first in the world in mathematics and science.” Shortly after this announcement, the National Education Goals Panel was created and charged with producing a series of publications aimed at reporting national and state progress toward achieving the goals. This amplified the need to develop performance measures for the U.S. educational system in an international context, particularly in mathematics and science.

During this period, genuine concern about the future of the U.S. economy and the importance of looking outside of the United States for solving problems was a common theme of policy discussions in a variety of arenas. For example, the National Governors Association report *Time for Results* (1986) named global economic competition and poor performance of U.S. students (compared to those of other countries) as reasons why governors should take a more active role in education. *America’s Choice: High Skills or Low Wages* (1990), pub-

lished by the National Center on Education and the Economy, presented international comparisons of investment in employment and training policies and called for higher U.S. expenditures in this area.

But in spite of the prominence of international comparisons, it was widely recognized that the data were very weak. The reason that *A Nation at Risk* used studies that were a decade old was that they were the only ones available. Similarly, it was agreed that statistics comparing expenditures for education—which were relevant to perennial questions about costs—were not usable because of their low quality.

## Comparability

Why does the international dimension present a particular challenge for statistics of education? The central idea is the notion of comparability. For basic statistics about education at the national level in the United States, there is general agreement about what constitutes the things being measured or counted (e.g., schools, teachers, students, school subjects). Although the decentralization of governance and diversity of approaches and programs require that care be taken when making comparisons among states or local districts, the issue is compounded many times when dealing with making comparisons among countries.

There are many instances in the arena of international education statistics in which differences among countries in fundamental aspects of the system can put statistics in jeopardy of being inaccurate and misleading. In the United States, for example, public schools are financed by public funds and private schools by private funds (at least the vast majority of the funding), whereas many countries in Europe finance privately governed schools with public funds. Thus, counting funding of public schools as a measure of a nation’s financial support of education would be misleading. In many countries, it is common for staff considered to be teachers to also function in a position equivalent to a principal in small elementary schools. From the U.S. perspective, counting such staff members as teachers would lead to an overcount of staff resources devoted to teaching, an undercount of resources for administration, and misleading student–teacher ratios. Similarly, achievement tests that do not take differences in curricula and practices associated with testing and test-taking into account may inaccurately represent school learning.

In cases where there are common definitions and concepts, it is of equal importance to collect and process the data in a manner that captures the information desired. This often requires that countries recalculate national statistics based on these common definitions. Issues are even more complex when surveys are involved. For example, countries must agree on common practices for selecting comparable samples, setting acceptable response rates, and calculating response rates and margins of error. Another methodological issue is translation, which requires a high level of understanding of the concepts involved. Translation can even affect the difficulty of test items, a factor requiring attention in the development of international assessments.

During the 1980s, the generally weak comparability of the international education statistics prepared by the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the Organisation for Economic Co-operation and Development (OECD) was well known, and the published works received limited circulation and attention. The comparability of comparative studies of achievement was also routinely questioned. But with the demand created by the introduction of an international aspect to the education policy questions of the day, the need for improvement was clear.

### Country Collaboration

The United States was not alone in its interest in improved statistics for comparing education systems. Similar circumstances—particularly pressure on public services to demonstrate their productivity and efficiency and a new awareness of economic competitiveness in a global market—led to a growing interest in education statistics in other OECD countries. The OECD responded to this demand by initiating the Indicators of Education Statistics (INES) program after two preparatory meetings, one hosted by the U.S. Department of Education in 1987, and the other by the French Ministry of Education in 1988.

To improve the quality of international statistics, it was necessary to have the participation of individuals with deep knowledge of their national education systems, access to national data systems, and the motivation and commitment to collaborate on an ongoing basis with those from other countries. The INES project put these elements together. The Netherlands, Scotland, the United States, and Sweden contributed substantial resources to lead work-

ing groups on topics such as enrollment in education, finance, learning outcomes, labor force outcomes, school functioning, and attitudes about education. Australia, Austria, and France also made important financial contributions. Meeting at regular intervals, individual delegates, sponsored by their countries, worked through comparability issues and served as contact points in their countries for the preparation and submission of data prepared specifically to meet the international standards. The result was much-improved comparability and a quality-control process that was supported by peer review and the personal commitment of participants in the working groups. In addition, the participants gained expertise that enhanced their countries' resources for interpreting the statistics in a national context.

The OECD had extensive involvement in coordinating the process, collecting the data, and preparing and publishing a series of volumes of indicators under the title *Education at a Glance: OECD Indicators*. The first *Education at a Glance* (1992) was about 150 pages long, with parallel text in French and English, and several of the indicators were designated as provisional because of general questions about their validity or applicability. With succeeding years, new indicators have been added, as well as extensive background information relevant for interpreting the indicators. The 1995 and 1996 editions have annotated charts prepared by each country describing the organization of their education systems, including types and levels of schools and ages of students in each. The 2001 edition is almost 400 pages long, includes data from many non-OECD countries, and is available in English, French, and German. Selected editions of *Education at a Glance* have been translated into Czech, Italian, Japanese, Korean, and Spanish.

The establishment of the Program for International Student Assessment (PISA) highlights the importance of country collaboration in the development of international education statistics. To those working in the INES project, it quickly became clear that there was a lack of coherent data for indicators of student achievement. There was no extant database and no structure designed for governments to collaborate on an ongoing basis for regular data collections. Factors that needed to be overcome included major comparability issues ranging from conceptualization of outcomes to general survey practices; some countries' reluctance to publish indicators of achievement in a limited number of school

subjects; and the large cost associated with producing the indicators. After several years of ongoing discussions, a consensus was reached to set up a project in which for the first time, countries shared the central cost of developing and implementing the assessment (countries typically are responsible for the cost of local data collection). The effort is governed by a board composed of representatives of participating countries and managed by the OECD secretariat. It includes assessments at three-year intervals of reading, mathematics, and science literacy, and of selected cross-curricular competencies such as attitudes and approaches related to learning.

Among the many other accomplishments associated with the country collaboration through the INES project, two that stand out are improvements in the comparability of expenditure data and of the categories for different levels of education (e.g., primary, secondary, tertiary). In the case of the levels of education, UNESCO's International Standard Classification of Education (ISCED), developed during the 1970s, was revised to reflect various changes—for example, growth in continuing education and training outside of education institutions and programs that straddle the boundaries between upper secondary and postsecondary education, and a manual was developed to facilitate consistent interpretation of the new system.

Studies conducted by the International Association for the Evaluation of Educational Achievement (IEA) also involve collaboration among governments and researchers. Three studies that have contributed to the data available for international education statistics are the Third International Mathematics and Science Study (TIMSS), the Second Information Technology in Education Study (SITES), and the Civic Education Study (CivEd). The Civic Education Study, working in an area in which different countries have different notions about many of the concepts involved (such as democracy and participation of individuals in democracy), relied heavily on international teams throughout the entire project for identifying common core ideas, developing assessment items, and interpreting results.

### What Has Been Learned?

Because of the range and depth of international education statistics, it is impossible to provide more than a very brief summary in this limited space. What follows are a few illustrative highlights taken

from publications of the OECD, the IEA, and the U.S. National Center for Education Statistics (NCES). NCES publications include explanatory notes and background information useful for interpreting the material from a U.S. perspective. Readers are encouraged to consult the publications directly to find additional statistics relevant to their particular interests.

**Context of education.** It is widely recognized that there is a large association between poverty and school achievement. Among a large number of countries participating in one study, the United States had by far the largest percentage of youth who were poor.

**Participation in education.** Into the 1990s, there was a general impression that the young people remained enrolled in school longer in the United States than in other countries. However, statistics show that the percentage of those fifteen to nineteen years old and those twenty to twenty-nine years old enrolled in education in the United States is quite close to the average percentage among OECD countries.

**Expenditures.** The United States spends a similar percentage of its gross domestic product (GDP) on education as other countries. On a per pupil basis, its expenditures are among the highest for elementary and secondary education. In higher education, the U.S. also spends considerably more per student than any other OECD country.

**Teachers and teaching.** Teachers in the United States have the highest number of teaching hours, although teachers in a few other countries put in almost as many hours. The student–teacher ratio in the United States is similar to the average of OECD countries in elementary, secondary, and postsecondary education, with the exception of vocational postsecondary education, where there are fewer students per teacher in the United States than in most other countries.

**Learning outcomes for school-age youth.** On studies of mathematics and science achievement, U.S. students typically score lower in relation to other countries as they progress through the grades. Performance of fifteen year olds in the United States was similar to the average for countries participating in PISA in reading, mathematics, and science literacy tasks designed to reflect real-life situations (in contrast to school curriculum). Many countries have variation in achievement in the same range as that

of the United States, although some have less variation. Some countries with relatively little variation have high achievement, indicating that it is not necessary to “sacrifice” the bottom to have a high average score. Among countries participating in the IEA Civic Education Study, the United States is among the highest in knowledge of civic content among fourteen year olds, as well as the highest in civic skills, such as interpreting information.

**States and nations.** Because states have primary responsibility for education in the United States and are similar in size to many countries, comparisons between the states and other nations are of special interest to policymakers. Some U.S. states and school districts compare favorably in math and science with the highest-scoring countries, while others have scores in the same range as the lowest-performing ones. This pattern is repeated in other indicators that include both states and nations.

**Adult literacy.** Variation in adult literacy is strongly associated with income variation—countries that have a wider income distribution also have a higher percentage of adults in both high- and low-literacy groups, with the United States having the highest variation in both income and literacy.

### Conclusion

Increased demand in the mid-1980s for data to support solid comparisons among the education systems of different countries fueled major advances in the quality and quantity of international education statistics. These advances would not have been possible without an organizational structure that incorporated collaborative working relationships among statisticians and education professionals from different countries. This model was essential throughout the many phases of the work, including agreeing on common definitions of the concepts to be represented by statistics, developing methodologies for surveys and translation, and generating commitment and adherence to high standards and quality control. It will continue to be important to assure comparability as work proceeds to improve and broaden statistics in areas such as learning outcomes for students and adults, expenditures for education, teachers and teaching, and the relationship between education and the labor market.

## THE USE OF INDICATORS TO EVALUATE THE CONDITION OF EDUCATION SYSTEMS

The use of widely published *statistical indicators* (also referred to as *social indicators* outside the purely economic realm) of the condition of national education systems has in the early twenty-first century become a standard part of the policymaking process throughout the world. Uniquely different from the usual policy-related statistical analysis, statistical indicators are derived measures, often combining multiple data sources and several statistics, that are uniformly developed across nations, repeated regularly over time, and have come to be accepted as summarizing the condition of an underlying complex process. Perhaps the best known among all statistical indicators is the gross national product, which is derived from a statistical formula that summarizes all of the business activity of a nation's economy into one meaningful number. In the closing decades of the twentieth century, international statistical indicators of educational processes made considerable advances in quantity, quality, and acceptance among policymakers.

These cross-national indicators often have significant impact on both the public and the education establishment. In the United States, for example, the *New York Times* gives high visibility to reports based on indicators of where American students rank in the latest international math or science tests, or those revealing how educational expenditures per student, teacher salaries, or high school dropout rates compare across countries. National education ministries or departments frequently use press releases to put their own spin on statistical indicator reports such as the annual *Education at a Glance* (EAG), published by the Organisation for Economic Co-operation and Development (OECD). The use of indicators for comparisons and strategic mobilization has become a regular part of educational politics. Dutch teachers, for example, used these indicators to lobby for increases in their salaries after the 1996 EAG indicators of teacher salaries showed that they were not paid as well as their Belgian and German neighbors. Similarly, in the United States, comparisons of a statistical indicator of dropout rates across nations were used to highlight comparatively low high school completion rates in 2000. In an extreme, but illustrative, case, one nation's incumbent political party requested that the publication of the EAG be delayed until after parliamentary

election because of the potentially damaging news about how its education system compared to other OECD nations.

These examples of the widespread impact of international education statistical indicators are all the more interesting when one considers that an earlier attempt to set up a system of international statistical indicators of education during the 1970s failed. While attempts to create a national, and then an international, system of social indicators (known as the *social indicators movement*) faltered, early attempts by the OECD to develop statistical indicators on education systems fell apart as idealism about the utility of a technical-functionalist approach to education planning receded.

### History of Social Indicators

The social indicators movement, born in the early 1960s, attempted to establish a "system of social accounts," that would allow for cost-benefit analyses of the social components of expenditures already indexed in the National Income and Product Accounts. Many academics and policy makers were concerned about the social costs of economic growth, and social indicators were seen as a means to monitor the social impacts of economic expenditures. *Social indicators* are defined as time series that are used to monitor the social system, which help to identify change and to guide efforts to adjust the course of social change. Examples of social indicators include unemployment rates, crime rates, estimates of life expectancy, health status indices such as the average number of "health days" in the past month, rates of voting in elections, measures of subjective well-being, and education measures such as school enrollment rates and achievement test scores.

Enthusiasm for social indicators led to the establishment of the Social Science Research Council (SSRC) Center for Coordination of Research on Social Indicators in 1972 (funded by the National Science Foundation) and the initiation of several continuing sample surveys, including the General Social Survey (GSS) and the National Crime Survey (NCS). As reporting mechanisms, the Census Bureau published three comprehensive social indicators data and chart books in 1974, 1978, and 1980. The academic community launched the international journal *Social Indicators Research* in 1974. Many other nations and international agencies also produced indicator volumes of their own during this period. In the 1980s, however, federal funding cuts

led to the discontinuation of numerous comprehensive national and international social indicators activities, including closing the SSRC Center. Some have argued that a shift away from data-based decision making towards policy based on conservative ideology during the Reagan administration, coupled with a large budget deficit, helped to pull the financial plug on the social indicators movement. While field-specific indicators continue to be published by government agencies in areas such as education, labor, health, crime, housing, science, and agriculture, the systematic public reporting envisioned in the 1960s has largely not been sustained, although comprehensive surveys of the condition of youth have arisen in both the public and private spheres, such as those by the Annie E. Casey Foundation (2001) and the Forum on Child and Family Statistics (2001).

Some of the main data collections that grew out of the social indicators movement, including the GSS and NCS, continue, as do a range of longitudinal and cross-sectional surveys in other social areas. On the academic side, a literature involving social indicators has continued to grow, mostly focused on quality-of-life issues. While education is seen as a component of quality of life, it tends to be used in a fairly rudimentary fashion. For example, out of 331 articles published in *Social Indicators Research* between 1994 and 2000, only twenty-six addressed education with any depth. And although the widely cited Human Development Index compiled by the United Nations Development Programme has education and literacy components, these are limited to basic measures of school enrollments and, arguably, non-comparable country-level estimates of literacy rates, which are often based on census questions about whether someone can read or write. As a sub-field of social indicators, however, the collection and reporting of education statistics has expanded rapidly since the early 1980s in the United States, the early 1990s in OECD countries, and, more recently, in developing countries.

### **State of International Education Statistical Indicators Today**

Among the current array of statistical indicators of education within and across nations are some that go far beyond the basic structural characteristics and resource inputs, such as student-teacher enrollment ratios and expenditures per student, found in statistical almanacs. More data-intensive and statistically

complex indicators of participation in education, financial investments, decision-making procedures, public attitudes towards education, differences in curriculum and textbooks, retention and dropout rates in tertiary (higher) education, and student achievement in math, science, reading, and civics have become standard parts of indicators reports. For example, the OECD summarizes total education enrollment through an indicator on the average years of schooling that a 5-year-old child can expect under current conditions, which is calculated by summing the net enrollment rates for each single year of age and dividing by one hundred. Unlike the gross enrollment ratios (calculated as total enrollment in a particular level of education, regardless of age, divided by the size of the population in the “official” age group corresponding to that level) that have traditionally been reported in UNESCO statistical yearbooks, the *schooling expectancy* measures reported by the OECD aggregate across levels of education and increase comparability by weighting enrollment by the size of the population that is actually eligible to enroll.

Examples of other indicators that attempt to summarize complex issues into concise numerical indices include measures of individual and societal rates of return of investments in different levels of education, measures of factors contributing to differences in relative statutory teachers’ salary costs per student, and *effort indexes* for education funding, which adjust measures of public and private expenditures per student by per capita wealth. Furthermore, the OECD is working to develop assessment and reporting mechanisms to compare students’ problem-solving skills, their ability to work in groups, and their technology skills. There are few components of the world education enterprise that statisticians, psychometricians, and survey methodologists are not trying to measure and put into summary indicator forms for public consumption.

High-quality indicators require data that are accurate and routinely available. Behind the creation of so many high-quality indicators of national education systems is the routine collection of a wide array of education data in most industrialized countries. In addition to the costs of gathering data and information for national purposes, a large amount of human and financial investment is made to ensure that the data meet standards of comparability across countries. Country-level experts, whether from statistical or policy branches of governments,

frequently convene to discuss the kinds of data that should be collected, to reach consensus on the most methodologically sound means of collecting the data, and to construct indicators.

### Growth and Institutionalization of International Data Collections

Numerous international organizations collect and report education data, with the range of data types expanding and the complexity of collection and analysis increasing. Hence, the total cost of these collections has increased dramatically since 1990. Government financial support, and in some cases control, has been a significant component of this growth in both the sophistication of data and the scope of collections. Briefly described here are some of the basic institutional components involved in the creation of a set of international organizations or organizational structures that provide the institutional infrastructure for creating and sustaining international education statistical indicators.

**IEA.** Collaboration on international assessments began as early as the late 1950s when a group composed primarily of academics formed the International Association for the Evaluation of Educational Achievement (IEA). In 1965, twelve countries undertook the First International Mathematics Study. Since that time, the IEA has conducted fourteen different assessments covering the topics of mathematics, science, reading, civics, and technology. Findings from IEA's Second International Mathematics Study were the primary justification for the finding in the early 1980s that the United States was a "nation at risk." In the 1990s, government ministries of education became increasingly important for both funding and priority setting in these studies.

The results of the Third International Mathematics and Science Study (TIMSS) were widely reported in the United States and served as fuel for the latest educational reform efforts. As governments became increasingly involved in setting the IEA agenda, some key aspects of the research orientation of earlier surveys were no longer funded (e.g., the pre-test/post-test design in the Second International Science Study), while other innovative activities were added. For example, the TIMSS video study conducted in Germany, Japan, and the United States applied some of the most cutting-edge research technology to international assessments. As part of the 1999 repeat of TIMSS (TIMSS-R), additional coun-

tries have agreed to have their teachers videotaped and science classrooms have been added to the mix.

Over time, the IEA assessments have become more methodologically complex, with TIMSS employing the latest testing technology (e.g., item response theory [IRT], multiple imputation). As the technology behind the testing has become more complex, cross-national comparisons of achievement have become widely accepted, and arguments that education is culturally determined or that the tests are invalid, and thus that achievement results cannot be compared across countries, have for the most part disappeared.

**OECD.** While the IEA has been the key innovator in the area of education assessment, the OECD has led the development of a cross-nationally comparable system of education indicators. After a failed attempt to initiate an ambitious system of data collection and reporting in the early 1970s, the OECD, with strong support from the United States, undertook the development of a new system of cross-nationally comparable statistical indicators in the late 1980s. The ministers of education of OECD countries agreed at a meeting in Paris in November 1990 that accurate information and data are required for sound decision-making, informed debate on policy, and accountability measures. Ministers also agreed that data currently available lacked comparability and relevance to education policy.

Although led by the OECD, the core of the International Indicators of Education Systems (INES) projects was the organization of four country-led developmental networks: Network A on Educational Outcomes, Network B on Student Destinations, Network C on School Features and Processes, and Network D on Expectations and Attitudes towards Education—led by the United States, Sweden, the Netherlands, and the United Kingdom, respectively. The OECD secretariat chairs a technical group on enrollments, graduates, personnel, and finances. These networks—involving up to 200 statisticians, policymakers, and, in some cases, academics—designed indicators, negotiated the definitions for data collections, and supplied data for annual reporting. This model of shared ownership in the development of *Education at a Glance* (which was at first published biennially and later became an annual publication) contributed to its success. Participants in the networks and the technical group invested the time needed to supply high-quality data because they had a stake in the publication's success.

INES was initially a reporting scheme where administrative databases within countries were mined and aggregated, and it has evolved into an initiative that mounts its own cross-national surveys, including school surveys, public attitudes surveys, adult literacy surveys, and surveys of student achievement. The largest and most expensive project to date is the OECD Programme for International Student Assessment (PISA). PISA is an assessment of reading literacy, mathematical literacy, and scientific literacy, jointly developed by participating countries and administered to samples of fifteen-year-old students in their schools. In 2000 PISA was administered in thirty-two countries, to between 4,500 and 10,000 students per country. Expected outcomes include a basic profile of knowledge and skills among students at the end of compulsory schooling, contextual indicators relating results to student and school characteristics, and trend indicators showing how results change over time. With the results of PISA, the OECD will be able to report, for the first time, achievement and context indicators specifically designed for that purpose (rather than using IEA data) for country rankings and comparisons.

**UNESCO.** The United Nations Educational, Scientific and Cultural Organization (UNESCO) has been the main source of cross-national data on education since its inception near the end of the Second World War. UNESCO's first questionnaire-based survey of education was conducted in 1950 and covered fifty-seven of its member states. In the 1970s UNESCO organized the creation of the International Standard Classification of Education (ISCED), a major step forward towards improving the comparability of education data. Although as many as 175 countries regularly report information on their education systems to UNESCO, much of the data reported is widely considered unreliable. Throughout the 1990s the primary analytical report on education published by UNESCO, the *World Education Report*, based many of its analyses and conclusions on education data collected by agencies other than UNESCO.

Between 1984 and 1996 personnel and budgetary support for statistics at UNESCO declined, and UNESCO's ability to assist member countries in the development of their statistical infrastructure or in the reporting of data was severely limited. In the late 1990s, however, the World Bank and other international organizations, as well as influential member countries such as the Netherlands and the United

Kingdom, increased pressure and financial contributions in order to improve the quality of the education data UNESCO collects.

Collaboration between UNESCO and OECD began on the World Bank-financed World Education Indicators (WEI) project, which capitalized on OECD's experience, legitimacy, and status to expand the OECD *Indicators Methodology* to the developing world. Although this project includes only eighteen nations (nearly fifty if OECD member nations are included), it has helped to raise the credibility of indicator reporting in at least some countries in the developing world. Even though this project has in many ways "cherry-picked" countries having reasonably advanced national education data systems, the collaborative spirit imported from OECD's INES project has been quite effective.

A major step for the newly constituted UNESCO Institute for Statistics will be to take this project to a larger scale. Significantly expanding WEI will be quite a challenge, however, as the financial and personnel costs needed to increase both the quality of national data collection and reporting, as well as processing and indicator production on an international level, are likely to exceed the budget and staff capacity of the institute in the short term. The visible success of the WEI project, however, shows that the interest in high-quality, comparable, education indicators expands far beyond the developed countries of the OECD.

### **Integration of National Resources and Expertise into the Process**

Many of the international organizations dedicated to education data collection were in operation well before the renaissance of the statistical indicator in the education sector, but these groups lacked the political power and expertise found in a number of key national governments to make them what they have recently become. A central part of the story of international data and statistical indicators has been the thorough integration of national governments into the process. As technocratic operations of governance, with its heavy reliance on data to measure problems and evaluate policies, became standard in the second half of the twentieth century, wealthier national governments invested in statistical systems and analysis capabilities. As was the case for the IEA and its massive TIMSS project, several key nations lent crucial expertise and legitimization to the process, factors that were clearly missing in earlier at-

tempts. Although this “partnership” has not always been a conflict-free one, it has taken international agencies to new technical and resource levels.

The integration of national experts, often from ministries of education or national statistical offices, into international indicator development teams has improved both the quality of the data collected and the national legitimacy of the data reported. A number of decentralized states, including Canada, Spain, and the United States, have used the international indicators produced by OECD as benchmarks for state/provincial indicators reports. As more national governments build significant local control of education into national systems, this use of international indicators at local levels will become more widespread. In the case of Canada, the internationally sanctioned framework provides legitimacy to a specific list of indicators that might not otherwise have gained a sufficient level of agreement among the provinces involved.

The initial release of results from the PISA project will take this one step further, in that the OECD will provide participating countries reports focused on their national results, in a way similar to how the National Assessment of Educational Progress (NAEP) produces reports for each of the fifty U.S. states. This reporting scheme will allow participating countries to “release” their national data at the same time as the international data release. The same could easily happen with releases of subnational indicators in conjunction with international releases. This form of simultaneous release is seen as an effective way to create policy debate at a number of levels within the American system, as illustrated by the U.S. National Center for Education Statistics’ ability to generate public interest in its release of achievement indicators from TIMSS and TIMSS-R. International education indicators provide constituencies within national education systems another vantage point to effect change and reform.

### Conclusions

There have been four main trends behind the massive collection of data and the construction of cross-national statistical indicators in the education sector over the past several decades. These trends are: (1) greater coordination and networks of organizations dedicated to international data collection; (2) integration of national governments’ statistical expertise and resources into international statistical efforts that lead to statistical indicators; (3) political use of

cross-national comparisons across a number of public sectors; and (4) near universal acceptance of the validity of statistical indicators to capture central education processes.

Although examples presented here of each factor focus more on elementary and secondary schooling, the same could be said for indicators of tertiary education. The only difference is that the development of a wide range of international statistical indicators for higher education (i.e., indicators of higher education systems instead of research and development products of higher education) lags behind what has happened for elementary and secondary education. However, there are a number of signs that the higher education section will incorporate similar indicators of instruction, performance, and related processes in the near future. It is clear that international statistical indicators of education will continue to become more sophisticated and have a wider impact on policy debates about improving education for some time to come.

## INTERNATIONAL GAP IN TECHNOLOGY, THE

At the dawn of the twenty-first century, there was a major gap between industrialized and developing countries in terms of their access to information and communications technology (ICT). This gap has come to be known as the *digital divide* and is illustrative of the vast differences in development among nations resulting from the process of globalization. While most industrialized countries were linked into the global information economy through high speed information networks and computers, the majority of people in the developing world had very little or no access to basic information and communications networks—let alone the new technology of the Internet. Indeed, more than half the people on the planet, mostly in the developing world, had yet to make a telephone call.

There are many ways of measuring the digital divide. One measure is the extent to which people in the industrialized and developing countries have access to the Internet. Table 1 provides a rough estimate of the approximately 500 million worldwide Internet users by region at the beginning of the current century. It shows that the industrialized countries represented some 65 percent of all Internet users.

Another measure is the location of Internet content providers. Here the dominance of the developed world is still more accentuated: the United States shows a ratio of 25.2 Internet domains per thousand population and parts of Europe 15 per thousand, compared to Brazil’s 0.5, China’s 0.2, and India’s 0.1.

The digital divide is far more than a gap in access to ICT, however. It is a major impediment to the social and economic development of poor nations. In the twenty-first century, knowledge and information and a highly skilled labor force are increasingly important determinants of growth in the global economy. Or as Manuel Castells has observed, “Information technology, and the ability to use it and adapt it, is the critical factor in generating and accessing wealth, power, and knowledge in our time” (1998, p. 92). ICT has already revolutionized economic life and business in the industrialized countries and is transforming these societies in equally profound ways. ICT is a key weapon in the war against world poverty. When used properly, it offers huge potential to empower people in developing countries to overcome development obstacles, to

address the most important social problems they face, and to strengthen communities, democratic institutions, a free press, and local economies.

According to some, the development of information and communications technology is increasing the gap between the rich and the poor, the knowledgeable and the knowledge deprived, the information rich and the information poor. Instead of closing the divide, the introduction of more ICT exacerbates social and economic divides—not only between rich and poor countries, but also among various socioeconomic groups within countries. Others argue that ICT closes the divide by integrating countries in the global economy and providing them access to global knowledge and information for development. Nonetheless, there are stark differences in access across the world according to gender, geography (i.e., urban versus rural), income, education, age, occupation, and even ethnicity and race. The groups with the greatest access to new information and communications technology are generally well-educated, high income urban males. Poor, illiterate females in rural areas are least likely to have access to ICT.

### The Digital Divide in Education

The global dimensions of the digital divide are most prominent in education. At the beginning of the twenty-first century many industrialized countries had begun to gear up their education systems for the knowledge economy by making major investments in computers for classrooms, in networking their schools, and in training teachers to use technology in their teaching. Thus, in the United States the ratio of students to instructional computers reached five to one and 98 percent of schools were connected to the Internet. In the United Kingdom, the ratio of students to computers was twelve to one in primary school and seven to one in secondary school while access to the Internet was virtually universal, as it was in the European Union as a whole. Canada showed similar patterns, as did Australia and New Zealand. In addition, many students either owned their own computers or had access to the Internet outside of school hours. Getting online had also become the buzz of the higher education sector in industrialized countries; most universities had or were acquiring access to both fiber optic and wireless high speed digital networks.

In contrast, most of the developing countries, with few exceptions, were more concerned with very

**TABLE 1**

<b>Worldwide Internet users by region, 2001</b>		
<b>Region</b>	<b>Number of users</b>	<b>Percentage</b>
Africa	4 million	1
Asia/Pacific	144 million	28
Canada and United States	181 million	35
Europe	155 million	30
Latin America	25 million	5
Middle East	5 million	1
<b>World Total</b>	<b>514 million</b>	<b>100%</b>

SOURCE: Adapted from Nua Internet Surveys. August 2001.

difficult educational issues—low primary and secondary school enrollments, inadequately trained teachers, little or no access to textbooks, and ineffective school management—rather than with improving ICT. The exceptions were a small number of countries in Asia, Latin America, and other parts of the developing world that began introducing computers in classrooms, networking schools, and developing digital content to address the educational requirements of the global knowledge economy.

Among Asian countries, Singapore, Malaysia, Korea, China, and Thailand were making important investments in ICT in higher education and at the primary and secondary levels. Thailand developed the first nationwide, free-access network for education in Southeast Asia, SchoolNet@1509. This program also made Thai content available on the Internet. China's Ministry of Education planned to provide online education services to five million higher education students by 2005. In Latin America, Brazil, Mexico, and Chile were making significant ICT investments. Brazil built high speed data networks for university research and installed large numbers of computers in primary and secondary schools nationwide. Chile had linked 5,000 primary and secondary schools and produced educational software under its Enlaces program. In other parts of the world, Turkey launched a major initiative to install computers in more than 5000 classrooms, and the South African SchoolNet (SchoolNetSA) began providing Internet services to local schools and developed online educational content.

### Education and Technology in the Balance

Does access to computers and the Internet give the education systems of industrialized countries an advantage over those in developing countries? Or has

technology balanced rich and poor countries, because poor countries now have access to high quality information, data, and research via the Internet they never would have had without technology? The answers to these questions depend in large measure upon how one assesses the impact and cost-effectiveness of ICT on the education systems in the industrialized countries. At the start of the twenty-first century, the educational impact of computers and the Internet was not widely in evidence in many schools, although it is clear that ICT was being widely adopted and used at all levels of education. Moreover, a new “Net Generation” of learners weaned on the Internet was stimulating new approaches to teaching and learning online, initially within the traditional classroom, but increasingly outside that venue, without regard to physical location or time of day.

While there has been good progress in providing access to ICT in schools and universities in industrialized countries, the expected benefits to education, as noted, have been difficult to measure: (1) increasing productive teaching and learning; (2) transforming teaching and learning from traditional textbook lessons to more learner-friendly, student-centered approaches that employ powerful interactive tools and methods; and (3) equipping students with higher order thinking and problem-solving skills that prepare them for life in an information-based society and workplace.

Some researchers, such as James Kulick, have recorded positive outcomes from the use of computers for teaching and learning basic skills and for information and knowledge management. Others, such as Larry Cuban, believe that computers have been oversold and underused; they argue that most educational institutions remain essentially as they were decades ago, despite the availability of technology, and are not reaping enough benefits from technology to justify the investments. Further, others question the cost-effectiveness of computers relative to other inputs for improving the quality of education in the classroom: smaller class sizes, self-paced learning, peer teaching, small group learning, innovative curricula, and in-class tutors.

The experience of the industrialized countries would suggest that access to the Internet and the wealth of knowledge and information it provides does not automatically lead to measurable improvements in the quality of teaching and learning in schools. Rather, such improvements are the result of

parallel efforts to enhance the teaching and learning process by training teachers, reducing class size, making textbooks available, and establishing standards of learning. Nonetheless, it is obvious that school systems everywhere, and especially in the developing countries, need to find ways of providing more students with regular and frequent access to information and communications technology and to enable students to acquire the knowledge and skills needed to support a knowledge economy.

### **Bridging the Digital Divide in Education**

The developing countries face massive challenges in bridging the digital divide in education. What are these challenges? And is progress possible? In order to bridge the digital divide in education, developing countries will first need to overcome the key constraints to the development of ICT in general. Too often programs fail to address the problems in a comprehensive and sustainable way. To reduce the technology gap developing countries need to discover ways to expand information infrastructure, increase access by improving markets, and reduce the cost of service, especially for Internet access. A reduction in Internet costs—both telecommunications company charges and Internet service provider charges—in developing countries is necessary for a broadening of the information society there, and for more widespread and cost-effective use of new technologies to improve education.

Even with the best of intentions, however, achieving these goals will not be easy for developing countries. They lack both the funding and the technical expertise to overcome infrastructure and human resource constraints. Many international financial organizations, aid agencies, and private foundations are committed to helping developing countries bridge the digital divide and are being mobilized into action by the United Nations, the World Economic Forum, and other bodies.

Additionally, many feel that advances in technology will help bridge the digital divide between industrial and developing countries. Overall, diffusion of Internet access is expected to be rapid in the first decade of the twenty-first century. Indeed, access to information over the Internet is already being greatly facilitated for consumers in developing countries by the existence of new data caches and innovative networking of servers around the world. The development of wireless telecommunications is also expected to facilitate access to the Internet in remote

rural areas where telephone service has been unavailable. And, above all, computers are likely to become both pervasive and affordable, not just on the desk top and as handheld appliances, but embedded in intelligent objects everywhere.

While access to computers and telecommunications networks is necessary to bridge the digital divide, access alone is not sufficient to ensure that education systems in developing countries benefit from the Internet revolution. The governments of these countries also need to: (1) train teachers and trainers to exploit the potential of learning technologies; (2) offer free or inexpensive Internet access to schools; (3) foster capacity to develop content and instructional resources in their own language; (4) build networks and well-maintained facilities for both accessing knowledge and providing affordable lifelong learning and skill upgrading; and (5) preserve the freedom of teachers and students to explore the myriad educational resources on the web without filtering and censorship such as that which exists in China, Saudi Arabia, Iran, and other countries.

Both industrialized and developing countries must also seek to address the digital divide between rich and poor. The United States has made significant progress in bridging the gap, although there are still considerable inequities, especially in instructional practice—that is, in how effectively modern learning technologies are being used with different groups of students. In the developing countries, public policies to promote competition (which lowers prices and improves quality) and to make new technologies more accessible will ultimately influence availability and adoption of technology and access. However, special community-based programs by governments and nongovernmental organizations involving marginalized or rural communities, women, and minorities are also essential for bridging the digital divide.

## INTERNATIONAL ISSUES OF SOCIAL MOBILITY OF UNDERPRIVILEGED GROUPS

Children of lower socioeconomic status (SES) groups tend to perform worse in school than upper SES groups, and they tend to stay in school for a shorter time. In addition, these children tend to be underrepresented in higher education. These patterns exist regardless of region of world, sociopolitical system, and level of economic development of a country. This article examines the universality of these observations. It also discusses exceptions to these general tendencies and promising interventions that enable children of lower socioeconomic groups to overcome barriers to progress in school.

### Education, Equality, and Equity

The theme of education and social mobility of underprivileged groups is integrally related to issues of social equality and equity. Equality, according to Martin Bronfenbrenner, refers to the numerical distribution of a good or service (such as income, land, or years of schooling), whereas equity refers to judgments concerning the fairness or justice of that distribution. The sociological study of equality of educational opportunity and outcomes usually focuses on the relationship between stratification—the hierarchical ordering of people on such dimensions as wealth, power, and prestige—and the amount and type of schooling available to different social groups. According to Ann Parker Parelius and Robert James Parelius, it is widely assumed that “‘equality of opportunity’ exists when each person regardless of such ascribed characteristics as family background, religion, ethnicity, race, or gender, has the same chance of acquiring a favorable socioeconomic position” (p. 264).

It should be noted that equal educational opportunity does not necessarily imply that people will end up equal but simply that an individual’s socioeconomic position will be the result of a “fair and open contest—one in which the winners are those who work hardest and demonstrate the most ability” (Parelius and Parelius, p. 264). In the debate over inequality, one critical question concerns the degree to which advantage is passed on from one generation to another. For example, if the social-class standing of a family is high in terms of income, occupational status, and educational attainment, will the family’s offspring have greater access to the highest levels of

a school system? And what is the effect of family socioeconomic position on the relationship between level of schooling attained and subsequent income and occupational status? Christopher J. Hurn noted in 1993 that if a society’s education system is truly meritocratic (that is, based on ability and not on ascriptive factors such as social class, gender, and ethnicity), then (1) the correlation between individuals’ educational attainment (how far one goes in school) and future occupational status should increase over time; (2) the correlation between students’ educational attainment and their parents’ socioeconomic status should decrease over time; and (3) the correlation between parents’ SES and their offspring’s SES should also decrease.

Evidence strongly supports the proposition that, around the world, education increasingly is becoming the strongest determinant of occupational status and the type of life chances individuals experience. Evidence does not, however, support the thesis that the relationship between family background and how far one goes in school and what one learns is decreasing over time. Indeed, the relationship between family SES and school success or failure appears to be increasing since the 1980s as the result, in part, of public policies that tend to decentralize and privatize education. While primary education has expanded to near universal coverage of the relevant age group, access to the levels of education that are most important for social mobility and entry into the most modern and competitive sectors of the increasingly globalized economies remain elusive for all but elites. Consequently, the relationship between parents’ SES and their children’s SES has shown little evidence of changing over time.

### Significant Educational Interventions

Moreover, comparative longitudinal studies of factors influencing what is learned in school and level of educational attainment suggest that as societies industrialize and modernize, social class increasingly plays a significant role in determining educational outcomes. This finding does not discount the importance of school-based factors in determining how well students, especially those living in conditions of poverty, fare in school. Well-designed interventions aimed at improving the quality of instruction can make a difference. These include quality preschool and early childhood programs with supplementary nutrition and health care services; more adequate school infrastructure so that poor, rural, and indige-

nous children have the same amenities (school desks and chairs, electricity, running water, and toilets) enjoyed by their more advantaged peers in urban and private schools; a flexible academic calendar responsive to the socioeconomic context of schools in different regions of a country; sufficient supplies of textbooks and culturally sensitive as well as socially relevant curricular materials in the appropriate languages; teaching guides matched to transformed curricula; student-centered, more active pedagogies that involve collaborative work as well as personalized attention to each child; significantly improved pre-service and in-service teacher education and professional development programs and opportunities; incentive pay for teachers working under difficult conditions and, generally, more adequate remuneration and social recognition of the importance of teaching; and, importantly, greater participation of teachers, parents, and communities in the design of education programs to meet their self-defined needs.

For female students, who are often the most discriminated against with regard to access to schooling and the types of curricula that lead to high-status jobs, a complementary set of interventions would include placement of schools closer to their homes, female teachers and administrators as role models, opportunities to be taught separately where appropriate, academically challenging curricula, waiver of tuition and book fees, and, in some cases, monetary incentives to families to compensate for lost income or opportunity costs borne by them. In some cases, agencies working to promote greater school participation rates by females have employed a variety of outreach activities and media, including extension agents and sociodramas performed in communities, to counter notions that religious doctrine or cultural traditions prohibit the education of daughters.

Intangible factors such as school culture (the values propounded by school personnel and student peer groups) also are significant. Bradley Levinson's ten-year study of a Mexican junior high school, for example, documents how the egalitarian ideology of the 1910 Revolution enters the discourse and practices of school personnel and is appropriated by students. The belief that *Todos Somos Iguales* ("We Are All Equal") strongly shapes interactions between students and, contrary to much U.S. and European social and cultural reproduction theory, overrides the forces that would stratify students by social class, ethnicity, and gender. Elizabeth Cohen and asso-

ciates' research on "equitable classrooms" underscores the importance of multidimensional and complex instruction that demand high levels of performance of all students and encourages the use and evaluation of multiple abilities. In such classrooms, "the interaction among students is 'equal-status,' that is all students are active and influential participants and their opinions matter to their fellow students" (Cohen, p. 276). Similarly, *effective schools* research indicates that an overall ethos of high expectations and a climate of respect have a positive impact on the achievement of lower SES students.

### **Problematic Reforms: National Standards and High-Stakes Examinations**

Along with greater respect accorded to students and the knowledge and values they bring to school, teacher expectations and general curricular standards are important factors in raising student performance. The worldwide trend to establish national standards in core academic subjects and hold schools and individual teachers and students accountable for them through systematic testing may contribute to higher test scores for disadvantaged groups. These efforts, however, are fraught with serious problems and may, instead, lead to greater failure for the intended beneficiaries of these reforms. While standards may be uniformly applied to all students, the resources to accomplish heightened expectations usually are not equally available. The standards themselves may be questioned as to whose knowledge and values are represented; the language in which tests are administered is a particularly significant issue in multilingual, pluralist societies. Generally, there is widespread criticism that the tests constrain the professional autonomy of teachers to determine what is in the best interest of students, often involve a *dumbing down* and narrowing of what is taught, and tend to be a one-size-fits-all strategy for educational improvement.

### **Cultural and Social Capital**

As indicated above, educators concerned with educational interventions that are culturally sensitive and contextually appropriate take into account the so-called cultural and social capital of their students, families, and communities. The term *cultural capital* refers to the knowledge, linguistic skills and speech codes, and modes of behavior that students bring to school, whereas *social capital* refers to the networks of support and resources that families and their chil-

dren can draw upon to interact successfully with various public agencies such as schools. The failure of students from lower socioeconomic groups and ethnic minorities to succeed in school often resides in the mismatch between the expectations of state curricula and school personnel and what students actually know and value. Education systems must build upon this individual and local knowledge while expanding it so that students, with a heightened sense of their own identity and efficacy, also can participate in the larger society in ways beneficial to themselves and others.

The significance of social capital and how to mobilize it has received substantial attention since the late 1980s. Ways to strengthen the social capital of lower SES families include enabling closer and more systematic involvement of teachers with parents (rather than only when problems arise), arranging for parent-teacher conferences to take place at convenient locations and times, making information about the workings of the education system and individual schools available in the home language, and focusing on the strengths of the children and what they can do. In the absence of other social-service agencies in rural areas and depressed urban neighborhoods, schools necessarily must offer a number of educational and social services, such as extended day care, recreational facilities and sports programs, health programs (including inoculations and birth-control information), and literacy and adult education classes.

### Neoliberal Economic and Education Policies

Unfortunately, as noted by such authors as Robert Arnove, Joel Samoff, Fernando Reimers, and Maria Bucur, the full panoply of interventions and reforms is rarely implemented. Reform efforts usually are piecemeal, haphazardly implemented, and inadequately funded. Furthermore, current neoliberal policy initiatives that are being uniformly initiated around the world are likely to widen the gap between academic achievement (what students learn in school) and the educational attainment of the rich and the poor. The term *neoliberal* derives from the neoclassical economic theories expounded by the major international donor agencies, such as the World Bank and the International Monetary Fund, as well as by national governments that pursue economic and social policies that give priority to the workings of market forces. The theories are based on writings of the classical economists Adam Smith

(1723–1790) and David Ricardo (1772–1823), who believed the role of the state consisted in establishing the conditions by which the free play of the marketplace, the laws of supply and demand, and free trade based on competitive advantage would inevitably redound to the benefit of all. Government policies based on these notions have led to a drastic reduction in the state role in social spending, deregulation of the economy, and liberalization of import policies. The educational counterparts of these policies have included moves to decentralize and privatize public school systems.

Initiatives to decentralize national education systems most commonly involve transfer of a number of previously centralized functions (such as hiring of teachers) to local levels of government along with greater responsibility for the financing of education. At the same time, in many countries, a core national curriculum is established, and, increasingly, national standards, systematic testing, and various accountability measures are introduced. In countries with dramatic differences in wealth by regions, these policies tend to exacerbate the availability and quality of schooling. Comparisons of test scores between more-advantaged urban areas and depressed rural areas, and between elite private schools and poor urban schools, reveal a growing gap between children of upper and lower socioeconomic strata. Moreover, cost-recovery measures are usually introduced, which means that previously free services are no longer provided. Parents, for example, must pay for textbooks, school uniforms, special classes, and equipment (usually related to computers and the learning of a foreign language). These fees, in countries where a majority of the population is living in poverty, may drive children out of the school system. Frequently, parents must choose between paying school fees and buying food, clothing, and medicines. Sometimes, the principal incentive for sending children to school is the milk or a hot meal that will be provided. Various measures facilitating the creation and subsidization of private education further widen the gap between the rich and the poor, as well-to-do families are encouraged to send their children to private schools, thereby eroding the base of support for public schooling.

### Higher Education and Stratification

At the higher education level, postsecondary education has become so integrally linked to individual economic well-being that it is now deemed one of

the “essential components of cultural and socioeconomic development of individuals, communities and nations” (United Nations Development Programme, p. 2). As such, the higher education degree credential, over time, has become the principal entry point into the most modernized sectors of the economy and middle- or upper-class status. Nevertheless, as countries around the globe contend with issues of increased demand for, and access to, higher education institutions, financially sustaining those institutions has become a dilemma for all societies. As a result, while the costs of higher education in many countries traditionally involve no or minimal tuition fees, policy reforms increasingly shift the costs of higher education to students and their families. Ironically, at the very moment when historically marginalized groups have begun to gain access to higher education, the neoliberal move to decentralize and privatize education has become most prominent. Such reform initiatives have frequently led to student as well as faculty seizures of higher education facilities, public protests, and occasionally violent demonstrations.

One reason for this opposition to reform is that despite the diverse histories of, and demands, cultures, and clients for, higher education throughout the world, dissimilar nations are increasingly connected by their policy decisions without sufficient local adaptation. For higher education, the 1990s was a period of financial crisis around the world. These financial pressures have led to surprisingly similar reforms for higher education. Oftentimes, policy solutions of industrialized nations (e.g., the United States, the United Kingdom, and Australia) become the prevailing model used by other nations facing the same fiscal pressures. The most widespread financial reform mechanism involves increasing tuition and fees at the same time that financial-aid systems of grants and student loans are introduced. Student loan programs exist in more than fifty countries. Because student loan programs are costly to administer, they often compete with grants for governmental program support. As loan programs are introduced, grant programs are frequently reduced.

The conflict between student loans, which must be repaid by the student, and outright grants, which do not need to be repaid, is contested by policy analysts. Some researchers support charging students and their families for an increasing share of the cost of higher education because keeping tuition prices

low through governmental support mainly benefits high-income students. Other analysts assert that the high cost of tuition discourages minority and low-income students from even considering college attendance. Most researchers agree that the enrollment of high-income students in tertiary education does not change because of price. Shifting the costs of higher education to students and their families has also served to stratify educational opportunities by institution type such that the students from high- and middle-income backgrounds increasingly seek degrees from more prestigious universities, while low-income students increasingly enroll in the less prestigious institutions and vocational institutions.

More than adequate financial support is important for low-income and nontraditional students to succeed in higher education. Equally crucial for student success are a welcoming environment; a variety of support services; adaptation of academic calendars, curricula, and pedagogy to the characteristics of students; and flexible class schedules and modalities for delivering instruction. Taking into account the cultural and social capital of students from diverse backgrounds as well as their financial resources constitutes a major move toward more inclusive and equitable higher education systems.

### **The Need for Poverty Reduction: International Data**

While the association between levels of educational attainment and lifetime earning streams is substantial and becoming stronger, economic policies can alleviate the dramatic wage differences between those who have a higher education and those who do not. Stephen Nickell and Brian Bell note that comparative data (from Germany, the Netherlands, Switzerland, and the United Kingdom) point out that wage policies and efforts made to provide high-level skills to those not receiving a higher education can lead to more equitable systems of income distribution.

Ultimately, public policies related to poverty alleviation are critical to overcoming the gap between the rich and poor within and between countries. Lyle V. Jones draws attention to the strong correlation between poverty levels, school expulsions and suspensions, and achievement scores in the United States, Germany, and Japan to underscore the point “that within every one of the nations that participated, poverty is related to achievement. . . . Based on these findings, there can be little basis for surprise

when we discover that the U.S. [with more than double the level of children living in poverty] may lag behind Japan, Germany, and some other countries in average school achievement in mathematics” (p. 8).

Unfortunately, current national development and economic policies based on the application of market forces to the provision of social services, and especially education, have led to an expansion and deepening of poverty not only within countries but also between countries and large regions of the world. While certain countries have successfully integrated into the global economy, many countries have not. Among those excluded from the so-called benefits of international market forces and policies of privatization and decentralization are large sectors of Africa, Latin America, Russia and eastern Europe, and Asia. The poorer the country, the greater is the probability that a higher percentage of children will never even enter or complete primary education. For example, in 1990 Marlaine E. Lockheed and Adriaan M. Verspoor found that in thirteen countries with low gross national product the median dropout rate was 41 percent compared with 14 percent for seven upper-middle-income countries. More recent research, summarized in 2000 by the International Institute of Educational Planning as a ten-year follow-up to the 1990 Jomtien, Thailand, international conference on “Education for All,” found that “the lower the national income, the greater the inequalities in education within a country,” with “the differences between rich and poor, between center and periphery, between men and women, generally greater . . . the poorer the country” (Hernes, p. 2). While enrollment figures are important indicators of access to schooling, they do not reveal high dropout and repetition rates, especially among disadvantaged groups. Instead, educational attainment and years of schooling have been identified as the key factors in determining subsequent occupational attainment, income, and SES, particularly in highly industrialized countries. Therefore, Table 1 demonstrates the disparity in educational attainment and years of schooling for different regions of the world by income group. Education systems and teachers most frequently bear the brunt in cost reductions in social spending, resulting in the erosion of previous gains for the poorest and most marginalized sectors of the society and an undermining of public schooling relative to that of the private sector.

## Conclusions

The relationships among family background, educational achievement and attainment, and subsequent life chances are obviously complex. Research that clarifies these relationships must take into account the interaction among contextual (macro-level) as well as local institutional (micro-level) variables. At the level of national comparisons, promising research needs to be conducted along the lines of explaining how certain countries, such as Finland, that excel in international tests of academic achievement, are able to do a good job with all students.

Over time the meaning of equality of educational opportunity has changed significantly. If one thinks of equal educational opportunity in relation to a race or contest, the initial conceptualization was to ensure that all students started the race on fairly comparable terms and, subsequently, that they would attend schools with similar resources and a common curriculum. Students who were disadvantaged would have early intervention programs to bring them up to par. More recent conceptualizations emphasize the outcomes of the education process—that is, the ability of schools to develop to the fullest the potential of students with different backgrounds and talents. In 1972 Torsten Husén referred to this new definition of equal educational opportunity in these terms: “every student should have an equal opportunity to be treated unequally” (p. 26). What this seemingly paradoxical principle means is that every single student should receive an education that is personally appropriate and beneficial. It also implies that more resources are likely to be required for those who are most disadvantaged—just as more costly, intensive care in a hospital is required to remedy a critical health situation. As John Rawls noted, given the years and decades of neglect and often discrimination faced by lower SES groups, ethnic minorities, and females, principles of redistributive justice would require that greater resources be dedicated to achieving maximum benefits for them. Without such idealism, it is unlikely that current trends toward greater inequalities and inequities in the economic, social, and educational spheres will be reversed.

TABLE 1

## Highest level of education attained in the percentage of population age twenty-five and over, 1995

	No school (percent)	Primary attainment (percent)	Secondary attainment (percent)	Tertiary attainment (percent)	Average years of schooling in population over 25
World	26.7	32.2	28.0	13.0	6.49
Low and middle income	41.8	33.5	18.3	6.3	4.47
Sub-Saharan Africa	45.6	32.5	19.0	2.6	3.62
East Asia and Pacific	27.1	36.6	26.2	10.1	6.03
South Asia	54.7	26.2	15.2	4.0	3.73
Latin America and Caribbean	19.2	41.8	18.4	10.5	5.38
Middle East and North Africa	43.9	28.7	20.0	7.4	4.46
Transitional economies	1.4	35.9	48.4	14.2	9.72
High income	4.0	28.7	41.4	25.9	9.57

Note: The authors used the International Standard Classification of Education criteria adopted in 1976 as the common criterion for international comparison. This may vary from the criteria used by the United Nations Educational, Scientific and Cultural Organization in its reporting of educational attainment data.

## INTERNATIONAL READING ASSOCIATION

The International Reading Association (IRA) is a nonprofit professional organization that seeks to

promote high levels of literacy by improving the quality of reading instruction. The association works to achieve this mission by studying the reading process and teaching techniques, serving as a clearinghouse for the support and dissemination of reading research through conferences and publications, and actively encouraging a lifetime reading habit. The association is concerned with reading at all levels—from the school readiness stage through college and adult learning.

The five organizational goals of the association are: (1) professional development to enhance and improve professional development of reading educators worldwide; (2) advocacy to provide leadership in support of research, policy, and practice that improves reading instruction and supports the best interests of all learners and reading professionals; (3) partnerships to establish and strengthen national and international alliances with a wide range of organizations; (4) research to encourage and support evidence-based policy and practice at all levels of reading and language arts education; and (5) global literacy development to identify, focus, and provide leadership on significant literacy issues.

### History and Development

The International Reading Association was established in 1956 through a merger of two existing groups, the National Association for Remedial Teachers and the International Council for the Improvement of Reading Instruction. The membership has increased from about 5,000 in 1956 to nearly 90,000 in 2002. A headquarters office was first established in Chicago, but was moved to Newark, Delaware, in 1961. IRA's Government Relations and International Development divisions are located in Washington, D.C., and an editorial office for the journal *Lectura y vida* is located in Buenos Aires, Argentina.

### Projects and Programs

The association publishes six peer-reviewed journals. Issued monthly from October to May are *The Reading Teacher*, which reports on research and practice at the elementary level, and the *Journal of Adolescent and Adult Literacy*, which focuses on information relating to middle school, secondary, college, and adult levels. *Reading Research Quarterly* is oriented toward reading theory and research and is published in both print and electronic formats. *Lectura y vida* is a Spanish language journal published

in Argentina four times per year. *Reading Online* is a free Internet-based interactive journal for literacy educators at all levels. *Peremena* is published quarterly in English and Russian for literacy educators in newly emerging democracies in eastern Europe and elsewhere. The organization's bimonthly newspaper, *Reading Today*, provides coverage of the reading profession and activities of the association. The association's active publishing program, which includes a list of more than 200 print and nonprint publications, produces an average of twenty new books and other resources each year, and supports a full-service online bookstore.

An annual convention is held each spring in either the United States or Canada. This five-day program of scholarly and social events attracts some 18,000 dedicated professionals from throughout the world. The association also sponsors a biennial world congress to promote global cooperation and the dissemination of information. In addition to these regularly scheduled conventions, many regional conferences, seminars, and meetings are held.

The association has embarked on a series of comprehensive projects to expand global literacy in both industrialized nations and developing countries. The Reading and Writing for Critical Thinking (RWCT) Project has grown from nine to twenty-four participating countries since its inception in 1997. This project links educators from North America, Europe, and Australia with those from emerging democracies in central and eastern Europe and the former Soviet Union. The Language to Literacy Project in Africa will help to advance literacy in several African nations through professional networking, community development, and increased access to technology.

Through research, the International Reading Association provides a cornerstone for professional development and influence. This includes the creation and dissemination of position papers, collaboration with a wide range of organizations throughout the world, and the active support of research through grants, awards, and the prestigious annual Reading Research Conference. The association also speaks for its members before many government bodies, which has led to increased funding for reading programs, expanded professional development opportunities for members, and the development of new legislation.

## Organizational Structure

The International Reading Association serves members at local, state, provincial, national, and international levels through more than 1,250 councils and forty-two national affiliates. The ultimate governing body of the association is the Delegates Assembly, which convenes each year at the annual convention and is made up of representatives from the councils and affiliates. During the year an elected board of directors, made up of three officers and nine directors, controls the activities of the association. An executive director and a staff of 100 people carry out the daily business of the organization.

Membership in the association is open to any individual interested in the field of reading. Membership options allow members to receive a choice of professional publications and discounts on association publications, conferences, and services.

## INTERNATIONAL SOCIETY FOR PERFORMANCE IMPROVEMENT

Formerly known as the National Society for Programmed Instruction, the International Society for Performance Improvement (ISPI) is dedicated to improving performance in education and industry through a better understanding and use of evolving technology and methodology. It draws on the expertise of individuals from academia, the military, and industry, aiming for a truly multidisciplinary organization representing a broad range of practical and theoretical perspectives.

### Program

The society's members are involved in a wide variety of activities, from research on technological advances and their utility in the educational and work settings to publishing books and journals dealing with technology and performance enhancing initiatives. Its original mission, set forth in its earliest charter, was "to enhance education and training through the collection, development, and diffusion

of information concerned with programmed instruction." In the early twenty-first century the concerns of the organization exceed its original focus on the application of technology to education and extend to using technology to improve performance in the workplace as well.

The society carries out its mission through its annual meetings, conferences, seminars, and workshops. It puts out a number of publications dedicated to performance improvement technology, including the *Performance Improvement Journal*, the *Performance Xpress* (formerly titled *News and Notes*), and the *Performance Improvement Quarterly*, as well as books relating to the subject written by distinguished society members.

In addition to these activities, the ISPI, in conjunction with Boise State University, also operates an online, nonprofit educational and research facility called the Human Performance Technology Institute, which offers courses to members and nonmembers alike. It also sponsors grants ranging from \$2,000 to \$9,000 for research relating to the field of performance technology.

### Organization

The ISPI is governed by a board of directors elected for a year's term by the membership. Serving on the board are the current year's president, vice president, secretary, and treasurer, as well as the president of the previous term and the president-elect for the upcoming term. A board of editors is responsible for the publications arm of the organization. All positions except that of managing editor of the journal are voluntary.

### Membership and Support

Members are drawn from the academic community, the professions, the military, and industry. The society has more than 10,000 members in the United States, Canada, and in forty other countries, making it truly international in scope. The society maintains its independence by being fully self-supporting, earning revenues from annual membership dues, subscriptions to its periodicals, the sale of books, and course fees collected from its seminars, workshops, and the Human Performance Technology Institute.

### History

The 1950s and early 1960s were a time of rapid technological and methodological innovation. As early

as 1954 the potential practical impact of these changes on education was envisioned by noted psychologist B. F. Skinner, who proposed that the practices of scientific inquiry could be profitably applied to what he termed the “art” of teaching. He asserted that educators could use the techniques of the psychology laboratory—techniques designed to elicit desired behaviors—to improve performance in individual students. He called this methodology “programmed instruction.”

At the time of these insights, professional educators were becoming increasingly alarmed at what was seen to be the declining performance of the nation’s schools. It was not long before the concept of programmed instruction began to be adopted, and it spread rapidly throughout the public school system. Soon an interest in the application of programmed instruction extended beyond the field of education.

In 1961 a group of Air Force training officers began a study of the effectiveness of programmed instruction, and they discovered that the use of this approach generated a 33 percent reduction in the time it took for a student to master a subject and a 9 percent improvement in overall achievement. Inspired by their findings, several of the study’s participating officers joined with a group of nonmilitary educators to form the Programmed Learning Society of South Texas in January 1962. Within a month these first seven charter members were joined by twenty-five more, and the group decided to establish a national charter. Remarkably unified in their convictions and principles, the greatest point of contention among these early members appears to have been over the spelling (one *m* or two) of the word *Programmed* in the society’s official name.

Over the next eight months the organization grew rapidly, spreading throughout Texas and spilling over into California when the San Diego chapter was formed there in October 1962. By March 1963 the society had more than 600 members, and by 1968 the organization had achieved true national scope, which prompted the board to move its executive offices to Washington, D.C. During the 1970s the growth of the organization was spurred by further technological advances—driven largely by the rapid evolution of the field of computing—and interest in the society spread to the international community.

In its earliest incarnation, ISPI was primarily concerned with applying principles of programmed

instruction to the classroom through the incorporation of then-new technologies, such as films, slides, and other innovations as well as the development of formal lesson plans and the use of standard methods by which to measure the progress of individual students. Over time this focus has been enlarged to include the introduction of technology in the workplace, as corporate executives began to recognize the need to provide in-house training programs for their employees. Nonetheless, the society’s mission remains consistent with its founding principles: to extend the benefits of instructional technology to the society at large. At the same time, the society is concerned to minimize the problems that arise from the blind adoption of the latest technological fad. To this end it devotes much of its time and energy to training consumers of educational technology in the optimal selection and use of such materials.

## INTERNATIONAL STUDENTS

U.S. COLLEGES AND UNIVERSITIES

Kathryn Gray Skinner

THE GLOBAL COMMERCE OF HIGHER EDUCATION

Anuradha Shenoy

### U.S. COLLEGES AND UNIVERSITIES

Formerly referred to as *foreign* students, *international students* are students from abroad who are enrolled for courses at American schools, colleges, or universities and admitted under a temporary visa. These students’ primary intent is to obtain an American undergraduate, graduate, or professional degree and return to their home countries.

The number of international students studying at American colleges and universities is rising. More international students pass through America’s doors than those of any other country, making the United States the world’s most sought-after and diverse educational region in the world. More than half a mil-

lion (514,723 in the year 2000) international students, or 3.8 percent of all U.S. higher education students, were enrolled between 1999 and 2000. This 3.8 percent included 2.7 percent of all four-year undergraduates and 12 percent of graduate enrollments. These individuals were admitted expressly for the purpose of study. They did not include recent immigrants, resident aliens, or refugees.

### Characteristics of International Students

In 2000 Asian students (from China, Japan, and India) constituted more than half of international enrollments, and Europeans were the second largest regional group, with 15 percent of U.S. enrollments. More than two-thirds (67%) of all international students in the United States receive their primary source of support from non-U.S. sources. These sources include personal and family funds. U.S. colleges and universities provide approximately 19 percent of funds and home governments/universities provide 4 percent.

More than 20 percent of all international students are enrolled in universities and colleges located in just ten U.S. counties in or around New York City, Los Angeles, Boston, and Washington, D.C. International students currently study in areas where there are centers of finance, information, technology, media services, education, and industry, which are crucial to the emerging global economy.

Business and management are the most popular fields of study among international students, followed by engineering, mathematics, and computer science. These students come to America to study fields that are not well developed in their countries. International undergraduates have in the past outnumbered graduates; however, the pattern changed in the late 1980s, when the graduate and undergraduate proportions were roughly equal. Male foreign students have consistently outnumbered female students; however, the proportion of females is rising steadily. More than 2,500 U.S. institutions host international students and the international presence varies widely from institution to institution.

International students, scholars, and faculty enrich American colleges and universities and, eventually, U.S.-based firms. It is the collective responsibility of lawmakers, university administrators, and state government to ensure that the best of them continue to choose the United States for their education. In addition to providing diversity on American

campuses, these students and their dependents make an economic contribution of \$12.3 billion dollars per year (1999–2000).

### Admissions Process for International Students

Admissions offices at universities, which admit large numbers of international students, are well versed in the recruitment and admission of international students. Colleges, which admit smaller numbers of international students, must develop recruitment and admission procedures and often rely on knowledgeable colleagues at nearby universities to answer admission and immigration questions.

**Testing.** Each U.S. college and university has its own admission standards for admitting international students. Most universities require the Test of English as a Foreign Language (TOEFL), proof of graduation from high school, and either the SAT or ACT Assessment. The question often arises if the SAT and ACT Assessment are appropriate tests to be used for admission of international students into American colleges and universities, as it has been argued they are culturally bound tests (made for American students). Although there is truth to this argument, the SAT and ACT Assessment are the two tests that are most familiar to American universities for admissions decisions. Traditionally, test scores alone are not the sole determinants for university admission. Usually university admissions offices use a composite of international students' high-school course work (its rigor and depth), English-language ability, participation in school and community activities, scores on standardized tests, and commitment to academic purpose in making admissions decisions. International students are often asked to provide a writing sample and are given mathematics and English-language placement tests, once they are admitted, to determine their correct academic placement in classes.

**Foreign transcript evaluation.** International students seeking to transfer to American universities from foreign universities abroad must have their transcripts evaluated by a transcript-evaluation service in order to determine if their course work taken abroad will transfer (for degree credit) to the American semester or quarter system. Large universities often evaluate foreign credentials in-house, while smaller universities require that international students have their credentials evaluated by a professional evaluation service (specializing in the translation and evaluation of foreign academic cre-

dentials) either prior to or during the admissions process.

**Entering the United States.** International students currently apply to American universities via university websites, through overseas advising centers, by written form, and in person while visiting the United States. The most common visa category for international students is F-1 (student visa) followed by the J-1 (exchange visitor). Visas are obtained abroad in the student's home country once he or she has been fully admitted to an American college or university, and a document—either I-20 (for F-1 students) or IAP-66 (for J-1 students)—has been sent to the student.

Foreign student advisers must determine that each international student has sufficient academic preparation to enter the college or university, appropriate English-language ability (or the student will enroll for English as a second language [ESL] classes prior to pursuing academic credit), and sufficient funding to cover the total cost of tuition, room, board, fees, books, insurance, and so forth, while studying in the United States. Foreign student advisers are the front line for American embassies abroad and their roles are vital in that they are responsible for determining which students possess the academic, linguistic, and financial ability to be admitted to study in the United States. Academic institutions in the United States, which have been designated by the Immigration and Naturalization Service (INS) to offer courses of study, are allowed to admit international students for a specific educational or professional objective. Just because a student has the appropriate academic background, sufficient financial resources, and is issued a Form I-20 or a Form IAP-66 does not always mean that he or she will receive a visa to study in the United States.

U.S. consulates abroad determine which students receive visas. If a visa officer determines that a student does not (in his or her estimation) have the appropriate academic background, sufficient English-language fluency, and the financial means of support, or if the officer determines that the student has intent to immigrate (or has otherwise misinterpreted his or her intent) the visa may be denied. The Immigration and Nationality Act of 1952 (INA) allows a nonimmigrant student to enter the United States, who is a bona fide student qualified to pursue a full course of study and who seeks to enter the United States temporarily and solely for the purpose of pursuing a course of study at an established col-

lege, university, seminary, conservatory, academic high school, elementary school, or other academic institution, or in a language-training program.

The school, through the official responsible for admission, accepts the prospective student for enrollment in a “full course of study” that leads to the attainment of a “specific educational or professional objective” (Fosnocht, p. 3). In order to be admitted to an American college or university, the international student's application, transcripts, and all other supporting documents normally necessary to determine scholastic and linguistic eligibility for admission, as well as the student's financial documentation, must be received, reviewed, and evaluated at the school's location in the United States. Newly admitted international applicants should be advised that they are likely to be required to present documentary evidence of financial support at the time they apply for a visa and again to the INS when they arrive in the United States. Close communication during the application and admission process between a prospective international student and the foreign student adviser can prevent most (but not all) unexpected problems and visa denials.

### **Adjustments for International Students**

International students who choose to study in the United States usually are among the brightest and most highly motivated of the student-age population in their home countries. Only students with a high degree of motivation can cope simultaneously with the necessary language learning, travel, and dislocation anxiety necessary to enter American universities. Pierre Casse defines cross-cultural adaptation as the process by which an individual is forced to function effectively, but without alienation, in a setting that does not recognize all or parts of the assumptions and behavioral patterns that the person takes for granted. Culture shock is brought on by the anxiety that results from losing all the familiar signs and symbols of social intercourse.

**The challenges.** International students often arrive in the United States unaware of the immense hurdles in adjustment they must overcome to be successful in the American educational system. These hurdles include English-language acquisition, adaptation to differences in education systems, differences in philosophy/purpose of education, learning styles, and the challenges of other social, religious, and economic values. International students arrive with their own strategies for coping, studying, and social-

izing; however, these strategies often do not fit the dominant culture and must be reworked.

A myriad of adaptive behaviors, including cognitive self-awareness, behavior modification, and experimental learning take place. Studies by Jin Abe, Donn M. Talbot, and Robyn J. Geelhoed indicate that social adjustment and institutional attachment are significantly lower for international students than for their U.S. counterparts. In addition non-cognitive variables, such as self-confidence, availability of a strong support person, realistic self-appraisal, leadership opportunities, and preference for long-range academic goals all impact international students' academic success and persistence. The pressure for international students created by inadequate language skills, inappropriate study skills and habits, and ineffective coping strategies for being a student reveal themselves in many areas of students' lives. Ongoing organized interactions between international and American students are crucial for successful integration into the campus environment. International students experience a constant adaptational process as they attempt to integrate into the American university system.

**Cultural adaptation.** According to Carmel Camilleri, there is much tension and many psychological problems that international students face related to difficulties of cultural adaptation. Five areas that give foreign students the most difficulty are: abandonment of important cultural values, compromises to merge modern privileges while preserving traditional values, viewing one's community in a position of inequality with respect to society, inability to make sense of nonverbal communication, and dual roles related to parental issues.

The acquisition of culture for international students occurs inside and outside the classroom. There are the lessons that are taught formally and the lessons that are learned informally. These lessons enable international students to make meaning of their environment. Certain agreed-on values reside within and become part of the international student's cultural repertoire and are used to cope with the student's academic environment.

The process of international students entering and graduating from American colleges and universities is a dynamic one fraught with many chances to fail. It is the collective responsibility of administrators, professors, staff, and community volunteers to attempt to connect international students to their

American higher education experience. Philip G. Altbach states that the presence of a half million international students and scholars from virtually every country in the world is the most important single element of globalization on American campuses.

### **Services Designed to Assist International Students**

International education is growing in importance and as enrollments of international students in the United States increase, the abilities of teachers and administrators on American campuses must increase to meet these students' unique needs. The international dimension is critical to a well-conceived educational program. The internationalization of the university is one of the most significant challenges facing higher education in the twenty-first century.

**The foreign student adviser.** Typical services for international students at American colleges and universities include visa and immigration services, English as a second language (ESL) classes, orientation programs, and host family programs. Staff in international student services, admissions, and student affairs, and academic advisers and professors all help these international students. The foreign student adviser (in the international office or student services office) has the specialized function of dealing with international students. Skilled counselors, often housed in international offices on large campuses, provide services that include referral, coordination, and a special field of knowledge that deals with international students and their specific problems and needs. Traditionally, foreign student advisers and the staff of international offices help students with academic, immigration/visa, acculturation, language, financial, racial, cultural, religious, and ethnic issues.

The major function of the foreign student adviser is to help international students optimize their American educational experience. From orientation programs at the beginning of an international student's degree program to assistance with résumés as the student prepares to graduate, these advisers are interested in the international student's success. Foreign student advisers are responsible for international students and also to their universities. An odd situation exists in that foreign student advisers do not work for the federal government, yet they represent the federal government as Designated School Official (DSO) and Responsible Officer (RO) for the

U.S. Department of Justice and the State Department in issuing visa paperwork. They are not paid or trained by the U.S. government, relying instead on professional training from organizations, such as NAFSA: Association of International Educators, a nonprofit professional organization, which provides thorough and authoritative sources of information for international educators in the United States.

KATHRYN GRAY SKINNER

## THE GLOBAL COMMERCE OF HIGHER EDUCATION

International students contribute billions of dollars to the economy of the United States every year. The U.S. Department of Commerce recognizes education and training as the fifth largest export of the United States and formally classifies it as an industry. During the 1998–1999 academic year, 490,933 international students studied in the United States and they brought almost \$11.7 billion into the economy. During the 1999–2000 academic year, 514,723 international students were studying in the United States and they brought \$12.3 billion into the economy, through expenditures on tuition and living expenses. While the number of international students studying at higher education institutions has steadily increased over the years, policymakers, market analysts and advocates have been concerned because U.S. competitiveness in the international student market has been declining. The U.S. share of internationally mobile students seeking higher education at universities outside their country of birth in 1982 was 40 percent. Statistics compiled by the Organisation for Economic Co-operation and Development (OECD) in the year 1998 show that this percentage has now declined to approximately 32 percent.

Recognizing the contribution of international students to their economies, countries such as the United Kingdom, France, and Australia have introduced vigorous recruitment campaigns to compete for international students. The United States, in its bid to remain competitive in this market, is also formulating a series of measures to regain its market share in this industry.

### Definition and Distribution

For the purposes of this entry, an international student will be defined as a student who (1) is a citizen or permanent resident of a country other than that in which he or she intends to study; (2) has a legal residence outside the country that he or she intends to study in; and (3) is or proposes to be in the host country solely for educational purposes on a temporary student visa. The United States today uses the term *international student* to describe individuals

who fit this description, rather than *foreign student*, as in the past. Other countries still refer to students from other countries as foreign students. In this entry, these terms will be used interchangeably since different sources use either term. Table 1 provides figures for the distribution of foreign students in OECD countries by host country in academic year 1998–1999.

### Global Market for International Higher Education

The global market for international higher education may be explained in terms of an interaction between supply-side factors and demand-side factors. It is important to note that the available literature in this area focuses only on students from developing nations choosing to pursue their higher education in developed countries. The literature does not shed light on reasons that students from developed countries choose to study in either developing countries or in other developed countries.

**Supply-side factors.** Supply-side factors refer to factors that motivate host countries to invite international students to study at their institutions of higher education. Supply-side factors may be classified into economic, political, security, and academic factors. Many of the factors mentioned here are specific to the United States, but may be generalized to other countries as well.

**Economic factors.** First, as mentioned earlier, international students and their dependents bring money into the economy. International students in Australia contributed more than \$1 billion to the Australian economy and foreign students in the United Kingdom contributed approximately \$1.8 billion to the economy of the United Kingdom. Second, international graduate students serve as research assistants in labs and projects at universities in the United States, thereby contributing to technological and scientific advancements. Third, in a country like the United States that has a strong tradition of immigration, foreign-born doctoral recipients, especially those in the science and technology fields, often stay on to enter the labor market as academicians or researchers, thereby making positive contributions to the U.S. economy and national interests. Finally, the presence of international students contributes to the creation of new jobs in the field of international educational exchange.

**Political and security factors.** First, students who study in the United States and then return to

**TABLE 1**

#### Distribution of foreign students in OECD countries by host country, 1998–1999

Country	Percent
United States	32
United Kingdom	16
Germany	13
France	11
Australia	8
Japan	3
Canada, Spain, Austria, and Italy	2 each
Other countries	6

SOURCE: Based on data from the Organisation for Economic Co-operation and Development, 2000.

their home countries are seen to go back with a sense of good will towards the United States. This good will benefits both U.S. political interests and business interests globally. Second, educating international students presents an opportunity to shape the future leaders who will guide the political, social, and economic development of their countries. International students in the United States gain an in-depth exposure to American values such as democracy and take those values home to support democracies and free-market economies in their own countries. Third, educating international students plays an important role in American development assistance programs. Students educated in the United States form a cadre of trained professionals that understand the mission of U.S. development agencies such as the U.S. Agency for International Development (USAID). Development activities, while promoting social and economic progress in nations, also help to create a greater demand for American goods and services. Finally, international students provide Americans with an exposure to different cultures and political philosophies that, in addition to its social value, is seen as vital for U.S. security concerns.

**Academic factors.** First, international students provide cultural diversity to American campuses. Second, since they are often the best and the brightest in their countries, international students often provide a healthy dose of competition to American students, thereby raising the standards at institutions.

**Demand-side factors.** Demand-side factors refer to factors that motivate international students to seek higher education in countries outside their home countries. Economic models of student mobility

have been developed since the mid-1960s by researchers including Everett Lee, Larry Sirowy and Alex Inkeles, Gerald Fry, William Cummings, Vinod B. Agarwal and Donald R. Winkler, and Philip G. Altbach. Most studies analyze demand-side factors that are classified as “push” factors and “pull” factors.

**Push factors.** The term *push factors* refers to factors that push students to seek higher education in countries other than their host or native countries. These can include poor educational facilities in certain subjects, social discrimination, limited openings at the university level, and an array of political and economic factors at home.

**Pull factors.** The term *pull factors* refers to incentives that pull students towards host countries. These factors include availability of scholarships, better facilities, political ties, cultural and linguistic similarities with the host country, and finally the hope that a foreign educational credential will help in obtaining a better job on their return to their home country.

### Attracting International Students

The 1970s and 1980s saw a set of restrictive mechanisms, including tougher entry requirements and sharply higher tuition costs, come into place to restrict the flow of foreign students into the United States, Britain, France, Germany, Australia, and Canada. Reasons for this development included arguments that enrollments of foreign students damaged chances of students at home, that foreign students concentrated themselves in urban centers, and that foreign students often stayed and obtained employment in the host countries, thereby reducing opportunities for noninternational students in certain fields in those countries. However, recognizing the contributions that foreign students make to the economy, the United States and other countries have started making efforts to attract foreign students again.

Since late in the twentieth century, the United States has been in the process of formulating an international education policy to ease visa requirements, ease prohibitive tuition costs, and increase scholarships for international students.

The United Kingdom, the primary competitor of the United States for international students, has declared a formal international education policy designed to attract international students. The government and the British Council developed a program

known as “the U.K. Education Brand” in 1999. The U.K. Education Brand is a research and development program that, according to the British Council, is intended to “re-establish and maintain the United Kingdom’s credentials as a world class provider of education and training.” In addition to aggressive marketing strategies, Prime Minister Tony Blair proposed a four-point program in 1999 to increase their current market share from 16 percent to 25 percent by 2005. The four point program includes (1) a streamlined visa process for qualified applicants; (2) state-of-the art electronic information systems in other countries to provide information to potential students; (3) removal of work restrictions so that international students can work and pay for school; and (4) 1,000 extra scholarships for international students funded by government and private industries.

Australia and other countries created easy-to-read websites that are inviting to students. Australia has established a comprehensive website that deals with all aspects of international education, sponsored by the government.

France, in 1998, announced a new initiative called EduFrance, jointly created by the French ministry of national education, research, and technology; the ministry of foreign affairs; and the ministry for international cooperation. EduFrance was created with a budget of 100 million French francs for four years and a target of attracting 500,000 students overall.

Japan’s government is developing a plan to raise the number of foreign students studying in Japan from approximately 20,000 to 100,000. In 1999 the Japanese ministry of education instituted a simplified testing requirement for foreign students in Japan. Until 1999 students who came to Japan either at their own expense or on private scholarships had to take two tests, the Japanese Language Proficiency Test and the General Examination for Foreign Students. Now they need to take only one. Students interested in studying a liberal arts curriculum take the language proficiency test and students interested in studying science-based subjects take the general examination. Also, the tests are now given in ten overseas locations in Asia and are administered twice a year, compared to the previous system where they were administered only in Japan and only once a year.

Most countries interested in attracting international students are now formulating policies which

ease work restrictions and visa requirements and simplify testing procedures.

### Implications of September 11, 2001

The events of September 11, 2001, when international terrorists (several of whom had been in the United States under student visas) hijacked and crashed four American passenger planes, do not portend well for the United States as an attractive destination for international students. First, national security concerns have demanded that the United States tighten its immigration and admission procedures. Legislative demands for better tracking of international students could increase the oversight of international students in ways that some may find oppressive. Second, foreign students' own concerns for their personal safety might cause students not to choose the United States as a destination for study. Since neither the nature nor the degree of U.S. and international students' responses to the events of September 11, 2001 are clear at this time, it is too early to gauge the short- or long-term impact of potential changes.

## INTERNATIONAL TEACHERS ASSOCIATIONS

---

A large majority of teachers' unions and associations around the world are represented internationally by one unified organization, Education International (EI). Headquartered in Brussels, Belgium, EI was created by the merger of two major teachers' organizations in 1990. It includes 310 teachers' organizations from 159 countries, with a membership of more than 25 million teachers and other education workers.

The creation of a unified international organization of teachers was the result of several major post-World War II international trends and political developments (e.g., the cold war, the end of European colonization, the expansion of the worldwide movement for civil and human rights, the rise of teacher unionism, the collapse of communism) that brought together two former teachers' internationals and doomed two others.

### Ideologies and the International Labor Movement

Following World War II the international labor movement, of which teachers formed a small part, divided into three major strands, each of which was associated with a competing political ideology. These strands were aligned with democratic, communist, and Christian Democratic ideologies.

At the close of the war, there was a short period during which union federations in Europe, North America, and the Soviet Union joined to form a common international confederation of national union federations, the World Federation of Trade Unions (WFTU), as well as corresponding international trade secretariats (ITSs) for unions in common sectors, such as metal workers, textile workers, and government employees. (ITSs actually predate World War II, but were reorganized after the war as part of the family of international labor confederations.)

From the beginning a small minority of national unions questioned the wisdom of creating an inter-

national union organization that included organizations from the Soviet Union and communist-controlled Eastern European countries, arguing that such unions were not independent from the state and from controlling communist parties. (For example, in the United States, the American Federation of Labor [AFL] refused to join the new international, while the more leftist Congress of Industrial Organizations [CIO] did join.) However, at that time the impulse to create a workers' international overcame any qualms about the validity of unions in communist-controlled countries.

This brief period of labor unity ended in 1949. Between 1945 and 1948, it became increasingly clear to union leaders in democratic countries that so-called unions in Russia and Eastern Europe were actually front organizations that served the foreign policy interests of the Soviet Union, rather than the legitimate interests of workers. The efforts of these communist-controlled unions to block any criticism of the Soviet role in the 1948 coup in Czechoslovakia proved to be a breaking point.

In 1949 democratic union federations in Western Europe and other parts of the world split from the broad labor international to form, with the AFL, the International Confederation of Free Trade Unions (ICFTU). ITSs that had previously included both communist and noncommunist members also split, and new democratic ITSs were organized. The word *free* in the titles of new international labor organizations signaled that they were democratic internationals (e.g., the International Federation of Free Teacher Unions). Socialist and social democratic unions typically led these international labor organizations. The Soviet Union's internationals were composed of labor fronts from Eastern-bloc nations and communist-dominated unions in Western Europe and other parts of the world.

The third political strand in the international labor world was that of the Christian Democrats. The Christian Democratic political movement, founded by the Catholic Church in the first half of the twentieth century in response to the growth of communist and socialist movements, included the organization of fraternal labor movements at the national and international levels. Christian Democratic teachers' organizations were members of the International Federation of Employees in Public Services (INFEDOP; part of the Christian trade unions family) until 1963, when they split off to form the World Confederation of Teachers (WCT).

### The Four Trade Internationals

By the early 1960s there were three international teachers' organizations, each associated with one of these three political strands: the International Federation of Free Teachers' Unions (IFFTU—social democratic), the World Federation of Teachers' Unions (known by its French acronym, FISE—communist), and the World Confederation of Teachers (WCT—Christian Democratic). Then, in 1952, a group of smaller regional and international teachers' organizations that existed before World War II formed a fourth international organization, the World Confederation of Organizations in the Teaching Profession (WCOTP).

The WCOTP differed from the other teacher internationals by its lack of political orientation and, at least originally, any union orientation. It was created at a time when most national teachers' organizations were dominated either by school administrators or by teachers who had little interest in traditional union activity. For example, in the United States, the National Education Association (NEA) was founded as a professional teachers' association and was a founding member of the WCOTP (from 1952 to 1972 the WCOTP office was located in the NEA building in Washington, DC). The American Federation of Teachers was founded as a labor union and was a member of the original AFL, as well as being a founding member of the IFFTU—the social democratic-oriented teachers' international.

The background of member organizations in the IFFTU, the FISE, and the WCT were ideologically related, respectively, to the social democratic, communist, and Christian Democratic political movements. In contrast the WCOTP would accept organizations with any or no political orientation—and with little concern about an organization's independence from government or political parties, as long as it claimed to represent educators.

The ideological identification of the IFFTU did not mean that all its members were affiliated with, or directly connected to, a democratic socialist party. Rather, it indicated that the traditional leadership of the IFFTU unions tended to relate to social democratic movements or with similar parties, such as the Democratic Party in the United States. However, not all European teachers' organizations with social democratic ties affiliated with the IFFTU. For example, most Scandinavian teachers' organizations were

affiliated with the WCOTP until the beginning of the 1990s.

With one notable exception, the internationals did not prohibit members from being simultaneously affiliated with other teacher internationals. Generally, teachers' organizations from developed countries did not hold dual affiliations, for economic reasons, among other factors—it was not practical to pay dues to multiple organizations. Many teachers' organizations from poorer countries, however, held more than one affiliation in order to benefit from financial assistance from different international organizations and free participation in international conferences and congresses—while paying little or nothing in membership fees to any international. Each international teachers organization had a dues structure that adjusted dues to take into consideration the per-capita income of different countries.

While WCOTP and the FISE had no such prohibition, the IFFTU constitution restricted its members from holding dual affiliation with the communist teachers' international, the FISE. WCT members generally did not hold dual affiliations. As a result, the WCOTP included organizations that also belonged to either the FISE or the IFFTU. The IFFTU included members that also belonged to the WCOTP, but not to the FISE. This situation simultaneously contributed to and impeded the IFFTU-WCOTP merger movement in the late 1980s.

### Competition and Convergence

Throughout the cold war era, there was a constant competition, especially between the IFFTU and the WCOTP, for members, prestige, and recognition. Initially, both the IFFTU and the WCOTP were primarily composed of organizations from Europe and North America. Decolonization in Africa and Asia, and the creation of teachers' associations in newly independent nations, resulted in a major expansion of all the four teacher internationals. During the 1960s the membership of the WCOTP expanded rapidly, with the greatest growth coming from Africa, Latin America, and Asia. The membership growth in the IFFTU lagged behind the WCOTP, but began to catch up in the late 1960s and early 1970s. Much of the new membership in the IFFTU came from organizations that were already members of the WCOTP.

It was always difficult to compare the size of the four international teacher organizations with any

degree of accuracy. Membership figures for national affiliates were often unreliable. For example, Indian teachers' unions claimed millions of members, but few of the claimed members paid dues to the national organizations, nor did the national organizations pay more than token dues to the internationals. In general, due to economic hardship, almost no members from developing countries paid more than token dues to international teacher organizations. In addition, the competition between the internationals for members, and therefore to claims of strength on the international stage, made it difficult for an international to pressure members to pay dues for fear of losing those members.

As a result, member organizations from the developed world (Europe, North America, and Japan) were responsible for more than 60 to 70 percent of the core budgets of the WCOTP and the IFFTU. The WCT's and the FISE's core budgets were less transparent. It was assumed that the majority of operating funds for the FISE came from the Soviet government, and that of other communist countries. The WCT received a combination of funding from its major members and from government subsidies in countries with strong Christian Democratic parties.

### The Rise of Teacher Unionism

From the 1960s to the 1980s, the WCOTP was the largest international teacher organization—measured by membership, funding, and prestige—in the international education world. In the earlier years, the IFFTU was smaller and financially weaker than the WCOTP. However, the issue of teacher unionism began to change this balance. Teacher unionization was, by and large, a post-World War II phenomenon. Even teachers' organizations that were founded as unions and belonged to union federations, such as the American Federation of Teachers (AFT), only began engaging significantly in traditional union activities, such as collective bargaining and strikes, in the late 1950s.

The first major teachers' strike in the United States took place in New York City in 1967, when the New York City local of the AFT went on strike for fourteen days. This was the beginning of modern teacher unionism in the United States. Eventually all the major locals in the AFT adopted the demand for union representation and collective bargaining rights. The success of this new strategy for teachers also influenced the National Education Association to change from a management-dominated profes-

sional association to a union led by teacher representatives. In the 1970s and 1980s this transition from professionalism to unionism was duplicated in most of the developed democracies and in many parts of Africa, Asia, and Latin America.

This trend among members of the IFFTU and the WCOTP, and the accompanying emphasis by both internationals on the right of teachers to unionize, increased the coincidence of interests between the two organizations. A second factor that contributed to the harmonization of the two internationals was the development of the European teachers' unions' organization, the ETUC. The ETUC was created in response to the creation of the European Community (EC) and included all European teachers' organizations, regardless of their international affiliations. While European teachers' organizations were divided between those who were members of the IFFTU and the WCOTP or the WCT, the same organizations worked together at the European level.

### Merger

This growing convergence of memberships, interests, and union orientation led to formal merger discussions between the IFFTU and the WCOTP in the late 1980s. After approximately two years of talks, the two organizations reached a merger agreement that was ratified at a joint unity congress held in Stockholm in December 1990. The most significant political requirements of the new organization, Education International, were that its members be independent democratic organizations and not be members of any other international organization of teachers. These two requirements were departures from the practice of the former WCOTP, which had not imposed such qualifications for membership. The impact of these requirements meant that if a national teachers' organization desired membership in the largest, and potentially most influential, teachers' international, it had to give up any affiliation it might have with the two smaller organizations, the FISE and the WCT.

The breakup of the Soviet Union, and the accompanying decline in support of communist movements in other parts of the world in the late 1980s, made this dual membership prohibition somewhat of a moot issue. The FISE closed its Paris offices in the early 1990s and ceased to exist, and the WCT was never as large and influential as either the WCOTP or the IFFTU. In general, the international

Christian Democratic labor movement seems to have withered in terms of numbers and financial support since the 1980s, and the prohibition against EI members holding dual memberships has restricted the membership potential of the WCT. Currently, EI and the WCT are discussing some form of a merger or, short of that, an agreement of cooperation.

### New Century, New Challenges

At the start of the twenty-first century the vast majority of national teachers' unions are represented by Education International. The post-World War II ideological conflicts and divisions have faded away, while many traditional issues, such as recognition of union rights for teachers, remain in several parts of the world. At the same time, organized teachers are facing new challenges to public education, to teacher welfare, and to security, as well as a growing concern over national and international equity issues. The unification of the international teacher's movement has created a vehicle for teachers to address these issues in an international environment. The new focus for EI is to develop the flexibility, financial base, and expertise to effectively defend teachers' interests and promote quality education systems for all countries in the context of the globalization of education issues and policies.

DAVID DORN

## INTERNATIONAL TRADE IN EDUCATION PROGRAMS, GOODS, AND SERVICES

---

Historically, education has provided the medium for transferring knowledge and skills to a global society. Research by the World Bank has demonstrated that education is "essential for civic order and citizenship

and for sustained economic growth and the reduction of poverty” (1996, p. 1). As the Independent Commission on Population and the Quality of Life states, “education is one of the keys to social development, and virtually every aspect of the quality of life” (p. 170).

As Stanley Katz explains, the commercialization of education took a large leap forward with the development of the personal computer. From the 1950s through the 1970s, computers were expensive and were therefore used mainly for research, instructional, and administrative purposes. But the computer revolution of the 1980s and 1990s saw the development of cheaper computers, better software programs, and the Internet. This resulted in institutions of higher learning expanding their computer capabilities in order to remain competitive. The technology revolution produced many opportunities for the commercialization of education.

Unfortunately, education is facing difficult times in many countries. There are problems with budget shortfalls, increasing enrollment demands, escalating educational costs, and a reduction in foreign aid. Coupled with this has been the protectionism policies practiced by governments to restrict international trade in education.

### General Agreement on Trade and Services

In 1986 a series of trade negotiations was initiated in order to find solutions for these problems. These negotiations, called the Uruguay Round, lasted for seven and a half years with 125 countries, including the United States, as participants. It concluded in 1994 with the formation of the World Trade Organization and the creation of the General Agreement on Trade and Services (GATS).

This pact has been called the most significant agreement ever negotiated by the World Trade Organization. It took effect on January 1, 1995, and is considered to be the first and only collection of multilateral rules governing international trade. Its major goal is to remove or reduce barriers that obstruct international trade. The agreement covers goods, services, and intellectual property. Other major features include procedures for dispute resolution and special treatment guidelines for developing countries. As signatories, governments have made commitments to lower tariffs and other trade barriers, and to open their markets for trade in services to all World Trade Organization members. This is known as *most-favored-nation treatment*.

The trade sectors covered under the agreement include services related to business, communications, construction and related engineering, distribution, environmental, financial, health and social, tourism and travel, recreational, culture and sports, transport, and education. Until the creation of the GATS, such a wide variety of activity had never been recognized in global trade policy.

The trade in services area is important because it is the fastest growing segment of the global economy. According to the World Trade Organization, the trade in services area increased from 17 percent in 1980 to 22 percent in 1995, and service exports expanded by 8.4 percent between 1980 and 1995.

### Trade in Education Services

Education services are defined as primary education services, secondary education services, higher or tertiary education services, adult education services, and other education services. The higher education services sector has been subdivided into advanced/theoretical/professional and practical/occupational categories to allow for more accurate statistical reporting. Other education services are related activities that support the educational process, such as educational testing services and student exchange program services.

The implementation of this arrangement for education services and goods is presently limited to member nations whose governments decided in 1994 to incorporate this section into their agreement. This amounts to forty countries out of the 143 World Trade Organization members. The forty countries that have committed to this section may limit the extent of their use of the concepts of most favored nation and national treatment. They can partially control access to their markets from foreign investors and restrict the movement of persons who cross their territorial borders. In addition, these countries are prohibited from creating new restrictions on foreign service providers without compensating those countries affected by the restrictions. At this time, none of the nations have agreed to open their education markets without restrictions.

The benefits of education services liberalization under the compact are numerous. By opening domestic markets to foreign education service providers, countries create competition with their domestic education service providers, which results in greater efficiency, lower prices, improved service, more con-

sumer choices, reduced inequality, and increased employment. A 1994 study by the World Bank found that employment in the telecommunications industry in Asia and Latin America rose by 20 percent in markets in which competition was permitted, but by only 3 percent in monopolized markets.

Martin Rudner points out that international trade in postsecondary education services is rising. He attributes this to a number of factors, including an increasing number of students studying abroad, more international marketing of academic programs, enhanced educational cooperation between institutions, and the development of foreign institution branch campuses. The United States is the largest exporter of education services in the world followed by France, Germany, the United Kingdom, and the Russian Federation. The United Nations Educational, Scientific and Cultural Organization (UNESCO) estimated that in 1996 the United States exported \$7 billion in higher education services—its fifth largest service-area export.

As these statistics indicate, the major avenue of trade in educational services is through student exchange. In an effort to reduce this student migration, some governments are partnering with foreign educational institutions to establish local branch campuses. Another commercial educational strategy gaining popularity is the “twinning arrangement.” This consists of an educational institution in one country linking up with an educational institution in a foreign county to offer courses leading to a degree from the foreign institution. Sometimes local campus facilities are used in this arrangement. In other instances, the educational programs are “franchised” from the foreign institution so there is little participation at the local level. This approach is particularly popular for distance-education programs.

### **Trade Barriers to Education Services**

The major emphasis of the ongoing trade negotiations for General Agreement on Trade and Services is the reduction of protectionism. Lowering or eliminating barriers to trade will accomplish this goal. But several existing trade barriers continue to provide grist for continuing negotiations. One major hurdle that faces negotiators is governmental use of its immigration laws to restrict not only students from leaving the country to study at foreign institutions and but also the number of foreign teachers employed. These restrictions usually take the form of quotas, nationality requirements, restricted visas,

and limitations on financial aid eligibility. To assist in compliance monitoring, all countries are required to publish and make easily accessible all laws and regulations related to trade. Another barrier to trade involves the local recognition of degrees from foreign institutions. This is an important issue for distance-education service providers because students enrolled in distance-education programs from a foreign country need to have their credentials approved in the country where they intend to work.

Educational credentials from unauthorized institutions cannot be used to acquire governmental certifications or licenses needed to secure employment in the professions. Continued negotiations are needed in this area to develop common standards and quality assurance measurements for professional education. Foreign education service providers often have difficulties acquiring governmental authorization or national operating licenses. For example, governments sometimes permit foreign education service providers to enter their markets but will not recognize them as legitimate degree granting institutions. Future negotiations should include the formulation of acceptable global accreditation standards for institutions and programs in order to eliminate this problem.

### **Trade in Electronic Education Services**

Transformation in communication and information technology is changing the institution of education. Technological breakthroughs of the late 1990s provided a world communications network with global capability. Education providers have the potential to offer their programs throughout the world. In 1997, the Clinton administration published a paper promoting the Internet as a “duty-free zone,” and calling for keeping trade on the Internet free of all tariffs. If governments decide to impose tariffs on electronic transmissions in the future, it would be difficult to enforce because many online transactions are services and require the creation of a mutually acceptable classification system for the content of the transmission. Therefore, negotiations on the tariff treatment of electronic transmissions should be an integral part of any trade barrier reduction effort.

### **Trade in Intellectual Property**

In addition to the GATS, another significant agreement, the Trade Related Aspects of Intellectual Property Rights (TRIPS), was created during the Uruguay Round. It has major implications for edu-

cation service providers since the programs that they sell are copyrighted or contain copyrighted material. This agreement requires governments to guarantee enforcement of their intellectual property rights laws and to assure the World Trade Organization that their penalties for violations are severe enough to effectively deter potential offenders.

### Objections to the Liberalization of Trade Policies in Education

Philip Altbach maintained that higher education regulated by the World Trade Organization would result in a loss of academic autonomy. According to his theory, individual nations would find it difficult to enforce copyright laws, patent and licensing regulations, and trade regulations on academic institutions, programs, and credentials from foreign education service providers. By providing hard-to-regulate educational programs to less developed nations without regard to the local educational culture, educational service providers may inadvertently supplant that country's educational ideas and practices.

MICHAEL A. OWENS

## INTERNSHIPS IN HIGHER EDUCATION

Internships, along with cooperative education, field studies, service-learning, and practica, are part of the

field of experiential education. Internships require students to apply classroom learning, theories, and experiences to professional settings. Internships or other forms of practical learning for undergraduate, as well as graduate, students have been part of American higher education since its beginning. The most influential ideas about experiential education are from John Dewey's educational philosophy of Pragmatism, particularly his 1938 book *Experience and Education*.

### Goals

All internships have the general goal of having students apply learning. Academic internships, which are characterized by being linked to the undergraduate curriculum in one or more ways, have more specific learning goals and broader outcomes than just career exploration or learning the basics of professional practice. Nonacademic internships for which students do not receive credit are usually limited to work experience for the student; there are no measurable learning outcomes. Part-time internships offer less time at the work site and thus the learning outcomes are limited. Full-time internships, usually defined as thirty-two hours per week, significantly increase the students' learning and enhance intellectual and skill development. Credit-bearing internships are very distinctive because they share common goals and elements with on-campus study. These include reading, writing, critical thinking, and problem solving. While many goals are specific to each internship program or course, the list below is of intended benefits or goals for students that are most commonly found:

- Engaging the intern in the discipline or major
- Causing interaction with a variety of individuals, systems, and organizations
- Improving self confidence
- Using a variety of learning styles and frequently challenging participants to use new ways of learning and thinking
- Improving skills in research, communication in groups, interpersonal communication, and observation
- Improving critical thinking and problem-solving skills
- Personalizing learning, giving it relevance and meaning
- Putting learning into context to improve understanding and retention of concepts

- Providing networking and mentoring opportunities
- Conditioning the participant to adapt to change
- Frequently challenging attitudes and beliefs, which often change
- Helping a participant grow emotionally and learn from failure and success
- Helping an intern become a more motivated life-long learner

### Structure

While administrative structures vary across successful internship programs, educational and instructional structures are very important. The crucial structural components include participating in an experiential education seminar, writing a learning plan, engaging in reflection, completing reading and writing assignments, undergoing assessment, and creating a learning portfolio. These structures are rooted in Dewey's argument that for experience to be educative it has to be purposefully structured; these structures include the field part of the experience as well as the reflective learning activities that are part of the curriculum.

A credit-bearing internship seminar is a hallmark of a serious internship program. This seminar assists the student in understanding the process of learning and encourages self-directed learning. The academic components of a seminar include assignments such as preparing a thoughtful learning plan; writing reflective journal entries that include analysis of on-site issues and critical incidents; understanding the stages of the internship; completing an analysis of the organization; writing a reflective essay which serves as part of the final learning portfolio; articulating the learning; and giving a final, formal presentation of the learning portfolio or capstone project associated with the internship.

Special attention should be given to the student's learning plan, which is a tool that allows the student to plan personal learning objectives for the internship. It should include content, activities, and methods of evaluation. The learning plan may have different categories of learning, such as knowledge goals, professional goals, technical goals, and cultural goals. The learning plan provides a framework for the student to use throughout the internship and to use when evaluating the learning at the end of the period. The learning plan has been adopted for internships from the practice of adult education by Malcolm Knowles.

Reflection is an essential element of experiential education and therefore of an internship program. Reflection, or critical reflection as it is sometimes called, is the process of deriving meaning from experience through questioning what is experienced or observed. Typical reflection questions are “What is happening? Why? How could this be so? So what?” Reflection can be done in a variety of ways, including classroom discussion, presentations, journal writing, or structured assignments. The point is to provide students an environment and the tools with which to think about what they are doing and what they are learning. Experience without reflection is just experience. However, experiential learning occurs when there is a fusion of theory, practice, and reflection. Reflection allows students to integrate what they are learning and doing at the internship site with what they have learned in the classroom.

Assessment is another important component of an internship program. Someone with academic credentials who can accurately assess student learning should conduct assessment of the student. In addition, the agency sponsor (site supervisor) should be asked to write an evaluation of the student. A learning portfolio often serves as the culmination of the internship and as the major product for assessment.

Internship program goals will determine which structures are used and at what stages of a student’s curriculum. Freshman or sophomore internships may be exploratory in nature and include few project elements. A capstone internship course, like the one required for students in the Human and Organizational Development major at Vanderbilt University, will emphasize cumulative learning. This internship is done in one of the last semesters before graduation and includes a senior project that is assessed for mastery of the content and skills of the major. Other internships are tied to a specific course topic or to mastering the skills of a profession, such as social work. Education majors often do an internship or practicum before they do student teaching at the end of their teacher-training curriculum.

### Process

Like other educational processes, internships have identifiable stages or phases. In their very practical manual, *The Experienced Hand: A Student Manual for Making the Most of an Internship*, Timothy Stanton and Kamil Ali outline ten steps to obtaining an internship, beginning with self-assessment of goals and ending with the first day of starting an intern-

ship. They argue that students who pay attention to each of the ten steps are more likely to obtain a quality and interesting internship. Preparing students thoroughly for an internship is a key element of the process.

Another view of the internship process comes from a developmental theory perspective where predictable stages can be identified and the challenges and tasks of each stage can be addressed. One model by Marijean Suelzle and Lenore Borzak uses the stages of entry, initiation, competence, and completion. Interns have found it helpful to view the semester-long process through this framework so they can be aware of what they should be learning and how they are doing at each stage. Another model developed by H. Frederick Sweitzer and Mary A. King has five stages of an internship: anticipation, disillusionment, confrontation, competence, and culmination. Sweitzer and King’s five stages provide a very useful way for interns to anticipate and understand their journeys to deal with problems that often arise after the excitement of the initial stages has passed. Whichever model one uses, it is important for interns to be aware of their increasing levels of competence and the learning challenges they are mastering.

### Standards

There is no set of “Principles of Good Practice” for internships but there is some general agreement in the field that “The Seven Principles for Good Practice in Undergraduate Education” offered by Arthur Chickering and Zelda Gamson are relevant. Educational research supports the need for structure so that learning takes place and is assessed. Because internships lack a standard definition and have few recognized norms for evaluating and comparing different types of internships that students pursue, Mary Ryan, executive director of the Institute for Experiential Learning, in Washington, DC, compiled a list of standards of excellence that gives a succinct statement of what is known about undergraduate education as applied to internships. These principles, summarized below, illustrate the goals, processes, and structures that are discussed above.

**Enhancing On-Campus Excellence.** The internship program should be integrated with and enhance the college’s mission and curriculum.

**Institutional Excellence and Integrity.** For internships away from campus, the

organization offering the internship program should have an appropriate management structure, staff, and policies to support the provision of a sound and high quality internship program that includes concurrent curricula, support services, and housing.

**Academic Excellence and Rigor.** The internship incorporates a defined project(s) resulting in outcomes and products of benefit to the organization and involving college-level learning on the student's part.

**Individual Attention and Involvement.** The internship program should provide individualized attention and support for the students and should provide for active involvement of students in their education.

**Appropriate Internships.** Internships should be designed to support the student's educational program.

**Appropriate Course Work.** The internship program should provide course work that facilitates the experiential learning process and that supports each student's academic program.

**Diversity.** The program should introduce the student to participants in the larger world of all ages and nationalities and to a variety of opinions, ideas, and philosophies.

**Assessment and Evaluation.** The student's progress and learning should be assessed based on learning outcomes, in other words, students should be able to articulate and apply what they have learned. The assessment process should be ongoing throughout the semester.

## ISLAM

Islam has, from its inception, placed a high premium on education and has enjoyed a long and rich intellectual tradition. Knowledge (*ilm*) occupies a significant position within Islam, as evidenced by the more than 800 references to it in Islam's most revered book, the Koran. The importance of education is repeatedly emphasized in the Koran with frequent injunctions, such as "God will exalt those of you who believe and those who have knowledge to high degrees" (58:11), "O my Lord! Increase me in knowledge" (20:114), and "As God has taught him, so let him write" (2:282). Such verses provide a forceful stimulus for the Islamic community to strive for education and learning.

Islamic education is uniquely different from other types of educational theory and practice largely because of the all-encompassing influence of the Koran. The Koran serves as a comprehensive blueprint for both the individual and society and as the primary source of knowledge. The advent of the Koran in the seventh century was quite revolutionary for the predominantly illiterate Arabian society. Arab society had enjoyed a rich oral tradition, but the Koran was considered the word of God and needed to be organically interacted with by means of reading and reciting its words. Hence, reading and writing for the purpose of accessing the full blessings of the Koran was an aspiration for most Muslims. Thus, education in Islam unequivocally derived its origins from a symbiotic relationship with religious instruction.

### History of Islamic Education

Thus, in this way, Islamic education began. Pious and learned Muslims (*mu' allim* or *mudarris*), dedicated to making the teachings of the Koran more accessible to the Islamic community, taught the faithful in what came to be known as the *kuttāb* (plural, *katātīb*). The *kuttāb* could be located in a variety of venues: mosques, private homes, shops, tents, or even out in the open. Historians are uncertain as to when the *katātīb* were first established, but with the widespread desire of the faithful to study the Koran, *katātīb* could be found in virtually every part of the Islamic empire by the middle of the eighth century. The *kuttāb* served a vital social function as the only vehicle for formal public instruction for primary-age children and continued so until Western models of education were introduced in the modern period. Even at present, it has exhibited remarkable durability and continues to be an important means of religious instruction in many Islamic countries.

The curriculum of the *kuttāb* was primarily directed to young male children, beginning as early as age four, and was centered on Koranic studies and on religious obligations such as ritual ablutions, fasting, and prayer. The focus during the early history of Islam on the education of youth reflected the belief that raising children with correct principles was a holy obligation for parents and society. As Abdul Tibawi wrote in 1972, the mind of the child was believed to be “like a white clean paper, once anything is written on it, right or wrong, it will be difficult to erase it or superimpose new writing upon it” (p. 38).

The approach to teaching children was strict, and the conditions in which young students learned could be quite harsh. Corporal punishment was often used to correct laziness or imprecision. Memorization of the Koran was central to the curriculum of the *kuttāb*, but little or no attempt was made to analyze and discuss the meaning of the text. Once students had memorized the greater part of the Koran, they could advance to higher stages of education, with increased complexity of instruction. Western analysts of the *kuttāb* system usually criticize two areas of its pedagogy: the limited range of subjects taught and the exclusive reliance on memorization. The contemporary *kuttāb* system still emphasizes memorization and recitation as important means of learning. The value placed on memorization during students' early religious training directly influences their approaches to learning when they enter formal education offered by the modern state. A common frustration of modern educators in the Islamic world is that while their students can memorize copious volumes of notes and textbook pages, they often lack competence in critical analysis and independent thinking.

During the golden age of the Islamic empire (usually defined as a period between the tenth and thirteenth centuries), when western Europe was intellectually backward and stagnant, Islamic scholarship flourished with an impressive openness to the rational sciences, art, and even literature. It was during this period that the Islamic world made most of its contributions to the scientific and artistic world. Ironically, Islamic scholars preserved much of the knowledge of the Greeks that had been prohibited by the Christian world. Other outstanding contributions were made in areas of chemistry, botany, physics, mineralogy, mathematics, and astronomy, as many Muslim thinkers regarded scientific truths as tools for accessing religious truth.

Gradually the open and vigorous spirit of enquiry and individual judgment (*ijtihād*) that characterized the golden age gave way to a more insular, unquestioning acceptance (*taqlīd*) of the traditional corpus of authoritative knowledge. By the thirteenth century, according to Aziz Talbani, the ‘*ulama*’ (religious scholars) had become “self-appointed interpreters and guardians of religious knowledge. . . . learning was confined to the transmission of traditions and dogma, and [was] hostile to research and scientific inquiry” (p. 70). The mentality of *taqlīd* reigned supreme in all matters, and religious scholars condemned all other forms of inquiry and

research. Exemplifying the *taqlīd* mentality, Burhān al-Dīn al-Zarnūjī wrote during the thirteenth century, “Stick to ancient things while avoiding new things” and “Beware of becoming engrossed in those disputes which come about after one has cut loose from the ancient authorities” (pp. 28, 58). Much of what was written after the thirteenth century lacked originality, and it consisted mostly of commentaries on existing canonical works without adding any substantive new ideas. The lethal combination of *taqlīd* and foreign invasion beginning in the thirteenth century served to dim Islam’s preeminence in both the artistic and scientific worlds.

Despite its glorious legacy of earlier periods, the Islamic world seemed unable to respond either culturally or educationally to the onslaught of Western advancement by the eighteenth century. One of the most damaging aspects of European colonialism was the deterioration of indigenous cultural norms through secularism. With its veneration of human reason over divine revelation and its insistence on separation of religion and state, secularism is anathema to Islam, in which all aspects of life, spiritual or temporal, are interrelated as a harmonious whole. At the same time, Western institutions of education, with their pronounced secular/religious dichotomy, were infused into Islamic countries in order to produce functionaries to feed the bureaucratic and administrative needs of the state. The early modernizers did not fully realize the extent to which secularized education fundamentally conflicted with Islamic thought and traditional lifestyle. Religious education was to remain a separate and personal responsibility, having no place in public education. If Muslim students desired religious training, they could supplement their existing education with moral instruction in traditional religious schools—the *kuttāb*. As a consequence, the two differing education systems evolved independently with little or no official interface.

### Aims and Objectives of Islamic Education

The Arabic language has three terms for education, representing the various dimensions of the educational process as perceived by Islam. The most widely used word for education in a formal sense is *ta’līm*, from the root *‘alima* (to know, to be aware, to perceive, to learn), which is used to denote knowledge being sought or imparted through instruction and teaching. *Tarbiyah*, from the root *raba* (to increase, to grow, to rear), implies a state of spiritual

and ethical nurturing in accordance with the will of God. *Ta’dīb*, from the root *aduba* (to be cultured, refined, well-mannered), suggests a person’s development of sound social behavior. What is meant by *sound* requires a deeper understanding of the Islamic conception of the human being.

Education in the context of Islam is regarded as a process that involves the complete person, including the rational, spiritual, and social dimensions. As noted by Syed Muhammad al-Naqib al-Attas in 1979, the comprehensive and integrated approach to education in Islam is directed toward the “balanced growth of the total personality . . . through training Man’s spirit, intellect, rational self, feelings and bodily senses . . . such that faith is infused into the whole of his personality” (p. 158). In Islamic educational theory knowledge is gained in order to actualize and perfect all dimensions of the human being. From an Islamic perspective the highest and most useful model of perfection is the prophet Muhammad, and the goal of Islamic education is that people be able to live as he lived. Seyyed Hossein Nasr wrote in 1984 that while education does prepare humankind for happiness in this life, “its ultimate goal is the abode of permanence and all education points to the permanent world of eternity” (p. 7). To ascertain truth by reason alone is restrictive, according to Islam, because spiritual and temporal reality are two sides of the same sphere. Many Muslim educationists argue that favoring reason at the expense of spirituality interferes with balanced growth. Exclusive training of the intellect, for example, is inadequate in developing and refining elements of love, kindness, compassion, and selflessness, which have an altogether spiritual ambiance and can be engaged only by processes of spiritual training.

Education in Islam is twofold: acquiring intellectual knowledge (through the application of reason and logic) and developing spiritual knowledge (derived from divine revelation and spiritual experience). According to the worldview of Islam, provision in education must be made equally for both. Acquiring knowledge in Islam is not intended as an end but as a means to stimulate a more elevated moral and spiritual consciousness, leading to faith and righteous action.

## JAMES, WILLIAM (1842–1910)

William James was the American philosopher whose work in psychology established that science as an important element in the revision of social and philosophical doctrines at the turn of the nineteenth century. Thereafter it was no longer possible to erect systems in purely deductive fashion. All thought must take account of the deliverances of current natural science, and particularly the branch relating to man's mind. This respect for the organized experience of the laboratory inevitably influenced educational theory and practice, then still known by their proper name of *pedagogy*.

But James was not merely a scientist in psychology and a proponent of scientific rigor in moral philosophy, including education. He was a philosophical genius—the greatest that America has produced—who touched upon every department of life and culture and who ranks as a chief architect of the reconstruction in Western thought that took place in the 1890s. In the company of Nietzsche, Dilthey, Renouvier, Bergson, Mach, Vaihinger, and Samuel Butler, he led the revolt against orthodox scientism, Spencerism, and materialism and contributed to that enlargement of outlook that affected the whole range of feeling and opinion and has since earned the name of Neo-Romanticism. Every academic discipline and every art was involved in the change; and, in each, thinkers of uncommon scope laid the foundation for the new systems of ideas on which the twentieth century still lives.

William James was in a favored position for adding something unique to the movement: He possessed the American experience as his birth-right and was early acclimated to European ways, British

and Continental. He studied in Germany and was fluent in both German and French, and his family circumstances were propitious. He was the eldest son of Henry James Sr., son of the original William James who had emigrated from Ireland to this country and made a fortune. Henry Sr. could devote himself to study and did so. His original ideas on religion and society won no acceptance in his day, but they have been found important by modern scholars, and they certainly influenced the two geniuses who were his sons, William the philosopher and Henry the novelist.

William James's own intellectual career is marked by his father's easy unconventionality, which as will be seen permitted long exploration before "settling down." Every shift in his own development is caught up in, and contributory to, his mature work. James wanted at first to become a painter, but he had the critical sense to see that his talent was insufficient. Next he took up chemistry at Harvard, went on to study physiology in response to his interest in living things, and wound up preparing for a medical degree. He interrupted his course to spend a highly formative year as one of Louis Agassiz's assistants in the Thayer expedition to Brazil. He then went abroad, where he read literature, attended university lectures, and became acquainted with the new psychology, which the Germans had made experimental and exact. He returned to take his Harvard M.D. in 1869 and after further study abroad began to teach anatomy and physiology.

It was not long before his inquiring spirit led him to offer courses in the relations of psychology to physiology, for which he soon established the first psychology laboratory in America. After the publication of his great book, *The Principles of Psychology*,

in 1890, James's work exhibited the flowering of an intellect that had from the beginning been haunted by the enigmas of life and mind: He gave himself exclusively to metaphysics, morals, and religion.

By an oddity of academic arrangements, James was a professor of philosophy four years before he was made a professor of psychology, but nomenclature is irrelevant: His beginnings in the psychology laboratory were very soon followed by his offering of a course in philosophy. In other words, the subjects for him commingled and he was always a philosophical writer and teacher. Those were the great days of the Harvard department of philosophy, and during his thirty-five years of teaching James's direct influence spread over a wide range of students, as disparate as George Santayana and Gertrude Stein.

To the end of the century James, despite his new goals, continued to write and lecture on the subject that had first brought him fame. He pursued his research on the newest topics of abnormal psychology, he read Freud and helped bring him over for a lectureship at Clark University. And what is more to the point of the present entry, between 1892 and 1899, James delivered at a number of places the *Talks to Teachers*, which were an offshoot of the *Psychology* and which constitute his important contribution to educational theory.
